No work such as The 5-Minute Clinical Consult comes about without the dedicated and creative work of an entire team. I am deeply grateful for the critical analysis and collegiality of my 5MCC coeditors (and especially to Frank Domino, MD, who is the model of an evidence-based, practical, compassionate, and delightfully iconoclastic leader). I wish to thank our editorial staff at Wolters Kluwer—Rebecca Gaertner and Leanne Vandetty—who make this fun while getting the job done.

I also thank and acknowledge my wife, Michele Roberts, MD, PhD, whose skills as a medical editor surpass my own and whose love, patience, and determination inspire and sustain me daily.

To our team and to my wife of 30 years, I dedicate this book.

Jeremy Golding, MD, FAAFP
“With most men, unbelief in one thing springs from blind belief in another.”
—GEORG LICHTENBERG

“Intelligence requires that you don’t defend an assumption.”
—DAVID BOHM

Two quotes this year underscore the pressures of the last 12 months. In our personal, political, and medical lives, misinformation and opinion have risen from the shadows to medical society “guidelines,” and even to the law of the land.

Take the 2017 American Heart Association/American College of Cardiology Hypertension Guidelines (http://hyper.ahajournals.org/content/guidelines2017). The “executive summary” was over 190 pages in length, and much of the guideline is expert opinion rather than scientific fact. Rational thought, logic, respect for honesty, for individuals, and for the greater good have, in some ways, been replaced by the opportunity to influence. If one says something often enough and loudly enough, it is seen as “fact,” no matter how absurd.

Those who care for patients must remain firm in their approach; patient-centered and transparent. Leave the pejorative, in medicine and in politics, aside.

You are the patient’s advocate. Think carefully about putting a 68-year-old on a statin for primary prevention. Understand the possible harms from aggressive blood pressure lowering. Be good stewards of both antibiotics and opioids. We have the potential to give wonderful care that benefits our patients AND society. But we can be easily confused, distracted, and “misguided” by vested interests and external pressures.

One last quote, from a fellow New Jerseyan:

“Someday we’ll look back on this and it will all seem funny.”
—BRUCE SPRINGSTEEN

I certainly hope so. Till then, the answer is to do no harm and put the patient (not some guideline or quality score fear) first.
Welcome to the 2019 edition of *The 5-Minute Clinical Consult*. This is a book of diseases, diagnostic methods, and treatment recommendations. Much of the work provided by primary care providers is focused on helping the patients help themselves to be healthier. Diet, exercise, safety, and prevention are the interventions that provide the greatest number of people with the greatest return on longevity and its enjoyment.

This year’s *The 5-Minute Clinical Consult* is here to assist in fulfilling our role as health care providers. In each patient interaction, in addition to bringing your clinical expertise, remember how others view you, as a leader, and the power of your words and actions. Encourage them to dream more, learn more, do more, and to be more.

Our editorial team has collaborated with hundreds of authors so that you may deliver your patients the best care. Each topic provides you with quick answers you can trust, where and when you need them most, either in print or online at www.5MinuteConsult.com.

This highly organized content provides you with the following:
- Differential diagnosis support from our expanded collection of algorithms
- Current evidence-based designations highlighted in each topic
- 540+ commonly encountered diseases in print, with an additional 1,500 online topics, including content from *The 5-Minute Pediatric Consult*
- FREE point-of-care CME and CE: 1/2 hour credit for every digital search
- Thousands of images to help support visual diagnosis of all conditions
- Video library of procedures, treatment, and physical therapy
- A to Z drug database from Facts & Comparisons
- Laboratory test interpretation from *Wallach’s Interpretation of Diagnostic Tests*
- More than 3,000 patient handouts in English and Spanish
- ICD-10 codes and DSM-5 criteria; additionally, SNOMED codes are available online.

Our website, www.5MinuteConsult.com, delivers quick answers to your questions. It is an ideal resource for patient care. Integrating *The 5-Minute Clinical Consult* content into your workflow is easy and fast. And our patient education handouts can assist in helping you meet meaningful use compliance.

If you purchased the Premium Edition, your access includes 1 year FREE use of our expanded website; the Standard Edition includes a free 10-day trial! The site promises an easy-to-use interface, allowing smooth maneuverability between topics, algorithms, images, videos, and patient education materials as well as more than 1,500 online-only topics.

Evidence-based health care is the integration of the best medical information
with the values of the patient and your skill as a clinician. We have updated our evidence-based medicine (EBM) content so you can focus on how to best apply it in your practice.

The algorithm section includes both diagnostic and treatment algorithms. This easy-to-use graphic method helps you evaluate an abnormal finding and prioritize treatment. They are also excellent teaching tools, so share them with the learners in your office.

This book and website are a source to solve problems; to help evaluate, diagnose, and treat patients’ concerns. Use your knowledge, expressed through your words and actions, to address their anxiety.

_The 5-Minute Clinical Consult_ editorial team values your observations, so please share your thoughts, suggestions, and constructive criticism through our website, [www.5MinuteConsult.com](http://www.5MinuteConsult.com).

**Frank J. Domino, MD**
WHAT IS EVIDENCE-BASED MEDICINE?

Remember when we used to treat every otitis media with antibiotics? These recommendations came about because we applied logical reasoning to observational studies. If bacteria cause an acute otitis media, then antibiotics should help it resolve sooner, with less morbidity. Yet, when rigorously studied (via a systematic review), we found little benefit to this intervention.

The underlying premise of EBM is the evaluation of medical interventions and the literature that supports those interventions, in a systematic fashion. EBM hopes to encourage treatments proven to be effective and safe. And when insufficient data exist, it hopes to inform you on how to safely proceed.

EBM uses end points of real patient outcomes, morbidity, mortality, and risk. It focuses less on intermediate outcomes (bone density) and more on patient conditions (hip fractures).

Implementing EBM requires three components: the best medical evidence, the skill and experience of the provider, and the values of the patients. Should this patient be screened for prostate cancer? It depends on what is known about the test, on what you know of its benefits and harms, your ability to communicate that information, and that patient’s informed choice.

This book hopes to address the first EBM component, providing you access to the best information in a quick format. Although not every test or treatment has this level of detail, many of the included interventions here use systematic review literature support.

The language of medical statistics is useful in interpreting the concepts of EBM. Below is a list of these terms, with examples to help take the confusion and mystery out of their use.

**Prevalence:** proportion of people in a population who have a disease (in the United States, 0.3% [3 in 1,000] people >50 years have colon cancer)

**Incidence:** how many new cases of a disease occur in a population during an interval of time; for example, “The estimated incidence of colon cancer in the United States is 104,000 in 2005.”

**Sensitivity:** percentage of people with disease who test positive; for
mammography, the sensitivity is 71–96%.

**Specificity**: percentage of people without disease who test negative; for mammography, the specificity is 94–97%.

Suppose you saw ML, a 53-year-old woman, for a health maintenance visit, ordered a *screening* mammogram, and the report demonstrates an irregular area of microcalcifications. She is waiting in your office to receive her test results, what can you tell her?

Sensitivity and specificity refer to characteristics of people who are *known to have disease* (sensitivity) or those who are *known not to have disease* (specificity). But, what you have is an abnormal test result. To better explain this result to ML, you need the positive predictive value.

**Positive predictive value (PPV)**: percentage of *positive* test results that are truly positive; the PPV for a woman aged 50 to 59 years is approximately 22%. That is to say that only 22% of abnormal screening mammograms in this group truly identified cancer. The other 78% are false positives.

You can tell ML only 1 out of 5 abnormal mammograms correctly identifies cancer; the four are false positives, but the only way to know which mammogram is correct is to do further testing.

**The corollary of the PPV is the negative predictive value (NPV)**, which is the percentage of negative test results that are truly negative.

The PPV and NPV tests are population-dependent, whereas the sensitivity and specificity are characteristics of the test and have little to do with the patient in front of you. So when you receive an abnormal lab result, especially a screening test such as mammography, understand their limits based on their PPV and NPV.

**Treatment information is a little different.** In discerning the statistics of randomized controlled trials of interventions, first consider an example. The Scandinavian Simvastatin Survival Study (4S) (*Lancet*. 1994;344[8934]:1383–1389) found using simvastatin in patients at high risk for heart disease for 5 years resulted in death for 8% of simvastatin patients versus 12% of those on placebo; this results in a relative risk of 0.70, a relative risk reduction of 33%, and a number needed to treat of 25.

There are two ways of considering the benefits of an intervention with respect to a given outcome. The absolute risk reduction is the difference in the percentage of people with the condition before and after the intervention. Thus, if the incidence of myocardial infarction (MI) was 12% for the placebo group
and 8% for the simvastatin group, the absolute risk reduction is 4% (12% - 8% = 4%).

The relative risk reduction reflects the improvement in the outcome as a percentage of the original rate and is commonly used to exaggerate the benefit of an intervention. Thus, if the risk of MI were reduced by simvastatin from 12% to 8%, then the relative risk reduction would be 33% (4% / 12% = 33%); 33% sounds better than 4%, but the 4% is the absolute risk reduction and reflects the true outcome.

Absolute risk reduction is usually a better measure of clinical significance of an intervention. For instance, in one study, the treatment of mild hypertension has been shown to have relative risk reduction of 40% over 5 years (40% fewer strokes in the treated group). However, the absolute risk reduction was only 1.3%. Because mild hypertension is not strongly associated with strokes, aggressive treatment of mild hypertension yields only a small clinical benefit. Don’t confuse relative risk reduction with relative risk.

Absolute (or attributable) risk (AR): the percentage of people in the placebo or intervention group who reach an end point; in the simvastatin study, the absolute risk of death was 8%.

Relative risk (RR): the risk of disease of those treated or exposed to some intervention (i.e., simvastatin) divided by those in the placebo group or who were untreated

- If RR is <1.0, it reduces risk—the smaller the number, the greater the risk reduction.
- If RR is >1.0, it increases risk—the greater the number, the greater the risk increase.

Relative risk reduction (RRR): the relative decrease in risk of an end point compared to the percentage of that end point in the placebo group

If you are still confused, just remember that the RRR is an overestimation of the actual effect.

Number needed to treat (NNT): This is the number of people who need to be treated by an intervention to prevent one adverse outcome. A “good” NNT can be a large number (>100) if risk of serious outcome is great. If the risk of an outcome is not that dangerous, then lower (<25) NNTs are preferred.

The NNT should be compared to a similar statistic, the number needed to harm (NNH). This is the number of people who have to be given treatment before one excess side effect or harm occurs. When the NNT is compared to the
NNH, you and the patient can judge whether the benefit of the intervention is great enough to outweigh the risk of harm.

EVIDENCED-BASED GRADING

To help you interpret diagnostic and treatment recommendations within The 5-Minute Clinical Consult, we have graded the best information within the text and highlighted this content.

An “A” grade means the reference is from the highest quality resource, such as a systematic review. A systematic review is a summary of the medical literature on a given topic that uses strict, explicit methods to perform a thorough search of the literature and then provides a critical appraisal of individual studies, concluding in a recommendation. The most prestigious collection of systematic reviews is from the Cochrane Collaboration (www.cochrane.org).

A “B” grade means the data referenced comes from high-quality randomized controlled trials performed to minimize bias in their outcome. Bias is anything that interferes with the truth; in the medical literature, it is often unintentional, but it is much more common than we appreciate. In short, always assume some degree of bias exist in any research endeavor.

A “C” grade implies the reference used does not meet the A or B requirements; they are often treatments recommended by consensus groups (such as the American Cancer Society). In some cases, they may be the standards of care. But implicit in a group’s recommendation is the bias of the author or the group that supports the reference. For example, the American Urological Society’s recommendation around screening for prostate cancer may be motivated by their narrow scope and financial benefit. Compare this to the recommendations of the U.S. Preventive Services Task Force (www.ahrq.gov), which recommends against screening for prostate cancer.

BIAS

Bias is anything that interferes with the truth. There are many types of bias that should be considered by the publishers of medical information. Below describes a number of bias types that often affect our care without us knowing it is present.

Publication bias occurs when research is not published; this is often when a study finds data that does not support an intervention. The motivation
to publish information that “didn’t work” is low. It is estimated that up to 40% of all medical research never get published. When you read of an effective intervention, wonder if other studies did not show benefit and went unpublished.

**Comparator bias** occurs when research compares an intervention to not the standard of care. Knowing a new treatment is more effective than placebo for treating a condition is not helpful if you typically use a drug or procedure. Why not study comparing the new to the standard of care? Sometimes, the new treatment is no better than the current standard. And if a study was done to see if the new is better than the old and not published, you have an example of publication bias.

**Selection bias** involves choosing study populations that might be different than the average patient or just reporting a just subset of study participants from a study. Either will result in the data being skewed because it can only be applied to small subset of people.

**Attrition bias and the concept of intention to treat.** Attrition bias is when researchers do not fully acknowledge and address how a study deals with participants who do not adhere to the research protocol or drop out completely. Intention to treat analysis hopes to diminish attrition bias by statistically considering the nonadhering or dropped out patients as unsuccessfully benefiting from the intervention.

**Commercial (funder) bias** involves who paid for the research being done, and do they have a vested interest in the outcome. If the developer of a new drug does a large study, or a researcher has a personal financial interest in seeing a study succeed, they may consciously or unconsciously alter what is reported in a study. The data may be accurate, but until this is studied by less vested interests, some feel its outcome cannot be clinically applied.

Have you been annoyed how 1 week you learn of a randomized controlled trial that supports a treatment, to be followed the next week with a contradictory article? Statisticians have figured out how to resolve this using something called a systematic review.

A **systematic review** gathers all the literature on a topic, say using antibiotics to treat otitis media, and combines the data to determine if the sum of all the trials tells a different story than any single trial. The large number of participants in this type of research results in a much more statistically (and clinically) significant conclusion than any single paper. Want more? Check this out: [http://community.cochrane.org/about-us/evidence-based-health-care](http://community.cochrane.org/about-us/evidence-based-health-care).
A meta-analysis is a quantitative systematic review and demonstrates its outcomes in the form of a forest plot. The bottom line with interpretation of a forest plot is to look for the diamond on the bottom. If it is to LEFT of the vertical line, it means risk of an outcome was reduced by the intervention. If it is fully to the RIGHT, then risk of that outcome was increased. And if the diamond touches the vertical line, it means there was no statistical influence of the intervention on the outcome.

We hope this brief introduction to EBM has been informative, clear, and helpful. If any of the information above seems unclear, or if you have a question, please contact us via www.5MinuteConsult.com.
ACKNOWLEDGMENTS

This is the 27th edition of The 5-Minute Clinical Consult, a comprehensive point-of-care tool to assist in the care of patients. From beginning to end, one cannot find a more current and easy-to-use collection of clinically useful content.

Developing and maintaining a book and website of this magnitude requires an equally broad effort from its supporting team. I wish to thank the dedication and tireless efforts of many: executive editor, Rebecca Gaertner; digital product development editor, Leanne Vandetty; marketing manager, Rachel Mante Leung; and publisher, Lisa McAllister.

This 2019 edition is the direct result of the dedication and insights of our associate editors. I wish to thank Drs. Robert Baldor, Jeremy Golding, and Mark Stephens for their hard work and overwhelming commitment to The 5-Minute Clinical Consult.

I wish to especially thank my wife, Sylvia, and my daughter, Molly, who have given greatly for this book.

The challenge of completing a book covering this broad a spectrum of medicine requires insights and skills far beyond my own. Many thanks to my mentors Bob Baldor and Mark Quirk who have been an enormous support—always there to encourage, reassure, and impart wisdom.

Many in the academic and health care worlds are due thanks for support, insight, and friendship: Daniel Lasser, Alan Chuman, Michele Pugnaire, Karen Rayla, Maryanne Adams, Jennifer Masoud, Phil Fournier, Erik Garcia, Jeff Stovall, Jim Comes, Len Levin, Judy Norberg, J. Herb Stevenson, Robert Jenal, Michael Kidd, Zainab Nawab, Sanjiv and Amita Chopra, Vasilios (Bill) Chrisostomidis, James (Jay) Broadhurst, Danuta Antkowiak, Atreyi Chakrabarti, Joseph Frappier, Kate Peasha, the staff of Shrewsbury Family Medicine, Mark Powicki, Steve Messineo, and the faculty and amazing students of the University of Massachusetts Medical School.

Medicine is a challenge I have fortunately not had to meet alone. Thanks to my parents, Frank and Angela (Jean); my brother, John, and his family, Marylou, Cate, and Jane; Frank, Mary Anne, Diane, and David Christian; the Diana and Hymie Lipschitz family; and the Bob and Ruth Pabreza family; they are responsible for who I am and my success in life.
I am blessed with the best of friends; without them, I would not be a physician. Thanks to Bob Bacic, Ron Jautz, Richard Onorato, John Horcher, Auguste Turnier, Bob Smith, Paul Saivetz, Bob and Nancy Gallinaro, Drew and Jill Grimes, Louay Toma, Laurie, Alan, Daniel, Jenny, and Matt Bugos, Alan Ehrlich, Andy Jennings, Bill Demianiuk, Mark Steenbergen, John and Kathleen Polanowicz, Phil and Carol Pettine, Mark Shelton, Steve Bennett, Vicki Triolo, and Michael Bernatchez.

University of Vermont Medical Center
Burlington, Vermont

Jennifer Tickal Kehbauch, MD, FAAFP†
Associate Professor of Family Medicine
University of Vermont Medical Center
Burlington, Vermont

Brian P. Keene, DO†
Resident
Martin Army Community Hospital
Fort Benning, Georgia

Jeremy R. Kenison, DO†
Senior Medical Officer
USN, MC
Marine Corp Base Hawaii
Kaneohe Bay, Hawaii

Anne Marie Kennedy, DO†
Family Medicine Resident Physician
Eglin Family Medicine Residency Clinic
Eglin Air Force Base, Florida

Tara M. Kennedy, MD
Resident
Department of Family and Community Medicine
Pennsylvania State College of Medicine
Hershey, Pennsylvania

Robert M. Kershner, MD, MS, FACS†
Eye Physician and Surgeon
Professor and Chairman
Department of Ophthalmic Medical Technology
Palm Beach State College
President and CEO
Ophthalmic Consulting
Jupiter, Florida

Todd Kettering, DO, FAAFP
Director of Medical Education
Site Designated Institutional Official
Graduate Medical Education
Advocate BroMenn Medical Center
Normal, Illinois

Tarun Kewalramani, MD
Department of Hematology and Oncology
Lahey Hospital & Medical Center
Burlington, Massachusetts

Misbahuddin Khaja, MD
Attending
Pulmonary & Critical Care
Bronx-Lebanon Hospital Center Health Care System
Bronx, New York

Anila Khaliq, MD
Primary Care & Faculty
Touro College of Osteopathic Medicine
Middletown, New York
Abid Khan, MD
Resident
Rush University Medical Center
Chicago, Illinois

Ali A. Khan, MD, MPH†
Internal Medicine Resident
George Washington University
Washington, DC

Aruna S. Khan, MD
Resident Physician
Department of Family Medicine
Mayo Clinic
Jacksonville, Florida

Jenna M. Khan, MD
Radiation Oncologist
Richmond, Virginia

Omar Khan, MD, MHS, FAAFP
Physician Leader of Primary Care and Community Medicine
Christiana Care Health System
Wilmington, Delaware
Clinical Associate Professor
Department of Family and Community Medicine
Sidney Kimmel Medical College/Thomas Jefferson University
Philadelphia, Pennsylvania

Sajid Khan, MD†
Assistant Professor of Emergency Medicine
University of Missouri—Kansas City
Kansas City, Missouri

Shiva Kheradmand, DO†
Traditional Rotating Intern
Largo Medical Center  
Largo, Florida

Teresa Khoo, MD  
University of California, Riverside  
Riverside, California

Christopher R. Kieliszak, DO  
Department of Otolaryngology Head and Neck Surgery  
OhioHealth Doctors Hospital  
Columbus, Ohio

Barbara M. Kiersz, DO  
Family Medicine Physician  
Austin Regional Clinic—Far West  
Austin, Texas

Daniel Y. Kim, MD, FACS  
Chairman  
Department of Otolaryngology–Head & Neck Surgery  
University of Massachusetts  
Worcester, Massachusetts

Gemma Kim, MD  
Associate Professor

Associate Professor of Clinical Medicine
University of Illinois at Chicago
Oak Lawn, Illinois

Mridula Krishnan, MBBS
Department of Internal Medicine
Creighton University
Omaha, Nebraska

Sathya S. Krishnasamy, MD†
Associate Professor
Department of Medicine
Division of Endocrinology, Diabetes and Metabolism
University of Louisville
Louisville, Kentucky
Merrill Krolick, DO, FACC, FACP, FSAl
Interventional Cardiology
The Heart Institute at Largo
Largo Medical Center
Largo, Florida

David C. Krulak, MD, MPH, MBA†
Physician
United States Navy
Aiea, Hawaii

David W. Kruse, MD
Orthopaedic Specialty Institute
Associate Faculty
Long Beach Memorial Primary Care Sports Medicine Fellowship
Orange, California

E. James Kruse, DO†
Associate Professor of Surgery
Chief of Surgical Oncology
Augusta University
Augusta, Georgia

Archana Kudrimoti, MD, MBBS, MPH
Associate Professor
Residency Program Director
Department of Family and Community Medicine
Lexington, Kentucky

Karl A. Kuersteiner, MD†
Chief Resident
Department of Family Medicine
Naval Hospital Jacksonville
Jacksonville, Florida

Jeffrey D. Kueter, MD, FAAFP†
Col, MC, USAF
Family Medicine Faculty Physician
Eglin Air Force Base Family Medicine Residency
Eglin Air Force Base, Florida

Christina N. Kufel, DO, MS
Resident
Obstetrics and Gynecology
Aultman Hospital
Canton, Ohio

Keshav Kukreja, MD†
Resident
Department of Internal Medicine
University of Texas Health Sciences Center at Houston
Houston, Texas

Vineet Kumar, MD
Division of Cardiovascular Disease
University of Alabama at Birmingham School of Medicine
Birmingham, Alabama

Jason Kurland, MD
Assistant Professor of Medicine
Division of Renal Medicine
University of Massachusetts Medical School
Worcester, Massachusetts

Daniel B. Kurtz, PhD, BS†
Associate Professor and Chair, Biology
Utica College
Utica, New York

Melinda Y. Kwan, DO, MPH
Urgent Care/Family Medicine Physician
Urgent Care Department
Southwest Medical Associates
Las Vegas, Nevada

Jeffrey Lai, MD

Nicole Nelson, DO†
Academic Chief Resident
Dwight D. Eisenhower Army Medical Center
Fort Gordon, Georgia

Vicki R. Nelson, MD, PhD
Clinical Assistant Professor
Department of Family Medicine
University of South Carolina School of Medicine—Greenville
Greenville, South Carolina

Brian E. Neubauer, MD†
Assistant Professor of Medicine
Uniformed Services University of the Health Sciences
Bethesda, Maryland

Michael Nguyen, MD, FACEP†
Director of Simulation
Emergency Medicine Residency
Lehigh Valley Health Network
Bethlehem, Pennsylvania
Assistant Professor of Medicine
Morsani College of Medicine
University of South Florida
Tampa, Florida

Nancy V. Nguyen, DO
Clinical Faculty Physician
Mercy Methodist Family Medicine Residency Program
Sacramento, California

Tam T. Nguyen, MD†
Clinician/Clinical Instructor
Washington Township Medical Group
Union City, California

Tu Dan (Kathy) Nguyen, MD
Primary Care Sports Medicine Fellow
University of Texas Health Science Center
Houston, Texas

Yummy Nguyen, MD†
Family Medicine Physician
Naval Hospital Pensacola
Pensacola, Florida

Frederick W. Nielson, MD†
Staff Family Physician
United States Air Force
Spangdahlem Air Base, Germany

Kathy Niu, MD†
Resident
Department of Neurology and Psychiatry
University of Massachusetts Medical School
Worcester, Massachusetts

Thomas Noh, MD
Resident
Department of Neurological Surgery
Henry Ford Hospital
Detroit, Michigan

Bakr Nour, MD, PhD, FACS
Professor and Vice-Chairman
Department of Surgery
Weill Cornell Medical College, New York City
Senior Adviser to the Dean
Surgery Clerkship Director
Weill Cornell Medical College in Qatar
Al Rayyan, Qatar

Laura Novak, MD
Assistant Director Family Medicine Residency Program
Summa Barberton Family Medicine Residency
Barberton, Ohio

Olga L. Nunez, MD
Resident
Family and Community Medicine
University of Texas Health Science Center at San Antonio
San Antonio, Texas

Crystal Nwagwu, MD
Assistant Professor
Department of Family and Community Medicine
Baylor College of Medicine
Houston, Texas

Kamala M. Nyamathi, MD†
Adjunct Instructor/Clinician Teacher
Department of Family Medicine
Oregon Health & Science University
Portland, Oregon

David T. O’Gurek, MD, FAAFP
Assistant Professor
Department of Family and Community Medicine
Temple University School of Medicine
Philadelphia, Pennsylvania

Elisa D. O’Hern, MD†
Pediatrician
Madigan Army Medical Center
Joint Base Lewis–McChord
Tacoma, Washington
Keith O’Malley, MD, FACS
Attending Surgeon
Augusta University Medical Center
Augusta, Georgia

Andrea Ochab, DO†
Naval Hospital Jacksonville
Jacksonville, Florida

Jin Sol Oh, MD
General Surgery Resident
Department of General Surgery
Medical College of Georgia
Georgia Regents University
Augusta, Georgia

Arthur Ohannessian, MD
Assistant Clinical Professor
Residency Associate Program Director
Department of Family Medicine
David Geffen School of Medicine at UCLA
Los Angeles, California

Cynthia Y. Ohata, MD†
Attending Physician
Advocate Christ Family Medicine Residency
Hometown, Illinois
Community Faculty
Family Medicine Leadership Program
Rush Medical College
Chicago, Illinois

Smriti Ohri, MD†
Assistant Professor
Department of Family Medicine
Oregon Health and Science University
Portland, Oregon
Tambetta Ojong, MD
Family Medicine Resident
Department of Family Medicine
SUNY Downstate Medical Center
Brooklyn, New York

Nneka I. Okafor, MD, MPH
Resident
Department of Family & Community Medicine
The University of Texas Health Science Center at San Antonio
San Antonio, Texas

Obiefuna P. Okoye, MD, MPH†
Infectious Disease Consultant
Southeastern Health
Lumberton, North Carolina

Amy Okpaku, DO
Associate Program Director
Family Medicine Residency
Dell Medical School, University of Texas at Austin
Austin, Texas

Erika Oleson, DO, MS
Assistant Professor
Department of Family Medicine and Community Health
Division of Geriatric Medicine
University of Massachusetts Medical School
Worcester, Massachusetts

Jacqueline L. Olin, MS, PharmD, BCPS, CDE, FASHP, FCCP
Professor of Pharmacy
Wingate University School of Pharmacy
Wingate, North Carolina

Karla A. Oliveros, MD
Department of Medicine
Universidad Catolica Santiago de Guayaquil
Guayaquil, Ecuador

Folashade Omole, MD, FAAFP†
Professor and Chair
Department of Family Medicine
Morehouse School of Medicine
Atlanta, Georgia

Cherry Onaiwu, MD, MS
Resident
Department of Internal Medicine
Creighton University Medical Center
Omaha, Nebraska

Amy Ondeyka, MD
Clinical Assistant Professor
Department of Emergency Medicine
Rowan University School of Osteopathic Medicine
Stratford, New Jersey
Teaching Faculty
Emergency Medicine Residency Program
Inspira Medical Center
Vineland, New Jersey

Cinthya Pena Orbea, MD†
Internal Medicine
John H. Stroger Jr. Hospital of Cook County
Chicago, Illinois

Imola K. Osapay, MD
Assistant Director
Family Medicine Residency
Summa Barberton Hospital
Clinical Assistant Professor
Department of Family and Community Medicine
College of Medicine
Northeast Ohio Medical University
Barberton, Ohio

Sean M. Oser, MD, MPH
Associate Professor
Department of Family and Community Medicine
Pennsylvania State University College of Medicine
Hershey, Pennsylvania

Tamara K. Oser, MD
Associate Professor
Department of Family and Community Medicine
Pennsylvania State University College of Medicine
Hershey, Pennsylvania

Chidinma Osineme, MD
Assistant Professor and Family Medicine—Obstetrics Residency Faculty
Virginia Tech Carilion School of Medicine
Edward Via College of Osteopathic Medicine
Virginia Tech Carilion
Roanoke, Virginia

Shannon A. Sanchez Oviedo, MD, MS
Novant Health Family Residency Program
Cornelius, North Carolina

Berenice Subero Pablo, MD
Family Medicine
Chicago, Illinois

Andrea Padilla, MD
Resident
Family and Community Medicine
University of Texas Health Science Center at San Antonio
San Antonio, Texas
Kelly Pagidas, MD†
Professor
Division and Program Director
Reproductive Endocrinology and Infertility
Department of Obstetrics, Gynecology and Women’s Health
University of Louisville School of Medicine
Louisville, Kentucky

Richard Albert Paguia, MD
Infectious Disease Fellow
Department of Medicine
Division of Infectious Disease
Creighton University School of Medicine
Omaha, Nebraska

Miguel A. Palacios, MD
Assistant Professor/Clinical
Department of Family and Community Medicine
University of Texas Health Science Center at San Antonio
San Antonio, Texas

Yow-Jeng Franny Pan, MB, BCh, BAO
Resident
Department of Family Medicine
Creighton University Medical Center
Omaha, Nebraska

Linda Paniagua, MD†
Department of Emergency Medicine
Brownsville, Texas

Sally-Ann L. Pantin, MD, FAAFP†
Instructor and Associate Family Medicine Residency Program Director
Department of Family Medicine
Mayo Clinic
Jacksonville, Florida
Anupama Parameswaran, MD  
Dermatology Resident Physician  
University at Buffalo  
State University of New York  
Buffalo, New York

Jai D. Parekh, MBBS  
Internal Medicine Resident  
Creighton University School of Medicine  
Omaha, Nebraska

Jon S. Parham, DO, MPH  
Associate Professor and Associate Director of Predoctoral Education  
Department of Family Medicine  
University of Tennessee, Graduate School of Medicine  
Knoxville, Tennessee

Douglas S. Parks, MD  
Associate Professor  
University of Wyoming Family Medicine Program at Cheyenne  
University of Wyoming  
Cheyenne, Wyoming  
Clinical Associate Professor  
Department of Family Medicine  
University of Washington School of Medicine  
Seattle, Washington

Naomi Parrella, MD, FAAFP  
Medical Director  
Center for Weight Loss and Lifestyle Medicine  
Rush University Medical Center  
Assistant Professor  
Department of Family Medicine  
Department of Surgery  
Rush University Medical School  
Chicago, Illinois
David O. Parrish, MS, MD, FAAFP
Director of Family Medicine Residency
Bayfront Health
St. Petersburg, Florida
Clinical Associate Professor
University of South Florida College of Medicine
Tampa, Florida

Rachel Soffer Parritz, MD
Obstetrics and Gynecology Resident
Advocate Illinois Masonic Medical Center
Chicago, Illinois

Sarah Parrott, DO
Assistant Professor
Division of Primary Care Medicine
Kansas City University of Medicine and Biosciences
Kansas City, Missouri

Gregory A. Parson, DO†
Department of Emergency Medicine
Inspira Health Network
Vineland, New Jersey

Michael Passafaro, DO, DTM&H, FACEP, FACOEP
Attending Physician
Department of Emergency Medicine
CarePoint Health
Jersey City, New Jersey

Paul Pastor, MD
Catholic University of Santiago de Guayaquil
Guayaquil, Ecuador

Birju B. Patel, MD, FACP, AGSF†
Clinical Associate
Northeast Georgia Diagnostic Clinic
Krunal Patel, MD
Gastroenterology Fellow
Department of Medicine
University of Massachusetts Medical School
Worcester, Massachusetts

Mahesh C. Patel, MD
Assistant Professor of Medicine
Division of Infectious Diseases, Immunology, and International Medicine
University of Illinois at Chicago College of Medicine
Chicago, Illinois

Manisha J. Patel, MD
Department of Internal Medicine
Lahey Hospital & Medical Center
Burlington, Massachusetts

Nihal K. Patel, MD
Fellow
Section of Gastroenterology and Hepatology
Dartmouth Hitchcock Medical Center
Lebanon, New Hampshire

Nupam A. Patel, MD
Resident
Pathology and Laboratory Medicine
University of Cincinnati College of Medicine
Cincinnati, Ohio

Rajen Patel, MD
Resident
Department of Family & Community Medicine
School of Medicine
The University of Texas Health Science Center at San Antonio
San Antonio, Texas

Ravin V. Patel, MD
Family Medicine
Department of Family Medicine
Saint Louis University/Belleville Campus
Belleville, Illinois

Joseph E. Patruno, MD
Associate Clinical Professor
Department of Obstetrics and Gynecology
Lehigh Valley Health Network
University of South Florida—College of Medicine
Allentown, Pennsylvania

Jared M. Patton, MD, MS†
Resident Physician
Family Medicine Residency
Naval Hospital Camp Lejeune
Camp Lejeune, North Carolina

Jill Patton, DO†
Program Director and Vice Chairperson
Department of Medicine
Advocate Lutheran General Hospital
Park Ridge, Illinois

Charles Pavia, PhD
Associate Professor of Microbiology
Departments of Medical Education and Biomedical Sciences
College of Osteopathic Medicine
New York Institute of Technology
Old Westbury, New York

Gisela M. Lopez Payares, MD
Department of Family and Community Medicine
The University of Texas Health Science Center at San Antonio
San Antonio, Texas

Matthew S. Peckham, MD
Resident
Department of Radiology
University of Massachusetts Medical School
Worcester, Massachusetts

Maryse A. Pedoussaut, MD
Assistant Professor
Division of Medicine and Society
Department of Humanities, Health, and Society
Herbert Wertheim College of Medicine
Florida International University
Miami, Florida

Randall Pellish, MD
Assistant Professor of Medicine
Department of Medicine
Program Director
Gastroenterology Fellowship
University of Massachusetts Medical School
Worcester, Massachusetts

Brian P. Peppers, DO, PhD
Allergy and Immunology Research Fellow
Department of Allergy and Immunology
University Hospitals Cleveland Medical Center
Case Western Reserve University
Cleveland, Ohio

Luis Liu Pérez, DO
Program Director
Transitional Year Program
Firelands Regional Medical Center
Firelands Physician Group
Sandusky, Ohio
Jose L. Perez-Lara, MD  
Resident  
Department of Internal Medicine  
Bronx Lebanon Hospital Center  
New York, New York

T. Ray Perrine, MS, MD, FAAFP  
Faculty Attending  
Family Medicine Residency Center  
North Mississippi Medical Center  
Tupelo, Mississippi

Christine S. Persaud, MD  
Medical Director  
Division of Sports Medicine  
Primary Care Sports Medicine  
Department of Orthopaedic Surgery  
SUNY Downstate Medical Center  
Brooklyn, New York

Gene Pershwitz, MD  
Resident  
Creighton University School of Medicine  
Omaha, Nebraska

Robert K. Persons, DO†  
Staff Physician  
Family Medicine Residency  
Eglin Air Force Base  
Valparaiso, Florida

Bobby Peters, MD, FAAEM  
Assistant Professor  
Emergency Department  
University of Iowa Hospitals  
Iowa City, Iowa
Keith E. Petersen, DO†
Associate Program Director
Family Medicine Residency
Madigan Army Medical Center
Tacoma, Washington

Lindsay Petersen, MD
Breast Surgeon
Department of Surgery, Breast Oncology Program
Henry Ford Hospital System
Detroit, Michigan

Hugh Peterson, MD, FACP
Associate Professor of Medicine
Division of General Internal Medicine, Palliative Care, and Medical Education
University of Louisville School of Medicine
Louisville, Kentucky

Chief of Gastroenterology
The Miriam Hospital
Gastroenterology Associates, Inc.
Providence, Rhode Island
S. David Shahbodaghi, MD, MPH, CTropMed†
Family Medicine Resident Program
Chief Resident
Dwight D. Eisenhower Army Medical Center
Fort Gordon, Georgia

Rory M. Shallis, MD
Clinical Fellow
Department of Hematology-Oncology
Yale University School of Medicine
New Haven, Connecticut

Kevin C. Shannon, MD, MPH, FAAFP
Associate Professor
Department of Family Medicine
Loma Linda University School of Medicine
Loma Linda, California

Denise Sharon, MD, PhD, FAASM†
Assistant Professor
Tulane University School of Medicine
Clinical Director
Advanced Sleep Center
Metairie, Louisiana
UCHealth Poudre Valley Hospital Sleep Disorders Center
Claremont, California

Victoria R. Sharon, MD, DTMH
Assistant Professor of Dermatology & Mohs Surgery Director
Dermatology Inpatient Consultation
University of California, Davis
Davis, California

Karen Sheflin, DO
Assistant Professor
Department of Family Medicine
College of Osteopathic Medicine
Paula A. Shelton, MD
Family Medicine
University of Texas Health Science Center at San Antonio
San Antonio, Texas

Rameeza Sheriff, MD
Resident Physician
Department of Family and Community Medicine
University of Kentucky College of Medicine
Lexington, Kentucky

Nicole Shields, MD
Assistant Professor of Family Medicine
DeBusk College of Osteopathic Medicine
Lincoln Memorial University
Harrogate, Tennessee

Jeffrey Shih, MD
Assistant Professor of Medicine
Advanced Heart Failure and Cardiac Transplantation
Cardiovascular Medicine
University of Massachusetts
Worcester, Massachusetts

David C. Shin, MD
Sports Medicine Fellow
Long Beach Memorial Primary Care Sports Medicine
University of California, Irvine
Irvine, California

Amal Shine, MD
Resident
Department of Internal Medicine
University of Louisville School of Medicine
Louisville, Kentucky

Scott D. Sholem, DO, MS
General Surgery Resident
St. Joseph’s Regional Medical Center
Paterson, New Jersey

Jacob C. Shook, DO†
Family Medicine Resident
Fort Hood Family Medicine Residency
Fort Hood, Texas

Irfan Siddiqui, MD
Resident, Internal Medicine
University of Illinois College of Medicine
Chicago, Illinois

Rohanjit S. Sidhu, MD†
Nephrology Fellow
University of Massachusetts Medical School
Worcester, Massachusetts

Hugh Silk, MD, MPH, FAAFP
Professor
Department of Family Medicine and Community Health
University of Massachusetts Medical School
Worcester, Massachusetts

Matthew A. Silva, PharmD, RPh, BCPS
Professor of Pharmacy Practice
Massachusetts College of Pharmacy and Health Sciences University
Worcester, Massachusetts

Sabrina L. Silver, DO, CAQSM†
Sports Medicine Medical Director
Family Medicine Residency
United States Air Force
Eglin Air Force Base, Florida

Diagnosis and Treatment: An Algorithmic Approach

This section contains flowcharts (or algorithms) to help the reader in the diagnosis of clinical signs and symptoms and treatment of a variety of clinical problems. They are organized by the presenting sign, symptom, or diagnosis.

These algorithms were designed to be used as a quick reference and adjunct to the reader’s clinical knowledge and impression. They are not an exhaustive review of the management of a problem, nor are they meant to be a complete list of diseases.
ABDOMINAL PAIN, CHRONIC

Common causes: irritable bowel syndrome, functional dyspepsia, domestic violence, ho of incest/rape, celiac, PID, endometriosis, anxiety, child abuse/neglect

Screen for history of abuse, domestic violence.

Red flags:
- Weight loss
- Age <18 years
- Anemia
- Fever

Age <18 years

Screen for abuse (physical, sexual, emotional abuse), neglect.

CBC w/th, ESR, LFTs, TSH, amylose, lipase, tissue transglutaminase (anti-TG), PPD, TSH, stool guaiac, O&P, Clostridium difficile

Pelvic exam, transvaginal US, STI culture

DDx: IBS, IBD, functional abdominal pain, celiac

CBC w/diff
- ESR
- TSH, LFTs
- Amylose, lipase, tissue transglutaminase (anti-TG)
- PPD
- Stool guaiac, O&P, C. difficile

Mental status for acute or chronic stressors or anxiety

Establish safety plan, 1-800-799-7223, refer counseling.

Lower abdomen of female

Pelvic exam, transvaginal US, STI culture

Note: Only check for C. difficile if the patient has concurrent diarrhea.

Shadi Hamdeh, MD and Adil Abdalla, MD

ABDOMINAL PAIN, LOWER

Abdominal abscess, diverticulitis, appendicitis, ovarian torsion, ectopic pregnancy, endometriosis, ischemic bowel, ovarian cyst, ovarian torsion, pancreatitis, PID, pyelonephritis, strangulated hernia, testicular torsion

**Duration of symptoms**

**Acute**

Peritoneal signs (guarding, rebound tenderness), temp >38°C, elevated WBC with left-shift

- Yes
  - Strangulated hernia, appendicitis, AAA, ovarian torsion, ectopic pregnancy, mesenteric adenitis, colitis, pancreatitis, ischemic bowel
  - Consider: qualitative hCG, CBC, UA, lipase, urinalysis, FSR, UA with culture, blood culture x 2, stool guaiac, abdominal ultrasound, CT of the abdomen/pelvis with and without contrast (contrast only if creatinine <1.3). Consider surgical consult if peritoneal signs present; pelvic exam with cultures, wet prep, and bimanual exam if female

- No
  - Pyelonephritis, PID (ulcerative colitis, Crohn disease), retroperitoneal abscess, testicular torsion
  - Consider: qualitative hCG, CBC, UA with culture and PCR for chlamydia, abdominal ultrasound, pelvic exam with bimanual exam, wet prep and cultures (UTI, chlamydia)

**Chronic**

Cyclic pattern to the pain?

- Yes
  - Endometriosis, ovarian cyst, mittelschmerz
  - Consider: qualitative hCG, CBC, UA with culture and PCR for chlamydia, abdominal ultrasound, pelvic exam with bimanual exam, wet prep and cultures (UTI, chlamydia)

- No
  - IBS, PD, interstitial cystitis, ectopic pregnancy
  - Appendicitis, ovarian torsion, PID, depression, anxiety, chronic trauma (domestic partner abuse), colonic adhesions, history of abdominal surgery. Consider: CBC, CMP, UA with cultures, lipase, CT abdomen/pelvis (with contrast if creatinine ≤1.3)

Andrew G. Alexander, MD, Kenneth A. Ballou, MD, and Maegen Dupper, MD

ABDOMINAL PAIN, UPPER

Common causes: GERD, functional dyspepsia, PUD, pancreatitis, biliary dysfunction, angina, esophageal/gastric cancer, medications, IBS

- Acute severe pain hypotension?
  - Yes: Acute abdomen
  - No: Evaluation for cardiac disease

- GI alarm symptoms
  - Bleeding, tachycardia, hypotension, hematemesis, melaena, drop in hematocrit
  - Neoplasia: weight loss, age >50 years, family hx of gastrointestinal malignancy, anemia

- Endoscopy
  - PUJ, esophageal/gastric carcinoma
  - Fever, tenderness

- LUS pain
  - Elevated bilirubin, alkaline phosphatase, jaundice

- RUQ pain
  - Elevated AST/ALT, elevated alkaline phosphatase on US
  - Associated with meals, +/- elevated WBC/fever, + Murphy sign
  - If US is negative, obtain hepatobiliary scintigraphy (HIDA scan)

- Pain radiating to back, hx of alcohol abuse, gallstones, recent ECG, hyperglycemia, hypercholesterolemia, smoking

- Indigestion, bloating
  - Heartburn, acidic taste at mouth, worse at night

- Symptoms that do not resolve with PPI
  - Cough, fever, CXR

- ERCP

Praphophat Adhatamsoontra, MPH, MD and Marie L. Borum, MD, EdD, MPH

ACETAMINOPHEN POISONING, TREATMENT

Marissa T. Christian, PharmD, Ryan B. Feeney, PharmD, and Frank M. Mazzotta, DO

ACIDOSIS

Consider acidosis in setting of the following:
- Altered mental status
- Abnormal breathing
- Known drug overdose
- Severe infection, trauma, inflammation
- Respiratory distress

Note: Renal response to respiratory acidosis may occur over days, may not see low HCO₃ until immediately

ABG
pH < 7.35, CO₂ > 40, or HCO₃ < 18

PO₂ > 45?

No

Metabolic

Serum anion gap normal?
Na – (Cl + HCO₃) = 3–11 mEq/L

Normal anion gap (hyperchloremic) metabolic acidosis

Renal tubular acidosis (RTA):
- H1A type 1: distal failure of acid secretion; hypokalemia; high urine pH (>5.3)
- RTA type 2: proximal failure of bicarbonate reabsorption; low urine pH (<5.3)
- RTA type 4: decreased proximal ammonia production due to hypoalbuminemia, hyperkalemia

GI losses of HCO₃, diarrhea, fistula, or hyperalimentation, parenteral nutrition, overeating

Ketosis: DKA, alcoholics, lactic acidosis, Check urine and plasma ketones.

Lactic acidosis: sepsis, shock, malignancy, medications, metabolic disorders. Check lactate levels.

Toxic: alcohols, sedatives, ASA

Renal injury: acute or chronic kidney injury. Check Crand and GFR.

Yes

Respiratory

Frank J. Domino, MD

ALCOHOL WITHDRAWAL, TREATMENT

**History**: duration and quantity of alcohol intake; time since last drink; previous episodes of alcohol withdrawal; concurrent substance use; previouse medical and psychiatric conditions, prior detoxification attempts; prior seizures; alcohol craving; history; smoking, social support, stressors, triggers.

**Physical Exam**: VS (tachycardia, tachypnea, hypertension); CWSA (see below); MDC (arousal, orientation, hallucinations); HEENT (ptosis, ptosis, ptosis, ptosis); CV (tachycardia, MRRG, evaluate Sx of liver failure; ascites, varices, caput medusa, asterixis, palmar erythema); ECG (tachycardia, tremor, seizure activity); include assessment of conditions likely to complicate, exacerbate, or precipitate alcohol withdrawal: arrhythmias, CHF, CAD, pneumonia, 3rd bleeding, infections, liver disease, pancreatitis, neurologic deficits.

**Clinical Institute Withdrawal Assessment (CIWA) of Alcohol Scale**
- Nausea and vomiting 0-7 (none, 4, moderate, 7, severe, 7)
- Tension 0-7 (none, 4, moderate, 7, severe, 7)
- Anxiety 0-7 (none, 4, moderate, 7, extreme, 7)
- Agitation 0-7 (none, 4, moderate, 7, extreme, 7)
- Tachycardia 0-7 (none, 4, moderate, 7, severe, 7)
- Auditory hallucinations 0-7 (none, 4, severe, 7)
- Visual hallucinations 0-7 (none, 4, severe, 7)
- Headache 0-7 (none, moderate, severe, extreme)

**Mild withdrawal**
- CIWA of Alcohol Scale 0-7
- onset of withdrawal after 8 hours of a 24-hour abstinent period.
- Wernicke's encephalopathy, delirium tremens, agitation, nausea, myoclonus, tachycardia, hypertension, possible mild cognitive impairment.

**Moderate withdrawal**
- CIWA of Alcohol Scale 8-14
- 3-4 hours of a 24-hour abstinent period.
- Marked restlessness, agitation, moderate tremors, and disorientation.

**Severe withdrawal/delirium tremens**
- CIWA of Alcohol Scale 15-25
- Marked restlessness, agitation, severe tremors, delirium.

**Outpatient Management**
- Risk stratification:
  - Age ≥60 years
  - Tachycardia >100 bpm
  - Hypertension
  - Seizure disorder
  - History of alcohol withdrawal

**Admit to inpatient treatment/transport**
- High-risk patients:
  - Age ≥60 years
  - Tachycardia >100 bpm
  - Hypertension
  - Seizure disorder
  - History of alcohol withdrawal

**Admit to ICU or inpatient detoxification**
- Vitals signs
  - CIWA-Ar
  - NPO
  - Lactated Ringer’s
  - Bilirubin
  - PT-INR
  - INR
  - albumin

**Medications**
- Diazepam 2-5 mg IV q4h
- Haloperidol 2-5 mg IV q4h
- Compazine 25 mg IV q4h
- Benzodiazepines

**Example outpatient regimen**
- Fixed dose organ schedule
  - CIWA-Ar score ≤ 10
  - T1: 1 mg PO
  - T2: 3 mg PO
  - T3: 5 mg PO
  - T4: 7 mg PO

**Discharge planning**
- CIWA scores ≤ 10
  - T1: 1 mg PO
  - T2: 3 mg PO
  - T3: 5 mg PO
  - T4: 7 mg PO

**Medications**
- Long-acting benzodiazepines (diazepam)
  - Treatment of alcohol withdrawal
  - Prevention of delirium tremens

**Patients**
Reem Hadi, MD and Fozia Akhtar Ali, MD

AMENORRHEA, SECONDARY

Absence of menses >5 months in woman with regular periods or absence of menses >6 months in a woman with irregular periods

Common causes: pregnancy, ectopic pregnancy, anorexia/starvation, infection, PCOS, ovarian failure (menopause), pituitary adenoma, hypothyroidism

Urine hCG or serum test

Intrauterine pregnancy, ectopic pregnancy

Vaginal/rectal exam
FSH, LH, TSH, prolactin, BMG

Stress
Weight loss
Extreme exercise

Eating disorders

Acne, hirsutism, BMI >30, deepening of voice, LH/FSH ratio >2

Hot flashes
Sleep difficulty
Decreased libido

Check labs: DHEA-S, testosterone (increased), transvaginal ultrasound

PCOS

Menopause

Pituitary adenoma

Normal lab

3YN exam, transvaginal US

Obtain the following: cortisol, serum testosterone

Cushing disease Androgen tumor

Asherman syndrome Cervical stenosis

Maria Montanez, MD and Fozia Akhtar Ali, MD

ANEMIA

Common causes: iron deficiency, anemia of chronic disease, chronic renal failure, acute blood loss, hemolysis, vitamin B₁₂ deficiency, myelodysplasia, chemotherapy

Low MCV
- Check labs: Fe, TIBC, TTR, hemoglobin electrophoresis
- Iron deficiency
- Thalassemia
- Hemoglobinopathy
- Sickle cell anemia
- Lead poisoning

Normal MCV
- Check labs: Fe, TIBC, TTR, TSH, BUN, creatinine
- Anemia of chronic disease
- Chronic renal failure
- Hypothyroidism
- Mixed macrocyte/microcytic anemia

High MCV
- Check labs: reticulocyte count
- Increased reticulocyte count
- Vitamin B₁₂ deficiency
- Folate deficiency
- Alcohol abuse
- Liver disease
- Myelodysplasia

No increased bilirubin
- Hemolysis
- G6PD deficiency
- Pyruvatekinase deficiency
- Hereditary spherocytosis
- Hereditary elliptocytosis
- Mechanical heart valve
- Viral infections
- SLE

Increased bilirubin
- No increased bilirubin
- Acute blood loss
- Sulfonamides
- ZDV (AZT)
- Othornotherapy
- Phenytin

ASTHMA EXACERBATION, PEDIATRIC ACUTE

Initial evaluation: brief history of present illness, physical exam
- Asthma history: emergency department visits, hospital and ICU admissions, home medications, frequency of oral steroid use, history of intubation, rapid progressive episodes, food allergies
- Physical exam: auscultation, use of accessory muscles, ability to speak, heart rate, oxygen saturation, PEF, or FEV₁

Severity | Respiratory rate (<3 years) | Wheezing | Inspiration: expiratory ratio | Accessory muscle use | Oxygen saturation (room air)
---|---|---|---|---|---
Normal | 30 | None | 2:1 | None | 96–100%
Mild | 31–35 | 21–35 | End expiration | 1:1 | + | 96–98%
Moderate | 46–60 | 46–60 | Full expiration | 1:2 | ++ | 60–95%
Severe | >60, >50 | Inspiration and expiration (may have silent chest) | 1:3 | +++ | <93%

Mid exacerbation: inhaled β-agonist (nebulized or MDI with spacer q20–30min × 3 doses), consider systemic corticosteroids (PO/MIV) if not immediate response or history of recent course of corticosteroids; check initial oxygen saturation level; no need for continuous pulse-ox monitoring
- Consider levalbuterol in place of albuterol if h/o ADR

FEV₁ or PEF >40%

Moderate exacerbation: inhaled β-agonist (nebulized q20–30min × 3 doses, systemic corticosteroids (PO/MIV), supplemental O₂ to achieve SaO₂ >90%
- Consider levalbuterol in place of albuterol if h/o ADR

FEV₁ or PEF <40%

Severe exacerbation: severe symptoms at rest, accessory muscle use, no improvement after initial treatment, nebulized β-agonist in combination with ipratropium q30–45min or continuous, consider magnesium sulfate IV next; consider terbutaline intubation if NC response; consider heliox; consider endotracheal intubation for presumed or actual respiratory failure; make admit decision if <4 hours.

Discharge criteria met?
- In the last 2 hours:
  - Decreased diaphoresis and retractions
  - Sustained SaO₂ >90% at least 60 minutes after last albuterol dose

Yes

Improved FEV₁ or PEF (lung function tests)

Discharge home
- Patient education: Review home medications and inhaler/spacer technique
- Instructions for dose follow-up within 1 week
- Continue treatment: inhaled β-agonist and PO corticosteroids
- Continue or consider initiation of nebulized corticosteroid
- Written asthma action plan

No

FEV₁ or PEF <40%

Moderate exacerbation:
- Inhaled β-agonist q60min, continue treatment 1–3 hours; provided there is improvement; make admnt decision in <4 hours; reassess after each treatment

Admission: ICU or closely monitored as needed

No

FEV₁ or PEF >40%

Discharge criteria met?
- In the first 2 hours:
  - Decreased diaphoresis and retractions
  - Sustained SaO₂ >90% at least 60 minutes after last albuterol dose

Yes

Jasmit S. Minhas, MD and John A. Saryan, MD

**ASTHMA, INITIAL TREATMENT**

**Management of chronic asthma**

**Classification of asthma severity in youth ≤ 18 years of age and adults**

| Preferred and alternative pharmacotherapy based on step | Preferred: Short-acting β₂ agonist as needed  
Alternative: Low-dose inhaled corticosteroids (ICS) or leukotriene modifier or theophylline | Preferred: Low-dose ICS + LABA or medium-dose ICS  
Alternative: Low-dose ICS + leukotriene modifier, theophylline, or zileuton | Preferred: Medium-dose ICS + LABA  
Alternative: Medium-dose ICS + leukotriene modifier, theophylline, or zileuton  
Identify triggers: cold air, dust, allergic exposures/pollen, and control exposures |
|         |        |        | Preferred: Medium-dose ICS + LABA  
Identify triggers and control exposures |
|         |        |        | Preferred: High-dose ICS + LABA + oral corticosteroids, and consider omalizumab for patients with allergies  
Identify patient risk for reactions to aspirin and NSAIAs and avoid exposure |

At each step, discuss patient education, environmental control, and management of comorbidities.

Michael C. Barros, PharmD, BCPS, BCACP, Colleen M. Prinzivalli, PharmD, BCPS, CGP, and Alia Chisty, MD, MS, FACP

Michael C. Barros, PharmD, BCPS, BCACP, Colleen M. Prinzivalli, PharmD, BCPS, CGP, and Alia Chisty, MD, MS, FACP

ATAXIA

Acute (seconds–days)
- Obtain careful exposure history; consider infectious evaluation (CBC with diff, lumbar puncture, CT scan, or MRI)
- Toxins (alcohol, carbon monoxide, carbon tetrachloride, heavy metals, cyanide, toxic exposure to solvents, methymercury poisoning)
- Medications (antiepileptics, chemotherapy agents, aminoglycosides, antiadrenergics, metronidazole, Fluphen-induced cerebellar toxicity)
- Infectious meningitis, postinfectious cerebellitis—varicella, measles, EBV
- Ischemic/hemorrhagic stroke
- Head or neck trauma

Subacute (days–weeks)
- Obtain anti-TTG, TSH, CBC, RPR, LFTs, vitamin B₁₂, TSH, calcium, phosphorous, PTH
- Atypical infectious process (FML, PNH, disease, Whipple disease)
- Autoimmune diseases (MS, celiac disease with enteropathy, Hashimoto encephalopathy, neurosarcoidosis)
- Benign tumors (vestibular schwannoma, meningioma)
- Primary malignant tumors (ependymoma, glioma, hemangioblastoma, medulloblastoma)
- Metastatic tumors (breast, colon, lung, melanoma, renal cell CA)
- Lymphoma
- Alcohol abuse and vitamin deficiencies (Wernicke encephalopathy, vitamin B₁₂, E, and zinc deficiencies)
- Systemic disorders (movement disorders—Parkinson, chorea, hypothyroid, hypoparathyroid)

Chronic (months–years)
- Congenital (kumod-Chiari malformation, Dandy-Walker syndrome, hydrocephalus, Joubert syndrome, vermierencephaloceles)
- Autosomal dominant (spinocerebellar ataxias, episodic ataxia, adult-onset leukodystrophy)
- Autosomal recessive (Franceschetti ataxia, ataxia telangiectasia, Wilson disease)
- X-linked (agile-X)

Other
- Obtain RPR, vitamin B₁₂, CT, or MRI
- Normal pressure hydrocephalus
- Sensory ataxia (tabes dorsalis, vitamin B₁₂ deficiency)
- Migraine HA with brainstem aura
- Labryrinthis Ménère disease
- Acoustic neuroma
- Dementia

Fozia Akhtar Ali, MD and Teny Anna Philip, MD
AZOTEMIA AND UREMIA

Azotemia is the elevation of blood urea nitrogen (BUN). It can be divided into prerenal, intrinsic renal, and postrenal azotemia based on the cause. This is important as treatments differ. Uremia is essentially symptomatic azotemia and is mostly due to the accumulation of BUN and other toxins or waste products normally filtered by the kidneys. Untreated uremia may progress to seizures, coma, and death.

**History and physical suggestive of etiology?** Risk factors include older age, sepsis, shock due to any etiology, liver failure, use of IV contrast agents, and diabetes mellitus.

- **BUN/Cr ratio > 15?**
  - **Prerenal azotemia**
    - ~70% of AKI
    - Poor perfusion due to:
      - Shock (septic, cardiogenic, or hypovolemic)
      - Sepsis
      - Congestive heart failure
      - Dehydration
      - Cirrhosis/liver failure
      - Medications: NSAIDs, ARBs, ACE inhibitors, Cystosporine, Loop diuretics
  - **Urinary retention, palpable bladder, and/or positive bladder ultrasound?**
    - Consider renal ultrasound and UA w/micro.
    - **Obstruction?**
      - **Postrenal azotemia**
        - Obstructive uropathy
      - **Renal azotemia**
        - BPH
        - Cancers of prover, prostatic, or bladder
        - Neurogenic bladder
        - Medications:
          - Aminoglycosides
          - Sulfonamides
          - IV contrast
          - Lithium
          - NSAIDs
          - Penicillins
          - Caphalosporins
          - Ayclovir
          - Interferon
          - Phenytoin
          - Rifampin
          - PPs

  - **Cronic renal disease:**
    - Diabetes mellitus
    - Hypertension
    - Glomerulonephritis
    - Sarcoidosis
    - Lupus

Steven A. House, MD, FAAFP, FAAHPM, HMDC

CARDIAC ARRHYTHMIAS

Common cause: coronary artery disease, hyperthyroidism, electrolyte abnormality, valvular heart disease, CHF, sick sinus syndrome

Check labs: electrolytes, glucose, calcium, magnesium, TSH

Tachycardia

Irregular pulse
- Atrial fibrillation
  - Hyperthyroidism
  - Valvular heart disease
  - Cardiac hypertrophy
  - Lone atrial fibrillation

Regular pulse
- PSVT
  - Atrial flutter
    - Tachycardia

Sinus tachycardia

PVCs
- APCs
- Sinus arrhythmia

Normal heart rate

Bradycardia

Sinus bradycardia
- AV block
- Sick sinus syndrome

Mixed tachycardia/bradycardia
- CAD
- Valvular heart disease
- HTN

Fever
- Pain
- Hypothyroidism
- HTN
- Orthostatic hypotension
- Pheochromocytoma

Medications
- β-blockers
- Calcium channel blockers
- Digoxin

Aging
- Hypothyroidism
- CAD
- Spinal cord injury
- Young athlete
- Congenital causes

Amaninderpal S. Ghotra, MD, Suma Chennubhotla, MD, and Kelly McCants, MD

CERVICAL HYPEREXTENSION INJURY

**Sufficient mechanism of injury**
- Most common: MVA, deceleration, sports, falls, etc.
- Also: trauma above the clavicles (e.g., orbital, head, etc.)

Away
Breathing
Circulation
Disability

EMS primary survey

**On-scene/EMS evaluation (EMS)**
- Assessment of mechanism—high risk?
- Neurologic exam—impaired motor, sensory, or reflexes? Numbness/impairment?

If necessary, intubate using manual in-line intubation before proceeding to secondary survey/mobilization.

**On-scene/EMS evaluation (EMS)**

Yes to any

Immobilize C-spine and transport to medical facility.

Rigid collar, spine board

Physician primary survey

*Leave helmet/pads in place. Remove facemask.

Physician primary survey

Hemodynamically unstable

IV crystalloid, blood transfusion, and pressors search for hemorrhagic source. Intubate with MIL if necessary.

Hemodynamically stable

Physician secondary survey

Imaging for clinically significant spinal injury

**NERIS I criteria**
- No posterior neural deficits or weakness
- No abnormal level of alertness
- No evidence of intoxication
- No painful/distracting injuries
- No normal neurologic symptoms (paresis, numbness, weakness, palsy, or neck pain/cervical ten­derness)

If all live criteria

Neurogenic shock
- Administer IV steroids
- Emergent surgical decompression with rigid fusion
CHILD ABUSE

Physical abuse
- When a child makes a disclosure
- When there is no history to explain an injury
- When the history is not consistent with the injury seen
- When parts of the history change
- Any bruise on an unrehabilitating child
- Any unusual or unexpected delay in seeking medical care

Sexual abuse
- Child makes a disclosure
- Child discloses sexualized behaviors
- Doing something for a sexual purpose
- Being made to do something sexual
- Child has genital injury or infection
- Any pregnancy in child <16 years old

Medical history
- When >5 years old, ask spontaneous questions that do not intrude on children's awareness of abusive acts or abuse. For children >5 years old, acquire information away from the child's presence if possible.
- For all children, listen attentively, believe them, and thank them for telling you. Reassure them and avoid any anger, as the child may misinterpret this as you being angry with them.
- Obtain a covered physical history (especially fractures).
- Review past medical history, including prior trauma, injuries, surgeries, and hospitalizations.
- Family history: history of bone fracture, skeletal deformities, metabolic or genetic issues.
- Developmental and behavioral health history.
- Social history: where they live, who they live with, including their children in households, substance use/abuse, job loss or other stressors.
- Child's race/ethnicity if likely.
- Note: History is the most important part of the entire process.

Physical examination
- General assessment: child's appearance, demeanor, degree of pain, growth parameters, evidence of neglect (severe burns, diaper dermatitis, neglected wound care, and so on)
- Complete head-to-toe examination, looking for bruises, ecchymoses, burns, bites, etc. This includes oral cavity, ears, external genitalia, and perineal regions.
- One or two x-rays, examination, imaging studies, or laboratory tests to identify skeletal abnormalities or behavioral health
- Consider photographs, and sketches of physical injuries.
- Perform skeletal survey, including plain radiographs, computed tomography, and magnetic resonance imaging.
- A sexual assault nursing evaluation (SANE) may be warranted as well if the event occurred in the past 5 days. Post-assault laboratory tests and HIV prophylaxis may also be needed. Please call your local child abuse team. SANE services are available for further assistance.
- Only secure cameras should be used to photograph patients. This typically excludes personal cell phones.
- Ensure photographs are made, please contact local social services or child abuse team.

Diagnostic testing for suspected child physical abuse

Age 0-6 months
- Child protection team consult
- FEED UT or MRI
- Draining survey
- Laboratory:
  - CBC
  - ESR
  - Liver function tests

If unexplained:
- Bruising—send CBC, PT, and aPTT
- Fractures—send Ca, Mg, AST, ALT, liver function tests, INR, Coagulation panel

Age 0-4 months
- Child protection team consult
- Skeletal survey
- Laboratory:
  - CBC
  - ESR
  - Liver function tests
- Low threshold for head CT or MRI

If unexplained:
- Bruising—send CBC, PT, and aPTT
- Fractures—send Ca, Mg, AST, ALT, liver function tests, INR, Coagulation panel

Management
- Referral to investigative agencies: protective agencies according to state-specific mandated reporting laws. (e.g., reporting neglect and other issues available from Child Welfare Information Gateway [www.childwelfare.gov]. Additional information on child abuse and neglect (CCWAN): www.aspp.org/cw/en/ResourceProjects/)
- Referral to appropriate medical providers (such as a pediatric trauma center)
- Referral to appropriate behavioral health counselors for trauma symptom screening and treatment. Early mental health intervention within the first 60 days following a traumatic event. Educational information under resources of the National Child Traumatic Stress Network website (http://www.nctsn.org/resources)
- Medical documentation
- Safety plan in place prior to discharge with appropriate follow-up plan.

Wynne S. Morgan, MD and Peter J. Sell, DO

CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD), DIAGNOSIS AND TREATMENT

Suspect COPD if
- Chronic cough and/or sputum production
- History of smoking or chemical exposure
- Dyspnea at rest and exertion

Spirometry with pre- and postbronchodilator

Severity of COPD
- FEV₁/FVC
- FEV₁
- Mild: <0.7 >80%
- Moderate: <0.7 50–80%
- Severe: <0.7 30–50%
- Very severe: <0.7 <30%

Functional Dyspnea Scale
- 0 Not troubled with breathlessness except with strenuous exercise
- 1 Troubled by shortness of breath when hurrying or walking up a slight hill
- 2 Walks slower than people of same age due to breathlessness or has to stop for breath when walking at own pace on the level
- 3 Stops for breath after walking ~100m or after a few minutes on the level
- 4 Too breathless to leave the house or breathless when dressing or undressing

Diagnosis confirmed, initiate preventative measures:
- Influenza vaccine (yearly). 23-valent pneumococcal vaccine once before age of 65 years and every 5 years until age of 65 years;
- 23-valent and 13-valent pneumococcal vaccines once after age of 65 years

Aggressive smoking cessation counselling if actively smoking
William Wong, DO and Scott E. Kopec, MD

CIRRHOSIS

Common causes: alcohol abuse, viral hepatitis, α1-antitrypsin deficiency, collagen vascular disease, nonalcoholic steatonephatitis, hemochromatosis, medications, primary biliary cirrhosis, primary sclerosing cholangitis.

Check liver function tests, HepAAb, HCVAb, HBsAg, HBSAb, Fe, TIBC, ferritin, CBC w/ diff., mcnospot, ANA, CRP, antimitochondrial antibodies, US or CT of liver.

History of alcohol or hepatotoxic medication exposure?

Yes

Alcoholic hepatitis

Meathexase Amiodarone INH Valproic acid Many others

+ Viral studies

Hepatitis B Hepatitis C Hepatitis A Mononucleosis

Elevated Fe/TIBC and increased ferritin

- Viral studies

Normal Fe studies

No autoimmune findings

Hemochromatosis

Order CRP, antimitochondrial antibody (AMA), anti-smooth muscle antibody (ASMA), ANA, liver–kidney microsomal type 1 antibody (LKM-1).

Elevated ANA, ASMA, LKM-1, and CRP

Elevated antimitochondrial antibody

Decreased α1-antitrypsin levels

History of ulcerative colitis

Fatally infiltrate on liver imaging

All tests normal

Autoimmune hepatitis

Primary biliary cirrhosis

α1-Antitrypsin deficiency

Primary sclerosing cholangitis

Nonalcoholic steatohepatitis

Gilbert syndrome

CONCUSSION, SIDELINE EVALUATION

Stable, No C-spine injury

CONCUSSION: traumatic event AND change in neurologic function OR one of the following signs/symptoms: somatic (HA, nausea/vomiting [NV], dizziness, vertigo, visual problems, sensitivity to light/sound, nsebness/dizziness), cognitive (LOC, memory problems, feeling "foggy"/drowsy reaction times, confusion), emotional/behavioral (i.e., irritability, sadness), sleep (i.e., drowsiness, difficulty falling asleep)

Evaluate ABCs and check for C-spine injury. Remove from play.

Stable and normal C-spine exam

Unstable or C-spine injury possible

Assess with standardized tool (SCAT3, SAC, Maddocks questions, BESS, etc.): Vital signs, GCS, orientation, past and immediate memory, concentration, balance, coordination, delayed recall. SCAT3 available at http://physicians.carolinelife.com/scat

Vital signs q30min. Do not leave patient alone.

Condition good to baseline

Condition not back to baseline

Full history and PE (head and neck evaluation, complete neurologic exam)

OGCS ≤ 14, signs of altered mental status, or signs of skull fracture

Red flags: focal neurologic deficit, loss of consciousness > 1 minute, neck pain or distracting injury unable to clear C-spine, persistent NV, amnesia, worsening neurologic

No

Yes

continued

Oczipal, sartorial, or temporal scalp hematomas > 25 seconds

Severe mechanism of injury: not acting normally per parent

No imaging

Appropriate treatment (neurosurgical consult for bleeding or edema)

Mononuclear head CT (or less common, MRI)

Normal

Abnormal

A. Follow up with medical professional in 24 hours.

- History and PE (including complete neurologic exam) using Sport Concussion Assessment Tool (SCAT3) available online www.sportconcussions.ca/DocumentsSCAT3.pdf
- Consider neurosych testing
- If at neurosych baseline, review Return to Play protocol
- If not a neurosych baseline, consider ED evaluation or imaging, close follow-up, and symptomatic treatment.

B. Consider neurosych testing (soon and remote). IMAGe, CogState, HeadMinder, ANAM, etc.

- The ideal timing, frequency, and type of neurosych testing have not been determined.
- Most concussions can be managed appropriately without the use of neurosych testing.
- Neurosych testing may be most helpful for high-risk athletes, those with prior concussions, and those who may decompensate in an effort to return to play sooner.

C. Return to Play protocol

- No athlete may return to play the same day.
- All school-aged athletes must return to school before they can return to play.
- Once asymptomatic at a stage for 24 hours, may move to next stage if symptoms arise. Must take a 24-hour period to complete rest before dropping back one stage and starting from there.
- Most athletes should return no sooner than 7 days after concussion:
  - Stage 1: no activity (complete physical and neurocognitive rest; cognitive rest includes no reading).
  - Stage 2: light aerobic exercise (walking, swimming, or stationary cycling) at <70% max HR).
  - Stage 3: sport-specific exercise (sport-specific drills or scrimmages, no head impact activities).
  - Stage 4: non-contact training drills (progress to more complex training drills such as passing, may start progressive resistance training).
  - Stage 5: full contact practice.
  - Stage 6: return to gameplay (should also be free of any medications that could mask symptoms of concussion).

- Please note initial cognitive rest and early graded resumption of social cognitive activity is also important. Patients may require accommodations such as a shortened school day, reduced academic workload, extended time for tests, and so on. When recovering from a concussion:
  - For children under 16, or those that look > 1-2 days for initial symptoms resolution, consider wait 1 week before steps 14-16

D. Symptom management: if concussive symptoms (typically HA, sleep, cognitive, and mood disturbances) are persistent and interfering with function, consider symptomatic treatment:

- In the acute setting ARA and NICE guidelines should be used with caution due to increased risk of intracranial bleeding. Acetaminophen and physical modalities are OK.
- If HA persists for > 4 days, consider typical abortive treatment. There is no established role for pharmacotherapy in the acute treatment of concussion-induced HA, sleep, cognitive, or mood disturbances.
- If symptoms persist beyond a few weeks, consider referral to specialist neurology sports medicine, etc. Multidisciplinary approach is often needed.
- If symptoms do not resolve despite appropriate evaluation and treatment, consider terminating athletes season or athletic career (no clear guidelines have been established; this decision should be made on a case-by-case basis).

*Signs of altered mental status: agitation, somnolence, repetitive questioning, or slow response to verbal communication.

- General recommendations for injury, treatment, vehicle, and equipment specific, weather, performance, or skill fatigue, predisional or diagnosis without helmet struck by motorized vehicle falls > 3 ft for patients ≤ 2 years old or > 3 ft for patients ≥ 2 years old or head struck by high-impact object.

Caitlyn M. Rerucha, MD and Michelle E. Szczepanik, MD

CONGESTIVE HEART FAILURE: DIFFERENTIAL DIAGNOSIS

Common causes: CAD, MI, valvular disease, arrhythmia, idiopathic cardiomyopathy, pulmonary hypertension, renal disease, medication noncompliance

Diagnosis made clinically

History: exercise intolerance, dyspnea on exertion or at rest, cough, orthopnea, paroxysmal nocturnal dyspnea, chest discomfort, fatigue, weight gain

Exam: elevated jugular venous pressure, rales, S3/S4 gallop, hepatomegaly, increased abdominal distention, pitting edema, lower, extremity edema

Testing: chest x-ray, ECG, troponin, echo, BNP, BMP, LFTs, TSH, UA, uric acid

Diagnosis of CHF: Framingham Diagnostic Criteria
Requites 2 major criteria or 1 major and 2 minor criteria

Major criteria
- Acute pulmonary edema
- Cardiomegaly
- Hepatomegaly
- Elevated jugular venous pressure
- Paroxysmal nocturnal dyspnea
- Rales
- S3

97% and 99% sensitive for systolic and diastolic heart failure, respectively

Minor criteria
- Dyspnea on exertion
- Hepatomegaly
- Nocturnal cough
- Pitting edema
- Tachycardia >100 bpm

Alternative diagnosis:
- COPD
- Asthma
- Lung disease
- Pulmonary embolism

BNP <500

LVEF <50% (systolic HP)

LVEF >50% (diastolic HP)

CHF

Ischemic
- History of CAD/MI
- Positive stress test
- CAD or cardiac catheterization
- Troponin elevation

Cardiac catheterization unless contraindicated

Non-ischemic cardiomyopathy

Evaluate for causes of CHF:
- Ischemic: CAD/MI
- Non-ischemic: HTN, idiopathic CM, valvular disease, HCM, arrhythmia, myocarditis/pericarditis, collagen vascular disease
- Due to volume: medication noncompliance, renal failure

Idiopathic cardiomyopathy

Other: HTN, thyrotoxicosis, alcoholism, chemotherapy-induced, cocaine, autoimmune, collagen vascular disease, infiltrative (amyloid, hemochromatosis), obstructive sleep apnea

Tachycardia-mediated (atrial fibrillation/flutter, SVT, frequent PVCs)

Valvular disease cardiomyopathy

Viral-mediated (coxsackievirus, adenovirus, HIV, EBV)

Frank J. Domino, MD

Daniel J. Stein, MD, MPH and Stephen K. Lane, MD, FAAFP

CONSTIPATION, TREATMENT (PEDIATRIC)

Red flags:
- Constipation <1 month
- No meconium in 48 hours
- Family history of Hirschsprung disease
- Ribbons stools
- Blood in the stools without anal fissures
- Failure to thrive
- Fever
- Biliary vomiting
- Abnormal thyroid gland
- Severe abdominal distention
- Perianal fistula
- Abnormal position of anus
- Absent anal or cromasteric reflex
- Decreased lower extremity tone
- Turt of hair on spine
- Sacral dimple
- Gluteal deft deviation
- Extreme fear during anal inspection
- Anal scars

Rome III Criteria (2 criteria):
- ≤2 defecations per week
- At least one episode of incontinence per week after toilet training
- History of excessive stool retention
- History of painful/hard bowel movements
- Presence of a large fecal mass
- History of large diameter stools that may obstruct the toilet

Careful history and physical exam: digital rectal exam is not required for diagnosis.

Are red flags present?

Obtain based on symptoms: CBC, glucose, TSH, calcium, glucose, creatinine, tissue transglutaminase (TTG), and endomyxium antibody (EMA)

Differential diagnosis:
- Celiac disease
- Hypothyroidism
- Hypercalcaemia
- Hyperkalaemia
- Diabetes mellitus
- Drug/toxins—opiates, anticholinergics, antipsychotics, chemotherapy, heavy metals
- Vitamin D intoxication
- Botulism
- Cystic fibrosis
- Hirschsprung disease
- Anal atresia
- Colonic inertia
- Ano malformations
- Pelve mass
- Spinal cord abnormalities
- Abnormal abdominal musculature
- Pseudodocclusion
- Multiple endocrine neoplasia type 2B

Refer for specialty evaluation

Fecal impaction?

Yes

First line: polyethylene glycol 3350 1–1.5 g/kg/day for 3–6 days

Second line: enemas daily for 0–6 days

No

Functional constipation

Maintenance therapy:
- First line: PEG 0.4 g/kg/day adjusted for one to two soft bowel movements/day
- Lactulose is acceptable if PEG is not available

Dietary changes/family education:
- High-fiber diet (1–5 years: 14 g/day; 5–10 years: 17–25 g/day; >13 years: 25–31 g/day): Increase fiber gradually to minimize flatulence.
- Add fiber gummies (inulin up to 15 g BID as tolerated)
- Limit caffeine and milk products (<16 oz/milk/day)
- If symptoms persist, add: 0.6–1.2g tartaric acid per day; >6 months–lactulose (1–3 mL/kg/day to max 60 mL/day) or polyethylene glycol 3350 (0.5–1 g/kg/day to max 17 g/day).

Bethany N. Teer, MD

Amanda M. Carnes, MD

DEEP VENOUS THROMBOSIS, DIAGNOSIS AND TREATMENT

Determine Wells score

- Active cancer +1
- Calf swelling >3 cm +1
- Collateral superficial veins +1
- Pitting edema +1
- Previous DVT +1
- Pain along venous system +1
- Paralysis or recent immobilization (cast) +1
- Recently bedridden for >3 days or general anesthesia +1
- Recent diagnosis of DVT +1
  - ≤2 DVT unlikely
  - ≥2 DVT likely

Scoring

0: low probability

≥1: intermediate probability

≥3: high probability

D-dimer:

- Negative
  - DVT ruled out
- Positive
  - Duplex US with compression
    - Negative
      - D-dimer
        - Negative
          - DVT ruled out
        - Positive
          - Consider repeating US in 5–7 days.
    - Positive
      - DVT confirmed
        - Any respiratory symptoms
          - Outpatient management (See next page.)
        - Proximal VTE
          - Admit (See next page.)
        - Candidate for thrombolysis
        - Active bleeding
        - Renal failure
        - History of HIT
        - Severe cyanosis or edema

Positive

Negative
Treatment of Venous Thromboembolism

**Outpatient Management**
- Low-molecular-weight heparin (LMWH):
  - Enoxaparin 1 mg/kg SC BID or
  - Dalteparin 200 IU/kg SC daily for patients with cancer
- LMWH is the preferred treatment in pregnancy.
- Hirudin (factor Xa inhibitor):
  - 1.5 mg BID or 3.0 mg SC daily for 3 weeks, followed by 0.5 mg SC daily for 6–12 months
  - Contraindicated in patients with active pathologic bleeding or history of severe hypersensitivity reaction to the drug
  - Avoid in patients with CrCl <30 mL/min
  - Use is not recommended in pregnancy or breastfeeding
  - Current use is limited due to cost and lack of reversal agent

**Maintenance Therapy**
- Hypercoagulation test before starting anticoagulation therapy
- UFH is preferred in patients with renal impairment
- Treatment with LMWH, UFH, or fondaparinux is recommended for at least 5 days and until INR is 2–3 for 2 consecutive days
- Start warfarin on same day as LMWH, UFH, and fondaparinux
  - Goal INR 2–3
  - Continue for 3–3 months after first DVT
  - Warfarin is contraindicated in pregnancy
  - Rivaroxaban 20 mg daily for 6–12 months
  - Dabigatran (direct thrombin inhibitor): 150 mg BID after 7–10 days of LMWH and continue for at least 6 months
  - Adjust dose for CrCl <50 mL/min
  - Do not use in CrCl <15 mL/min
  - Contraindicated in active pathologic bleeding, history of severe hypersensitivity reaction to the drug, and mechanical prosthetic heart valve
  - Use is not recommended in bicuspid prosthetic heart valve, pregnancy, and breastfeeding
  - LMWH or heparin SC can be continued for patients with allergy to warfarin
  - Consider TEE for individuals with non-valvular AF to rule out anticoagulation

**Inpatient Management**
- Massive DVT
  - Symptomatic PE
  - High-risk bleeding with anticoagulation therapy
  - Comorbid conditions
- IV unfractionated heparin (UFH): 80 U/kg bolus or 5,000 U → continuous infusion with initial dose 18 U/kg/hr → target to goal PTT 80–145 seconds or
  - UFH 12,500 U/kg SC BID or
  - Enoxaparin 1.5 mg/kg SC daily or
  - Fondaparinux 5–10 mg SC daily depending on weight

**Bency K. Louidor-Paulynice, MD**

DEHYDRATION, PEDIATRIC

Determine severity of dehydration:
1. Calculate % dehydration = preinjury wt (kg) - illness wt (kg)/preinjury wt (kg) × 100
2. Use clinical assessment using below physical findings.

<table>
<thead>
<tr>
<th>Physical finding</th>
<th>Mild (3-5%)</th>

Pt has ongoing losses, intractable vomiting, acute abdomen, severe gastrointestinal distress, or >10 mL/hr stool loss?

Oral replacement solutions (ORS)
Pedialyte, rehydralyte, WHO solution

Parenteral rehydration
Phase I: emergency bolus
20 mL/kg isotonic fluid (NS or LR) over 5-10 min
Repeat up to 80 mL/kg total.

Parenteral rehydration
Phase II: maintenance
100 mL/kg for first 10 kg, then
50 mL/kg for next 10 kg, and then
25 mL/kg for each kg >20 kg
Give first half over 8 hours and second half over next 16 hours.

L. Michelle Seawright, DO and Nathaniel Stepp, DO

Camila Avila, MD and Holly L. Baab, MD

DEMENTIA

1. Clinical suspicion
   2. Demonstrate cognitive impairment.

   Mini-Mental State Examination (MMSE)

   Common causes:
   - Alzheimer disease
   - Vascular dementia
   - Lewy body dementia
   - NPH; HIV, depression

   MNSE <24

   Geriatric Depression Scale
   - Positive
   - Negative

   Treatment: depression and reevaluate in 3 months.

   MNSE ≥24

   Laboratory studies
   Routinely recommended:
   - TSH, vitamin B₁₂, CMV, CBC, folate
   - High clinical suspicion:
     - RPR, HIV, UA, heavy metals, LP

   Abnormal labs
   - Thyroid disorder
   - Vitamin B₁₂ deficiency
   - Electrolyte abnormalities
   - Anemia
   - Folate deficiency
   - Syphilis
   - HIV
   - Infectious causes

   Normal labs
   - Consider imaging: CT or MRI (preferred)
     - If abrupt or rapid decline
     - Age <60 years
     - Focal deficit
     - Precipitating condition (malignancy, anticoagulation)

   Abnormal
   - Multi-infarct dementia
     (stepwise decline)
   - Normal-pressure hydrocephalus
     (gait disturbance, incontinence)
   - Pick disease
     (personality change)
   - Subdural hematoma

   Normal
   - Alzheimer disease
   - Parkinson disease
     (shuffling gait, tremor)
   - Lewy body dementia
   - Chronic alcohol use

Kristin A. Troubaugh, DO

DEPRESSIVE EPISODE, MAJOR

Obtain symptom score using PHQ-9.
1. Depressed mood*
2. Loss of interests/pleasure*
3. Change in sleep
4. Change in appetite or weight
5. Change in psychomotor activity
6. Loss of energy
7. Trouble concentrating
8. Thoughts of worthlessness or guilt
9. Thoughts about death or suicide

Determine and document DSM-5 criteria for MDD. *Presence of symptoms 1, 2, or both, plus 5 or more symptoms during the same 2-week period leading to dysfunction.

Depression screen
Depressed mood and/or loss of interest/pleasure, most of the day >2 week

Imminent risk of serious self-harm/suicide?
Yes

Refer to emergency mental health for treatment and stabilization.

Medications, comorbid medical conditions, substance abuse causing depression?
Yes

Provide medical treatment (including substance abuse treatment) and follow-up

No

History of treatment resistant depression, current manic, hypomania or psychosis?

Yes

Refer to mental health specialty care.

No

Determine symptom severity and functional impairment

Severity
Mild 10–14
Moderate 15–19
Severe >20

PHQ-9 Score

Mild

Start with monotherapy of either antidepressant or psychotherapy referral.

Moderate

Use a combination of both antidepressant and psychotherapy.

Severe

Emphasize combination of both antidepressant and psychotherapy, may consider multiple drug therapy, or referral to psychiatrist or inpatient stabilization.

Increase dose, change antidepressant, or add therapy. Full effect from antidepressant can take 8 weeks.

No

Improvement in 2-3 weeks?

Yes

Maintain effective treatment, follow up q1–3mo PRN

If 2 or 3 antidepressants trials ineffective or patient status worsening

Refer to psychiatrist.

Wendy K. Marsh, MD, MSc

DIABETIC KETOACIDOSIS (DKA), TREATMENT

Emily Bouley, MD and Frank J. Domino, MD

DIARRHEA, CHRONIC

**Common causes:** infectious (bacterial, viral, parasitic), inflammatory bowel disease (IBD), malignancy, irritable bowel syndrome (IBS), medications, thyroid dysfunction, lactase deficiency, malabsorption syndromes (celiac disease, pancreatic insufficiency, bile acid malabsorption [BAM]).

**History:** characteristics of stool, associated symptoms, iatrogenic risk factors (medications, radiotherapy), antibiotics, recent hospitalization, surgical history, dietary history (carbohydrates, sugar alcohols, coffee, fatty foods), family history, sexual history, immunosuppression.

**Medications?**

- **Yes:** Acid-reducing agents (PPIs, H2 blockers), antacid (containing magnesium), antibiotics, NSAIDs, colchicine, herbal medications, vitamin and mineral supplements, antineoplastic agents, antiretroviral agents, steroids, fructose abuse, chronic laxative abuse.

- **No:**
  - **Alarm symptoms** (GI bleeding, fever, significant weight loss)?
    - **Yes:** Labs: stool studies (culture, Clostridium difficile, ova and parasites, fat, electrolytes, c-reactive protein, blood), blood tests (TSH, glucose, celiac serology [TTG yA, HLA, Gi peptide assays], hydrogen breath test).
    - **No:** Evaluate for IBS/irritable bowel syndrome: recurrent abdominal pain on average, at least 1 day/week in the last 3 months, associated with two or more of the following criteria: related to defecation, associated with a change in frequency of stool, associated with a change in form (appearance) of stool.

**Stool:**
- Positive for ova and parasites: test for C. difficile toxin or stool culture positive for bacteria: infectious diarrhea.
- Positive fecal blood, leukocytes, calprotectin: inflammatory diarrhea.
- Positive celiac serology: upper endoscopy.
- Positive fecal fat: see "Malabsorption Syndrome" algorithm.
- Positive breath test: small intestinal bacterial overgrowth.
- Hypothyroidism, diabetes, pernicious anemia.

**Coelecscopy:**
- Abnormal: Colonoscopy and/or biopsies.
- Normal: IBD, malignancy, ischemic colitis, infectious colitis, microscopic colitis.

**IBS:**
- If no improvement with IBS treatment, consider empiric trial of bile acid sequestrant to determine if BAM is present.

Najwan Alsulaimi, MBBS and Marie L. Borum, MD, EdD, MPH

DIZZINESS

I. Vertigo: Illusion of self or environmental nction
II. Presyncope: fainting almost passing out
III. Light-headed: floating sensation
IV. Disequilibrium: falling/trouble with balance

Vertigo

Presyncope

Light-headed or woozy

Disequilibrium

No

Hearing loss?

Yes

A. Otitis media
B. Otochorea
C. Acoustic neuroma
D. Drug toxicity
E. Perilymphatic fistula
F. Labyrinthitis

Abnormal

1. Check H/H, electrolytes, creatinine, TSH
2. Review medications.

Normal

Psychiatric disorder
1. Anxiety
2. Depression
3. Panic disorder
4. Bipolar disorder
5. Hyperventilation syndrome

Rapid deep in and out breathing can reproduce dizziness in hyperventilation syndrome.

Vertigo duration

Seconds–Minutes
1. Benign paroxysmal positional vertigo

Perfom Dix-Hallpike maneuver.

Findings
Postural system
Last component toward affected ear

Epley maneuver
Vestibular rehabilitation

Hours
1. TIA, posterior brain circulation
2. Ménière disease
3. Multiple sclerosis
4. Perilymphatic fistula
5. Vestibular migraine

1. Orthostatic drug-induced (CV drugs, opioids, etc.; dehydration)
2. Arrhythmias (SVT, AFib, heart block, etc.)
3. Autonomic dysfunction
4. Anemia/GI bleed
5. Hypoglycemia
6. Anxiety

Days
1. Vestibular neuritis
2. Stroke: cerebellar or brain stem
3. Via de dähancement (after ca or ce shap)

Decreased

A. Peripheral neuropathy
1. Diabetic neuropathy
2. Vitamin B12 deficiency
D. OND abnormality
1. Parkinson
2. Spinalstenosis
3. Spinal cord disorder
C. Toxins
1. Alcohol
2. Lead
3. Mercury
D. Systemic
1. Hypothyroidism
2. Amyloidosis
E. Brain hypoxia

Increased

1. Cerebellar disease
2. Intoxication (ETA, mercury, lithium, gils, solvent, glue)

 Jamal Islam, MD, MS

DYSPEPSIA

Jennifer L. Hamilton, MD, PhD, FAAFP

DYSPHAGIA

Shari Anthony, MD and Maria Cynthia S. Lopez, MD

ERYTHROCYTOSIS

Common causes:
- COPD, right-to-left cardiac shunt, obstructive sleep apnea,
- anabolic steroids/testosterone, renal cell CA,
- pheochromocytoma, uterine leiomyoma, high-affinity Hgb,
- polycythemia vera

Definition:
Increase in red cell mass
Men with Hgb > 18.5 or Hct > 52%
Women with Hgb > 17.5 or Hct > 48%

Workup of cardiopulmonary causes of erythrocytosis:
for example, COPD, right-to-left cardiac shunt, sleep apnea

Oxygen saturation ≥ 92%

No

Yes

EPO level and JAK2 V517F
PCR

EPO low and JAK2 positive

Polycythemia vera

EPO low and JAK2 negative

JAK2 exon 12: assessment

Testing bone marrow biopsy, BCR-ABL, calreticulin PCR

EPO elevated/normal and JAK2 negative

Secondary erythrocytosis

Causes and testing
- Congenital
  - High oxygen affinity Hgb
  - PS10 evaluation
  - Von Hippel Lindau disease: genelic testing
- Acquired
  - Renal cell carcinoma: CT scan
  - Pheochromocytoma: CT scan
  - Uterine leiomyoma: ultrasound
  - Use of androgen preparations: biooc test

Manisha J. Patel, MD and Tarun Kewalramani, MD

FATIGUE

Common causes: depression, anxiety, substance abuse, medications, viral illness, anemia, thyroid dysfunction, carcinoma, infection, obstructive sleep apnea

Daytime sleepiness? Snoring? BMI >30 kg/m²?

Yes

Obtain nocturnal polysomnogram (PSG)

No

Obstructive sleep apnea

Improves with rest?

Yes

Psychological and/or psychiatric conditions

No

Substance use disorder
Personality disorder
Physical/emotional abuse
Anxiety
Depression

Consider evaluation for coexisting medical condition.

Organic cause

Yes

Cough or dyspnea on exertion?

No

Consider CHF, TB, atypical pneumonitis. Check PPD and chest x-ray and ECG.

Check labs: TSH, BMP, LFTs, CBC w/diff, EBV mono spot, ESR, HIV, PPD, ferritin.

Abnormal

thyroid disease, anemia, malignancy, HIV, diabetes mellitus, autoimmune disease, infections, mononucleosis

Normal

Reevaluate for psychological causes.

Paavan Mehta, MD and Frank J. Domino, MD

FEVER IN THE FIRST 3 MONTHS OF LIFE

Rectal temperature ≥38°C or 100.4°F

Age <28 days?

Yes

1. Admit
2. CBC w/ diff, UA, blood culture, urine culture
3. LP CSF: Gram stain, chemistry, culture. Consider CSF HSV and acyclovir PCR.
4. CXR if respiratory symptoms
5. Stool analysis and culture / diaphoresis
6. Respiratory viral panel + RSV test if URI (fever and cough)
7. Consider herpes HSV PCR and CSF HSV PCR if elevated transaminases or CFS pleocytosis.

Empic treatment

Amoxicillin (MIIV)
<7 days and <2 kg: 50 mg/kg q12h
≥7 days and <2 kg: 50 mg/kg q8h
≥7 days and ≥2 kg: 50 mg/kg q8h
AND
Cefotaxime (MIIV)
<7 days: 2 kg: 50 mg/kg q12h; ≥7 kg: 50 mg/kg q8h
≥7 days: 12-24 kg: 50 mg/kg q12h; 24-36 kg: 50 mg/kg q8h; >36 kg: 50 mg/kg q8h

If mucocutaneous vesicles, elevated transaminases, seizures, or CSF pleocytosis add acyclovir 20 mg/kg q8h. If MRSA is suspected, add vancomycin.

No

1. CBC w/ diff, UA, blood culture, urine culture
2. CXR if respiratory symptoms
3. Stool analysis and culture / diaphoresis
4. Respiratory viral panel + RSV test if URI (fever and cough)
5. Consider HIV testing if <40 days.

Low risk

- WBC 5-15,000/ml
- Absolute band count <1,500/ml
- UA <10 WBC/HPF and no bacteria
- CXR no infiltrate
- HR ≤90 BPM
- Meninges appearance
- No focus of infection (e.g. bone, skin, etc.)
- Reliable follow-up

Yes

Outpatient management is practical to be reevaluated in 24 hours

1. Consider empiric therapy with daily follow-up; only if P. stutzeri
2. Avoid blood, urine cultures.

No

Culture at 24 hours.

Negative

Watch

Positive

Fever?

No

Observe

Fever but low risk: Treat with ceftriaxone 50 mg/kg < 1 dose and daily follow-up.

Fever?

Yes

Admit and IV antibiotic treatment.

Treat as outpatient if follow-up is reliable with antibiotics based on culture result.

Robyn Wing, MD, MPH and Madeline L. McCarthy, MD, MS

FEVER OF UNKNOWN ORIGIN

Common causes: HIV, SBE, osteomyelitis, TB, malaria, malignancy, collagen vascular disease, medication

Discontinue implicated medications.

Recent hospitalization?

Yes

Check: lower extremity Doppler, CT angiogram

Check: Clostridium difficile enteritis

Deep vein thrombosis, Pulmonary embolism

C. difficile infection

No

Check: HIV, CBC with diff, ESR, LDH, LFTs, blood culture, urine culture, CXR, PPD, Quantifoil: TB

HIV positive?

Yes

HIV+ opportunistic infection

HIV negative?

HIV-

Neutropenia?

Neutropenic?

Neutropenia

PJP pneumonia, CNV, Lymphoma, TD, MAI

Opportunistic bacteria

HIV

Candidiasis

Aspergillosis

Yes

No

Malignancy suspected

Noninfectious

Homatoptasia

Autoimmune condition suspected

Check: rheumatoid factor, ANA

Check: biopsy (temporal artery, lymph node)

Check: bone marrow biopsy

Chronic infection suspected

Check: AF3, sputum cultures, N/R, ASO/CMV/EBV titers

Check: TEE, sinus CT, PCT scan, lumbar puncture

Check: brain MRI, biopsy (skin, lymph nodes), exploratory laparoscopy

Chock: peripheral smear, sputum protein electrophoresis

Rachelle E. Toman, MD, PhD, Kevin Stephens Jr., MD, MBA, and Emily Zucker, MD

**GASTROESOPHAGEAL REFLUX DISEASE (GERD), DIAGNOSIS AND TREATMENT**

Hadi Atassi, DO and Thomas L. Abell, MD

Chidinma Osineme, MD
GRANULOCYTOSIS (LEUKOCYTOSIS)

WBC >11.0 x 10^9/L.

Common causes: Infection, inflammation, drugs (steroid/lithium/β-agonists, G-CSF, GM-CSF, etc.), stress, smoking, alcohol, hypoxia, stress, pregnancy, myeloproliferative disorder, thalassemia thymoma.

Repeat CBC, Order manual smear.

Leukocytosis confirmed?

Leukocytosis explained by additional pertinent history and/or physical examination?

No

No further workup necessary

Yes

Yes

Consider malignancy: Review peripheral blood smear. Hematology/oncology consultation. Bone marrow biopsy and flow cytometry, cytogenetics or molecular testing on bone marrow or peripheral blood.

No

Patient presents with weight loss, fatigue, fevers, night sweats, splenomegaly, lymphadenopathy, bruising?

Abnormal red blood cell and platelet count?

Risk of or history of prior malignancy?

Determine affected cell line.

LYMPHOCYTOSIS (>4,300/mm^3; 4.5 x 10^9/L)

MONOCYTOSIS (>800/mm^3; 0.88 x 10^9/L)

Look for: Chronic infection (EBV, fungal, prozoal, toxoplasmosis). Autimmune splenomegaly. Myeloid/myeloproliferative syndrome. Consider: Contact history, medical history, monosport test, PPD, ESR, CRP, ANA.

Monomorphic (reactive)

Pleomorphic (reactive)

MONOMORPHIC Suspect lymphoproliferative disorder.

If persistent

Hematology/oncology consult. Bone marrow biopsy. Flow cytometry, cytogenetics, and molecular analysis of bone marrow or peripheral blood.

BASOPHILIA (>500/mm^3; 0.5 x 10^9/L)

Eosinophilia (>500/mm^3; 0.5 x 10^9/L)

NEUTROPHILIA (>5,000/mm^3; 5 x 10^9/L)

WBC >50,000: malignant. WBC <50,000: leukemic reaction.

Sarah Jamshed, MD and L. Michael Snyder, MD

HEADACHE, CHRONIC

HEADACHE, chronic >15 days/month

Rec flag? recent trauma, abnorm al neuro exam?

Yes

Pediatric <12 years old

Yes

Vision test?

Abnormal

Optometry F/U, correction

No

Normal

Brain CT or MRI?

Abnormal

Possible causes:
subdural or epidural hematoma, hydrocephaly, tumor

Normal

Consider posteroaural headache or complicated migraine

Migraine headache

Treatment: NSAIDs, caffeine, triptans, metoclopramide or ondansetron

Prophylaxis: Identify and eliminate trigger, beta-blockers, calcium channel blockers, TCA, depakote, gabapentin and loptinamate.

No

Location

Unilateral

Paroxysmal hemocriana, hemianopia continua, temporal arteritis

No

Autonomic features (nausea, vomiting, ptosis, miosis?)

Yes

Cluster headache

Tension headache

Occipital neuralgia, cervicogenic headache

TCA, Bb, anticonvulsants, antihypertensives

No response to therapy

Consider brain MRI and then lumbar puncture.

Bilateral

Posterior

Analgesic overuse?

Yes

Consider medication overuse/rebound headache.

No

Consider medication overuse/rebound headache.

Amy Okpaku, DO

HEMATEMESIS (BLEEDING, UPPER GASTROINTESTINAL)

Lisa N. Jarnagin, MBBCh, BAO, Lowla Al-Obaid, MD, and Stephen C. Fabry, MD

HEMATURIA

Risk factors for urinary tract malignancy:
- Age >55 years
- Male sex
- Analgesic abuse
- Exposure to chemicals/agents
- Exposure to alkylating chemotherapeutic agents
- Past or current smoking
- Chronic UTI
- Pelvic irradiation
- Gross hematuria.

Common causes: cystitis, urethritis, pyelonephritis, tumor, prostatitis

H&P urinalysis centrifuge

Supernatant red

Dipstick supernatant

Sediment red

Hematia

Heme-negative

Heme-positive

Beeturia, phenazopyridine, porphyria

Plasma color

Clear

Red

Myoglobinuria

Hamoglobinuria

<3 RBC/PF

Repeat UA 3 times at 0-week intervals.

Positive

>3 RBC/HPF

Assess for UTL vigorous exercise, menstruation, recent urologic procedure.

Assess for risk factors for malignancy, renal insufficiency.

Negative

Dysmorphic RBCs: proteinuria >200 mg/dl

Positive

Assess for nephrology referral

Low risk for malignancy, renal insufficiency

High risk for malignancy, normal renal functions

US/contrast CT and urology referral

Cystoscopy

CT with IV contrast and urology referral

Low

Obtain complement levels C3, C4

Normal

Systemic diseases

Renal

PAN, GPA, HSP, GP, hypersensitivity vasculitis

Systemic diseases

IgA, idiopathic R*GN: anti-GBM, pauci-immune

Annual UA for 2 years

Negative

Positive

Relieve from care.

Repeat anatomic evaluation in 3–5 years.

Poststreptococcal GN MPGN

DLE, cryoglobulinemia, bacterial endocarditis, stunted nephritis

Krishna Manda, MD, MRCP and Jagathi Govindu, MD

HEPATOMEGALY

Common causes: Liver disease, obesity (non-alcoholic fatty liver disease and steatohepatitis), tumors, infection, vascular disease, fatty liver disease, and metabolic disturbances.

History:
Evaluate for heart failure, obesity, alcoholic use, infections, recent exposures and travel.

Initial labs:
- ALT/AST
- Total bilirubin (indirect/direct)
- Alkaline phosphatase
- Hepatitis serology

Abnormal
	- Imaging: CT, ultrasound

Abnormal
	- Liver biopsy

Normal

Liver is normal; reevaluate in 6 months.

Consider the following diagnoses:
- Cirrhosis
- Alpha-1 Antitrypsin deficiency
- Chronic hepatitis
- Wilson disease
- Hemochromatosis
- Glycogen storage disease (pediatric patients)
- Extramedullary hematopoesis
- Malignancy
- Biliary obstruction
- Nonalcoholic fatty liver disease

Vascular congestion:
- Hepatic congestion secondary to heart failure
- Budd-Chiari syndrome
- IVC obstruction

Malignancy:
- Primary liver tumor (benign or malignant)
- Metastatic liver disease
- Granulomatous liver disease (TB, sarcodosis, etc.)

Medications/toxins:
- Acetaminophen
- Statins
- Idiosyncratic drug reactions
- Mushroom poisoning

Other:
- Autoimmune hepatitis
- Wilson disease
- Alpha-1 Antitrypsin deficiency
- Hemochromatosis
- Nonalcoholic fatty liver disease
- Alcoholic hepatitis

Cholestatic injury:
- Predominant elevation of alkaline phosphatase

- Primary biliary cirrhosis
- Primary sclerosing cholangitis
- Malignancy
- Biliary obstruction

Abnormal

Choledochal cyst

Vascular:
- Heart failure
- Budd-Chiari syndrome
- IVC obstruction

Cyst

Abcess

Proven liver abscesses usually develop following portal vein or direct spread of biliary ascites.

Uniformly enlarged

Liver biopsy

Nonalcoholic fatty liver disease

Liver biopsy +/- Flourosis

Anna L. Silverman, MD and Marie L. Borum, MD, EdD, MPH

HYPERCALCEMIA

Common causes: hyperparathyroidism, malignancy hyperpyrexia, vitamin D toxicity, milk-alkali syndrome, medications

Obtain ionized calcium or total calcium corrected Ca = total Ca + 0.8 x (4.6 – albumin level)

Clinical suspicion:
- Signs and symptoms of hypercalcemia:
  - GI: nausea, vomiting, anorexia, and constipation
  - Neurologic: lethargic, hypotonic, confused, or comatose
  - Renal: polyuria, nephrocalcinosis, and dehydration
  - Cardiac: shortened heart rate-corrected QT intervals, broadened T waves, and severe-degree anoventricular blocks

Review medications:
- Increased calcium intake, vitamin A intoxication, vitamin D overdose, thiazides, milk-alkali syndrome, theophylline, lithium

Check parathyroid hormone.

Elevated PTH
- Consider ectopic secretions of PTH (i.e., ovarian carcinoma)
  - Measure urinary calcium:
    - Elevated
      - Consider primary hyperparathyroidism
        - Consider surgery
    - Low
      - Consider familial hypocalciuric hypercalcemia (a decreased sensitivity of receptors requiring higher calcium levels to suppress PTH secretion)
      - Obtain detailed family hx.

Normal PTH or low
- PTH-related protein (PTHrp) and 1,25-OH vitamin D and 1,25 OH vitamin D
  - Elevated PTHrp
    - Elevated 1,25 OH vitamin D
      - Consider endogenous production from granulocytic disease or lymphoproliferative disorders (i.e., TB and sarcoidosis)
    - Normal or low 1,25 OH vitamin D
      - Consider thyrotoxicosis, prolonged immobilization
        - Elevated 25 OH vitamin D
          - Consider supplemental vitamin D overdose
          - Review medications.
  - Consider malignancy:
    - Humoral hypercalcemia of malignancy (e.g., squamous cell carcinoma)
    - OR local osteolytic hyperparacaeemia (e.g., multiple myeloma, bone metastases)

Deborah A. Lardner, DO, DTM&H and Michael Passafaro, DO, DTM&H, FACEP, FACOEP
Jason E. Cross, PharmD, Dinesh Yogaratnam, PharmD, and Sudeep K. Aulakh, MD, FACP, FRCP
HYPERNATREMIA

Sodium >145 mEq/L

History and volume status

Hypovolemic
- Dermal losses
- GI losses
- Diuretics
- Postobstructive
- Acute and chronic renal disease
- Hyperosmolar nonketotic coma

Euvolemic
- Diabetes insipidus (central, nephrogenic)
- Hypodipsia
- Fever
- Hyperperistalsis
- Mechanical ventilation

Hypervolemic
- Iatrogenic
  - Hypertonic saline, tube feedings, antibiotic containing sodium
  - Hyperalactosteronism
  - Cushing disease

If cause is not clear from history, obtain a urine and plasma osmolality and urinary sodium.

Urine osmolality/plasma
osmolality <0.7 mOsm/kg

Diabetes insipidus (central, nephrogenic)
Hypodipsia
CNS lesion

Urine sodium >60 mEq/L

Feral
- Diuretics (osmotic loop)
  - Interstitial renal disease
  - High-protein diet

Endocrine
- Cushing disease
  - Primary hyperalactosteronism
  - Diabetes mellitus

GI losses
- Lactulose malabsorption
- Infectious diarrhea

Respiratory losses
- Hyperventilation

Skin losses
- Excessive sweating

Urine osmolality/plasma
osmolality >0.7 mOsm/kg

Urine sodium <30 mEq/L

Timothy J. Coker, MD, FAAFP

HYPERTRIGLYCERIDEMIA

HYPOALBUMINEMIA

Albumin <3.5 g/dL

History: coma, jaundice, alcoholism, hepatitis, loamy urine, muscle atrophy, ascites, weight gain, loss of appetite, malnutrition, decreased PO intake, hypoproteinemia, diarrhea, vomiting, burns, inflammation

Decreased protein synthesis

- Cirrhosis, sigmas, ascites, spicery anagmas
- Hypoglycemia
- Low serum insulin

Abnormal protein distribution

- Physiologic stress (infection, surgery, trauma)
- Hemodiagnostic states
- Diabetes
- t-CRP and ESR
- Acute and chronic inflammation
- Periphere edema, dyspepsia, fatigue, t-RNP, cracks
- Flank dullness, abdominal distension, fluid wave

Protein loss

- Elevated pHCG
- Amenorrhea
- Pregnancy

Deciminated height
- Poor weight gain
- Deficit in lean body mass
- Wasted
- Stunted linear growth
- Anorexia
- Frequent infection
- Vitamin deficiencies

Malnutrition and starvation

- Decreased lymphocyte count, BUN, transferrin, prealbumin

Liver cirrhosis

Nephrotic syndrome

Enteral protein loss
- α-antitrypsin in stool
- Upper GI endoscopy
- Protein-losing gastroenteropathy workup

skin burns and tissue damage

Urine dipstick analysis
- 3+ protein

- Spot urine
- Random urine protein/Cr ratio ≥3.3

- 24-hour urine:
  - If <2.5 g/24 hr

Lawrence M. Gibbs, MD, MSEd, FAAFP

HYPOCALCEMIA

Common causes: lab error, chronic renal failure, postsurgical, hypoparathyroidism, hypocalcemia, hypomagnesemia, hyperphosphatemia, medication, PTH deficiency or resistance, vitamin D deficiency or resistance.

Check labs: Repeat serum calcium, ionized calcium, electrolytes, BUN, creatinine, magnesium, phosphorus, albumin, LFTs, PT, PTT, PTH.

Serum calcium >85 mg/dL

Probable false-positive result

Calcium <9.5 mg/dL, ionized or corrected calcium low, albumin normal or slightly low

If ionized calcium not available, correct calcium for albumin; calcium concentration falls by 0.9 mg/dL for every 1 g/dL fall in albumin.

PTH high

Pseudohypoparathyroidism

Vitamin D deficiencies

Hyponatremia

Calcium <8.5 mg/dL, ionized or corrected calcium normal, albumin low

If ionized calcium not available, correct calcium for albumin; calcium concentration falls by 0.9 mg/dL for every 1 g/dL fall in albumin.

PTH low

Hyponatremia

Cirrhosis

Nephrotic syndrome

Malnutrition

Burns

Chronic illness

Steppes

Timothy J. Coker, MD, FAAFP

HYPOKALEMIA

Aqib Chaudhry, MD and Frank J. Domino, MD

HYPONATREMIA

Serum Na < 135 mEq/L

Hyperglycemia?

No

Serum osmolality

Low

Pseudohyponatremia
- Hyperproteinaemia
- Hyperglycemia
- Mannitol

>280 mEq/L

<280 mEq/L

Hyperglycemia-induced hyponatremia

Calculate corrected serum Na*.

Normal

What is the volume status?

Hypovolemic: poor skin turgor, dry MM

- GI losses
- Sweating
- Burns
- Cystic fibrosis
- Exercise
- Bleeding

U Na < 20 mEq/L

U Na > 20 mEq/L

Diuretic use

Hypovolemic edema, ascites, third heart sound

U Na < 20 mEq/L

Renal failure

U Na > 20 mEq/L

U Na < 20 mEq/L

U Na > 20 mEq/L

- Hypothyroidism
- Addison disease
- SIADH I
- Cerebral salt wasting

Aqib Chaudhry, MD and Frank J. Domino, MD

Amar Talati, DO and David O. Parrish, MS, MD, FAAFP

INFERTILITY

Common causes
- Endocrine disorders—thyroid disease, polycystic ovarian syndrome (PCOS)
- Pelvic structural abnormality
- Ovulatory dysfunction—PCOS, obesity, strenuous exercise, anorexia/bulimia
- Male factor
- Improper coital timing
- Advanced age
- Unexplained

Detailed history & physical

Semen analysis is initial step

Poor coital timing
- Counseling

Irregular menses or suspicion of ovulation
- Ovulation predictor kits, basal body temperature, or individual progestrone confirms anovulation
- TS-hp谒lacin, hCG, CMA, free testosterone, FSH, LH, TVUS

Age ≥35 years
- Risk factors for pelvic abnormality (i.e., heavy menses; pelvic procedure, infection, ectopic)
- Risk factors for tubal occlusion (i.e., pelvic surgery, infection, previous ectopic)
- HSG

FSH ≥10 mIU/mL
- Consider referral to male fertility specialist vs. IUI

FSH < 10 mIU/mL
- Consider intrauterine insemination (IUI) if unexplained infertility (with superovulation)
- Consider surgery or surrogacy if uterus cannot be corrected
- Consider IVF vs. adoption

Family history of early menopause or menopausal symptoms
- Ovarian reserve testing: AMH, day 3 FSH and E2, AFC
- Consider IVF with embryo banking vs. donor egg IVF vs. adoption.

PCOS or obesity
- Abnormal
- Treat thyroid dysfunction; if elevated prolactin, obtain brain CT or MRI
- Ovarian induction meds.

Normal
- Offer ovulation induction meds.
- No spontaneous return of ovulation

TVUS
- Consider hysterosalpingogram; SIS = saline-infused ultrasound; TVUS = transvaginal ultrasound

Frank J. Domino, MD
JAUNDICE

Jaundice: yellow discoloration of skin, sclera, and mucous membranes by bilirubin. A bile pigment formed by the breakdown of heme rings; detected when the serum bilirubin level is >3.5 mg/dl. Bilirubin is a product of hemoglobin breakdown in the spleen. Here it is converted to unconjugated bilirubin, bound to albumin, and then sent to the liver where it is then conjugated.

Common causes: Gilbert syndrome, hemolytic, hepatitis, and cholelithiasis

C3C w/diff LFTs: ALT, AST, serum alkaline phosphatase (AP), total bilirubin (TB) and direct bilirubin (DB), haptoglobin, hepatitis serologies, enzytase, lipase, hCG, urinalysis with urine bilirubin: US or CT

Unconjugated hyperbilirubinemia

Direct bilirubin >0.3 mg/dl:

Conjugated hyperbilirubinemia

Elevated A2:

Intrahepatic

Orthopedic

Us: conjugated hyperbilirubinemia

- Gilbert syndrome: mild defect in UDF glucuronyltransferase (UGT), responsible for conjugation of bilirubin
- Crigler-Najjar syndrome: more severe defect in UGT, usually presents during infancy
- Conjugated hyperbilirubinemia
- Dubin-Johnson syndrome: defective secretion of conjugated bilirubin
-Rotor syndrome

Both conjugated and unconjugated hepatocholangiopathy injury:

- Hepatitis: viral, alcohol, or autoimmune insult leading to inflammation that impeds or prevents transport or secretion of conjugated bilirubin
- Medication: drug: acaminophen
- Cirrhosis
- Congestive heart failure;
- Hypoxia/anemia of heart failure leads to cellular injury

Intrahepatic cholestasis (no elevated LFTs. primarily, AP, US shows normal sized bile ducts)

Other:

- Medication: drug-induced
- Total parenteral nutrition (TPN)
- Sepsis
- Sarcoidosis
- Pregnancy

Extrahepatic cholestasis (labs: elevated TB and DB, increased AP, and positive urinalysis. US shows dilated bile ducts)

- Cholelithiasis: stone
- Chronic pancreatitis: acid
- Cholangitis: fever, pain, and jaundice, altered mental status, sepsis
- Biliary stenosis: reentry of surgical/invasive procedure
- Primary biliary cirrhosis
- Primary sclerosing cholangitis
- Bilary tract tumor/cholangiocarcinoma
- Hepatomegaly, weight loss, abdominal pain
- Pancreatic tumor: pancreas jaundice, palpable gallbladder (rare)

Krunal Patel, MD and Isabel Zacharias, MD

KNEE PAIN

Common causes: patellofemoral syndrome, ACL injury, meniscal tear, infections, D.D. fracture, pes anserine bursitis, Osgood-Schlatter disease

History of trauma or new activity?

Yes

Physical exam

No

Pain

Warm erythematous joint?

Physical exam

A°, lateral, sunrise views. Consider ipsilateral hip if knee pain after fall.

Effusion

Confusion

Meniscal tear, ACL tear, PCL tear, patellar dislocation, fractures

Osteomyelitis

Septic arthritis

Acute inflammation

Unilateral

Bilateral

RA, OA, systemic arthritis

Gout, pseudogout, Lyme

Hemarthrosis

Generalized anterior knee pain

Nighttime pain

Pain at tibial tuberosity

Mechanical symptoms: catching, popping, or locking

Overuse

Media: proximal tibial pain

Lateral: proximal tibial pain

Bleeding disorder

Age ≥50 years?

No

Yes

Pes anserine bursitis

Iliobial band syndrome

Patellofemoral syndrome

Positive Lachman or anterior drawer

ACL injury

Meniscal tear

Patellar tendonitis

Positive McMurray test: and medial or lateral joint line tenderness

Inferior patellar pole tenderness

Tumor (malignant or benign)

Osgood-Schlatter disease

Osteochondritis dissecans, meniscal tear

Alexei O. DeCastro, MD

LOW BACK PAIN, CHRONIC

Common causes: radiculitis, SI joint dysfunction, trauma, trochanteric bursitis, piriformis syndrome, osteoarthritis, osteoporosis, pars interarticularis fracture, ankylosing spondylitis, epidural abscess, malignancy, varicella zoster virus (postherpetic neuralgia), abdominal aortic aneurysm

Pain ~3 months

Abnormal gait, bowel/bladder incontinence, acute urinary retention, bilateral sciatica, IV drug abuse, history of malignancy, pain worse when supine, saddle anesthesia, progressive neurologic symptoms, recent infection

Yes

No

Yes

No

Urgent imaging (CT or MRI) and neurosurgical referral

Fever or concern of infection?

MRI or CT scan

Hx of trauma?

No need for imaging

Pharmacotherapy: NSAIDs, skeletal muscle relaxants (i.e., carisoprodol, tizanidine, cyclobenzaprine), anticonvulsants (i.e., topiramate), antidepressants (i.e., duloxetine), Botox

Pharmacotherapy: NSAIDs, skeletal muscle relaxants (i.e., carisoprodol, tizanidine, cyclobenzaprine), anticonvulsants (i.e., topiramate), antidepressants (i.e., duloxetine), Botox

Pharmacotherapy: cognitive-behavioral therapy, spinal manipulation therapy, structured exercise, weight loss, acupuncture, custom orthotics

Nonpharmacotherapy: cognitive-behavioral therapy, spinal manipulation therapy, structured exercise, weight loss, acupuncture, custom orthotics

No improvement: Consider surgical or psychiatry referral.

Christina Marsalisi McCoy, DO and Holly L. Baab, MD

LYMPHADENOPATHY

LYMPHOPENIA OR LYMPHOCYTOPENIA

WBC <4,500/μL

Isolated neutropenia
ANC <1,500/μL
Evaluate for neutropenia.

Isolated lymphopenia
ALC <1,500/μL

Concomitant anemia and/or thrombocytopenia

Common causes
• Infections (including HIV, influenza, tuberculosis)
• Medications (especially prednisone and other immuno-suppressives)
• Non-pathologic lymphopenia (especially in the elderly)

Evaluate for causes of pancytopenia.

Risk factors for infection
Consider workup for the following:
• HIV
• Influenza
• Hepatitis
• Tuberculosis
• Malaria
• Histoplasmosis

Healthy elderly patient
in the absence of infection, weight loss, or other concerning history, no further investigation is necessary.

History of suspicious medications
• Immunosuppressives
  • Prednisone, MTX, azathioprine, etc.
  • Monoclonal antibody therapy
  • Rituximab
  • Chemotherapy

Other
• Malnutrition
• Alcohol abuse
• Signs of underlying lymphoma or other malignancy
  • Weight loss, fever, night sweats
• Immuno-mediated disease
  • FA, SLE, sarcoidosis, IBD
• Systemic, chronic disorders
  • CKD, COPD

Andrew Smith, MD and Erin Bassett-Novoa, MD

Kelly Pagidas, MD

MIGRAINE, TREATMENT

Suspected migraine headache
- POUND
  - Painful quality
  - One-day duration (4–27 hours)
  - Unilateral location
  - Nausea or vomiting
  - Disabling intensity
  - With or without photophobia or phonophobia

Sudden onset
- Worst headache ever increasing in intensity
- Seizures
- Nausea
- Near death experience
- Focal neurologic signs
- Abnormal mental status
- Precipitated by Valsalva

NSAID
- Ibuprofen (200, 400 mg PO)^a
- Diclofenac potassium (50, 100 mg PO)^a
- Naproxen sodium (500, 550 mg PO)^a
- Indomethacin (75, 150 mg PO)^a
- Ketoprofen (100 mg PO)^a
- Aspirin (500 mg PO)^a

Triptan
- Sumatriptan (25, 50, 100 mg PO, IV)
- Zolmitriptan (2.5, 5 mg PO, SC)
- Naratriptan (2.5, 5 mg PO, IV)
- Frovatriptan (20, 40, 80 mg PO, IV)
- Rizatriptan (10, 15 mg PO, IV, SC)
- Amodipten (12.5 mg PO, IV)
- Fisupriten (2.5 mg PO, IV)

Magnesium sulfur (1–2 gr IV)^b

Move to quiet dark room
- IV hydration
- Anticonvulsants PRN
- Hydroyshere
- Midazolam (10 mg IV)^c
- Prochlorperazine (10 mg IV, IM or 25 mg PO)^b
- Caffeine

Consider consultation with headache specialist
- Ketorolac (30–60 mg IM)^b
- Indomethacin (50 mg PO, IV)
- Prochlorperazine (10 mg IM, 50 mg PO, IV)
- Chlorpromazine (12.5 mg IV, PO)^b
- Dexamethasone (4–6 mg IV, PO)
- Prednisone (60 mg PO, IV)
- Clobazolam (30–60 mg IM, 3 mg PO, IV)

Consult headache specialist
- Fentanyl (50–100 mg IV)
- Midazolam (10 mg IV)
- Oxymorphone (100 mg IV)
- Naloxone (0.4 mg IV)

Clobazol
- Hesin (1 mg IM, 2 mg PO, IV)
- Saline (20–40 mg IV)

Level of Evidence
- A: Level A: Medications are established as effective.
- B: Level B: Medications are probably effective.
- C: Level C: Medications are possibly effective.

Matthew A. Henry, DO, Edward H. Dawkins, MD, and Sabrina L. Silver, DO, CAQSM

NAIL ABNORMALITIES

Natasha J. Pyzocha, DO, FAWM and Douglas M. Maurer, DO, MPH, FAAFP

NEUTROPENIA

Andrew Smith, MD and Erin Bassett-Novoa, MD

PAIN, CHRONIC, DIAGNOSIS

Multidimensional pain assessment
- Brief Pain Inventory (written)
- Chronic Pain Grade (verbal)
- Functional assessment
- Physical Functional Ability Questionnaire (written)
- Psychological assessment
- Screen for depression, anxiety, substance abuse, and dependence.

Obtain CBC w/diff, UA, ESR, and I&I:
- If abnormal:
  - ANA, RF, Lyme, OIP
- If neuropathic, consider EMG.

Neuropathic pain (from disorder or damage to nervous system)
- Peripheral
  - Complex regional pain syndrome
  - Phantom limb pain
- Central
  - Parkinson disease
  - Multiple sclerosis
  - Post-stroke pain
  - Fibromyalgia

Nociplastic pain (from stimulation of nerve receptors, often from injuring or tissue irritation)
- Visceral pain
  - Myocardial infarction
  - Intestinal bowel syndrome
  - Endometriosis
- Somatic
  - Inflammatory pain
    - Arthropathies (RA)
    - Infection
    - Post-operative pain
    - Tissue injury
  - Mechanical compression
    - Low back pain
    - Musculoskeletal pain
  - Muscle pain
    - Myofascial pain syndrome

Ashik Lawrence, MD, Anubhav Kaul, MD, and Margaret Seaver, MD, MPH

PALPABLE BREAST MASS

Age <30 years or pregnant or lactating

Order breast sonogram (targeted to palpable finding).

Finding

Needle biopsy by radiologist or surgeon
Refer to surgeon if needle biopsy not possible.

Benign finding—no biopsy needed (i.e., cyst, lipoma, lymph node)

Negative

Pregnant or lactating
Refer to surgeon.

<30 years old

Physical reexamination day 10–12 of menstrual cycle

Age ≥30 years

Common causes: cyst, lymph node, malignancy

Order breast mammogram plus sonogram.

Finding for biopsy at the palpable site.

Needle biopsy by radiologist or surgeon
Refer to surgeon if needle biopsy not possible.

Design findings—no biopsy needed (i.e., cyst, lipoma, lymph node)

Negative

Premenopausal

Postmenopausal

Physical reexamination day 10–12 of menstrual cycle

MD and patient not concerned
Routine screening

MD and/or patient still concerned
Refer to surgeon.

Lindsay Petersen, MD and Andrea Madrigrano, MD
Frank J. Domino, MD

PAP, NORMAL AND ABNORMAL IN NONPREGNANT WOMEN AGES 25 YEARS AND OLDER

Paul Pastor, MD

PARKINSON DISEASE, TREATMENT

Cardinal features
- Bradykinesia
- Resting tremor
- Rigidity
- Postural instability

Drug-induced
- Antipsychotics (risperidone, aripiprazole)
- Antidepressants (SSRI, TCA, MAOI)
- Levodopa/entacapone
- Metoclopramide, prochlorperazine
- Diltiazem
- Medroxyprogesterone
- Valproate
- Lithium

Discontinue medication.

Evaluate for underlying causes of Parkinsonism.

Alternative diagnosis
- Essential tremor
- Posttraumatic
- Toxoa (carbon monoxide)
- Metabolic disease (Wilson)
- Pseudobulbar palsy
- Progressive supranuclear palsy
- Spinocerebellar ataxia
- Multiple system atrophy
- Idiopathic basal ganglia calcification
- Normal pressure hydrocephalus
- Neoplastic

Address underlying cause.

Goals of early management
- Symptom control
- Reduce functional disability
- Slow disease progression.

Encourage exercise tai chi, treat associated conditions.

Offer physical therapy (gait, instability), speech therapy (speech volume), and occupational therapy (activities of daily living, safety, motor function).

Initiate medications when symptoms significantly limit patient activities.

Motor symptoms

Early disease
Dopamine agonist monotherapy:
- Entacapone
- Framapril
- Ropinirole

Late disease
Levodopa/entacapone
+/ dopamine agonist

Disease progression: Dyskinesias, motor fluctuations increased ‘off time’

Consider neurology referral.

Adjunct medication:
- MAO-B inhibitors (rasagiline, selegiline)
- DCMT inhibitors (entacapone)
- Apomorphine

Severe disease or unresponsive to medication:
Consider surgical referral for deep brain stimulation.

Nonmotor symptoms

Sleep disturbance
- Sleep hygiene
- Change to levodopa/entacapone (consider PRx);
- Add methylenidate.
- Minimize dangerous activities (driving).

Autonomic dysfunction
- Erectile dysfunction: alprostadil
- Constipation: polyethylene glycol
- Drooling: botulinum toxin

Psychiatric disorder
- Depression without cognitive impairment: TCA
- Psychosis:
- Opioids

Dementia
- Gicinzine meds that contribute to cognitive impairment (dopamine or anticholinergic)
- Rivastigmine or donepezil

Sarah Coles, MD and William Dabbs, MD

PEDIATRIC EXANTHEMS, DIAGNOSTIC

Enanthem (involvement of mucous membranes)?

Rosacea (sixth disease, exanthem subitum)
- Herpes virus 6 & 7
- Incubation 5–15 days
- Rash: Erythematous maculopapular rash develops as fever resolves; starts on trunk and progresses to neck, extremities (rarely), face
- Prodrôme: fever
- Enanthem: erythematous macules on soft palate
- Peak prevalence: 7–13 months

Erythema infectiosum (fifth disease)
- Human parvovirus B19
- Incubation 4–14 days
- Rash: intense red malar rash "shaped cheek" followed in 1–2 days by reticular erythematous maculopapular rash on trunk, extremities, and buttocks; maculopapules last up to 1 month
- Prodrôme: generally mild, may have 1–4 days of headache, chills, URI symptoms
- Enanthem: none

Varicella (chickenpox)
- Varicella zoster virus
- Incubation 14–16 days
- Rash: Macules form on trunk and spread to face and extremities; progress quickly in clusters to papules then tear-dropped shaped vesicles ("dew drops on a rose petal") that crust over or umbilicate
- Prodrôme: 1–3 days of fever, malaise, anorexia
- Enanthem: Rarely vesicles can lead to erosions of hard palate

Coxsackie (hand-foot-mouth disease)
- Enterovirus 71 or coxsackie virus A16
- Incubation 3–6 days
- Rash: Erythematous macules and papules: 2–3 mm found on palmar surface of hand, plantar surface of feet, and oral mucosa; progresses quickly through vesicular phase to oral central gray ulcer
- Prodrôme: 12–36 hours of cough, fever, malaise, anorexia, abdominal pain
- Enanthem: occurs with exanthem as painful ulcerative lesions commonly found on tongue, hard palate, and buccal mucosa

Koplík spots (white papules on buccal mucosa)?

Fast-spreading rash?

Rubella (third disease, German measles)
- Rubella virus
- Incubation 14–17 days
- Rash: erythematous maculopapular rash with downward progression from face
- Prodrôme: 1–7 days of malaise, painful lymphadenopathy
- Enanthem: Forchheimer spots (petechiae on soft palate)

Scarlet fever (second disease)
- Group A streptococcus
- Incubation 1–4 days
- Rash: rapidly progressing erythematous macules and pinnate blanchable papules ("goose pimples") with sandpaper texture; general intensity at skin folds occurring at the same time
- Prodrôme: 1–6 days of fever, acute throat, vomiting, abdominal pain
- Enanthem: progression from white to red strawberry tongue
- Perform rapid strep testing, a throat culture, and initiate treatment

Molluscum (first disease, rubella)
- Molluscum virus
- Incubation 10–12 days
- Rash: erythematous maculopapular rash (developing as fever progresses) with downward progression from face and brownish hue during resolution
- Prodrôme: 3–4 days of conjunctivitis, sore throat, fever, cough
- Enanthem: Koplík spots

Frank J. Domino, MD

Justin L. Chapman, MD

PREOPERATIVE EVALUATION OF NONCARDIAC SURGICAL PATIENT

Patient scheduled for surgery with risk factors for coronary artery disease or known as CAD

Assess functional capacity: is patient able to climb two flights of stairs without significant shortness of breath?* 

*This activity is equivalent to 4 METs (metabolic equivalents)

No or unknown

Assess risk of major adverse coronary events (MACE) per risk calculator at www.surgicalriskcalculator.com*.

*Age, creatinine, ASA classification, functional living status, type of procedure

If MACE <1%

Yes

Proceed to surgery.

If MACE >1% and further testing will impact decision making

No

Yes

Pharmacologic stress testing is indicated.

Andrew Grimes, MD and Stacy L. Jones, MD

PROTEINURIA

Defined as >150 mg/24 hours proteinuria
Common causes and reasons to screen: hypertension, diabetes, glomerular disease, cardiovascular disease, congestive heart disease, multiple myeloma, nephrotic syndrome, fever, urinary tract infection, orthostatic hypertension, lupus

Qualitative dipstick analysis, routine or based on clinical suspicion (albumin only, limited sensitivity for other proteins)

Trace to 2+

3+ to 4+

Symptomatic w/ or w/o clear cause, known renal disease, positive microscopic analysis

Treat underlying cause.

Repeat dipstick analysis 2-3 times over 1 month, separated by 1-2 weeks.

<2+

Quantitative/semiquantitative eval w/ 24-hour urine (gold standard) or spot urine (first morning void preferred, random sample acceptable)

<2 g/24 hr

Calculate creatinine clearance (CrCl)

CrCl 1st 30 years

<20 ml/min

Clear cause of known renal disease?

Yes

Evaluate for orthostatic proteinuria with first morning void spot test; if neg (<20 mg/dL) and random spot test positive, then orthostatic proteinuria.

Pos

Recheck blood pressure and urinalysis in 1-2 years.

Isolated proteinuria

Neg

Recheck q1mo until stable or improving.

>2 g/24 hr

Calculate creatinine clearance (CrCl)

CrCl decreased

<55 g/24 hr, eval for edema, hypoalbuminemia (<3.0 g/dL), hypertetxia.

Consult nephrology for proteinuria.

This is symptomatic proteinuria or renal disease, consult nephrology.

Consult nephrology for proteinuria.

CrCl w/in

Consult nephrology for proteinuria.

Consult nephrology for proteinuria.

Consider nephrology consult and evaluate for the following tests as clinically indicated:

- ANA (nuclear)
- Antinucleoprotein O-1 (Anticellular glomerular antibody)
- C3/C4 (complement)
- ESRD (erythrocyte sedimentation rate)
- Fasting glucose (diabetes)
- HbA1c (glycosylated hemoglobin)
- Hct, VDRL, hepatic serologies
- Serum albumin and lipid levels (consider nephrotic syndrome)
- Serum electrolytes
- Urine and urine protein-creatinine ratio (abnormal in multiple diseases)
- Serum urates (elevation can cause tubulointerstitial disease)
- Renal ultrasound (structural renal disease)
- Chest radiograph (systemic disease, e.g. sarcoidosis)

PULMONARY EMBOLISM, DIAGNOSIS

Assess Pulmonary Embolism Rule Out Criteria (PERC)
If any of the following are true, then the patient is considered PERC-positive:
1. Patient is >60 years
2. Patient's pulse >99 beats/min
3. Patient's satsimetry reading <95% on room air
4. Patient with hemoptysis
5. Patient taking exogenous estrogen
6. Patient had a previous VTE diagnosis
7. Patient had surgery or trauma, which required intubation or hospitalization in the last 4 weeks
8. Patient has unilateral swelling if the calves.

Clinical signs/symptoms of pulmonary embolism (PE)

Clinically stable?  Yes  No

Assess PERC positive?

PE unlikely, Consider alternative diagnosis.

Clinical pretest probability score:

<4

High sensitive D-dimer?

No

PE unlikely, Consider alternative diagnosis.

Yes

Inconclusive results or unable to perform CT (i.e., renal failure or contrast allergy).

Spiral CT angiography

Inconclusive (low to intermediate probability)

Low probability and low CTPA

Normal VQ scan

High probability of PE

Consider alternative imaging (e.g., lower extremity venous ultrasound, pulmonary angiography, or MRI)

Treat with anticoagulation and consider thrombolyis if becomes unstable

PE confirmed

Stabilise and consider anticoagulation

TTE to evaluate RV strain or dysfunction

PE ruled out

Assess the clinical pretest probability of pulmonary embolism

Clinical pretest probability (CPTP = modified Wells PE Score)

Clinical signs

3

Alternative Di unlikely

3

Heat rate >100

1.5

Immobilization previous 4 days

1.5

Previous DVT/PE

1.5

Hemoptysis

1

Malignancy

1

PE less likely <4

PE likely >4

Consider alternative diagnosis.

Lawrence M. Gibbs, MD, MSED, FAAFP

PULMONARY EMBOLISM, TREATMENT

Probability of pulmonary embolism above treatment threshold

Anticoagulation contraindicated?
- Prior intracranial bleed
- Ischemic stroke <3 months
- Suspected aortic dissection
- Active bleeding diagnosis
- Recent brain or spinal surgery
- Closed head or facial trauma

IVC filter

Yes

No

Massive pulmonary embolism?
(SBP <90 mm Hg or >15 minutes)

Yes

Thrombolysis contraindicated?

Yes

No

Thrombolysis indicated?

Benefits of thrombolysis may outweigh risks IF: hemodynamic instability, worsening oxygenation, severe RV, or major myocardial necrosis.

Yes

No

Embolectomy, per local expertise

Begin either:
- Therapeutic-dose low-molecular-weight heparin (LMWH) and warfarin, discontinuing LMWH when INR ≥ 2 for at least 24 hours and minimum 5 days of treatment with both, goal INR 2-3 OR
- Direct antithrombin or anti-Xa oral anticoagulant (dabigatran, apixaban, rivaroxaban, or edoxaban): StaNo, low-risk patients may be treated as outpatients with an appropriate regimen above.

History of heparin-induced thrombocytopenia?

Yes

No

Clinical improvement

Ryan B. Feeney, PharmD, BCPS, BCGP and Frank M. Mazzotta, DO

Jason C. Sluzevich, MD

RECTAL BLEEDING AND HEMATOCHIEZIA

Mohammad Ansar Mughal, MD

RED EYE

Most common causes: conjunctivitis, episcleritis, scleritis, subconjunctival hemorrhage, uveitis, acute angle closure glaucoma, keratitis, corneal abrasion

Pain*

Burned vision?

Keenness**
Photophobia, discharge
Fluorescein test positive
Blurry vision possible, foreign body sensation

No

Maybe

Constricted
Mildly dilated
Nonreactive

Pupil

Corneal abrasion
Fluorescein test positive
Flare,examines,blurry vision possible

Yes

Discharge?

Mucopurulent

Vesicle

Subconjunctival hemorrhage
Asymptomatic, self-limiting

Infectious conjunctivitis
Abrupt onset morning scratching

Scleritis* Photophobia, no blurry vision, no discharge or foreign body sensation

Urethritis* Photophobia with pain worse with eye movement and during accommodation

Acute angle closure glaucoma* Photophobia, halos around lights, nausea and vomiting

Allergic conjunctivitis Very itchy associated allergy symptoms, accompanied foreign body sensation

Viral conjunctivitis Very contagious, accompanied foreign body sensation

Episcleritis No photophobia, no pain but foreign body sensation or irritation, rapid onset, self-limiting

*Diplopia with eye movement

**Consultation within 24 hours

*Diplopia with eye movement

Drew-Anne Drapala, MD and Vincent Lo, MD, FAAFP

SALICYLATE POISONING, ACUTE, TREATMENT

Assess airway, breathing, and circulation.

Provide appropriate ABC management. Avoid intubation unless patient is unable to protect airway. Intubation may increase acidosis and result in cardiovascular collapse.

Early toxicity: tachypnea, hyperpnea, nausea, vomiting, tinnitus, vertigo

Late toxicity: hyperthermia, hypotension, altered mental status

Does the patient exhibit signs of severe toxicity (altered mental status/conia, enuresis, pulmonary edema, or need for endotracheal intubation and mechanical ventilation)?

Yes

Initiate emergent hemodialysis.

Begin volume resuscitation and alkalinization using 150 mEq (3 amp) NaHCO₃ + 40 mEq KCl in 1 L DSW if volume is not resuscitated by cerebral/pulmonary edema. Administer 25 g (1 amp) D50 for altered mental status. Do not delay treatment for diagnostic studies.

No

History and physical

Obtain careful history of ingestion time, reported ingestion, coingestants, etc. and perform thorough physical exam for hemodynamic instability, alterations in respiratory pattern, and changes in mental status.

Is the patient asymptomatic, stable, and known to have ingested <150 mg/kg?

Yes

Initial treatment

1. Early volume resuscitation with isotonic saline
2. Urinary alkalinization using 150 mEq (3 amp) NaHCO₃ + 40 mEq KCl in 1 L DSW, infused at 2–3 mL/kg/hr
3. Administer 1st dose activated charcoal at 1 g/kg (max 50 g) only if patient is alert, cooperative, and can tolerate. Consider additional doses of 0.5–1 g/kg if patient remains intoleraent and has bowel sounds on exam.

Obtain diagnostic studies.

Labs: salicylate level (note time since ingestion), kB/G/VBG, basic electrolytes, BUN, creatinine, LFTs, coags, lactate, UA. Obtain tox screen if polydrug abuse is suspected. Imaging: chest radiograph (to evaluate for pulmonary edema). Consider head CT for altered mental status to evaluate for cerebral edema or alternative causes of mental status changes.

Evaluation/observation

Obtain first salicylate level, noting time since ingestion occurred.

ASA detectable?

No

Recheck if within 2 hours of presentation. Discharge after 6 hours observation if patient remains asymptomatic and levels are non-detectable.

Yes

Recheck levels q2h until consistently within therapeutic range, trending down. Discontinue/adjust treatment for changes in clinical status and initiate treatment if indicated.

Maintenance therapy and evaluation

1. Continue bicarbonate infusion to maintain urine output of 1–2 mL/kg/hr.
2. Measure urine pH hourly and titrate infusion to goal pH of 7.5–8.0.
3. Measure serum K hourly and replete if <4.5 mEq/L.
4. Measure ABG or VBG hourly and decrease rate of bicarbonate drip if serum pH exceeds 7.8.
5. Measure serum salicylate level q2h until salicylate level begins to decline and acid-base status is normal.

Disposition

Treatment should be continued with frequent clinical assessment for improvement. Treatment and testing may be stopped only when patient is asymptomatic, acid-base status is stable, and salicylate level is below therapeutic range (10–50 mg/dL).
Andrew S. Hellenga, MD and Matthew J. Snyder, DO

SICKLE CELL ANEMIA, ACUTE, EVALUATION AND MANAGEMENT

This algorithm is meant to assist clinicians in the workup and management of common complications of sickle cell disease. It should not replace a physician's clinical judgment or be considered a standardized protocol for all patients.

**Known Sickle Cell Patient (Part 1 of II)**

**Chief Complaint**
- Left or right upper quadrant pain

**Possible Causes**
- Vaso-occlusive crisis (VOC): infection

**No Specific Physical Findings**
- Low VOC

**Presentation**
- Fever
- Chills
- Myalgia (muscle pain)

**Tests**
- CBC w/diff and retic
- ESR
- CRP
- Blood cultures
- MRI/CT scan

**Initial Assessment**
- Must have rapid imaging: exam, labs, and empiric antibiotics—goal within 1 hour of presentation

**Treatment**
- Supportive care
- Oxygen therapy
- Pain control
- IV hydration
- Antibiotics
- Blood transfusions
- Exchange transfusions
- Pain management

**Severe Pain**
- Both IV and opiate control—NSAIDS (ibuprofen, aspirin, ketoprofen), opioids (hydrocode, oxycodone), PCA

Known Sickle Cell Patient (Part II of II)

Chief complaint: Abdominal pain

Possible causes:
- Visceral pain from VOC, cholecystitis/cholelithiasis, constipation due to opioid use, visceral infarct, appendicitis, splenic sequestration, UTI/urinary tract infection, pancreatitis

Physical exam:
- Focal pain + abdominal pain, tenderness at site
- Jaundice + abdominal pain, tender hepatitis, versus cholecystitis, versus interstitial, cholecystitis, versus liver sequestration

Tests:
- CBC w/diff and retic
- Type and crossmatch
- UA +/- J&J
- CT PE if PE suspected

Treatment:
- Supplemental O₂ (adults); for peds, only if hypoxia is present
- Pain control
- Treat appropriately once cause is determined
- Likely admit
- If splenic sequestration is suspected, call hematology immediately for directions regarding transfusion

Chief complaint: Respiratory sx's

Possible causes:
- Acute chest syndrome (ACS), pneumonia, pulmonary embolus, or infarct, reactive airways/asthma exacerbation

Tests:
- Pulse oximetry
- CBC w/diff and retic
- Blood culture
- Type and crossmatch
- ABG as needed

Tests if ABG shows:
- O₂ w/diff and retic
- Type and crossmatch
- UA + J&J
- Blood culture for fever or signs of urinary tract infection

Treatment:
- Supplemental O₂ (adults); for peds, only if hypoxia is present
- Pain control
- Abx to cover common urinary tract pathogens

Chief complaint: Gastrointestinal sx's

Possible causes:
- Pneumonia
- Urinary tract infection

Tests if pneumatic:
- CBC w/diff and retic
- Type and crossmatch
- UA + J&J
- Blood culture for fever or signs of urinary tract infection

Treatment:
- Supplemental O₂ (adults); for peds, only if hypoxia is present
- Pain control
- Pseudophedrine
- Consider catheterization if difficulty voiding

#Typical Hgb 6-9%; Hct 20-30%; retic 5-25%; slight leukocytosis 12,000-15,000, mild thrombocytosis 200,000.

#Preferred fluid is 1/2 NS at 1:1.5 mosm maintenance in pediatrics and NS in adults (consider bolus first if dehydrated).

#RBCs and LDH are often slightly to moderately elevated due to chronic and acute hemolysis.

#Always call hem/onc for further recommendations.

Andrew S. Hellenga, MD and Matthew J. Snyder, DO

Irene Coletsos, MD and Harold J. Bursztajn, MD

SUICIDE, EVALUATING RISK FOR

Screen all depressed patients annually (and additional testing if depression is mentioned as a concern). Over the past 2 weeks, how often have you been bothered by:
1. Little interest or pleasure in doing things?
2. Feeling down, depressed, or hopeless?

Score each of the 2 questions on a scale of 0–3 (0 ["not at all"] to 3 ["nearly every day"]).

Score <3 negative depression screen
Score ≥3 positive depression screen

Ask about suicidal ideation (if +, ask about a plan):
- "Have you ever felt that life isn’t worth living?"
- "Did you ever wish you could go to sleep and not wake up?"
- "Are you having thoughts about hurting yourself or others?"

If any + (or if negative and you suspect patient is not being honest or is incompetent), get further expert advice.

Higher risk
- Question for mood instability (worsening anxiety)
- Losses (support)
- Destabilizing events (injury, substance abuse, etc.)
- Personal/family history of suicide attempts
- Neurologic/psychiatric comorbidities

Lower risk
- Close clinical follow-up

Preoccupation with suicide is a medical emergency, and measures should be taken immediately to keep the patient safe. This includes putting the patient under constant 1:1 supervision and inpatient admission and consultation.
SYNCOPE

Common causes:
- vasovagal syncope (faint)
- seizure
- arrhythmia
- orthostatic (drop attack)
- psychiatric illness
- narcolepsy

History of palpitations or onset without preceding symptoms?

Yes

No

Arrhythmia
- Myocardial infarction

Abnormal neurologic examination?

Yes

No

Stroke
- Brain tumor
- Seizure

Precipitating event:
- excessive heat
- change in posture
- acute stress
- event, prolonged standing

Yes

No

Vasovagal syncope
- Orthostatic hypotension
- Anxiety

Obesity?

Yes

No

Obstructive sleep apnea
- Pickwickian syndrome

Seizure
- Drop attack
- Narcolepsy
- Psychiatric disorder

Frank J. Domino, MD

TRANSIENT ISCHEMIC ATTACK AND TRANSIENT NEUROLOGIC DEFECTS

Transient ischemic attack (TIA) is defined as a "transient episode of neurologic dysfunction caused by focal cerebral spinal cord or retinal ischemia without acute infarction" (AHA/ASA, 2009).

Common causes: migraine (± aura), carotid artery disease, stroke, seizure, syncope, subarachnoid hemorrhage, multiple sclerosis, ALS.

Clinical suspicion of a TIA: episode of neurologic deficit, unilateral paresis, memory loss, headache, blurred vision, dysarthria, hemianopia, or diplopia.

Risk factors: cigarette smoking, obesity, diabetes mellitus, dyslipidemia, hypertension, family history of coagulation disorder, or recent TIA.

Emergent evaluation:
- ECG
- Echocardiogram
- Blood glucose
- Serum electrolytes
- Lipids

Symptoms resolved?
- Yes
- No
  - CT or MRI evidence of stroke?
    - Yes: Stroke protocol
    - No: Differential diagnosis of TIA:
      - Brain tumor, CNS infection, trauma, hypoglycemia, migraine, multiple sclerosis, seizure disorder, and vertigo.

Mockup:
- MRI within 24 hr
- Geriatric studies
- Reconsider ABCD² score for admission

ABC²D² score:
- Age, blood pressure, clinical presentation, diabetes mellitus, duration of symptoms:
  - Age ≥ 60 years: 1 pt.
  - BP ≥ 140 mm Hg: 1 pt.

OR
- BP ≥ 90 mm Hg: 2 pts.
- Unilateral weakness: 1 pt.
- Speech impairment: 1 pt.
- Diabetes mellitus: 1 pt.
- Duration of TIA:
  - > 60 min: 2 pts.
  - 10–59 min: 1 pt.

Admit patients with an ABCD² score ≥ 8 who present within 72 hr of symptom resolution, evidence of focal ischemia, or cannot complete outpatient workup.

Deborah A. Lardner, DO, DTM&H and Michael Passafaro, DO, DTM&H, FACEP, FACOEP

TYPE 2 DIABETES, TREATMENT

Frank J. Domino, MD

mebooksfree.com
Common causes: PCOS, hypothryroid, uterine hyperplasia, pituitary adenoma

History and physical exam, including pelvic exam

Pubescent

Consider CBC, pelvic US, genital cultures, tumor markers and child abuse referral.

Pap test, HCG, consider genital cultures, CBC, PT, INR, von Willebrand antigen, histocompatibility antigen.

Postmenopausal

Pap test, US, and/or EMB; consider TSH, prolactin, and genital cultures.

Not pregnant, tests normal

Ovulatory dysfunction for >3 months

Adult

Age ≥ 45 years?

Yes

Pelvic US; consider EMB if ≥ 45 years, TSH, prolactin.

Normal results

Obtain coagulation evaluation: CBC, peripheral smear, FLT's, PT, INR, PTT, VWF antigen, histocompatibility cofactor, Factor VIII.

Abnormal results

Treat or refer.

Results normal, age < 45 years and without risk for hyperplasia

Reassurance, treat with hormones

Normal results, age ≥ 45 years or high-risk hyperplasia

Endometrial biopsy and/or pelvic US

Abnormal results

Regulate with hormones.

Normal results

Treat underlying condition or refer.

Abnormal results

Low BMI

No

<3 years from menarche

Reassurance: combination contraceptive

Ann Klega, MD, Tanya E. Anim, MD, and Jennifer Tickal Kehbauch, MD, FAAFP

VITAMIN D DEFICIENCY

Risk factors/common causes:
- Age >65 years
- Insufficient sunlight exposure (rare, unaided)
- Renal disease
- Liver disease
- Depression
- Dark skin
- Insufficient dietary intake
- Gastrointestinal disorders
- Osteoporosis (BMI <20)
- Immigrants to colder climates
- Chronic use of glucocorticoids
- Pseudotumor cerebri (e.g., sternum, ilium)

Significant risk factors?

Low suspicion for vitamin D deficiency

Laboratory test:
- Serum 25-hydroxyvitamin D concentration

Requirements:
- <1 year old: 400 IU/day
- 1 year old: 400 IU/day
- To reach levels >30 ng/mL, may require 1,000 IU/day
- Obese children: 2–3 times more vitamin D for their age group
- Maintenance dose: 0–6 months: 1,000–2,000 IU/day
- 6 months–1 year: 1,500–2,000 IU/day
- 1–3 years: 2,500–4,000 IU/day
- 4–8 years: 3,000–4,000 IU/day
- >8 years: 4,000 IU/day
- Vitamin D deficiency:
  - 0–1 year: 2,000 IU/day (for 6 weeks or 50,000 IU weekly) for 6 weeks followed by maintenance
  - 1–18 years: 2,000 IU/day (for 6 weeks or 50,000 IU weekly) for 6 weeks followed by maintenance
  - 600–1,000 IU/day

Level <20 ng/mL (vitamin D deficiency)

Treatment:
- Start 50,000 IU D2 once a week for 8–12 weeks and then begin 2,000–4,000 IU vitamin D per day.

After 8 months, consider repeating serum 25-hydroxyvitamin D level.

Redo serum 25-hydroxyvitamin D concentration.

Level <20 ng/mL?

Consult endocrinologist if no malabsorptive disease.

Level 21–29 ng/mL (vitamin D insufficiency)

Treatment:
- Start 2,000–4,000 IU vitamin D per day.

Supplement with 600–4,000 IU of vitamin D per day.

Level >30 ng/mL (normal)

Consult endocrinologist if no malabsorptive disease.

Gisela M. Lopez Payares, MD, Carla M. Basadre Quiroz, MD, and Fozia Akhtar Ali, MD

WEIGHT LOSS, UNINTENTIONAL

Crystal Nwagwu, MD and Fozia Akhtar Ali, MD

ABNORMAL (DYSFUNCTIONAL) UTERINE BLEEDING
Chantel T. Jacobs, MD • Kristin S. Sochet, MD

BASICS

DESCRIPTION
• Abnormal uterine bleeding (AUB) is irregular menstrual bleeding (usually heavy, prolonged, or frequent); it is a diagnosis of exclusion after establishment of normal anatomy and the absence of other medical illnesses and pregnancy.
• May be acute or chronic (occurring >6 months)
• The International Federation of Gynecology and Obstetrics (FIGO) revised the terminology system and now uses AUB rather than dysfunctional uterine bleeding (DUB).
• Commonly associated with anovulation

EPIDEMIOLOGY
Adolescent and perimenopausal women are affected most often.

Incidence
5% of reproductive age women will see a doctor in any given year for AUB.

Prevalence
10–30% of reproductive age women have AUB.

ETIOLOGY AND PATHOPHYSIOLOGY
• Anovulation accounts for 90% of AUB.
  – Loss of cyclic endometrial stimulation
  – Elevated estrogen levels stimulate endometrial growth.
  – No organized progesterone withdrawal bleeding
  – Endometrium eventually outgrows blood supply, breaks down, and sloughs from uterus.
  – 6–10% will have polycystic ovarian syndrome (PCOS).
• Adolescent AUB is usually due to an immature hypothalamic-pituitary-
ovarian (HPO) axis that leads to anovulatory cycles.

- The mnemonic PALM-COEIN was developed as the new nomenclature to describe AUB in reproductive-aged women.
- PALM describes structural causes of AUB, and COEIN describes nonstructural causes of AUB.
  - PALM: polyp, adenomyosis, leiomyoma, and malignancy and/or hyperplasia
  - COEIN: coagulopathy, ovulatory disorders, endometrial, iatrogenic, and not yet classified
  - Reproductive pathology and structural disorders
    - Uterus: leiomyomas, endometritis, hyperplasia, polyps, trauma
    - Adnexa: salpingitis, functional ovarian cysts
    - Cervix: cervicitis, polyps, STIs, trauma
    - Vagina: trauma, foreign body
    - Vulva: lichen sclerosis, STIs
- Malignancy of the vagina, cervix, uterus, and ovaries
- Systemic diseases
  - Hematologic disorders (e.g., von Willebrand disease, thrombocytopenia)
- Diseases causing anovulation
  - Hyperthyroidism/hypothyroidism
  - Adrenal disorders
  - Pituitary disease (prolactinoma)
  - PCOS
  - Eating disorders
- Medications (iatrogenic causes)
  - Anticoagulants
  - Steroids
  - Tamoxifen
  - Hormonal medications: intrauterine devices (IUDs)
  - Selective serotonin reuptake inhibitors (SSRIs)
  - Antipsychotic medications
  - Postmenopausal hormone therapy
- Other causes of AUB not defined in PALM-COEIN
  - Pregnancy: ectopic pregnancy, threatened or incomplete abortion, or hydatidiform mole
  - Advanced or fulminant liver disease
  - Chronic renal disease
  - Inflammatory bowel disease
  - Excessive weight gain
– Increased exercise

**Genetics**
Unclear but can include inherited disorders of hemostasis

**RISK FACTORS**
Risk factors for endometrial cancer (which can cause AUB)

- Age >40 years
- Obesity
- PCOS
- Diabetes mellitus
- Nulliparity
- Early menarche or late menopause (>55 years of age)
- Hypertension
- Chronic anovulation or infertility
- Unopposed estrogen therapy
- History of breast cancer or endometrial hyperplasia
- Tamoxifen use
- Family history: gynecologic, breast, or colon cancer
- Thyroid disease

**DIAGNOSIS**

**HISTORY**

- Menstrual history
  - Onset, severity (quantified by pad/tampon use, presence and size of clots), timing of bleeding (unpredictable or episodic)
  - Menorrhagia with onset of menarche is suggestive of a coagulation disorder.
  - Menopausal status
  - Association with other factors (e.g., coitus, contraception, weight loss/gain)
- Gynecologic history: gravidity and parity, STI history, previous Pap smear results
- Review of systems (Exclude symptoms of pregnancy and of bleeding disorders, bleeding from other orifices, stress, exercise, recent weight change, visual changes, headaches, galactorrhea.)
- Medication history: Evaluate for use of aspirin, anticoagulants, hormones, and...
herbal supplements (1,2).

**ALERT**
Postmenopausal bleeding is any bleeding that occurs >1 year after the last menstrual period; cancer must always be ruled out (2)[C].

**PHYSICAL EXAM**
Discover anatomic or organic causes of AUB.

- Evaluate for
  - Body mass index (obesity)
  - Pallor, vital signs (anemia)
  - Visual field defects (pituitary lesion)
  - Hirsutism or acne (hyperandrogenism)
  - Goiter (thyroid dysfunction)
  - Galactorrhea (hyperprolactinemia)
  - Purpura, ecchymosis (bleeding disorders)
- Pelvic exam
  - Evaluate for uterine irregularities and Tanner stage.
  - Check for foreign bodies.
  - Rule out rectal or urinary tract bleeding.
  - Include Pap smear and tests for STIs (2)[C].

**Pediatric Considerations**
Premenarchal children with vaginal bleeding should be evaluated for foreign bodies, physical/sexual abuse, possible infections, and signs of precocious puberty.

**DIFFERENTIAL DIAGNOSIS**
See “Etiology and Pathophysiology.”

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Everyone: urine human chorionic gonadotropin (hCG; rule out pregnancy and/or hydatidiform mole) and complete blood count (CBC) (1)
  - For acute bleeding, a type and cross should be obtained (3)[C].
- If disorder of hemostasis is suspected, a partial thromboplastin time (PTT), prothrombin time (PT), activated partial thromboplastin time (aPTT), and fibrinogen level is appropriate (3)[C].
If anovulation is suspected: thyroid-stimulating hormone (TSH) level, prolactin level (1)

Consider other tests based on differential diagnosis.
- Follicle-stimulating hormone (FSH) level to evaluate for hypo- or hypergonadotropism
- Coagulation studies and factors if coagulopathy is suspected (1)
- 17-Hydroxyprogesterone if congenital adrenal hyperplasia is suspected
- Testosterone and/or dehydroepiandrosterone sulfate (DHEA-S) if PCOS
- Screening for STI

Endometrial biopsy (EMB) should be performed as part of the initial evaluation for postmenopausal uterine bleeding and in premenopausal women with risk factors for endometrial carcinoma. Medical management can be initiated in premenopausal women with normal TVUS and low risk for malignancy (1)[A].

TVUS, sonohysterography, and hysteroscopy may be similarly effective in detection of intrauterine pathology in premenopausal women with AUB (1) [A].

If normal findings following imaging in patients without known risk factors for endometrial carcinoma, a biopsy should be performed if not done so previously (2)[C].

**Diagnostic Procedures/Other**
- Pap smear to screen for cervical cancer if age >21 years (2)[C]
- EMB should be performed in
  - Women age >35 years with AUB to rule out cancer or premalignancy
  - Postmenopausal women with endometrial thickness ≥5 mm
  - Women aged 18 to 35 years with AUB and risk factors for endometrial cancer (see “Risk Factors”)
  - Perform on or after day 18 of cycle, if known; secretory endometrium confirms ovulation occurred.
- Dilation and curettage (D&C)
  - Perform if bleeding is heavy, uncontrolled, or if emergent medical management has failed.
  - Perform if unable to perform EMB in office (2)[C].
- Hysteroscopy if another intrauterine lesion is suspected

**Test Interpretation**
Pap smear could reveal carcinoma or inflammation indicative of cervicitis. Most
EMBs show proliferative or dyssynchronous endometrium (suggesting anovulation) but can show simple or complex hyperplasia without atypia, hyperplasia with atypia, or endometrial adenocarcinoma.

**TREATMENT**

Attempt to rule out other causes of bleeding prior to instituting therapy.

**GENERAL MEASURES**

NSAIDs (naproxen sodium 500 mg BID, mefenamic acid 500 mg TID, ibuprofen 600 to 1,200 mg/day) (1)[B]

- Decreases amount of blood loss and pain compared with placebo, with no one NSAID clearly superior

**MEDICATION**

*First Line*

- Acute, emergent, nonovulatory bleeding
  - Conjugated equine estrogen (Premarin): 25 mg IV q4h (max 6 doses) or 2.5 mg PO q6h should control bleeding in 12 to 24 hours (4)[A].
  - D&C if no response after 2 to 4 doses of Premarin or sooner if bleeding >1 pad per hour (2)[C]
  - Then change to oral contraceptive pill (OCP) or progestin for cycle regulation, that is, IUD (5)[A]

- Acute, nonemergent, nonovulatory bleeding
  - Combination OCP with ≥30 μg estrogen given as a taper. An example of a tapered dose: 4 pills per day for 4 days; 3 pills per day for 3 days; 2 pills per day for 2 days, daily for 3 weeks then 1 week off, then cycle on OCP for at least 3 months

- Nonacute, nonovulatory bleeding (ranked in order based on decision analysis as best option based on efficacy, cost, side effects, and consumer acceptability) (5)[A]
  - Levonorgestrel IUD (Mirena) is the most effective form of progesterone delivery and is not inferior to surgical management.
  - Progestins: medroxyprogesterone acetate (Provera) 10 mg/day for 5 to 10 days each month. Daily progesterone for 21 days per cycle results in significantly less blood loss.
  - OCPs: 20 to 35 μg estrogen plus progesterone
• Do not use estrogen if contraindications, such as suspicion for endometrial hyperplasia or carcinoma, history of deep vein thrombosis (DVT), or the presence of smoking in women >35 years of age (relative contraindication), are present.

• Precautions
  – Failed medical treatment requires further workup.
  – Consider DVT prophylaxis when treating with high-dose estrogens (2)[C].

**Second Line**

• Leuprolide (varying doses and duration of action); gonadotropin-releasing hormone (GnRH) agonist

• Danazol (200 to 400 mg/day for a maximum of 9 months) is more effective than NSAIDs but is limited by androgenic side effects and cost. It has been essentially replaced by GnRH agonists.

• Antifibrinolytics such as tranexamic acid (Lysteda) 650 mg, 2 tablets TID (max 5 days during menstruation) (1)[A]

• Metformin or Clomid alone or in combination in women with PCOS who desire ovulation and pregnancy

**ISSUES FOR REFERRAL**

• If an obvious cause for vaginal bleeding is not found in a pediatric patient, refer to a pediatric endocrinologist or gynecologist.

• Patients with persistent bleeding despite medical treatment require reevaluation and possible referral.

**ADDITIONAL THERAPIES**

• Antiemetics if treating with high-dose estrogen or progesterone (2)[C]

• Iron supplementation with vitamin C if anemia (usually iron deficiency) is identified

**SURGERY/OTHER PROCEDURES**

• Hysterectomy in cases of endometrial cancer or if medical therapy fails or if other uterine pathology is found

• Endometrial ablation is less expensive than hysterectomy and is associated with high patient satisfaction; failure of primary medical treatment is not necessary (1,4)[A].
  – This is a permanent procedure and should be avoided in patients who desire continued fertility.
Uterine artery embolization if bleeding is refractory to medications or confirmed fibroids

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Significant hemorrhage causing acute anemia with signs of hemodynamic instability; with acute bleeding, replace volume with crystalloid and blood, as necessary (1)[A].
- Pad counts and clot size can be helpful to determine and monitor amount of bleeding.
- Discharge criteria
  - Hemodynamic stability
  - Control of vaginal bleeding (2)[C]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Once stable from acute management, recommend follow-up evaluation in 4 to 6 months for further evaluation (5).
- Routine follow-up with a primary care or OB/GYN provider

Patient Monitoring

Women treated with estrogen or OCPs should keep a menstrual diary to document bleeding patterns and their relation to therapy.

DIET

No restrictions, although a 5% reduction in weight can induce ovulation in anovulation caused by PCOS.

PATIENT EDUCATION

Explain possible/likely etiologies.

- Answer all questions, especially those related to cancer and fertility.
- http://www.acog.org/Patients
- http://www.uptodate.com (patient education)

PROGNOSIS
- Varies with pathophysiologic process
- Most anovulatory cycles can be treated with medical therapy and do not require surgical intervention.

**COMPLICATIONS**
- Iron deficiency anemia
- Uterine cancer in cases of prolonged unopposed estrogen stimulation

**REFERENCES**

**ADDITIONAL READING**
SEE ALSO

- Dysmenorrhea; Menorrhagia (Heavy Menstrual Bleeding)
- Algorithm: Abnormal Uterine Bleeding

CODES

ICD10

- N93.9 Abnormal uterine and vaginal bleeding, unspecified
- N93.8 Other specified abnormal uterine and vaginal bleeding
- N91.2 Amenorrhea, unspecified

CLINICAL PEARLS

- AUB is irregular bleeding that occurs in the absence of pregnancy or pathology, making it a diagnosis of exclusion.
- Anovulation accounts for 90% of AUB.
- An EMB should be performed in all women >35 years of age with AUB to rule out cancer or premalignancy, and it should be considered in women aged 18 to 35 years with AUB and risk factors for endometrial cancer.
- It is appropriate to initiate medical therapy in females <35 years of age with no apparent risk of endometrial cancer prior to performing an EMB.
ABNORMAL PAP AND CERVICAL DYSPLASIA

Tharani Ravi, MD • Fozia Akhtar Ali, MD

BASICS

DESCRIPTION

- Cervical dysplasia: Premalignant cervical disease that is also called cervical intraepithelial neoplasia (CIN); precancerous epithelial changes in the transformation zone of the uterine cervix almost always associated with human papillomavirus (HPV) infections.
- CIN encompasses a range of histologic diagnoses.
  - CIN I: mild dysplasia; low-grade lesion; cellular changes are limited to the lower 1/3 of the squamous epithelium.
  - CIN II: moderate dysplasia; high-grade lesion; cellular changes are limited to the lower 2/3 of the squamous epithelium.
  - CIN III or carcinoma in situ: severe dysplasia; high-grade lesion; cellular changes involve the full thickness of the squamous epithelium.
- System(s) affected: reproductive

Pediatric Considerations

Only 0.1% of cervical cancers occur before age 20 years. Screening women age <21 years (regardless of sexual history) does not reduce cervical cancer incidence and mortality compared with beginning screening at age 21 years. Screenings of adolescents lead to unnecessary evaluation and overtreatment of cervical lesions, which are highly likely to spontaneously regress (1)[A].

Geriatric Considerations

- Women age >65 years who have had adequate prior screening and no history of CIN II+ in the last 20 years should not be screened for cervical cancer. Adequate prior screening is defined as three consecutive, negative cytology results or two consecutive, negative HPV + cytology “contesting” results within 10 years before cessation of screening (with the most recent test within the last 5 years).
- Routine screening should continue for at least 20 years after spontaneous
regression or appropriate management of a high-grade precancerous lesion, even if this extends screening past the age 65 years.

**Pregnancy Considerations**
- Squamous intraepithelial lesions can progress during pregnancy but often regress postpartum.
- Colposcopy only to exclude the presence of invasive cancer in high-risk women.
- Endocervical curettage is contraindicated during pregnancy.
- Unless cancer is identified or suspected, treatment of CIN is contraindicated during pregnancy.

**Epidemiology**
Cervical cancer is the fourth most common type of cancer in women worldwide. It is the second leading cause of cancer death in women aged 20 to 39 years (2).
- Predominant age: can occur at any age, but incidence of CIN III peaks between ages 25 and 29 years; invasive disease peaks 15 years later. Cervical cancer most commonly occurs in women aged 35 to 55 years.

**Incidence**
- In United States: In 2017, approximately 12,820 new cases of invasive cervical cancer will be diagnosed and 4,210 women will die from the disease (2).
- The incidence of cervical cancer in the United States has decreased by >50% in the past 40 years, likely because of widespread cervical cancer screening tests.

**Prevalence**
- In 2004, in the United States, there were approximately 250,726 women who had a history of cervical cancer.
- Point prevalence of HPV positivity is highest in those 18 to 22 years of age (as high as 70%), falling off rapidly as women enter their 30s.

**Etiology and Pathophysiology**
HPV DNA is found in virtually all cervical carcinomas and precursor lesions worldwide.
- High-risk HPV types: 16, 18, 31, 33, 35, 45, 52, and 58 are common oncogenic virus types for cervical cancer.
• HPV 16 is the most carcinogenic HPV genotype and accounts for 55–60% of all cervical cancers.
• HPV 18 is the next most carcinogenic HPV genotype. HPV 18 causes a greater proportion of glandular cancers, adenocarcinoma, and adenosquamous carcinoma than squamous cell carcinoma.
• Most HPV infections are transient, becoming undetectable within 1 to 2 years. Persistent infections are what place women at significant risk for developing precancerous lesions.
• Low-risk types: HPV viral types 6, 11, 42, 43, and 44 are considered common low-risk types and may cause genital warts. HPV 6 and 11 (cause 90% of benign anogenital warts) can lead to low-grade squamous intraepithelial lesion (LSIL) and CIN I.

RISK FACTORS
• Previous or current HPV infection
• HIV infection and other immunosuppressive conditions
• In utero exposure to diethylstilbestrol
• Previous treatment of a high-grade precancerous lesion or cervical cancer
• Cigarette smoking
• Early age at first coitus (<20 years) and multiple sexual partners
• Some correlation with low socioeconomic status, high parity, oral contraceptive use, and poor nutrition

GENERAL PREVENTION
• Immunization: Immunization decreases high-risk HPV infections and cervical pathology for at least 5 to 7 years but has not yet been shown to decrease cervical cancer.
  – Ideally, HPV immunization of girls, boys, and women should be initiated prior to first intercourse. Per the Advisory Committee on Immunization Practices (ACIP), offer HPV vaccine to adolescents 11 to 12 years of age.
  – Three HPV vaccines were licensed for use in the United States: 9-valent HPV vaccine, quadrivalent HPV vaccine, and bivalent HPV vaccine. However, since January 2017, only 9-valent HPV vaccine is available in the United States.
  – Gardasil 9: approved in December 2014 for use in females and males ages 9 to 26 years; reduces dysplasia due to HPV types 16 and 18 (75% of cervical cancer), types 6 and 11 (anogenital warts), and protection against five additional HPV types which cause approximately 25% of CIN II+ lesions
  – Vaccine schedule: If vaccine begun before 15th birthday: 2 doses only 6 to
12 months apart
- If vaccine begun on or after 15th birthday: 3 doses at 0, 2, and 6 months
- Immunocompromising conditions: 3 doses needed

- Safe sex practices: condom use
- Screening
  - Pap smear is the main screening test for cervical cellular pathology.
  - Screening recommendations by age and source (see algorithm “Pap, Normal and Abnormal in Nonpregnant Women Ages 25 Years and Older” and separate algorithm “Pap, Normal and Abnormal in Women Ages 21–24 Years”)
    - <21 years: Do not screen (1) (USPSTF/ASCCP/ACS/ASCP/ACOG).
    - Frequency of screening recommendation: USPSTF/ASCCP/ACS/ASCP generally agree by age and screen.
      - 21 to 29 years: Screen with cytology (Pap smear) every 3 years (1)[A]. Do not screen with HPV testing alone or combined with cytology (1).
      - 30 to 65 years: Screen with cytology every 3 years (acceptable) or cotesting (cytology/HPV testing) every 5 years (preferred).
      - >65 years (who have had adequate prior screening and are not high risk):
        - Do not screen (1).
  - Special circumstances: women after hysterectomy with removal of the cervix and with no history of CIN II+: Do not screen (1)[A].
  - HIV-positive women: Screen every 3 years in those who have had three consecutive normal annual Pap tests and every 3 years cotesting in women ages 30 years and older.

**DIAGNOSIS**

**HISTORY**

Usually asymptomatic until there is invasive disease. Patients may present with vaginal discharge, abnormal vaginal bleeding, postcoital bleeding, pelvic pain, cervical mass, or bladder obstruction.

**PHYSICAL EXAM**

Pelvic exam occasionally reveals external HPV lesions. Examine for exophytic or ulcerative cervical lesions, with or without bleeding.

**DIFFERENTIAL DIAGNOSIS**
Acute or chronic cervicitis; cervical glandular hyperplasia; cervical polyp; cervical fibroid; HPV infection; invasive cervical malignancy; uterine malignancy

**DIAGNOSTIC TESTS & INTERPRETATION**

- Current evidence indicates no clinically important differences between conventional cytology and liquid-based cytology in detecting cervical cancer precursors. Conventional Pap smear involves a cervical sample plated on a microscope slide with fixative. Thin prep is a liquid-based collection and thin-layer preparation.
- To ensure an adequate sample of both the ecto- and endocervix, use a cytobrush and an extended tip spatula.
- Sensitivity of conventional Pap smear ranges from 30% to 70% for lesser cervical abnormalities. For detection of CIN II or higher, sensitivity was higher (44–99%) and had narrower specificity (91–98%) (3). Pap smears done routinely at recommended intervals increase the sensitivity further.
- The sensitivity and specificity of using HPV and Pap testing together (cotesting) for dysplasia is near 100% and 92.5%, respectively.
- Cytology report component: specimen type (conventional Pap smear or liquid based), adequacy (presence of endocervical cells), and categorization (negative for intraepithelial lesion or malignancy or epithelial cell abnormality; i.e., squamous/glandular)
- Bethesda system (cytologic grading) epithelial cell abnormalities
  - Squamous cell
    - Atypical squamous cells (ASC) (of undetermined significance [ASC-US], cannot exclude high-grade squamous intraepithelial lesion [ASC-H])
    - HPV, mild dysplasia, CIN I
    - Moderate/severe dysplasia CIS, CIN II, and CIN III
  - Glandular cell
    - AGCs (atypical glandular cells)
      - AGCs: not otherwise specified
      - AGCs: favor neoplasia
    - AIS (adenocarcinoma in situ)
    - Adenocarcinoma

**Diagnostic Procedures/Other**

Some algorithms differ for women age 21 to 24 years; see “ASCCP guidelines” (4) and algorithm “Pap, Normal and Abnormal in Women Ages 21–24 Years.” Below recommendations for ages as noted.
• HPV positive, cytology negative (30 years of age and older)
  – Option 1: HPV DNA typing: If HPV 16 or 18+, proceed to colposcopy; if negative, repeat cotesting at 1 year.
  – Option 2: Repeat cotesting at 1 year: If ASC or HPV positive, proceed to colposcopy; if negative, repeat cotesting at 3 years.
• ASC-US: (>24 years of age)
  – Option 1: HPV testing (preferred)
    o If HPV +, proceed to colposcopy (4)[B].
    o If HPV negative, repeat cotesting at 3 years (2)[B].
  – Option 2: Repeat cytology at 1 year (acceptable) (2).
    o If repeat cytology ASC or greater, proceed to colposcopy.
    o If repeat cytology is negative, proceed to routine screening in 3 years.
• ASC-H: colposcopy required
• LSIL: (>24 years of age)
  – LSIL with negative HPV test: Repeat cotesting at 1 year (preferred).
    o If repeat cotesting is negative, repeat cotesting in 3 years.
    o If cotesting is positive, proceed to colposcopy.
  – LSIL with no HPV test or positive HPV test: Proceed to colposcopy.
  – LSIL in pregnancy: colposcopy preferred, but it is acceptable to defer colposcopy to postpartum (2)
• HSIL: loop electrosurgical excision procedure (LEEP) or colposcopy (4)[B]
• AGCs: colposcopy with endocervical sampling and endometrial sampling (if 35 years or older or at risk for endometrial neoplasia) (4)[A]
• Atypical endometrial cells: endometrial and endocervical sampling
  – If negative, perform colposcopy.
• Women with no lesion on colposcopy or CIN I (preceded by “lesser abnormalities” such as ASC-US, LSIL, HPV 16+, HPV 18+, and persistent HPV)
  – Follow-up without treatment: cotesting at 12 months
  – If both HPV and cytology are negative, age-appropriate retesting 3 years later
  – If either positive, proceed to colposcopy. If persistent CIN I for at least 2 years, proceed to treatment with ablative or excisional methods.
• Ages 21 to 24 years: Management is slightly different than above; see “ASCCP guidelines” (4) or algorithm “Pap, Normal and Abnormal in Women Ages 21–24 Years.”
• Age >30 years: If cytology is negative but HPV is positive, repeat cotesting at 1 year is acceptable.
Test Interpretation
Atypical squamous or columnar cells, coarse nuclear material, increased nuclear diameter, koilocytosis (HPV hallmark)

TREATMENT
ASCCP guidelines: Evidence-based management algorithms guide Pap smear and postcolposcopic diagnostics and therapeutics and are available online at http://www.asccp.org/Guidelines (2).

GENERAL MEASURES
Office evaluation and observation; promote smoking cessation; promote protected intercourse; promote immunization.

MEDICATION
- Infective/reactive Pap smear: Treat trichomoniasis, symptomatic Candida, or shift in flora suggestive of bacterial vaginosis found on Pap smear results.
- Condyloma acuminatum: may be treated with cryotherapy or podophyllin topically q1–2wk or podofilox 0.5% applied BID × 3 days then off 4 days, repeated for 1 to 4 weeks, OR trichloroacetic acid applied topically by a physician and covered for 5 to 6 days, OR imiquimod cream 3 times per week at bedtime, up to 16 weeks

SURGERY/OTHER PROCEDURES
- Persistent CIN I, II, or III: ablative or excisional methods. If inadequate colposcopy for CIN II or III or recurrent CIN II or III, diagnostic excisional procedure is done. For adenocarcinoma in situ, hysterectomy is preferred.
- Cryotherapy, laser ablation, LEEP/large loop excision of transition zone, or cold-knife conization are all effective but require different training and with different side effects for patient. If cervical malignancy, see “Cervical Malignancy.”

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
After treatment (excision or ablation) of CIN II or III, women may reenter
routine screening only after negative cotesting between 12 and 24 months. Screening should be continued for 20 years.

**DIET**
Promote increased intake of antioxidant-rich foods.

**PATIENT EDUCATION**
HPV vaccination, smoking cessation, protected intercourse, regular screening with Pap smear per guidelines

**PROGNOSIS**
- Progression of CIN to invasive cervical cancer is slow, and the likelihood of regression is high: Up to 43% of CIN II and 32% of CIN III lesions may regress. CIN III has a 30% probability of becoming invasive cancer over a 30-year period, although only about 1% if treated (5).
- CIN III becomes invasive: Lesions discovered early are amenable to treatment with excellent results and few recurrences.
- 1- and 5-year relative survival rates for cervical cancer patients are 87% and 68%, respectively. The 5-year survival rate for patients diagnosed with localized disease is 91% (5).

**COMPLICATIONS**
Aggressive cervical surgery may be associated with cervical stenosis, cervical incompetence, and scarring affecting cervical dilatation in labor.

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

- Cervical Malignancy; Condylomata Acuminata; Trichomoniasis; Vulvovaginitis, Prepubescent
- Algorithms: Pap, Normal and Abnormal in Nonpregnant Women Ages 25 Years and Older; Pap, Normal and Abnormal in Women Ages 21–24 Years

**CODES**

**ICD10**

- R87.619 Unspecified abnormal cytological findings in specimens from cervix uteri
- N87.9 Dysplasia of cervix uteri, unspecified
- N87.1 Moderate cervical dysplasia

**CLINICAL PEARLS**

- HPV is present in virtually all cervical cancers (99.7%), but most HPV infections are transient.
- Vaccine should be offered prior to onset of any sexual activity for maximum effectiveness.
- Know and adhere to recognized screening guidelines to avoid the harms of overscreening.
- Optimal screening strategy is in evolution. HPV-primary with cytology-secondary strategies will likely supplant current guidelines in near future.
ACETAMINOPHEN POISONING

Luis T. Garcia, MD • Kenneth Polezoes, MD

BASICS

DESCRIPTION

- A disorder characterized by hepatic necrosis following large ingestions of acetaminophen. Symptoms may vary from an asymptomatic presentation to nausea, vomiting, diaphoresis, malaise, jaundice, confusion, somnolence, coma, and potentially death. The clinical hallmark is the onset of symptoms within 24 hours of ingestion of acetaminophen-only or combination products. Ideally, ingestion is treated before symptoms develop.

- Acetaminophen poisoning is most often encountered following large, single ingestions of acetaminophen-containing medications. Usual toxic doses are >10 g in adults and >200 mg/kg in children. However, poisoning also occurs after acute and chronic ingestions of lesser amounts in susceptible individuals, including those who regularly abuse alcohol, are chronically malnourished, or take medications that affect hepatic metabolism of acetaminophen.

- Therapeutic adult doses are 0.5 to 1 g q4–6h, up to a maximum of 4 g/day. Therapeutic pediatric doses are 10 to 15 mg/kg q4–6h, not to exceed 5 doses in 24 hours.

- System(s) affected: gastrointestinal, cardiovascular, renal/urologic, CNS
  - Multisystem organ failure can occur.

- Synonym(s): paracetamol poisoning

Geriatric Considerations

Increased risk of hepatic damage in frail elderly patients due to decreased hepatic phase II metabolism and likely coingestion of enzyme-inducing hepatotoxic medications. Expert opinion recommendations are to keep dose of acetaminophen at ≤3,000 mg/day in senior citizens, those with liver disease, and those with alcohol abuse disorders.

Pediatric Considerations

Hepatic damage at toxic acetaminophen levels is decreased in young children. This may be due to larger glutathione stores.
**Pregnancy Considerations**
- Increased incidence of spontaneous abortion, especially with overdose at early gestational age
- Incidence of spontaneous abortion or fetal death appears to be increased when N-acetylcysteine (NAC) treatment is delayed.
- IV NAC is generally preferred in pregnancy because it may offer greater bioavailability.

**Epidemiology**
- Predominant age: children and adults
- Predominant sex: no reported association
- Intentional versus unintentional ingestion (52% vs. 48%)

**Incidence**
The annual incidence of APAP in the ED increased from 2.0 (95% CI 0.2–7.2) cases per 10,000 patients in 2005 to 3.4 (95% CI 1.1–8.8) in 2010.

**Prevalence**
- >38,000 hospitalizations per year on average from 1998 to 2011 for acetaminophen-related poisonings in the United States, nearly one half were unintentional largely related to opioid–acetaminophen combinations.
- <1% of hospitalizations in those <18 years old had coexistent liver toxicity.

**Etiology and Pathophysiology**
- Accidental or intentional ingestion of acetaminophen or combination medications containing acetaminophen
- 96% of ingested acetaminophen is metabolized in the liver, with only 2–4% excreted unchanged in the urine. When taken in therapeutic doses, 90–95% of hepatic metabolism occurs via glucuronidation and sulfation and results in the formation of benign metabolites. 5–10% of hepatic metabolism is by oxidation through the cytochrome P450 enzyme system (CYP 3A4 and CYP 2E1), which results in the formation of the toxic metabolite N-acetyl-p-benzoquinoneimine (NAPQI). NAPQI is rapidly conjugated with glutathione to form a nontoxic metabolite. The metabolites are excreted in the urine along with a small amount of unchanged drug. Hepatocellular damage typically occurs when toxic doses of acetaminophen result in saturation of the glucuronidation and sulfation pathways with subsequent production of excessive amounts of NAPQI. Available glutathione stores become depleted,
NAPQI accumulates, and hepatocellular damage occurs.

**RISK FACTORS**
- Concurrent poisoning with other substances
- Psychiatric illness, history of suicide attempts
- Regular ingestion of large amounts of alcohol
- Possible risk related to previous weight loss surgery

**GENERAL PREVENTION**
Parent/caregiver education recommended during well-child exams regarding poisoning prevention
- Poison Control: 1-800-222-1222 for any questions

**DIAGNOSIS**
- May initially present as asymptomatic with history of ingestion in the last 8 hours. Signs and symptoms of poisoning are related to liver toxicity and develop over the first 24 hours following large ingestions; may last as long as 8 days
- Symptoms may develop gradually following long-term ingestion of near-maximal therapeutic amounts of acetaminophen. Such patients may present in stages 1 to 3 as below, without a history of ingestion of the usual toxic doses.
- Severe symptoms indicate large ingestions or coingestants:
  - Stage 1: first 24 hours after time of ingestion:
    - Nausea and anorexia
    - Vomiting
    - Diaphoresis
  - Stage 2: days 2 to 3:
    - Right upper quadrant pain
    - Typically less nausea, vomiting, diaphoresis, and malaise than in stage 1
  - Stage 3: days 3 to 4:
    - Nausea, vomiting, and malaise reappear.
    - Severe poisonings may result in jaundice, confusion, somnolence, and coma.
  - Stage 4: after day 5:
Resolution of clinical signs in survivors’ possible deterioration due to multiorgan failure and death

- Fulminant hepatic failure occurs in <1% of adults and is very rare in children <6 years of age.
- Patients with an unexplained rise in liver function tests (LFTs) with negative acetaminophen levels may be overdose patients presenting in stage 3.

HISTORY

Ingestion or suspected ingestion of acetaminophen-containing product

DIFFERENTIAL DIAGNOSIS

- Consider presence of coingestants, especially alcohol and aspirin.
- Other ingested toxins that produce severe acute hepatic injury, including the mushroom *Amanita phalloides*, and products containing yellow phosphorus or carbon tetrachloride

DIAGNOSTIC TESTS & INTERPRETATION

*Initial Tests (lab, imaging)*

- Plasma acetaminophen levels should be drawn on all patients ≥4 hours after ingestion (levels prior to 4 hours not helpful).
- Alanine transaminase (ALT), aspartate transaminase (AST), prothrombin time (PT)/international normalized ratio (INR), bilirubin, lactate dehydrogenase (LDH)
- Electrolytes, glucose, BUN, creatinine
- Pregnancy screen in females (urine or serum)
- Urinalysis
- Consider arterial blood gas (ABG) if pH disturbance is suspected on clinical or lab grounds.
- Screens for suspected coingestants (aspirin, iron, etc.) may be positive (especially when suicide attempt is a possibility).
- With toxic ingestions, AST (serum glutamic-oxaloacetic transaminase), ALT (serum glutamic-pyruvic transaminase), and bilirubin levels begin to rise in stage 2 and peak in stage 3.
- In severe poisonings, the PT/INR will parallel these changes and should be monitored.
- Markedly elevated ALT levels are consistent with the diagnosis, and improvement in ALT is a good sign.
- Laboratory abnormalities usually resolve by stage 4.
Renal function abnormalities are common in patients with hepatotoxicity.

Evidence of damage to pancreas and heart may present following severe poisonings.

Anion gap metabolic acidosis due to accumulation of 5-oxoprolene may rarely be seen.

Drugs that may alter lab results: none with clinically significant cross-reactivity with plasma acetaminophen assay

Disorders that may alter lab results: diseases or toxic substances that damage the liver, particularly alcohol

No specific imaging required

**Follow-Up Tests & Special Considerations**

During recovery, liver tests should normalize.

**Test Interpretation**

Centrilobular hepatic necrosis

---

**TREATMENT**

- Contact a regional/local poison control center for recommendations; in the United States: (800) 222-1222

- NAC should be given when plasma acetaminophen concentrations measured 
  ≥4 hours after ingestion are in the “possible risk” or higher levels on the Rumack-Matthew nomogram. This corresponds to acetaminophen levels >150 µg/mL (993 µmol/L), >75 µg/mL (497 µmol/L), and >37 µg/mL (244 µmol/L) at 4, 8, and 12 hours after ingestion, respectively. See [http://www.ars-informatica.ca/toxicity_nomogram.php?calc=acetamin](http://www.ars-informatica.ca/toxicity_nomogram.php?calc=acetamin).
  - The nomogram is not helpful in determining the need for NAC for sustained-release products or chronic ingestions. If a sustained-released product has been ingested, two serum acetaminophen levels should be obtained 4 to 6 hours apart and treatment given if either level is above the possible toxicity line.

- For chronic toxicity or for those patients who present after 24 hours postingestion, treatment is based on clinical effects, LFTs, and the acetaminophen level.

- NAC should be started within 8 hours of ingestion for best chance of hepatic protection. Patients presenting near 8 hours should empirically receive NAC while waiting for labs.
- All patients with acetaminophen liver injury (even after 8 hours) should receive NAC.
- NAC therapy may be effective up to ≥36 hours after ingestion.
- Single-dose activated charcoal should be given within 1 to 2 hours (and possibly up to 4 hours) of ingestion (especially in cases of coingestants) (1,2) [C].

**ALERT**

Never delay NAC administration for use of activated charcoal.

- Ipecac and gastric lavage are no longer recommended for routine use at home or in health care facilities.

**MEDICATION**

**First Line**

- Acetylcysteine (NAC, Mucomyst) should be initiated within 8 hours of ingestion whenever possible; single-dose activated charcoal (1 g/kg PO) may be effective if given within 1 to 2 hours of ingestion especially if other substances concomitantly ingested. Never delay oral NAC for activated charcoal.
- Acetylcysteine may be given PO or IV, depending on situation and availability:
  - IV loading dose of Acetadote 150 mg/kg over 60 minutes followed by an infusion of 50 mg/kg over 4 hours (12.5 mg/kg/hr); this is followed by an infusion of 100 mg/kg over the next 16 hours (6.25 mg/kg/hr) (20-hour regimen).
  - Oral loading dose of 140 mg/kg, followed by 70 mg/kg q4h for 17 additional doses (72-hour regimen)
- No treatment regimen has been shown to be superior over the other (1)[A].

- Contraindications: medication allergies
- Precautions:
  - Oral NAC may cause significant nausea and vomiting due to its sulfur content; consider nasogastric tube.
  - Nausea can be treated with metoclopramide (Reglan), 1 to 2 mg/kg IV, or ondansetron (Zofran), 0.15 mg/kg IV (for age >4 years, usually 4 mg/dose).
  - IV NAC (Acetadote) may cause anaphylactoid reactions (3–6%), including rash, bronchospasm, pruritus, angioedema, tachycardia, or hypotension (higher rates seen in asthmatics and those with atopy) (3,4)[C].
- Reactions usually occur with loading dose. Slow or temporarily stop the
infusion; may concurrently treat with antihistamines

- Failure rates of NAC of 3–7% have been observed (3)[C].

**Second Line**
- Oral racemethionine (methionine)
- In cases of massive ingestions (e.g., levels >1,000 mg/L, acidosis, coma/hypotension), hemodialysis may be a beneficial adjunct therapy and improve survival (5)[C].

**ISSUES FOR REFERRAL**
- Psychological evaluation in emergency room and close follow-up after intentional ingestions
- Consider child abuse reporting if neglect led to overdose.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Toxic and intentional ingestions
- Any reported ingestion with increased LFTs, acidosis on ABG, elevated creatinine, and so forth
- Initiate aggressive age- and weight-appropriate IV hydration.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- All patients should be evaluated at a health care facility.
- Patients with evidence of organ failure, increased LFTs, or coagulopathy should be evaluated for ELT (emergency liver transplant) at a transplant center.
- Activity may be restricted if significant hepatic damage is present.
- Outpatient management is adequate for nontoxic accidental ingestions.

**Patient Monitoring**
Ask about possible ingestion by others (i.e., suicide pacts).

**DIET**
No special diet, except with severe hepatic damage
PATIENT EDUCATION

- Patients should be counseled to avoid Tylenol if already using combination product(s) containing acetaminophen.
- Education of parents/caregivers during well-child visits
- Anticipatory guidance for caregivers, family, and cohabitants of potentially suicidal patients
- Education of patients taking long-term acetaminophen therapy

PROGNOSIS

- Complete recovery with early therapy
- <1% of adult patients develop hepatic failure. King criteria (pH <7.3, PT >100s [INR >65], creatinine >3.4 mg/dL [>300 μmol/L]) is associated with a poor prognosis and possible need for liver transplant (6)[C]. Early referral increases the chance for transplant success (4)[A].
- Hepatic failure is very rare in children <6 years of age.

COMPLICATIONS

Rare following recovery from acute poisoning

Algorithm: Acetaminophen Poisoning, Treatment

CODES

ICD10

- T39.1X4A Poisoning by 4-Aminophenol derivatives, undetermined, init
- K71.10 Toxic liver disease with hepatic necrosis, without coma
- T39.1X1A Poisoning by 4-Aminophenol derivatives, accidental, init

CLINICAL PEARLS

- Contact a regional poison control center for management recommendations; in the United States: (800) 222-1222
- NAC should be given when plasma acetaminophen concentrations measured ≥4 hours after ingestion are in the “possible risk” or higher levels on the Rumack-Matthew nomogram. This corresponds to acetaminophen levels >150 μg/mL (993 μmol/L), >75 μg/mL (497 μmol/L), and >37 μg/mL (244 μmol/L) at 4, 8, and 12 hours after ingestion, respectively.
- *Never* delay oral NAC for activated charcoal.
- NAC should be started within 8 hours of ingestion for best chance of hepatic protection. Patients presenting near 8 hours should empirically receive NAC while waiting for labs.
- All patients with acetaminophen liver injury (even after 8 hours) should receive NAC.
- To enhance palatability, oral NAC can be diluted with a beverage of choice and served in a cup with lid and straw.
- In January 2016, Cetylev, an effervescent lemon mint flavored tablet, was approved by the FDA. Tablets come in strengths of 500 mg and 2.5 g of NAC.
ACNE ROSACEA
Daniel R. DiBlasi, DO • Shane L. Larson, MD

BASICS

DESCRIPTION
- Rosacea is a chronic condition characterized by recurrent episodes of facial flushing, erythema (due to dilatation of small blood vessels in the face), papules, pustules, and telangiectasia (due to increased reactivity of capillaries) in a symmetric, central facial distribution; sometimes associated with ocular symptoms (ocular rosacea)
- Four subtypes:
  - Erythematotelangiectatic rosacea (ETR)
  - Papulopustular rosacea (PPR)
  - Phymatous rosacea
  - Ocular rosacea
- System(s) affected: skin/exocrine
- Synonym(s): rosacea

Geriatric Considerations
- Chronic inflammatory dermatosis with middle-age onset
- Effects of aging might increase the side effects associated with oral isotretinoin used for treatment (at present, data are insufficient due to lack of clinical studies in elderly patients ≥65 years).

EPIDEMIOLOGY

Prevalence
- Predominant age of onset: 30 to 50 years
- Predominant sex: female > male. However, males are at greater risk for progression to later stages.
- More common in Fitzpatrick skin types I and II

ETIOLOGY AND PATHOPHYSIOLOGY
- No proven cause
- Possibilities include the following:
  - Thyroid and sex hormone disturbance
– Alcohol, coffee, tea, spiced food overindulgence (unproven)
– Demodex follicular parasite (suspected)
– Exposure to cold, heat
– Emotional stress
– Dysfunction of the GI tract (possible association with *Helicobacter pylori*)

**Genetics**
- People of Northern European and Celtic background commonly afflicted
- Associated with three human leukocyte antigen (HLA) alleles: HLA-DRB1, HLA-DQB1, and HLA-DQA1 (MHC class II)

**RISK FACTORS**
- Exposure to spicy foods, hot drinks
- Environmental factors: sun, wind, cold, heat

**GENERAL PREVENTION**
No preventive measures known

**COMMONLY ASSOCIATED CONDITIONS**
- Seborrheic dermatitis of scalp and eyelids
- Keratitis with photophobia, lacrimation, visual disturbance
- Corneal lesions
- Blepharitis
- Uveitis

**DIAGNOSIS**

**HISTORY**
- Usually have a history of episodic flushing with increases in skin temperature in response to heat stimulus in mouth (hot liquids), spicy foods, alcohol, sun exposure
- Acne may have preceded onset of rosacea by years; nevertheless, rosacea usually arises de novo without preceding history of acne or seborrhea.
- Excessive facial warmth and redness are the predominant presenting complaints. Itching is generally absent.

**PHYSICAL EXAM**
Rosacea has four subtypes:
- The rosacea diathesis: episodic erythema, “flushing and blushing”
- Progression from one subtype to another is hypothetical.
- ETR: persistent erythema with telangiectases
- PPR: persistent erythema, telangiectases, papules, pustules
- Phymatous: persistent deep erythema, dense telangiectases, papules, pustules, nodules; rarely persistent “solid” edema of the central part of the face (phymatous)

- Facial erythema, particularly on cheeks, nose, and chin. At times, entire face may be involved.
- Inflammatory papules are prominent; pustules and telangiectasia may be present.
- Comedones are absent (unlike acne vulgaris).
- Women usually have lesions on the chin and cheeks, whereas the nose is commonly involved in men.
- Ocular findings (mild dryness and irritation with blepharitis, conjunctival injection, burning, stinging, tearing, eyelid inflammation, swelling, and redness) are present in 50% of patients.

DIFFERENTIAL DIAGNOSIS
- Drug eruptions (iodides and bromides)
- Granulomas of the skin
- Cutaneous lupus erythematosus
- Carcinoid syndrome
- Acne vulgaris
- Seborrheic dermatitis
- Steroid rosacea (abuse)
- Systemic lupus erythematosus
- Lupus pernio (sarcoidosis)

DIAGNOSTIC TESTS & INTERPRETATION
- Diagnosis is based on physical exam findings.
- A recent change in classification has been proposed based on the phenotype that reflects the clinical presentation and to better focus treatment options, which are targeted to address the main clinical presentation (1)[C].

**Test Interpretation**
Histology of affected skin may reveal:
- Inflammation around hypertrophied sebaceous glands, producing papules, pustules, and cysts
- Absence of comedones and blocked ducts
- Vascular dilatation and dermal lymphocytic infiltrate
- Granulomatous inflammation

## TREATMENT

### GENERAL MEASURES
- Proper skin care and photoprotection are important components of management plan (1)[B]. Use of mild, nondrying soap is recommended; local skin irritants should be avoided.
- Avoidance of triggers
- Reassurance that rosacea is completely unrelated to poor hygiene
- Treat psychological stress if present.
- Topical steroids should not be used, as they may aggravate rosacea.
- Avoid oil-based cosmetics:
  - Others are acceptable and may help women tolerate symptoms.
- Electrodesiccation or chemical sclerosis of permanently dilated blood vessels
- Possible evolving laser therapy
- Support physical fitness.

### MEDICATION

#### First Line
- Topical metronidazole preparations once (1% formulation) or twice (0.75% formulations) daily for 7 to 12 weeks was significantly more effective than placebo in patients with moderate to severe rosacea. A rosacea treatment system (cleanser, metronidazole 0.75% gel, hydrating complexion corrector, and sunscreen SPF 30) may offer superior efficacy and tolerability to metronidazole (2)[A].
- Azelaic acid (Finacea) is very effective as initial therapy; azelaic acid topical alone is effective for maintenance (3)[A].
- Topical ivermectin 1% cream (2)[A]
  - Recently found to be more effective than metronidazole for treatment of PPR
- Topical brimonidine tartrate 0.5% gel is effective in reducing erythema associated with ETR (4)[A].
– $\alpha_2$-Adrenergic receptor agonist; potent vasoconstrictor

- Oxymetazoline 1% cream, an $\alpha_{1A}$ adrenergic receptor agonist recently approved for the treatment of persistent erythema associated with rosacea in adults (5)[B]
- Doxycycline 40-mg dose is at least as effective as 100-mg dose and has a correspondingly lower risk of adverse effects but is much more expensive (6)[A].

- Precautions: Tetracyclines may cause photosensitivity; sunscreen is recommended.
- Significant possible interactions:
  - Tetracyclines: Avoid concurrent administration with antacids, dairy products, or iron.
  - Broad-spectrum antibiotics: may reduce the effectiveness of oral contraceptives; however, this finding has only been associated with rifampin; consider adding barrier method.

Second Line
- Topical erythromycin
- Topical clindamycin (lotion preferred)
  - Can be used in combination with benzoyl peroxide; commercial topical combinations are available.

- Possible use of calcineurin inhibitors (tacrolimus 0.1%; pimecrolimus 1%). Pimecrolimus 1% is effective to treat mild to moderate inflammatory rosacea (7)[A].
- Permethrin 5% cream; similar efficacy compared to metronidazole (8)[B]; for severe cases, oral isotretinoin at 0.3 mg/kg for a minimum of 3 months

Pediatric Considerations
Tetracyclines: not for use in children <8 years

Pregnancy Considerations
- Tetracyclines: not for use during pregnancy
- Isotretinoin: teratogenic; not for use during pregnancy or in women of reproductive age who are not using reliable contraception; requires registration with iPledge program

ADDITIONAL THERAPIES
Cyclosporine 0.05% ophthalmic emulsion may be more effective than artificial
tears for ocular rosacea.

**SURGERY/OTHER PROCEDURES**
Laser treatment is an option for progressive telangiectasias or rhinophyma.
- Pulsed dye laser (585 nm or 595 nm) is effective in treating telangiectases and erythema.
- CO₂ fractional ablative laser can be used to treat rhinophyma.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Outpatient treatment

*Patient Monitoring*
- Occasional and as needed
- Close follow-up and laboratory assessment for patients using isotretinoin per prescribing instructions and iPLEDGE program guidance
- Consider ophthalmology evaluation in patients with ocular symptoms.

**DIET**
Avoid alcohol and hot drinks of any type.

**PROGNOSIS**
- Slowly progressive
- Subsides spontaneously (sometimes)

**COMPLICATIONS**
- Rhinophyma (dilated follicles and thickened bulbous skin on nose), especially in men
- Conjunctivitis
- Blepharitis
- Keratitis
- Visual deterioration

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

- Acne Vulgaris; Blepharitis; Dermatitis, Seborrheic; Lupus Erythematosus,
Discoid; Uveitis

Algorithm: Acne

CODES

ICD10

- L71.9 Rosacea, unspecified
- L71.8 Other rosacea

CLINICAL PEARLS

- Rosacea usually arises de novo without any preceding history of acne or seborrhea.
- Rosacea may cause chronic eye symptoms, including blepharitis.
- Avoid alcohol, sun exposure, and hot drinks.
- Medication treatment resembles that of acne vulgaris, with oral and topical antibiotics.
ACNE VULGARIS

Gary I. Levine, MD

BASICS

DESCRIPTION

- Acne vulgaris is a disorder of the pilosebaceous units. It is a chronic inflammatory dermatosis notable for open/closed comedones, papules, pustules, or nodules.
- Systems affected: skin/exocrine

Geriatric Considerations

Favre-Racouchot syndrome: comedones on face and head due to sun exposure

Pregnancy Considerations

- May result in a flare or remission of acne
- Typically improves 1st trimester; may worsen 3rd trimester (1)
- Topical benzoyl peroxide, azelaic acid, erythromycin or clindamycin, and oral erythromycin or cephalaxin can be used in pregnancy; use topical agents when possible (1).
- Isotretinoin is teratogenic; pregnancy Category X
- Avoid topical tretinoin and adapalene as they may cause retinoid embryopathy (1); class C
- Contraindicated: isotretinoin, tazarotene, tetracycline, doxycycline, minocycline

Pediatric Considerations

- Neonatal acne (neonatal cephalic pustulosis)
  - Newborn to 8 weeks; lesions limited to face; responds to topical ketoconazole 2% cream (2)
- Infantile acne
  - Newborn to 1 year; lesions on face, neck, back, and chest; no Rx required (2)
- Early–mid childhood acne
  - 1 to 7 years; rare; consider hyperandrogenism (2).
- Preadolescent acne
– 7 to 11 years; common, 47% of children, usually due to adrenal awakening
- Do not use tetracyclines in those <8 years of age (2); other therapies similar to adolescent acne

**EPIDEMIOLOGY**

- Predominant age: early to late puberty, may persist in 20–40% of affected individuals into 4th decade
- Predominant sex
  - Male > female (adolescence)
  - Female > male (adult)

**Prevalence**

- 80–95% of adolescents affected. A smaller percentage will seek medical advice.
- 8% of adults aged 25 to 34 years; 3% at 35 to 44 years
- African Americans 37%, Caucasians 24%

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Androgens (testosterone and dehydroepiandrosterone sulfate [DHEA-S]) stimulate sebum production and proliferation of keratinocytes in hair follicles (3).
- Keratin plug obstructs follicle os, causing sebum accumulation and follicular distention.
- *Propionibacterium acnes*, an anaerobe, colonizes and proliferates in the plugged follicle.
- *P. acnes* promote proinflammatory mediators, causing inflammation of follicle and dermis.

**Genetics**

- Familial association in 50%
- If a family history exists, the acne may be more severe and occur earlier.

**RISK FACTORS**

- Increased endogenous androgenic effect
- Oily cosmetics, cocoa butter
- Rubbing or occluding skin surface (e.g., sports equipment such as helmets and shoulder pads), telephone, or hands against the skin
- Polyvinyl chloride, chlorinated hydrocarbons, cutting oil, tars
Numerous drugs, including androgenic steroids (e.g., steroid abuse, some birth control pills)
Endocrine disorders: polycystic ovarian syndrome, Cushing syndrome, congenital adrenal hyperplasia, androgen-secreting tumors, acromegaly
Stress
High-glycemic load and possibly high-dairy diets may exacerbate acne (3).
Severe acne may worsen with smoking.

COMMONLY ASSOCIATED CONDITIONS
- Acne fulminans, pyoderma faciale
- Acne conglobata, hidradenitis suppurativa
- Pomade acne
- SAPHO syndrome (synovitis, acne, pustulosis, hyperostosis, and osteitis)
- Pyogenic arthritis, pyoderma gangrenosum, and acne (PAPA) and seborrhea, acne, hirsutism, and alopecia (SAHA) syndromes
- Behçet syndrome, Apert syndrome
- Dark-skinned patients: 50% keloidal scarring and 50% acne hyperpigmented macules

DIAGNOSIS
HISTORY
- Ask about duration, medications, cleansing products, stress, smoking, exposures, diet, and family history.
- Females may worsen 1 week prior to menses.

PHYSICAL EXAM
- Closed comedones (whiteheads)
- Open comedones (blackheads)
- Nodules or papules
- Pustules (“cysts”)
- Scars: ice pick, rolling, boxcar, atrophic macules, hypertrophic, depressed, sinus tracts
- Consistent grading scale is useful; no specific universal grading system is recommended per guidelines (4).
- Grading system (American Academy of Dermatology, 1990) (3)
  - Mild: few papules/pustules; no nodules
- Moderate: some papules/pustules; few nodules
- Severe: numerous papules/pustules; many nodules
- Very severe: acne conglobata, acne fulminans, acne inversa

- Most common areas affected are face, chest, back, and upper arms (areas of greatest concentration of sebaceous glands) (3).

**DIFFERENTIAL DIAGNOSIS**
- Folliculitis: gram-negative and gram-positive
- Acne (rosacea, cosmetica, steroid-induced)
- Perioral dermatitis
- Chloracne
- Pseudofolliculitis barbae
- Drug eruption
- Verruca vulgaris and plana
- Keratosis pilaris
- Molluscum contagiosum
- Sarcoidosis
- Seborrheic dermatitis
- Miliaria
- Lupus erythematosus

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
Only indicated if additional signs of androgen excess; if so, test for free and total testosterone and DHEA-S and consider LH and FSH (PCOS).

**TREATMENT**
- Comedonal (grade 1): keratinolytic agent (see as follows for specific agents)
- Mild inflammatory acne (grade 2): benzoyl peroxide or topical retinoid or benzoyl peroxide +/- topical antibiotic +/- topical retinoid (4)
- Moderate inflammatory acne (grade 3): Add systemic antibiotic to grade 2 regimen.
- Severe inflammatory acne (grade 4): as in grade 3, or isotretinoin
- Topical retinoid plus a topical antimicrobial agent is first-line treatment for more than mild disease.
- Topical retinoid + antibiotic (topical or PO) is better than either alone for
mild/moderate acne.
- Topical retinoids are first-line agents for maintenance. Avoid long-term antibiotics for maintenance.
- Avoid topical antibiotics as monotherapy (4)[A].
- Can use isotretinoin for treatment of resistant moderate acne (4)
- Recommended vehicle type
  - Dry or sensitive skin: cream, lotion, or ointment
  - Oily skin, humid weather: gel, solution, or wash
  - Hair-bearing areas: lotion, hydrogel, or foam
- Apply topical agents to entire affected area, not just visible lesions.
- Mild soap daily to control oiliness; avoid abrasives.
- Avoid drying agents with keratinolytic agents.
- Gentle cleanser and noncomedogenic moisturizer help decrease irritation.
- Oil-free, noncomedogenic sunscreens
- Stress management if acne flares with stress

**MEDICATION**

**ALERT**
Most prescription topical medications are very expensive, costing from $100 to several hundred dollars per tube.

- Keratinolytic agents (alpha-hydroxy acids, salicylic acid, topical retinoids, azelaic acid) (side effects include dryness, erythema, and scaling; start with lower strength, increase as tolerated)
- Tretinoin (Retin-A, Retin-A Micro, Avita, Atralin) varying strengths and formulations: Apply at bedtime; wash skin; let skin dry 30 minutes before application.
  - Retin-A Micro, Atralin, and Avita are less irritating and stable with BP.
  - May cause an initial flare of lesions; may be eased by 14-day course of oral antibiotics
  - Avoid in pregnant and lactating women.
- Adapalene (Differin): 0.1%, apply topically at night.
  - Effective; less irritation than tretinoin or tazarotene
  - May be combined with benzoyl peroxide (Epiduo)—very effective in skin of color
  - First FDA-approved retinoid much less expensive than other Rx retinoids
- Tazarotene (Tazorac): Apply at bedtime.
  - Most effective and most irritating; teratogenic
- **Azelaic acid (Azelex, Finevin):** 20% topically, BID
  - Keratinolytic, antibacterial, anti-inflammatory
  - Reduces postinflammatory hyperpigmentation in dark-skinned individuals
  - Side effects: erythema, dryness, scaling, hypopigmentation
  - Effective in postadolescent acne
- **Salicylic acid:** 2%, less effective and less irritating than tretinoin
- **Alpha-hydroxy acids:** available over-the-counter
- **Topical antibiotics and anti-inflammatories**
  - Topical benzoyl peroxide
    - 2.5% as effective as stronger preparations
    - Gel penetrates better into follicles.
    - When used with tretinoin, apply benzoyl peroxide in morning and tretinoin at night.
    - Side effects: irritation; may bleach clothes; photosensitivity
- **Topical antibiotics:** Do not use as monotherapy (4)[A].
  - Erythromycin 2%
  - Clindamycin 1%
  - Metronidazole gel or cream: Apply once daily.
  - Azelaic acid (Azelex, Finevin): 20% cream: enhanced effect and decreased risk of resistance when used with zinc and benzoyl peroxide
  - Benzoyl peroxide-erythromycin (Benzamycin): especially effective with azelaic acid
  - Benzoyl peroxide-clindamycin (BenzaClin, DUAC, Clindoxyl)
  - Benzoyl peroxide-salicylic acid (Cleanse & Treat, Inova): similar in effectiveness to benzoyl peroxide-clindamycin
  - Sodium sulfacetamide (Sulfacet-R, Novacet, Klaron): useful in acne with seborrheic dermatitis or rosacea
  - Dapsone (Aczone) 5% gel: useful in adult females with inflammatory acne; may cause yellow/orange skin discoloration when mixed with benzoyl peroxide; very rare methemoglobinemia
- **Oral antibiotics:** use for shortest possible period, generally needs 8 to 12 weeks of therapy, reevaluate for discontinuation at 12 to 16 weeks duration (4); indicated when acne is more severe, trunk involvement, unresponsive to topical agents, or at greater risk for scarring (5)[A]
  - Tetracycline: 500 to 1,000 mg/day divided BID; high dose initially, taper in 6 months, less effective than doxycycline or minocycline (4), side effects: photosensitivity, esophagitis
  - Minocycline: 100 to 200 mg/day, divided daily—BID; side effects include photosensitivity, urticaria, gray-blue skin, vertigo, hepatitis, lupus.
- Doxycycline: 20 to 200 mg/day, divided daily—BID; side effects include photosensitivity.
- Erythromycin: 500 to 1,000 mg/day; divided BID–QID; decreasing effectiveness as a result of increasing *P. acnes* resistance
- Trimethoprim-sulfamethoxazole (Bactrim DS, Septra DS): 1 daily or BID
- Azithromycin (Zithromax): 500 mg 3 days/week × 1 month, then 250 mg every other day × 2 months
- **Oral retinoids**
  - Isotretinoin: 0.5 to 1.0 mg/kg/day divided BID to maximum 2 mg/kg/day divided BID for very severe disease; 60–90% cure rate; usually given for 12 to 20 weeks; maximum cumulative dose = 120 to 150 mg/kg; 20% of patients relapse and require retreatment (3)[A], 0.25 to 0.40 mg/kg/day in moderately severe acne
    - Side effects: teratogenic, pancreatitis, excessive drying of skin, hypertriglyceridemia, hepatitis, blood dyscrasias, hyperostosis, premature epiphyseal closure, night blindness, erythema multiforme, Stevens-Johnson syndrome, suicidal ideation, psychosis
    - Avoid tetracyclines or vitamin A preparations during isotretinoin therapy due to risk of pseudotumor cerebri.
    - Avoid tetracyclines or vitamin A preparations during isotretinoin therapy due to risk of pseudotumor cerebri.
    - Monitor for pregnancy, psychiatric/mood changes, complete blood count (CBC), lipids, glucose, and liver function tests at baseline and every month.
    - Patient and provider must be registered and adhere to manufacturer’s iPledge program ([www.ipledgeprogram.com](http://www.ipledgeprogram.com)), two forms of effective contraception required.
- **Medications for women only**
  - FDA-approved oral contraceptives (in order of effectiveness) (6)[B]
    - Drospirenone/ethinyl estradiol (Yaz, Yasmin), or drospirenone/ethinyl estradiol/levomefolate (Beyaz, Safyral) > norgestimate/ethinyl estradiol (Ortho Tri-Cyclen) > norethindrone acetate/ethinyl estradiol
    - Most combined contraceptives also effective.
- Spironolactone (Aldactone); 25 to 200 mg/day; antiandrogen; reduces sebum production

**ISSUES FOR REFERRAL**
Consider referral/consultation to dermatologist.
- Refractory lesions despite appropriate therapy
- Consideration of isotretinoin therapy
Management of acne scars

**ADDITIONAL THERAPIES**

- Acne hyperpigmented macules
  - Topical hydroquinones (1.5–10%)
  - Azelaic acid (20%) topically
  - Topical retinoids
  - Corticosteroids: low dose, suppresses adrenal androgens
  - Dapsone 5% gel (Aczone): topical, anti-inflammatory; use in patients >12 years.
  - Sunscreen for prevention

- Light-based treatments
  - Ultraviolet A/ultraviolet B (UVA/UVB), blue or blue/red light; pulse dye, KTP, or infrared laser
  - Photodynamic therapy for 30 to 60 minutes with 5-aminolevulinic acid × 3 sessions is effective for inflammatory lesions.
    - Greatest use when used as adjunct to medications or if can’t tolerate medications

**SURGERY/OTHER PROCEDURES**

- Comedo extraction after incising the layer of epithelium over closed comedo
- Inject large cystic lesions with 0.05 to 0.30 mL triamcinolone (Kenalog 2 to 5 mg/mL); use 30-gauge needle, inject through pore, slightly distend cyst.
- Acne scar treatment: retinoids, steroid injections, cryosurgery, electrodessication, micro/dermabrasion, chemical peels, laser resurfacing

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Evidence suggests tea tree oil, seaweed extract, Kampo formulations, Ayurvedic formulations, rose extract, basil extract, epigallocatechin gallate, barberry extract, gluconolactone solution, and tea extract may be useful (4).
- Limited data on use of dermocosmetics for acne Rx

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Use oral or topical antibiotics for 3 months; taper as inflammatory lesions
resolve.

DIET
Data suggests that high-glycemic index foods and skim milk may influence acne (4)[B].

PATIENT EDUCATION
- There may be a worsening of acne during first 2 weeks of treatment.
- Results are typically seen after a minimum of 4 weeks of treatment.

PROGNOSIS
Gradual improvement over time (usually within 8 to 12 weeks after beginning therapy)

COMPLICATIONS
- Acne conglobata: severe confluent inflammatory acne with systemic symptoms
- Facial scarring and psychological distress, including anxiety, depression, and suicidal ideation (3)
- Postinflammatory hyperpigmentation, keloids, and scars are more common in skin of color.

CODES

ICD10

- L70.0 Acne vulgaris
- L70.4 Infantile acne
- L70.1 Acne conglobata

CLINICAL PEARLS

- Full results for changes in therapy take 8 to 12 weeks.
- Decrease topical frequency to every day or to every other day for irritation.
- Use BP every time a topical or oral antibiotic is used.
ACUTE CORONARY SYNDROMES: NSTE-ACS (UNSTABLE ANGINA AND NSTEMI)

Aravdeep Jhand, MBBS • Harish C. Devineni, MD • Gene Pershwitz, MD

BASICS

DESCRIPTION

- Unstable angina (UA) and non–ST-segment elevation myocardial infarction (NSTEMI) are acute coronary syndromes without ST-segment elevation (NSTE-ACS).
- NSTEMI is defined by the rise and fall of cardiac biomarkers (preferably troponin) with at least one value above the 99th percentile upper reference limit and accompanied by one of the following: symptoms of ischemia, new ST-segment/T-wave changes, development of pathologic Q waves on ECG, or imaging evidence of loss of viable myocardium or new regional wall motion abnormality (1).
- UA is defined by the presence of clinical symptoms of cardiac ischemia (new-onset anginal chest pain, or change in typical anginal pattern, or development of angina at rest, or change in typical anginal equivalent), without myocardial necrosis as evidenced by normal cardiac biomarkers of injury (troponin). ECG changes, such as ST-segment depression or T-wave inversions, may be present (1).

EPIDEMIOLOGY

Incidence

- Estimated annual incidence of new and recurrent MI is 580,000 and 210,000 respectively (2).
- In United States, average age at first MI is 65.3 years for males and 71.8 years for females (2).
- The annual age-adjusted rates of first MI per 1,000 are 5.7 in black men, 3.3 in white men, 3.9 in black women, and 2.0 in white women (2).
**Prevalence**
An estimated 16.5 million Americans ≥20 years have coronary artery disease (CAD) with the overall prevalence of MI being 3.0% (3.8% for males and 2.3% for females) (2).

**MORTALITY**
- CAD is the leading cause of death in the adults in the United States with overall age-adjusted mortality of 98.8 per 100,000 (2).
- Death rate is higher in men as compared to women and in blacks as compared to whites (2).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- NSTE-ACS occurs primarily due to a sudden decrease in myocardial blood flow due to acute plaque rupture or plaque erosions leading to partially occluding thrombosis.
- Other mechanisms include:
  - Dynamic obstruction triggered by intense spasm of a coronary artery (Prinzmetal angina or coronary vasospasm induced by cocaine or methamphetamine)
  - Increased myocardial oxygen demand resulting in supply-demand mismatch, microcirculatory dysfunction without epicardial coronary obstruction
  - Less common causes include coronary arterial inflammation, dissection/rupture, thromboembolism.

**RISK FACTORS**
- Traditional/classic
  - Age (strongest risk factor), male gender, prior MI, hypertension, tobacco use, diabetes mellitus (DM), dyslipidemia and family history of premature CAD (premature CAD is defined as age of onset prior to 55 years in males and <65 years in females)
- Novel/emerging risk factors
  - Sedentary lifestyle, overweight/obesity (metabolic syndrome), inflammation (psoriasis, rheumatoid arthritis), psychosocial factors (anxiety/depression), chronic kidney disease, obstructive sleep apnea

**GENERAL PREVENTION**
- Smoking cessation, healthy diet, weight control, physical activity
Risk factor control: diabetes and blood pressure control, lipid-lowering therapy (statins), daily aspirin (in select patients)

COMMONLY ASSOCIATED CONDITIONS
- Vascular disease (cerebrovascular and peripheral vascular disease, aneurysms, erectile dysfunction)
- Other forms of heart disease (heart failure, valvular disease, high-output states)
- Disease related to underlying risk factors: COPD and thrombophilic disorders

DIAGNOSIS

HISTORY
- Chest heaviness/tightness lasting ≥10 minutes; occurs with or without exertion, may increase in frequency
- Pain or discomfort is typically retrosternal and can radiate to the neck, jaw, interscapular area, upper extremities, or epigastrium.
- Pain is typically described as a pressure, tightness, heaviness, squeezing, or fullness.
- Associated symptoms of palpitations, dyspnea, nausea, diaphoresis, light-headedness, syncope or dysphoria can occur.
- Patients especially elderly, diabetics, and women can present without chest pain with symptoms such as dyspnea, diaphoresis and extreme fatigue which represent “anginal equivalents.”
- Risk factors for CAD
- Use of cocaine or amphetamines
- Medication review

PHYSICAL EXAM
- General: abnormal vital signs including tachycardia or bradycardia, hypertension or hypotension, widened pulse pressure, tachypnea, fever, transverse ear crease, poor dental hygiene, stigmata of tobacco use
- Cardiovascular: dysrhythmia, jugular venous distention (JVD), new murmur, rub or gallop, diminished peripheral pulses, carotid bruits
- Respiratory: tachypnea, ↑ work of breathing, crackles
- Neurologic: fatigue, weakness, altered mental status
- Musculoskeletal: Sharp pain reproducible with movement or palpation is
unlikely to be cardiac.
- Skin: cool skin, pallor, diaphoresis, signs of dyslipidemia (xanthomas, xanthelasma)

DIFFERENTIAL DIAGNOSIS
- Cardiac: aortic dissection, myocarditis, pericarditis, pericardial effusion/tamponade, heart failure, hypertensive emergency, stress cardiomyopathy (Takotsubo), dysrhythmia, and mitral valve disease
- Pulmonary: pulmonary embolism, pneumothorax, pneumonia, pleuritis, bronchitis
- Panic disorder and anxiety disorders
- Musculoskeletal pain: costochondritis, rib fracture
- GI: gastroesophageal reflux disease (GERD), esophageal spasm, esophagitis, esophageal rupture or perforation, hiatal hernia, penetrating or perforating peptic ulcer, biliary or pancreatic pain

DIAGNOSTIC TESTS & INTERPRETATIONS

Initial Tests (lab, imaging)
- 12-lead ECG (3)[C]: applies to both UA and NSTEMI
  - New ST-segment depression ≥0.5 in two or more contiguous leads and/or T-wave inversions ≥1 mm in two or more contiguous leads with prominent R wave or R/S ratio >1
  - ST depression and/or tall R wave in V₁/V₂ with upright T waves may indicate transmural STEMI of posterior wall. ECG with posterior leads (V₇–V₉) should be performed.
  - If initial ECG is nondiagnostic but symptoms persist with suspicion for ACS, perform serial ECGs at 15- to 30-minute intervals.
- CBC, BMP, and serum biomarker (negative by definition in UA)
  - Troponin concentration rises 3 to 6 hours after onset of ischemic symptoms but can be delayed up to 8 to 12 hours (troponin T is not specific in patients with renal dysfunction).
  - Ultra-high sensitive troponins have a higher sensitivity than standard assays, but further validation is required.
  - With contemporary troponin assays, older cardiac markers of injury-like LDH, CK-MB, and myoglobin are less specific and have limited utility in the routine management of ACS (3)[A]. CK-MB has been shown to have better specificity than troponins in post-PCI MI.
  - Patients with negative biomarkers within 6 hours of the onset of symptoms
should have biomarkers remeasured 8 to 12 hours from onset of symptoms.

- CXR, CT with contrast to exclude other etiologies
- Transthoracic echocardiography is recommended to assess for regional wall motion abnormalities, systolic function, and to exclude alternate etiologies.

**Follow-Up Tests & Special Considerations**

- Fasting lipid profile, preferably within 24 hours
- Activated partial thromboplastin time (aPTT)
- Urine drug screen in selected patients
- Other lab tests: B-type natriuretic peptide or N-terminal pro–B-type natriuretic peptide; increases with MI and may not indicate heart failure

**Diagnostic Procedures/Other**

- For low to intermediate risk patients with resolution of symptoms and nondiagnostic ECG with negative biomarkers, consider noninvasive cardiac testing with standard exercise treadmill test (3)[A], stress echocardiography, or nuclear stress study (3)[B].
- Alternatively, coronary CTA can be performed as well to exclude NSTE-ACS (3)[A].

**GENERAL MEASURES**

- Risk stratify using TIMI or GRACE score to select use of early invasive approach (coronary angiography within 24 hours of admission) versus ischemia-guided therapy (3)[A]
  - Urgent invasive management for very high-risk patients, such as those with hemodynamic instability or cardiogenic shock, recurrent or ongoing chest pain refractory to medical therapy, life-threatening arrhythmias or cardiac arrest, mechanical complications, acute heart failure, and recurrent dynamic ST-T wave changes (3)[A]

- Bed/chair rest with continuous ECG monitoring, maintain O₂ saturation >90%, and tight BP control
- Avoid continuation of NSAIDs.
- Deep vein thrombosis prophylaxis
- Smoking cessation
- Correction of electrolyte abnormalities (K and Mg)
**MEDICATION**

**First Line**

- Antiplatelet therapy: Dual antiplatelet therapy is recommended for all patients with NSTE-ACS.

- Aspirin, nonenteric coated, initial dose of 162 to 325 mg chewed or crushed for all patients; decreases mortality and morbidity (3)[A]

- Maintenance dose of 81 to 325 mg/day indefinitely

- P2Y12 inhibitors:
  - Should be given at the time of diagnosis unless invasive approach is planned in a very high–bleeding-risk patient (3)[B]
  - Ticagrelor, loading dose 180 mg PO, followed by 90 mg PO twice daily; avoid in patients with second- and third-degree heart block (3)[B] OR
  - Prasugrel 60 mg PO, followed by 10 mg PO daily. Reserved for post-PCI patients treated with coronary stents; contraindicated in patients ≥75 years or those with history of CVA/TIA (3)[B] OR
  - Clopidogrel, loading dose 300 to 600 mg PO, followed by 75 mg PO daily. Use with caution in patients with thrombocytopenia and CKD.

- Patients unable to take aspirin should receive loading and maintenance dose of a P2Y12 inhibitor (3)[B].

- GP IIb/IIIa inhibitors: Add eptifibatide or tirofiban in select high-risk patients (persistent chest pain, large thrombus burden on angiography) after PCI (3)[B].

- Nitroglycerin (NTG) sublingual 0.4 mg every 5 minutes for total of 3 doses and then assess need for IV NTG. Avoid if hypotension or if used PDE (−) within the 24 to 48 hours.

- Morphine sulfate 1 to 5 mg IV in patients with continuous ischemic chest pain, with increments of 2 to 8 mg repeated at 5- to 30-minute intervals (3)[B]

- Oral β-blocker therapy should be initiated within 24 hours in patients without signs of heart failure, cardiogenic shock, or other contraindications. Recommended dose is metoprolol tartrate 25 to 50 mg every 6 to 12 hours or atenolol 25 to 50 mg twice daily. IV therapy may be considered in patients with severe ischemia (1,3)[A].

- In patients with concomitant ACS, stabilized heart failure, and reduced systolic function (LVEF <40%), the recommended β-blockers are metoprolol succinate, carvedilol, and bisoprolol (3)[C].

- Lipid-lowering therapy: Initiate or continue high-intensity statin therapy (preferred due to nonlipid benefit on vascular function) with atorvastatin 80 mg daily or rosuvastatin 20 to 40 mg daily. Ezetimibe, omega-3 fatty acids,
PCSK9 inhibitors, and/or fibrates can be considered in statin intolerant patients.

- ACE inhibitor is recommended in all patients with ACS particularly in the presence of diabetes, LV dysfunction or heart failure.
- Aldosterone antagonist (spironolactone or eplerenone) is recommended in NSTEMI for patients without significant renal dysfunction or hyperkalemia who are on a therapeutic dose of ACEi/ARB and β-blocker and have LVEF ≤40%, DM, or HF (3)[A].
- Antithrombotic therapy: Initiate anticoagulant: enoxaparin or unfractionated heparin (UFH), fondaparinux, or bivalirudin. Bivalirudin has been associated with a lower bleeding risk.

**Second Line**

- Nondihydropyridine calcium channel blocker (CCB) (verapamil or diltiazem) to reduce myocardial oxygen demand when β-blockers are contraindicated if normal EF (3)[C]. Use oral long-acting CCB only after β-blockers and nitrates have been fully used (3)[C]. Long acting CCBs are recommended in treatment of patients with coronary artery spasm (3)[C]. Avoid in patients with heart block (3)[B].

- Long-term nitrate therapy for recurrent angina/ischemia or heart failure
- Sublingual NTG at discharge
- Ranolazine indicated in treatment of chronic angina not responsive to other meds; 500 to 1,000 mg, twice a day (3)[A]
- Benzodiazepines in patients with cocaine/methamphetamine intoxication. Avoid β-blockers in cocaine or methamphetamine users.

**ISSUES FOR REFERRAL**

- Cardiology consultation is appropriate for NSTE-ACS.
- Patients will need close follow-up with a cardiologist.
- Referral to exercise-based cardiac rehabilitation program prior to hospital discharge (3)[B]

**SURGERY/OTHER PROCEDURES**

- Coronary reperfusion
  - PCI with stent placement
  - CABG surgery
- Intra-aortic balloon pump for patients with refractory symptoms/shock
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admit all patients with risk factors for cardiac disease (illustrated above) who present with chest pain and suspected NSTE-ACS and/or hemodynamic instability.
- Considerations in special populations
  - Older population (≥75 years)
    - Benefit of early invasive management in elderly ≥ young population (3)[A]
    - Pharmacotherapy should be individualized based on weight and renal function.
  - Pregnancy
    - Specific risk factors for ACS in pregnancy include advanced maternal age, gestational diabetes, and preeclampsia/eclampsia.
    - Spontaneous coronary artery dissection and thromboembolism should be considered in evaluation of pregnant women with ACS.
    - ACEi, ARBs, and statins are contraindicated.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- It is reasonable in patients with suspected ACS (low risk) who have normal serial ECGs and cardiac troponins to have a treadmill ECG (3)[A], stress myocardial perfusion imaging, or stress echocardiography before or within 72 hours after discharge (3)[B].
- Follow up 2 to 6 weeks (low risk) and 14 days (high risk).
- All patients with reduced EF need reevaluation for ICD placement for primary prevention >40 days to 3 months (postrevascularization) after discharge.

DIET
Diet relationship to CAD is complex; low-sodium and low-saturated-fat diets often recommended

PATIENT EDUCATION
- Education on new medications, diet, exercise, smoking cessation, and lifestyle modification
Safe to resume exercise, sexual activity within 2 weeks in asymptomatic patients after outpatient reevaluation.
Recommend pneumococcal and influenza vaccination.

PROGNOSIS
UA/NSTEMI patients have lower in-hospital mortality than those with STEMI but a similar or worse long-term outcome.

COMPLICATIONS
Cardiogenic shock, heart failure, left ventricular free wall rupture, interventricular septal rupture, mitral regurgitation, ventricular aneurysm, dysrhythmia, acute pulmonary embolism, acute thromboembolic stroke, pericarditis/Dressler syndrome, depression (increases mortality risk)

REFERENCES

ADDITIONAL READING
CODES

ICD10
- I24.9 Acute ischemic heart disease, unspecified
- I20.0 Unstable angina
- I21.4 Non-ST elevation (NSTEMI) myocardial infarction

CLINICAL PEARLS
- Discontinue NSAIDs, nonselective or selective cyclooxygenase (COX)-2 agents, except for ASA, due to increased risks of mortality, reinfarction, hypertension, heart failure, and myocardial rupture.
- Discontinue clopidogrel or prasugrel or ticagrelor 5 to 7 days before elective CABG.
- Do not use nitrate products in patients who recently used a phosphodiesterase-5 inhibitor (24 hours of sildenafil or vardenafil, or 48 hours of tadalafil).
- Duration of antithrombotic therapy after NSTEMI depends on type of stent received and medications administered.
- Avoid $\beta$-blockers in cocaine or methamphetamine user.
ACUTE CORONARY SYNDROMES: STEMI

Hambik Tankazyan, DO • Yutthapong Temtanakitpaisan, MD • Daniel Z. Fisher, MD

BASICS

DESCRIPTION
Acute myocardial infarction (AMI) is the rapid development of myocardial necrosis resulting from a sustained and complete absence of blood flow to a portion of the myocardium. ST-segment elevation myocardial infarction (STEMI) occurs when coronary blood flow ceases following complete thrombotic occlusion of a large coronary artery (usually) affected by atherosclerosis, causing transmural ischemia. This is accompanied by release of serum cardiac biomarkers and ST-segment elevation on an ECG.

EPIDEMIOLOGY

Incidence
In 2009, ~683,000 patients were discharged from U.S. hospitals diagnosed with acute coronary syndrome (ACS). STEMI comprises about 25–40% of MI presentations.

Prevalence

- Leading cause of morbidity and mortality in the United States
- ~7.5 million people in the United States are affected by MI.
- Prevalence increases with age and is higher in men (5.5%) than in women (2.9%)

ETIOLOGY AND PATHOPHYSIOLOGY

- Atherosclerotic coronary artery disease (CAD)
  - Atherosclerotic lesions can be fibrotic, calcified, or lipid laden. Thin-capped atheroma are more likely to rupture and result in thrombotic occlusion.
- Nonatherosclerotic
– Emboli: vegetation, thrombi from left ventricle or atrium
– Mechanical obstruction: chest trauma, dissection of aorta or coronary arteries
– Increased vasomotor tone, variant angina
– Arteritis, others: hematologic (disseminated intravascular coagulation [DIC]), aortic stenosis, cocaine, IV drug use, severe burns, prolonged hypotension

**RISK FACTORS**
Advancing age, hypertension, tobacco use, diabetes mellitus, dyslipidemia, family history of premature onset of CAD, sedentary lifestyle

**GENERAL PREVENTION**
Smoking cessation, healthy diet, weight control, regular physical activity, control of hypertension, hyperlipidemia, and diabetes

**COMMONLY ASSOCIATED CONDITIONS**
Abdominal aortic aneurysm, extracranial cerebrovascular (CV) disease, atherosclerotic peripheral vascular disease

**DIAGNOSIS**

**HISTORY**
- Classically, sudden onset of chest heaviness/tightness, with or without exertion, lasting minutes to hours
- Pain/discomfort radiating to neck, jaw, interscapular area, upper extremities, and epigastrium
- Previous history of myocardial ischemia (stable or unstable angina, MI, coronary bypass surgery, or percutaneous coronary intervention [PCI])
- Assess risk factors for CAD, history of bleeding, noncardiac surgery, family history of premature CAD.
- Medications: Ask if recent use of phosphodiesterase type 5 inhibitors (if recent use, avoid concomitant nitrates).
- Alcohol and drug abuse (especially cocaine)

**PHYSICAL EXAM**
- General: restless, agitated, hypothermia, fever
Neurologic: dizziness, syncope, fatigue, asthenia, disorientation (especially in the elderly)
CV: dysrhythmia, hypotension, widened pulse pressure, S₃ and S₄, jugular venous distention (JVD)
Respiratory: dyspnea, tachypnea, crackles
GI: abdominal pain, nausea, vomiting
Musculoskeletal: pain in neck, back, shoulder, or upper limbs
Skin: cool skin, pallor, diaphoresis

**Geriatric Considerations**
Elderly patients may have an atypical presentation, including silent or unrecognized MI, often with complaints of syncope, weakness, shortness of breath, unexplained nausea, epigastric pain, altered mental status, delirium. Patients with diabetes mellitus may have fewer and less dramatic chest symptoms.

**DIFFERENTIAL DIAGNOSIS**
Unstable angina, aortic dissection, pulmonary embolism (PE), perforating ulcer, pericarditis, dysrhythmias, gastroesophageal reflux disease (GERD) and spasm, biliary/pancreatic pain, hyperventilation syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- 12-lead ECG: ST-segment elevation in a regional pattern ≥1 mm ST elevation (at least two contiguous leads), with or without abnormal Q waves. ST depression ± tall R wave in V₁/V₂ may be STEMI of posterior wall. Absence of Q waves represents partial or transient occlusion or early infarction. New ST- or T-wave changes indicative of myocardial ischemia or injury. Consider right-sided and posterior chest leads if inferior MI pattern (examine V₃R, V₄R, V₇–V₉).
- ECG with continuous monitoring
  - 2D and M-mode echocardiographies are useful in evaluating regional wall motion in MI and left ventricular function.
  - Portable echo can clarify diagnosis of STEMI if concomitant LBBB.
  - Useful in assessing mechanical complications and mural thrombus
- Once diagnosis suspected, coronary angiography is preferred emergently, with PCI.
Follow-Up Tests & Special Considerations

- Serum biomarkers
  - Troponin I and T (cTnI, cTnT) rise 3 to 6 hours after onset of ischemic symptoms.
  - Elevations in cTnI persist for 7 to 10 days, whereas those in cTnT persist for 10 to 14 days after MI.
  - Myoglobin fraction of creatine kinase-MB (CK-MB): rises 3 to 4 hours after onset of myocardial injury; peaks at 12 to 24 hours and remains elevated for 2 to 3 days; CK-MB adds little diagnostic value in assessment of possible ACS to troponin testing.
  - Myoglobin: early marker for myocardial necrosis; rises 2 hours after onset of myocardial necrosis, reaches peak at 1 to 4 hours and remains elevated for 24 hours; myoglobin adds little diagnostic value in assessment of possible ACS to troponin testing.

- Fasting lipid profile, CBC with platelets, electrolytes, magnesium, BUN, serum creatinine, and glucose; hemoglobin A1C; international normalized ratio (INR) if anticoagulation contemplated; brain natriuretic peptide (BNP) is elevated in acute MI; may or may not indicate heart failure

Pregnancy Considerations

Pregnant patients presenting with STEMI will need discussion of risks and benefits of invasive coronary angiography with radiation exposure to fetus. Management should otherwise be same as in nonpregnant patients, with emergent coronary angiography and PCI.

Diagnostic Procedures/Other

High-quality portable chest x-ray; transthoracic and/or transesophageal echocardiography, contrast chest CT scan may occasionally be of value acutely in equivocal presentations to evaluate for alternative diagnoses (aortic dissection, PE, ventricular aneurysm). Coronary angiography is definitive test.

ALERT

Patients with chronic kidney disease need special attention to amount of contrast media used. Reduced volume of contrast and use of low or isosmolar contrast media may lower risk of progression of renal impairment.

Test Interpretation

Thrombotic occlusion of coronary artery seen on coronary angiography
TREATMENT

GENERAL MEASURES

- Following emergent revascularization, admit to telemetry/coronary care unit (CCU) with continuous ECG monitoring and bed rest. Anxiolytics, if needed; stool softeners
- Antiarrhythmics, as needed, for unstable dysrhythmia; deep vein thrombosis (DVT) prophylaxis
- Continuation of aspirin 81 mg/day and clopidogrel 75 mg/day or prasugrel 10 mg/day or ticagrelor 90 mg twice daily, β-blocker (BB), ACE inhibitors (or ARB if ACE-intolerant), lipid-lowering therapy, tight BP control, progressively increased physical activity, smoking cessation
- Assess for depression and treat with an SSRI or psychotherapy if present, as depression is present in 20% of patients post-MI and is a potent predictor for poor prognosis. Although it is unclear yet if treatment improves mortality, it does improve quality of life.

MEDICATION

Medication recommendations based on 2013 ACC/AHA focused guideline updates and level recommendations (1)[A,B] and 2017 ESC STEMI guidelines (2)[A,B]

First Line

(While awaiting revascularization)

- Supplemental oxygen 2 to 4 L/min for patients with oxygen saturation <90% or respiratory distress
- Nitroglycerin (NTG) sublingual 0.4 mg q5min for total of 3 doses, followed by nitroglycerin IV if ongoing pain and/or hypertension and/or management of pulmonary congestion if no contraindications exist (systolic <90 mm Hg or >30 mm Hg below baseline, right ventricle [RV] infarct, use of sildenafil or vardenafil within 24 hours or within 48 hours of tadalafil)
- Morphine sulfate 4 to 8 mg IV with 2 to 8 mg IV repeated at 5- to 15-minute intervals to relieve pain, anxiety, or pulmonary congestion
- Antiplatelet agents
  - Aspirin (ASA), non–enteric-coated, initial dose 162 to 325 mg chewed (1) [A]
  - A loading dose of a P2Y12 inhibitor is recommended for patients with
STEMI for whom PCI is planned. Prasugrel or ticagrelor is preferred.

- Prasugrel 60 mg should be given as soon as possible for primary PCI. Prasugrel is contraindicated in patients with previous stroke/transient ischemic attack. Do not recommend in patients aged >75 years or lower body weight (<60 kg).
- Ticagrelor 180 mg loading dose. Ticagrelor may cause transient dyspnea.
- Clopidogrel 600 mg should be given if neither prasugrel or ticagrelor is available.
- Cangrelor may be considered in patients not pretreated with oral P2Y12 receptor inhibitors at the time of PCI or in those who are unable to take oral agents.
- Duration of dual antiplatelet therapy (DAPT) is recommended 12 months after PCI. In patients who are at high risk of severe bleeding complications, a P2Y12 inhibitor may be discontinued after 6 months; anticoagulation therapy

- Unfractionated heparin (UFH) 50- to 70-U/kg IV bolus
- Enoxaparin 0.5-mg/kg IV bolus
- Bivalirudin 0.75-mg/kg IV bolus and then 1.75-mg/kg/h infusion for up to 4 hours after procedure
- PCI versus fibrinolysis: Goal is to keep total ischemic time within 120 minutes. Door to needle time should be within 30 minutes or door to balloon time within 90 minutes.
- Coronary reperfusion therapy
  - Primary PCI (balloon angioplasty, coronary stents)
    - Symptom onset of ≤12 hours
    - Symptom onset of ≤12 hours and contraindication to fibrinolytic therapy irrespective of time delay
    - Cardiogenic shock or acute severe HF irrespective of time delay from onset of MI
    - Evidence of ongoing ischemia 12 to 24 hours after symptom onset
  - Radial access is recommended over femoral access.
- Procedural considerations
  - Routine aspiration thrombectomy no longer recommended prior to PCI as usefulness and safety not fully established (3)[C]
  - PCI of infarct-related artery (IRA) is indicated.
  - PCI of a noninfarct artery may be considered in selected patients with STEMI and multivessel disease who are hemodynamically stable, either at the time of primary PCI or as a planned staged procedure.
- Fibrinolysis
If presenting at a hospital without PCI capability and cannot be transferred to a PCI-capable facility to undergo PCI within 120 minutes of first medical contact

If no contraindications, administer within 12 to 24 hours of onset of symptoms if there is evidence of ongoing ischemia.

- **Alteplase (tPA):** 15-mg IV bolus, followed by 0.75 mg/kg (up to 50 mg) IV over 30 minutes and then 0.5 mg/kg (up to 35 mg) over 60 minutes; maximum 100 mg over 90 minutes
- **Reteplase (rPA):** 10 units IV bolus; give second bolus 30 minutes apart.
- **Tenecteplase (TNK-tPA):** 30- to 50-mg (based on weight) IV bolus. Recommend to reduce to half dose in patients ≥75 years of age.

- **Adjunctive antiplatelet therapy with fibrinolysis**
  - **Aspirin (162- to 325-mg loading dose and then 81 mg daily) indefinitely**
  - **Clopidogrel (300-mg loading dose for patients <75 years of age, 75-mg dose for patients >75 years of age). Clopidogrel 75 mg daily should be continued for at least 14 days and up to 1 year.**

- **Adjunctive anticoagulation therapy with fibrinolysis**
  - **Use anticoagulants (UFH, enoxaparin, or fondaparinux) as ancillary therapy to reperfusion therapy for minimum 48 hours and preferably duration of admission (up to 8 days) or until revascularization, if performed.**

- **Glycoprotein IIb/IIIa receptor antagonists at time of primary PCI in selected patients if there is no reflow or thrombotic complications (abciximab, eptifibatide, or tirofiban)**

- **Intravenous BB should be considered at the time of presentation, if no contraindications exist (signs of congestive heart failure [CHF], low output state) and SBP >120 mm Hg.**

- **ACE inhibitors should be initiated orally within 24 hours of STEMI in patients with anterior infarction, HF, diabetes, or ejection fraction (EF) ≤0.40 unless contraindicated.**

- **High-intensity statin therapy should be started as early as possible.**

- **Mineralocorticoid receptor antagonist is recommended in patients with EF <40% and heart failure or diabetes, who are already receiving an ACE inhibitor and a BB, if there is no renal failure or hyperkalemia.**

**Second Line**

Long-acting nondihydropyridine calcium channel blocker (CCB) when BB is
ineffective or contraindicated if EF is normal; do not use immediate-release nifedipine.

**SURGERY/OTHER PROCEDURES**
Urgent coronary artery bypass graft (CABG) surgery is indicated in patients with STEMI and coronary anatomy not amenable to PCI who have ongoing or recurrent ischemia, cardiogenic shock, severe HF, or other high-risk features.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- All patients with STEMI should be admitted to a CCU or intensive cardiac care unit for evaluation and treatment.
- Transfer high-risk patients who receive fibrinolytic therapy as primary reperfusion therapy at a non–PCI-capable facility to a PCI-capable facility as soon as possible.
- Right ventricular infarction may need fluid resuscitation for hypotension.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Emphasize medication adherence. Identify high-risk patients for implantable cardioverter defibrillator (ICD) placement (especially those with EF <30%). Consider exercise-based cardiac rehabilitation program and encourage smoking cessation.

**DIET**
Low-fat diet: reduced intake of saturated fats (to <7% of total calories) (but dairy fats are not likely associated with CAD), *trans* fatty acids (to <1% of total calories). Impact of low-cholesterol diet remains uncertain.

**PATIENT EDUCATION**
May resume sexual activity 1 or more weeks after uncomplicated MI or 6 to 8 weeks after CABG; smoking cessation and low-fat diet.

**COMPLICATIONS**
Heart failure, myocardial rupture/left ventricular aneurysm, pericarditis,
dysrhythmias, acute mitral regurgitation, and depression (common)

REFERENCES

CODES

ICD10

- I24.9 Acute ischemic heart disease, unspecified
- I21.3 ST elevation (STEMI) myocardial infarction of unspecified site

CLINICAL PEARLS

For elective surgeries in patients on DAPT, it is recommended to wait until completion of mandatory regime and continue ASA perioperatively.
ACUTE KIDNEY INJURY

Jason Kurland, MD

BASICS

DESCRIPTION

Abrupt loss of kidney function, defined as a rise in serum creatinine (SCr) of ≥0.3 mg/dL within 48 hours; a 50% increase in SCr within 7 days, or urine output of <0.5 mL/kg/hr for >6 hours, resulting in retention of nitrogenous waste as well as electrolyte, acid–base, and volume homeostasis abnormalities (1)

EPIDEMIOLOGY

Incidence

5% of hospital and 30% of ICU admissions have a diagnosis of acute kidney injury (AKI). 25% of patients develop AKI while in the hospital, and 50% of those cases are iatrogenic. Development of AKI as an inpatient associated with >4-fold increased risk of death (2).

ETIOLOGY AND PATHOPHYSIOLOGY

Three categories: prerenal, intrarenal, and postrenal based on BUN/creatinine ratio

- Prerenal (BUN/creatinine ratio ≥20:1; ~55%)
  - Hypotension, volume depletion (GI losses, excessive sweating, diuretics, hemorrhage); renal artery stenosis/embolism; burns; heart failure; liver failure
  - Decreased renal perfusion (often due to hypovolemia) leads to a decrease in glomerular filtration rate (GFR) which (if prolonged or severe) can progress to ischemic acute tubular injury.

- Intrarenal (BUN/creatinine <10:1; ~40%)
  - Acute tubular injury (ATI) (from prolonged prerenal azotemia, radiographic contrast material, aminoglycosides, NSAIDs, or other nephrotoxic substances); glomerulonephritis (GN); acute interstitial nephritis (drug-induced); arteriolar insults; vasculitis; accelerated hypertension; cholesterol embolization (following an intra-arterial procedure); intrarenal deposition/sludging (uric acid nephropathy and multiple myeloma [Bence-
Postrenal (BUN/creatinine 10 to 20:1; ~5%)
- Extrinsic compression (e.g., benign prostatic hypertrophy [BPH],
carcinoma, pregnancy); intrinsic obstruction (e.g., calculus, tumor, clot,
structure, sloughed papillae); decreased function (e.g., neurogenic bladder)
leading to obstruction of the urinary collection system

**Genetics**
No known genetic pattern

**RISK FACTORS**
- Chronic kidney disease (CKD)
- Comorbid conditions (e.g., diabetes, hypertension, heart failure, liver failure)
- Advanced age
- Radiocontrast material exposure (intravascular)
- Medications that impair autoregulation of GFR (NSAIDs, ACE-I/ARB,
cyclosporine/tacrolimus)
- Nephrotoxic medications (e.g., aminoglycoside antibiotics, platinum-based
chemotherapy)
- Hypovolemia (e.g., diuretics, hemorrhage, GI losses)
- Sepsis, surgery, rhabdomyolysis
- Solitary kidney (risk in nephrolithiasis)
- BPH; malignancy (e.g., multiple myeloma)

**GENERAL PREVENTION**
See “General Measures.”

**COMMONLY ASSOCIATED CONDITIONS**
Hyperkalemia, hyperphosphatemia, hypercalcemia, hyperuricemia,
hydronephrosis, BPH, nephrolithiasis, congestive heart failure (CHF), uremic
pericarditis, cirrhosis, CKD, malignant hypertension, vasculitis, drug reactions,
sepsis, severe trauma, burns, transfusion reactions, recent chemotherapy,
rhabdomyolysis, internal bleeding, dehydration

**DIAGNOSIS**

**HISTORY**
● General: PO intake, urine output, body weight, medication use
● Prerenal: thirst, orthostatic symptoms
● Intrarenal: nephrotoxic medications, radiocontrast material, other toxins
  – Fever, arthralgias, and pruritic rash suggest allergic interstitial nephritis (AIN).
  – Edema, hypertension, and oliguria with nephritic urine sediment (RBCs and RBC casts) point to glomerulonephritis or vasculitis.
  – Livedo reticularis, SC nodules, and ischemic digits despite good pulses suggest athroembolization.
  – Flank pain suggests occlusion of the renal artery or vein.
● Postrenal: Colicky flank pain that radiates to the groin suggests a ureteric obstruction such as a stone; nocturia, frequency, and hesitancy suggest prostatic disease; suprapubic and flank pain are usually secondary to distension of the bladder and collecting system; ask about anticholinergic drugs that could lead to neurogenic bladder.
● Uremic sx: lethargy, nausea/vomiting, anorexia, pruritus, restless legs, sleep disturbance, hiccups

**PHYSICAL EXAM**

● Uremic signs: altered sensorium, seizures, asterixis, myoclonus, pericardial friction rub, peripheral neuropathies
● Prerenal signs: tachycardia, decreased jugular venous pressure (JVP), orthostatic hypotension, dry mucous membranes, decreased skin turgor; comorbid stigmata of sepsis, liver disease or heart failure
● Intrinsic renal signs: pruritic rash, livedo reticularis, SC nodules, ischemic digits despite good pulses
● Postrenal signs: suprapubic distension, flank pain, enlarged prostate

**DIFFERENTIAL DIAGNOSIS**

See “Etiology.”

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

● Compare to baseline renal function (creatinine/GFR) if at all possible.
● Urinalysis: dipstick for blood and protein; microscopy for cells, casts, and crystals
● Casts: transparent hyaline casts—prerenal etiology; pigmented granular/muddy brown casts—ATN; WBC casts—acute interstitial nephritis;
RBC casts—GN
• Urine eosinophils: ≥1% eosinophils suggests acute interstitial nephritis (poor sensitivity)
• Urine electrolytes in an oliguric state
  – $\text{FE}_{\text{Na}} = \left(\frac{U_{\text{Na}} \times P_{\text{Cr}}}{P_{\text{Na}} \times U_{\text{Cr}}}\right) \times 100$
  – $\text{FE}_{\text{Na}} <1\%$, likely prerenal; $>2\%$, likely intrarenal
  – If patient on diuretics, use $\text{FE}_{\text{urea}}$ instead of $\text{FE}_{\text{Na}}$: $\text{FE}_{\text{urea}} = \left(\frac{U_{\text{urea}} \times P_{\text{Cr}}}{P_{\text{BUN}} \times U_{\text{Cr}}}\right) \times 100$; $\text{FE}_{\text{urea}} <35\%$ suggests prerenal etiology (3)[B].

• CBC, BUN, SCr, electrolytes (including Ca/Mg/P); consider arterial blood gases (ABGs).
• Common lab abnormalities in AKI
  – Increased: $K^+$, phosphate, Mg, uric acid
  – Decreased: Hct, Na, Ca
• Calculate creatinine clearance (CrCl) to ensure appropriate medications dosing.
• Radiologic:
  – Renal ultrasound (US): first-line; excludes postrenal causes; identifies kidney size, hydronephrosis, and nephrolithiasis
  – Doppler-flow renal US: evaluates for renal artery stenosis/thrombosis; operator-dependent
  – Abdominal x-ray (kidney, ureter, bladder [KUB]): identifies calcification, renal calculi, kidney size
• Novel biomarkers such as urinary IL-18, neutrophil gelatinase-associated lipocalin (NGAL), kidney injury molecule-1 (KIM-1), plasma cystatin C, TIMP-2, and IGFBP7 under investigation (4)[C]

Follow-Up Tests & Special Considerations
• Consider CK (rhabdomyolysis) and immunologic testing (if suspect GN/vasculitis).
• Advanced imaging if initial tests unrevealing
  – Prerenal: US as effective as CT for obstruction
  – Noncontrast helical CT: most sensitive test for nephrolithiasis
  – Radionuclide renal scan: evaluates renal perfusion, function (GFR), and presence of obstructive uropathy and extravasation
  – MRI: Acute tubulointerstitial nephritis with increased T2-weighted signal. Gadolinium contrast is contraindicated if GFR $<30\ mL/min$ due to risk of nephrogenic systemic fibrosis.
Diagnostic Procedures/Other
Cystoscopy with retrograde pyelogram evaluates for bladder tumor, hydronephrosis, obstruction, and upper tract abnormalities without risk of contrast nephropathy.

Test Interpretation
Kidney biopsy: last resort if patient does not respond to therapy or if diagnosis remains unclear; most useful to evaluate intrinsic AKI of unclear cause (AIN, GN, vasculitis, or renal transplant rejection)

TREATMENT
GENERAL MEASURES
Identify and correct prerenal and postrenal causes.

- Stop nephrotoxic drugs and renally dose others.
- Strict intake/output and daily weight recordings
- Optimize cardiac output to maintain renal perfusion.
- Optimize nutrition and treat any infections.
- Indications for hemodialysis: volume overload, severe or progressive hyperkalemia, or severe metabolic acidosis refractory to medical management; advanced uremic complications (pericarditis, encephalopathy, bleeding diathesis)

MEDICATION
First Line

- Find and treat the underlying cause.
- Prevent fluid overload, correct electrolyte imbalances—hyperkalemia, hyperphosphatemia, and hypermagnesemia.
  - If patient is oliguric and not volume overloaded, a monitored fluid challenge may help.
- Furosemide is ineffective in preventing and treating AKI but can judiciously be used to manage volume overload and/or hyperkalemia. Furosemide stress test may predict the likelihood of progressive AKI, need for dialysis, and mortality (5)[B].
- Dopamine, natriuretic peptides, insulin-like growth factor, and thyroxine have no benefit in the treatment of AKI.
Fenoldopam, a dopamine agonist, has been equivocal in decreasing risk of RRT and mortality in setting of AKI; not currently recommended for use, large RCT in progress (1)[C]

Hyperkalemia with ECG changes: Give IV calcium gluconate, isotonic sodium bicarbonate (only if acidemic, and avoid use of hypertonic “amps” of NaHCO₃), glucose with insulin, and/or high-dose nebulized albuterol (to drive K⁺ into cells); Kayexalate and/or furosemide (to increase K⁺ excretion); hemodialysis if severe/refractory

Fluid restriction may be required for oliguric patients to prevent worsening hyponatremia.

Metabolic acidosis (particularly pH <7.2): Sodium bicarbonate can be given; be aware of volume overload, hypocalcemia, hypokalemia.

Effective strategies for AKI prevention: IV isotonic hydration, once-daily dosing of aminoglycosides; use of lipid formulations of amphotericin B, use of iso-osmolar nonionic contrast media

Risk of contrast-induced AKI reduced by avoidance of hypovolemia: isotonic saline 1 mL/kg/hr morning of procedure and continued until next morning, or isotonic NaHCO₃ 3 mL/kg/hr × 1 hour before and 1 mL/kg/hr × 6 hours after contrast administration; N-acetylcysteine not of benefit

**Second Line**

- Tamsulosin or other selective α-blockers for bladder outlet obstruction secondary to BPH
- Dihydropyridine calcium channel blockers may have a protective effect in posttransplant ATN.

**ISSUES FOR REFERRAL**

- Consider nephrology consultation.
- Urology consults for obstructive nephropathy

**SURGERY/OTHER PROCEDURES**

- Relief of obstruction with retrograde ureteral catheters/percutaneous nephrostomy
- Hemodialysis catheter placement

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Many herbal and dietary supplements can be nephrotoxic (aristolochic acid,
ochratoxin A, Djenkol bean, impila, orellanine, cat’s claw).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Most patients with AKI require admission.
- Evaluate for and treat potentially life-threatening complications: hyperkalemia, metabolic acidosis, volume overload, advanced uremia.
- If hypovolemic, give isotonic IV fluids.
- Monitor strict I/Os, daily weights.
- Consider bladder catheter to quantify urine output.
- Stabilize renal function and ensure a concrete treatment plan prior to discharge.
- Dialysis if necessary

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Nephrology follow-up if persistent renal impairment and/or proteinuria

DIET
- Total caloric intake of 20 to 30 kcal/kg/day to avoid catabolism (1)
- Restrict Na⁺ to 2 g/day (unless hypovolemic).
- Consider K⁺ restriction (2 to 3 g/day) if hyperkalemic.
- If hyperphosphatemic, consider use of phosphate binders, although no evidence of benefit in AKI.
- Avoid magnesium- and aluminum-containing compounds.

PATIENT EDUCATION
Keep well-hydrated. Avoid nephrotoxic drugs, such as NSAIDs and aminoglycosides.

PROGNOSIS
- Depending on the cause, comorbid conditions, and age of patient, mortality ranges from 5% to 80%.
- In cases of prerenal and postrenal failure, short duration of AKI correlates with good rates of recovery. Intrarenal etiologies take longer to recover.
• Even with complete recovery from AKI, affected patients are at higher subsequent risk of developing CKD and ESRD.

COMPLICATIONS
Death, sepsis, infection, seizures, paralysis, peripheral edema, CHF, arrhythmias, uremic pericarditis, bleeding, hypotension, anemia, hyperkalemia, uremia

• Singh NP, Prakash A. Nephrotoxic potential of herbal drugs. JIMSA. 2011;24(2):79–81.
- Glomerulonephritis, Acute; Hepatorenal Syndrome; Hyperkalemia; Prostatic Hyperplasia, Benign (BPH); Chronic Kidney Disease; Reye Syndrome; Rhabdomyolysis; Sepsis
- Algorithm: Anuria or Oliguria

**CODES**

**ICD10**
- N17.9 Acute kidney failure, unspecified
- N17.0 Acute kidney failure with tubular necrosis
- N00.9 Acute nephritic syndrome with unsp morphologic changes

**CLINICAL PEARLS**
- Three categories of AKI:
  - Prerenal: decreased renal perfusion (often from hypovolemia) leading to a decrease in GFR; reversible if perfusion is restored
  - Intrarenal: intrinsic kidney damage; ATN most common due to ischemic/nephrotoxic injury
  - Postrenal: extrinsic/intrinsic obstruction of the urinary collection system
- Indications for emergent hemodialysis: severe hyperkalemia, metabolic acidosis, or volume overload refractory to conservative therapy; uremic pericarditis, encephalopathy, or neuropathy; and selected alcohol and drug intoxications
- Management of ATN is supportive; no specific treatments are proven to effectively speed recovery.
ADENOMYOSIS

Bradley M. Turner, MD, MPH, MHA

BASICS

DESCRIPTION

- Benign invasion of the endometrium into the myometrium, producing a diffusely enlarged uterus
- Microscopically, there are ectopic, nonneoplastic endometrial glands and stroma surrounded by hypertrophic and hyperplastic myometrium.
- Can be either diffuse or focal, depending on the extent of myometrial invasion
- In some cases, it may manifest as a circumscribed myometrial mass referred to as an adenomyoma.
- Most commonly affects the posterior wall of the uterus
- Typically associated with the uterus; however, the term “adenomyosis” can also be applied to benign hyperplastic changes in the bile ducts, gallbladder, and ampulla of Vater.

EPIDEMIOLOGY

- Most frequently presents in the 4th and 5th decades
- Wide variation among racial and ethnic groups and among different geographic regions

Incidence

- Variability in the criteria used for diagnosis makes an accurate determination of true incidence difficult.
- Depending on the criteria used for diagnosis, the incidence has been estimated as between 5% and 50%.
- The incidence has been reported to be higher (35–50%) in women presenting with pelvic pain and infertility.

Prevalence

- As with incidence, an accurate determination of prevalence is difficult due to the variability in the criteria used for diagnosis.
- Depending on the criteria used for diagnosis, the prevalence has been reported to vary from 5% to 70%, with the mean frequency of adenomyosis at
hysterectomy given as approximately 20–30%.

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Adenomyosis has been described as an abnormal ingrowth and invagination of the basal endometrium into the inner layer of the myometrium (junctional zone [JZ]).
- The exact mechanism regarding how this occurs and is maintained is not clear and likely to be multifactorial.
- Sex steroid hormone aberrations, inflammation, altered cell proliferation, and neuroangiogenesis are likely key pathogenic mechanisms of pain, bleeding, and infertility in adenomyosis.
- In women with adenomyosis, the JZ may represent a region of morphologic dysfunction and structural weakness, with varying susceptibility to invagination of endometrial stromal cells.
- Increased uterine pressure associated with pregnancy, leiomyomas, or other pathology may modulate the JZ environment, making it more susceptible to invagination of endometrial stromal cells.
- Other theories for pathogenesis include the following:
  - *Metaplasia theory*: metaplasia of myometrial smooth muscle cells
  - *Müllerian remnants theory*: de novo development from müllerian rests in the myometrium
  - *Tissue remodeling theory*: ectopic endometrial tissue arising secondary to tissue remodeling associated with uterine trauma either physiologic (e.g., during menstruation, childbirth, or spontaneous abortion) or iatrogenic (e.g., during uterine surgery)
  - *Multipotential perivascular theory*: Multipotential perivascular stem cells may be associated with increased angiogenesis and pathophysiologic vascular remodeling, leading to vascular smooth muscle hypertrophy, proliferation, or migration.
  - *Epithelial–mesenchymal transition theory*: Increased estrogen concentrations may enhance endometrial tissue growth, angiogenesis, and invagination into the JZ.
  - *Hyperproliferation of uterine smooth muscle cell theory*: Activation of the MAPK/ERK pathway has been associated with hyperproliferative uterine smooth cells in women with adenomyosis.
  - *Mast cell activation theory*: Nerve growth factor, a mast cell–derived mediator, can be used as an indicator for the severity of adenomyosis. This and other mast cell–derived mediators may contribute to the differentiation and development of the myometrium and maintenance of adenomyosis.
Genetics
- DNA microarray and proteomics analysis have identified specific genes that are differentially expressed in adenomyosis and matched eutopic endometrium.
- Data suggest that genetic and epigenetic abnormalities contribute to the pathogenesis of adenomyosis.

RISK FACTORS
- Age >35 years, however, the disease may cause dysmenorrhea and chronic pelvic pain in women of younger age, including adolescents. Reports suggest that early-stage adenomyosis might present a different clinical phenotype compared to late-stage disease.
- Multiparity
- Tamoxifen treatment
- Other possible risk factors:
  - Previous uterine surgery (Studies have been inconsistent.)
  - Smoking (Studies have been inconsistent.)

COMMONLY ASSOCIATED CONDITIONS
- Leiomyomas (uterine fibroids)
- Endometriosis
- Endometrial polyps
- Urinary tract dysfunction

DIAGNOSIS
Pelvic pain, dysmenorrhea, and an enlarged uterus are the usual cues that prompt imaging by ultrasound or MRI; endometrial or uterine biopsies may be indicated in some cases.

HISTORY
- Presenting symptoms are nonspecific and the patient is often asymptomatic.
- Symptoms often include (1–3) the following:
  – Menorrhagia
  – Dysmenorrhea
  – Chronic pelvic pain
  – Abnormal uterine bleeding
Urinary tract symptoms (e.g., stress urinary incontinence, urgency, daytime frequency, and urge urinary incontinence) have been associated with an increased incidence of adenomyosis; however, data are limited (4).

**PHYSICAL EXAM**
Uterus may be enlarged and tender.

**DIFFERENTIAL DIAGNOSIS**
- Pregnancy
- Benign uterine tumors
- Malignant uterine tumors
- Metastatic disease

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Transvaginal ultrasound (TVUS) is the imaging method of choice for initial evaluation of suspected adenomyosis (2,3)[A].
- TVUS can be either two- or three-dimensional (2)[A].
- Three-dimensional TVUS can provide JZ thickness.
- TVUS has a sensitivity of 72–82.5% and a specificity of 81–84.6% (3)[A].
- TVUS is less sensitive than MRI in differentiating adenomyosis from leiomyoma (2)[A].
- TVUS with power color flow Doppler can be used to differentiate adenomyosis from leiomyoma (2,3)[B] depending on the operator (2)[C].
- Although MRI is more sensitive (3)[A] than TVUS, the higher cost of the procedure limits its use as a first-line diagnostic tool.
- MRI has a sensitivity of 77–93% and a specificity of 67–99% (3)[A].
- Leiomyomas are associated with adenomyosis in 36–50% of cases, making MRI an ideal imaging method (3)[A].
- MRI should be considered when TVUS cannot provide a definitive diagnosis.

**Diagnostic Procedures/Other**
- Uterine biopsy with histologic interpretation
- Uterine-sparing operative treatment (USOT) with histologic interpretation
- Hysterectomy with histologic interpretation

**Test Interpretation**
- The two-dimensional sonographic markers of adenomyosis include the
following (2,3)[A]:
– Uterine enlargement (with no visualized leiomyoma)
– Cystic anechoic spaces or lakes in the myometrium
– Uterine wall thickening
– Subendometrial echogenic linear striations
– Heterogeneous echo texture
– Obscure endometrial/myometrial border
– Thickening of the transition zone

With three-dimensional TVUS, a JZ maximum (JZmax) ≥8 mm and a JZ max
– JZ minimum (JZmin) ≥4 mm have been reported as significantly more
associated with adenomyosis than two-dimensional features (2)[B].

Features of adenomyosis on MRI include low-intensity widening of the JZ on
T2-weighted images, which corresponds to smooth muscle hyperplasia and
thickening of the JZ (2,3)[A].

Three objective parameters have been identified for an MRI diagnosis of
adenomyosis:
– Thickening of the JZ to at least 8 to 12 mm (2)[B]
– JZmax/total myometrium >40% (2)[B]
– JZmax – JZmin >5 mm (2)[B]

Histologic interpretation has traditionally been considered the most
practicable way to establish a definitive diagnosis of adenomyosis (3)[C].

Pathologic interpretation of uterine biopsy:
– Presence of endometrial glands and stromal elements within the
myometrium
– Often difficult to definitively diagnose adenomyosis due to sampling bias
and/or biopsy artifact (1)[A]

Pathologic interpretation of USOT and hysterectomy:
– In morcellated specimens, diagnostic difficulty arises due to modification of
the spatial arrangement of the tissue, leading to difficulty in referencing the
surface. Sampling bias can also be an issue (1)[A].
– Even in cases where the surface is accurately referenced, criteria vary
among pathologists regarding the depth of invasion, which “definitively”
defines adenomyosis (1,3)[A].

**TREATMENT**

– The mainstay of treatment has been surgical therapy.
– Medical therapy shows promise in certain patients.
**MEDICATION**
Continuous use of oral contraceptive pills, high-dose progestins, and selective progesterone receptor modulators can temporarily improve the symptoms. Moreover, use of a levonorgestrel-releasing intrauterine device, danazol, aromatase inhibitors, and GnRHa may temporarily induce regression of AD (5) [A].

**ADDITIONAL THERAPIES**
Immunomodulators of angiogenesis may offer future options for medical treatment of adenomyosis.

**SURGERY/OTHER PROCEDURES**
- Hysterectomy is curative.
- USOT might be considered for women who wish to preserve fertility or do not wish to have a hysterectomy.
- **USOT excisional** techniques (1)[B]:
  - Complete excision (adenomyomectomy)
  - Cytoreduction (partial adenomyomectomy)
- **USOT nonexcisional** techniques (1)[B]:
  - Laparoscopic techniques including electrocoagulation, uterine artery ligation
  - Hysteroscopic techniques including endometrial ablation, endomyometrial resection
  - MRI or ultrasound-guided high-frequency ultrasound ablation (high-intensity focused ultrasound [HIFU])
  - Uterine artery embolization (UAE)
  - Other reported techniques include the following: alcohol instillation (cystic adenomyosis), radiofrequency ablation (focal adenomyosis), microwave ablation, and thermoablation (diffuse adenomyosis).
- Of the nonexcisional techniques, HIFU and UAE seem to offer the most encouraging results (1)[C].
- Increasing percentages of necrosis after UAE may be an important factor associated with decreased recurrence of symptoms.
- A systemic review of USOT for adenomyosis in reproductive-aged women suggests that USOT may possibly improve fertility, although the best method of surgery is yet to be seen (6)[A].
ONGOING CARE

PATIENT EDUCATION

PROGNOSIS
- Adenomyosis is a benign proliferation of endometrial tissue.
- Symptoms usually resolve after menopause.
- Hysterectomy is curative.
- Additional studies are still needed to determine the impact of untreated adenomyosis and USOT on fertility and reproductive outcomes.
- Additional studies are still needed to clarify the role of medical treatment in women with adenomyosis.
- A consensus on the criterion for diagnosing adenomyosis needs to be reached.

COMPLICATIONS
- Anemia from blood loss associated with heavy periods
- Patients with adenomyosis have been reported to be at increased risk for malignant disease; however, to date, there has not been sufficient morphologic, genetic, or epigenetic evidence to substantiate the malignant transformation of adenomyosis.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

N80.0 Endometriosis of uterus

**CLINICAL PEARLS**

- Adenomyosis is often asymptomatic.
- Both TVUS and MRI are very accurate for the diagnosis of adenomyosis.
- MRI is more sensitive than TVUS, particularly in differentiating adenomyosis from leiomyoma. Differentiation of adenomyosis from leiomyoma is critical because the former is often treated with hysterectomy, whereas the latter is often treated with uterine conservation.
- Various medical and surgical therapeutic options, including uterine-sparing operative techniques, are available for adenomyosis.
- Hysterectomy is curative.
ADHESIVE CAPSULITIS (FROZEN SHOULDER)

Berenice Subero Pablo, MD • Mena Megellie, MD • George G.A. Pujalte, MD, FACSM

BASICS

DESCRIPTION

- Frozen shoulder, or adhesive capsulitis (AC):
  - Characterized by progressive pain and stiffness of the shoulder
  - Usually resolves after 18 months
  - Global limitation of movement for active and passive movements
  - Unlike early disease (typically painful), late AC can present as pain-free restricted motion.
  - Associated with deltoid atrophy, decreased range of motion (ROM), especially for external rotation

- Subtypes:
  - Primary adhesive capsulitis:
    - Idiopathic
    - Usually associated with diabetes mellitus (DM)
    - Typically resolves in 9 to 18 months (1)
  - Secondary adhesive capsulitis:
    - Typically due to prolonged immobilization
    - Sometimes called “shoulder-hand-syndrome” which is a complex regional pain syndrome (or reflex sympathetic dystrophy), if it is characterized by shoulder pain, diffuse swelling, and decreased ROM (1)

- Clinical course:
  - Phase 1 (2 to 9 months): painful phase. Pain is constant. Diagnosis may be difficult if restricted movement is not present in early disease.
  - Phase 2 (4 to 12 months): Stiffening or freezing phase. Movement becomes restricted, and pain is no longer constant but present during end ranges of movement. Pain is also less severe.
  - Phase 3 (12 to 42 months): Resolution or thawing phase. End range pain can persist until complete resolution.
EPIDEMIOLOGY
- Highest incidence in ages 50 to 60 years, women > men
- Incidence: 2.4 per 1,000 population per year
- Prevalence: 2–5% in the general population, 10–20% among diabetics (1)

ETIOLOGY AND PATHOPHYSIOLOGY
Underlying fundamental processes:
- Inflammation: Mast cells, T cells, B cells, and macrophages have been identified histologically, suggesting an inflammatory process.
- Angiogenesis
- Scarring: Fibroblasts and myofibroblasts have been identified histologically. Capsular contracture reduces the joint volume to 3 to 4 mL compared to the normal 10 to 15 mL.

Genetics
No predisposition identified

RISK FACTORS
- Shoulder immobilization; often due to impingement syndrome (most significant risk factor)
- Age >49 years
- Female gender
- Diabetes
- Cervical disc disease
- Nondominant shoulder involvement
- Hyperthyroidism
- Atherosclerotic cardiovascular disease (ASCVD): cerebrovascular accident (CVA)/myocardial infarction (MI)
- Autoimmune disease
- Antiretroviral medication use
- Parkinson disease
- Trauma/surgery
- Prior history of AC in contralateral shoulder

GENERAL PREVENTION
- Active lifestyle, while avoiding shoulder injury
- Control of diabetes, atherosclerotic disease, thyroid, and autoimmune conditions
COMMONLY ASSOCIATED CONDITIONS
DM, autoimmune disorders, Parkinson disease, highly active antiretroviral therapy (HAART) use, CVA/MI, cervical disc disease, hyperthyroidism

DIAGNOSIS

HISTORY
- Identify possible risk factors.
- Progressive and worsening stiffness of the glenohumeral (GH) joint
- Majority will have diffuse shoulder pain, especially at the beginning of the disease.
- On the late phase of the disease, stiffness becomes predominant.

PHYSICAL EXAM
- Limitation in both active and passive ROM (especially passive external rotation of shoulder <30 degrees)
- Pain to provocation of subacromial space
- Inability to reach overhead or back pocket
- Scapular substitution frequently accompanies active shoulder movement.
- Injection test can be helpful in differentiating AC from subacromial pathologies such as rotator cuff tendinopathy (which improves with injection of local anesthetics, in contrast to AC). This should only be done if the diagnosis is still uncertain after a thorough history and physical.

DIFFERENTIAL DIAGNOSIS
- Rotator cuff strain/tear/impingement syndrome
- GH or acromioclavicular joint osteoarthritis (OA)
- Cervical strain/radiculopathy/OA
- Subacromial bursitis
- Parsonage-Turner syndrome: brachial plexus inflammation secondary to a trigger, such as an infection, trauma, or autoimmune condition
- Myofascial pain syndrome
- Calcific tendonitis
- Fracture, posterior dislocation
- Bony neoplasm/metastasis

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- No labs are required for idiopathic AC. Blood tests can be used to rule out secondary causes such as diabetes, thyroid disease, a stroke, autoimmune diseases, and, in rare cases, Parkinson disease (e.g., thyroid stimulating hormone, hemoglobin A1C, erythrocyte sedimentation rate).
- Imaging:
  - Plain radiographs of the affected shoulder (postero-anterior, external rotation, axillary, and supraspinatus outlet views)
    - Preferred initial tests
    - In most cases, will be negative
    - Used primarily to rule out other pathologies such as GH OA, fractures, dislocation, or tumors (1)
  - In late AC, the plain radiographs can show diffuse osteopenia of the proximal humerus.
  - Magnetic resonance imaging (MRI)
    - Not indicated unless there is a concomitant pathology in the shoulder, or neurologic deficit
    - May show thickening of the joint capsule and the coracohumeral ligament, along with edema and increased joint fluid (1)
  - Ultrasound (US)
    - Indications similar to those for MRI
    - Selection depends on individual cases and clinician’s preference.
    - Can also reveal joint capsule thickening and increased joint fluid
    - Doppler can show increased vascularity around the intraarticular portion of the biceps tendon and coracohumeral ligament.

TREATMENT
- In most cases, self-limited
- Manage patient expectations; resolution often takes 18 months of medication and rehabilitation.

MEDICATION
- Pain management
  - Acetaminophen or nonsteroidal anti-inflammatory drugs (NSAIDs) are first line of treatment.
- Glucocorticoid injections:
– Can be beneficial especially when administered at the beginning of the disease
– A short course of physical therapy after an injection, for 4 to 6 weeks, can improve pain and ROM (2).
– Injection may be diluted with a local anesthetic like lidocaine. Triamcinolone 20 to 40 mg or methylprednisolone 20 to 40 mg can be used.

**Oral glucocorticoids**
– Short course of oral glucocorticoids can reduce pain and improve mobility (2).
– Usually given for approximately 3 weeks (prednisolone 30 mg/day × 3 weeks) but for no >6 weeks
– Not to be given as routine treatment (significant side effects)

**ADDITIONAL THERAPIES**

**Exercise and physical therapy:**
– Gentle ROM exercises should be offered to every patient.
– Exercises should be performed daily and as tolerated. A structured plan should be given to the patient (3).
– Physical therapy has been found to be beneficial especially in phases 2 and 3 of AC. Best data supports its use in conjunction with other treatment, like corticosteroids (4).

**Laser** has been suggested as a possible treatment, particularly for pain relief; not enough evidence for support

**SURGERY/OTHER PROCEDURES**

– No evidence of benefit
– Should be reserved for patients who do not respond to conservative measures for at least 1 year
– Arthroscopy release is the most common technique used.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

– After establishing a diagnosis, assess the need for pain control, and start the patient on NSAIDs, in combination with a gentle exercise program.
– Follow up in 3 to 4 weeks: if no significant improvement, may consider intra-articular corticosteroid injections along with physical therapy (4)
Follow up in 2 to 3 months: Increase intensity of the exercises as the patient progresses. Physical therapy can also be prescribed at this point.

For secondary AC, consider evaluation by a multidisciplinary team.

Follow up in 10 to 12 months: If no improvement, consider surgical intervention.

PATIENT EDUCATION

- Patient education is important; explain prognosis and ensure compliance with treatment.
- Climbing the wall: Face a wall and place the hand from the affected shoulder flat on the surface of the wall; use the fingers to “climb” the wall; pause 30 seconds every few inches. Repeat the exercise after turning the torso 90 degrees to wall (abduction).
- In case of secondary AC, address the importance of treating underlying causes.

PROGNOSIS

Up to 50% will have permanent limitation, mostly with external rotation.

REFERENCES

CODES

ICD10
- M75.00 Adhesive capsulitis of unspecified shoulder
- M75.01 Adhesive capsulitis of right shoulder
M75.02 Adhesive capsulitis of left shoulder

CLINICAL PEARLS

- Frozen shoulder or AC is generally a self-limiting global restriction in ROM of the shoulder joint. Up to 50% will have permanent inability to externally rotate the shoulder.
- Natural course consists of a painful phase, freezing phase, and thawing phase. It occurs mostly in older women; total prevalence is 2–5% of the general population and roughly 10–20% of the diabetic population.
- Most common physical exam finding is the inability to externally rotate the shoulder. Other signs include pain on provocation of subacromial space and inability to reach overhead or for back pocket.
- Plain x-rays are the preferred initial imaging modality. MRI and US are done only if there is concomitant pathology or neurologic deficit.
- Treatment includes pain control with NSAIDs, acetaminophen, or opiates; glucocorticoid therapy (injections or short course of oral steroids); physical therapy; or surgery.
- Resolution of symptoms often takes 18 or more months.
BASICS

DESCRIPTION
International adoptions have decreased in the past 10 years. They still represent a significant portion of ~136,000 yearly U.S. adoptions. Diverse birth countries, disease exposures, and unknown health histories of these children require special attention. Multidisciplinary teams are often necessary for appropriate care.

EPIDEMIOLOGY

Incidence
- 5,370 children were adopted internationally in 2016. This number has decreased every year since 2004.
- 5% of current U.S. adoptions are international, down from 17% in 2004.
- In 2016, the most common countries of origin for internationally adopted children were China, Ethiopia, Russia, South Korea, and Ukraine.
- In 2015, 47% of internationally adopted children were <5 years, 38% were ages 5 to 12 years, and 15% were ≥13 years. 50% were girls (1).

RISK FACTORS
- Unknown birth, medical, and vaccination histories
- Possible in utero or postnatal toxin exposure
- Inadequate nutrition before or after birth
- Exposures to infectious diseases not commonly seen in the United States (2)
- Previous living conditions overcrowded or institutionalized (e.g., orphanages)
- History of neglect, deprivation, or abuse
- For adoptive family, potential risks associated with foreign travel (3)

GENERAL PREVENTION
- U.S. State Department physician must examine the child in their native country before immigration to the United States. This is a limited examination targeted at identifying diseases that exclude visa qualification.
- Should be examined by a U.S. physician within 2 weeks of arrival (3)
- A follow-up visit 4 to 6 weeks after their postadoption appointment is
recommended.

- Screen for hearing, vision, growth, and developmental delay.
- Travel medicine visit for all family members traveling to adopted child’s country of origin (3).
- A preadoption visit can help clarify medical diagnoses, review available medical records (including photos and/or video) to confirm/refute specific diagnoses (2).

**COMMONLY ASSOCIATED CONDITIONS**

- 80% of international adoptees have medical or developmental issues, 20% of these are severe (4).
- Infectious diseases:
  - Hepatitis A/B/C
  - Intestinal parasites
  - Tuberculosis (TB), primarily latent
  - Syphilis, including inadequately treated
  - HIV
  - *Helicobacter pylori*
- Emotional or behavioral problems
- Developmental delay
- Fetal alcohol syndrome
- Feeding difficulties, malnutrition, rickets
- Anemia
- Congenital anomalies (e.g., cleft lip/palate, orthopedic deformities)
- Prematurity or low birth weight
- Inadequate immunizations
- Lead poisoning
- Sensorineural and conductive hearing loss
- Strabismus, blindness

**DIAGNOSIS**

**HISTORY**

- Medical records are often limited or difficult to access.
- Review immunization records carefully. Suspicious records are often “too perfect.”
  - Some vaccinations are (e.g., *Haemophilus influenzae* type B [Hib],
pneumococcal, varicella) are not routine in other countries.

- Birth/prenatal history, including exposures
- Available family history
- Documented history of emotional or nutritional deprivation, or physical or sexual abuse
- Time (if any) spent in orphanage or other institution
- Growth charts are critical. The first sign of malnutrition is failure to gain weight, followed by slow linear growth, and lagging head circumference.
- Review or observe (as able) data regarding developmental milestones, behavior, attachment, parent stress, and parent–child interactions.

PHYSICAL EXAM

- This may be the child’s first comprehensive exam; be sensitive to the child’s cues and use a translator if necessary.
- Comprehensive physical exam emphasizing:
  - Growth parameters
  - General appearance; presence of features suggestive of genetic disorder, syndromes, or congenital defects
  - Skin—infection or signs of prior abuse (4)[C]
  - Genitalia—signs of abuse or ritual cutting
  - Neurologic—sensorimotor skills, coordination, reflexes
  - Oral exam is important to look for tooth development and signs of decay.
- Developmental assessment using a validated instrument is important, especially if the date of birth is unknown (2)[C]. Developmental screening should be assessed at each visit to identify delay and potential need for additional services. 50–90% of internationally adopted children are delayed on adoption; however, most have normal cognition at long-term follow-up.

DIAGNOSTIC TESTS & INTERPRETATION

- Developmental screening
- Hearing and vision screening

Initial Tests (lab, imaging)

- Based on history and physical exam: (2)[C],(3,5)[A]:
  - Hepatitis A (Hep A IgM, Hep A IgG)
  - Hepatitis B (HBsAg, HBsAb, HBCab)
  - Hepatitis C (enzyme immunoassay [EIA])
  - HIV 1 and 2 antibody testing/ELISA
– Syphilis: nontreponemal (RPR, VDRL, or ART) and treponemal (MHA-TP, FTA-ABS, or TPPA)
– Tuberculin skin test (TST) in all ages or interferon-gamma release assay ages ≥5 years
– Three stool specimens for ova and parasites, specific request for *Giardia intestinalis* and *Cryptosporidium* species testing of one sample
– CBC with indices and differential
– Blood lead concentration for ages ≤6 years
– Thyroid-stimulating hormone (TSH)
– Urinalysis
– Hemoglobinopathy/blood disorder screen: sickle cell, thalassemia, glucose-6-phosphate dehydrogenase (G6PD) deficiency

**Consider:**
– Antibody titers depending on veracity of immunization records (6)[C]
– Stool cultures for bacterial pathogens (diarrhea) (2)[C]
– *H. pylori* testing (dyspepsia, abdominal pain, or anemia)
– Ca++, PO₄, alkaline phosphate, and 25 vitamin D level (rickets) (2)[C]
– >12 months of age: for Chagas disease via *Trypanosoma cruzi*, serologic testing in adoptees from endemic countries (Mexico, Central and South America)
– >24 months of age: Review CBC for eosinophilia to consider lymphatic filariasis in children from sub-Saharan Africa, Egypt, Southern Asia, Western Pacific Islands, the NE coast of Brazil, Guyana, Haiti, and the Dominican Republic (5)[A].

**Follow-Up Tests & Special Considerations**

**ALERT**
If initially negative, repeat of HIV, Hep B, Hep C, and TB testing are recommended at 6 months; negative tests may represent a “window” period or be falsely negative due to malnutrition in the case of TST.

- HIV: If antibody positive in children <18 months, confirm with DNA PCR (may represent maternal antibody) (3)[A].
- Hep C: Confirm positive tests with recombinant immunoblot assay (RIBA) and/or HCV RNA PCR; an initial positive in children <18 months may be due to maternal antibody, repeat after 18 months of age.
- Positive TST (TB): Do *not* attribute to bacille Calmette-Guérin (BCG) vaccine. Evaluate for active disease; treat latent TB.
- Test for intestinal parasites if GI symptoms persist.
- Eosinophilia >450 cells/mm$^3$ with negative stool ova and parasites: serologic testing for Schistosoma; add Strongyloides for adoptees from sub-Saharan African, Latin American, and Southeast Asian countries (2)[C].
- Behavioral concerns may first present during adolescence, even for children adopted in infancy.
- Follow children with history of treated congenital syphilis: ophthalmologic, audiologic, neurologic, and developmental delays with serial exams and/or serologies.

**TREATMENT**

**GENERAL MEASURES**
- Regular diet for children who arrive malnourished
- Monitor linear growth.
- Consider early intervention for children with suspected delays.
- Involve parents in local and online support groups.
- Post adoption depression may occur in parents.

**MEDICATION**
- Immunizations: Catch up per CDC schedule (http://www.cdc.gov/vaccines/schedules/).
  - No further Hep B vaccine if HBsAg positive, HBsAb and HBcAb positive, or HBsAb positive and HBV vaccine given appropriately
  - MMR for vaccination for mumps and rubella, even if measles antibodies present (6)[C]
- Possible approaches (5)[A]:
  - Repeating questionable vaccinations negates the need to obtain serologic tests.
  - To minimize/avoid vaccine administration, check antibody titers—infants 6 to 12 months: polio; diphtheria; children >1 year: Hep A; MMR; varicella (6)[C]
- Update adoptive parents, caretakers, and household members on Tdap, Hep A/B, and measles (3)[A],(4)[C].

**ISSUES FOR REFERRAL**
- Time referrals and defer elective surgical procedures to allow adjustment to
new home (2)[C].

- Individual or family counseling may help adoptive for adjustment.
- Internationally adopted children may exhibit self-stimulating behaviors (e.g., rocking, head banging); related to prior sensory deprivation. These behaviors typically decrease with time, and no treatment is necessary if otherwise developing normally. If in doubt, refer to developmental pediatrics or occupational therapy.
  - If a child continues to have disruptive behaviors, or would rather self-soothe than seek nurturing human interaction, consider developmental evaluation.
  - Persistent behavioral issues in the parent–child interactions merit further evaluation.
- Refer to pediatric ophthalmology for strabismus (seen in 10–25% of previously institutionalized adoptees).
- Refer to audiology and/or ENT for concerns, questionable screening results, or if slow to acquire language skills.
- No longer hearing native language slows speech development. Speech therapy helps children from non–English-speaking countries.
- Pediatric dental evaluation by 12 months of age; sooner if signs of dental pathology is present (2)[C]

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

#### Patient Monitoring
- Regular well-child visits, particularly within first months of entry into the United States
- Close monitoring of developmental milestones, behavior, and individual attachment

#### DIET
- Regular diet, with specific attention to known nutritional deficiencies in country of origin ([www.adoptionnutrition.org](http://www.adoptionnutrition.org))
- Up to 68% of international adoptees fall >2 standard deviations below the mean for one or more growth parameters; most begin to follow an appropriate growth curve (<2 deviations from the mean) within 9 to 12 months.
PATIENT EDUCATION

- Allow ad lib access to healthy foods to promote self-regulatory eating behaviors.
- Toileting: Some children may not be trained yet; others may regress in their new home. Time, positive reinforcement, and avoiding punishment often resolve this issue as the child adjusts to new surroundings.
- Sleeping: Children must learn to trust their new home and parents. Avoid aggressive sleep rules. Parents should be present physically and emotionally to establish safety and promote bedtime ritual.
- Language: Adoptive family should learn key phrases in the child’s native language prior to adoption. Use translator services if available, being careful to avoid perception of translator use equating to potential return to native country.
- Adopted children may grieve lost family, relationships, and culture; encourage parents to acknowledge openly work through. Provide counseling if needed.
- Encourage families to learn about the culture and ethnicity of origin (4).

PROGNOSIS

- Recovery from developmental delay correlates with time spent in institutional setting.
  - Risk of long-term developmental, behavioral, or academic problems increases with adoption age.
  - Rate of recovery exceeds rate of normal development (3).
- Children may regress in previously acquired skills (2).
- A desire to search for biologic family is common in adolescence (4).
- American Academy of Pediatrics’ Council on Foster Care, Adoption, & Kinship Care (http://www2.aap.org/sections/adoption/index.html)

REFERENCES

ADDITIONAL READING

CODES

ICD10
- Z02.82 Encounter for adoption services
- Z62.821 Parent-adopted child conflict

CLINICAL PEARLS

- Internationally adopted children may exhibit self-stimulating behaviors (e.g., rocking, head banging) that usually decrease over time. Refer to developmental or occupational specialist if concerns persist.
- To prepare for child’s arrival, a preadoption visit can identify medical concerns and prepare resources.
- Initial labs: Hep A/BC; HIV 1/2, CBC, TSH, lead, G6PD deficiency, hemoglobin electrophoresis, PPD/TST (or IGRA ages ≥5 years), ova and parasites (three stool specimens, including single specimen for Giardia and Cryptosporidium antigens), urinalysis
- If initially negative, repeat HIV, Hep B/C, and TST at 6 months.
- Catch up immunizations per CDC schedule (http://www.cdc.gov/vaccines/schedules/).
Ensure that adoptive family and caretakers have updated immunizations.
ADVANCE CARE PLANNING

Christopher Lin-Brande, MD • Heather A. Dalton, MD • Amy M. Davis, MD

BASICS

DESCRIPTION

- Advance care planning (ACP) refers to how patients make decisions about care they will receive if they can no longer speak for themselves.
- Several methods address uncertainty of goals of care as patients age, these include:
  - Advance directives, living wills (LW), health care powers of attorney, physician/medical orders for life-sustaining treatment POLST/MOLST forms, and facilitated conversations with family and significant others
- ACP is an important aspect of patient-centered care that has become more important as the population ages and people lose decision-making capacity.
- Interpreting patient wishes in the context of individual illness circumstances, negotiating conflicts in decisions, and aiding patients in determining what is in their best interest based on personal values can be challenging.
- Definitions
  - Advance directives (1): written instructions in the form of a LW, a health care durable power of attorney (DPOA) appointing a health care proxy (HCP), or other medical directive (e.g., Five Wishes) to guide decision-making in the event that a patient is unable to provide informed consent
    - LW and DPOA usually only take effect if the patient has been determined to lack capacity to decide care for him or herself; otherwise, patient preference takes precedence even if it contradicts a LW.
  - LW: written instructions of a patient’s wishes regarding medical care
    - Each state has laws governing notarization and witness requirements for the LW to be a legal document. Certain states do not recognize LW but have specific “medical directive” forms. LW and medical directives can take effect immediately (e.g., when a patient is diagnosed with a terminal illness) or when a patient can no longer make decisions for him or herself.
    - LW have the benefit of using direct instructions regarding treatment wishes.
- LW challenges include lack of standard format, completion far in advance of use, narrow scope.
- LW do not expire but they can be revised.
- The LW is NOT a medical directive, so it cannot prevent emergency medical services (EMS) from providing life-sustaining treatment as a POLST can (see below).

- DPOA: a written document designating a surrogate decision maker in the event the patient cannot speak for him or herself
  - An HCP speaks for the patient and makes decisions aligning as closely as possible to the patient’s wishes. Ideally, this is someone the patient knows well and trusts and who has had discussions with the patient about his or her values.
  - If multiple HCP are named, disagreements about who speaks for the patient must be resolved before a decision can be made.
  - If there is a conflict between a LW provision and a HCP decision, different states have varying rules regarding precedence. In some states, the DPOA supersedes the LW; in other states the most recently executed document is legally binding.

- POLST/MOLST: a medical directive, which (unlike LW) directs point of care decision-making by EMS for patients in advanced stages of illness
  - This is an adjunctive document to LW and DPOA as it provides clear instruction regarding resuscitation, intubation, and treatment options to minimize confusion.
  - These documents are portable and follow a patient across different care settings. Given their simplicity, POLST/MOLST is more likely to be followed than LW, which can be difficult to locate.
  - Although EMS may be concerned about the legal implications of withholding life-sustaining treatment, POLST forms provide legal protection if patient wishes are followed.
  - Studies have shown that patients with active POLST have fewer unwanted interventions.

- Nursing home residents and demented patients often do not have capacity to complete legal documents related to LW and DPOA.
- Primary care physicians should address ACP when patients are able to make decisions about their future care.
- There are no guidelines for when to initiate discussions about ACP, but age 65 years may be an appropriate time for a realistic conversation prior to the onset of dementia or incapacitating illness.
  - Each conversation needs to be individualized based on patient’s willingness.
to engage.
– A specific age threshold does not account for debilitating accidents earlier in life or disease processes that have a faster progression to morbidity and mortality.

**Pediatric Considerations**

- Pediatric ACP (pACP) is less common. For children with serious acute or terminal illness, it is a difficult (but important) part of treatment.
  - Provider fears about increasing parental distress when discussing pACP are unjustified.
  - pACP may unburden parents regarding difficult decisions and is associated with increased positive emotions, understanding of the patient’s illness, and provider rapport.

**TREATMENT**

- ACP discussions are often complicated by various emotional, cultural, and medical factors. It is important to engage in these conversations with sensitivity about the patient’s frame of reference and understanding about his or her health status.
  - African Americans are less likely than whites to complete AD. Preference for life-sustaining treatment, religiosity, poor health literacy, and distrust of the medical community all contribute to this difference.
- Do not force the conversation if a patient is resistant or unprepared to discuss ACP.
  - Motivational interviewing can be used to gauge interest and readiness to discuss ACP.
  - Addressing implications for friends and family who may be burdened with decision-making may help promote ACP conversations.
- The first time ACP is brought up may serve as an introduction to the topic as well as an opportunity for the patient to consider options. Subsequent visits can address specific scenarios and choices (2).
- Use specific lay terminology when addressing medical conditions and options. Patients may not understand the severity of illness or the implications of advanced life-saving interventions (CPR, mechanical ventilation, parenteral nutrition, etc.).
ONGOING CARE

Reimbursement: The Centers for Medicare & Medicaid Services has reimbursed physicians for ACP discussions since 2015.

- The current CPT codes are 99497 for the first 30 minutes of discussion and completion of forms, and 99498 for each additional 30 minutes (3).
- There are no limits to the number of times ACP can be reported in a given period of time.
- An advance directive does not have to be completed in order to bill for services.
- No specific diagnosis is required for the ACP codes.

Patient Monitoring

- There are no specific guidelines for how often a LW or DPOA discussion should be revisited after they are completed.
- When there is a new diagnosis or a significant change in clinical status, it is prudent to have the patient consider how it would affect his or her ACP decision-making.
- Have patients display POLST/MOLST form prominently so it is easily visible to EMS.

PATIENT EDUCATION

- The National Hospice and Palliative Care Organization, Aging with Dignity, National Healthcare Decisions Day, and the American Bar Association have online resources to help patients.
- Online platforms such as My Directives allow patients to specify their wishes electronically.
- DeathWise is a nonprofit organization with worksheets patients can use to help them with the health, financial, care of body, and service components of ACP.

COMPLICATIONS

- Often LW, DPOA, and POLST are completed but physicians do not have access to them. Electronic health records are a convenient place to store these documents but due to poor integration between systems, they may be difficult to retrieve.
  - When a patient completes an ACP form, it should be part of the medical record with open access (if possible) to facilitate appropriate decision-making.
making regardless of location or system.

- Medical bracelets or other devices are often used to notify EMS of patient directives.

- Emergency rooms are vulnerable to uncertainty about what interventions patients want if they cannot communicate for themselves.

- POLST forms should accompany patients if possible to avoid confusion.

- There is often misunderstanding on the part of both doctors and patients regarding do not resuscitate (DNR) and do not intubate (DNI) orders.

- DNR/DNI orders can be reversed or should not be honored in certain situations. DNR/DNI in a person with a chronic progressive illness does not necessarily mean DNR/DNI for an acute reversible process.

- The prognosis for successful resuscitation on a hospital ward is approximately 14%; it is 50–80% for patients undergoing surgery.

CODES

ICD10
• Z71.89 Other specified counseling
• Z51.5 Encounter for palliative care
• Z66 Do not resuscitate

CLINICAL PEARLS
• ACP is important and underutilized.
• The primary barriers to discussing advanced directives in the primary care setting from the patient perspective include lack of knowledge, fear of burdening family, and the desire for physicians to initiate the discussion.
• The primary barriers from the physician perspective include discomfort with the topic, lack of emotional support, lack of reimbursement, and lack of adequate time to fully address the topic.
ALCOHOL USE DISORDER (AUD)
Gennine M. Zinner, RNCS, AN

BASICS

DESCRIPTION

- Any pattern of alcohol use causing significant physical, mental, or social dysfunction; key features are tolerance, withdrawal, and persistent use despite problems.
- Alcohol abuse: maladaptive pattern of alcohol use manifested by ≥1 of:
  - Failure to fulfill obligations at work, school, or home
  - Recurrent use in hazardous situations
  - Recurrent alcohol-related legal problems
  - Continued use despite related social or interpersonal problems
- Alcohol dependence: maladaptive pattern of use manifested by ≥3 of the following:
  - Tolerance
  - Withdrawal
  - Using more than intended
  - Persistent desire or attempts to cut down/stop
  - Significant amount of time obtaining, using, or recovering from alcohol
  - Social, occupational, or recreational activities sacrificed for alcohol use
  - Continued use despite physical or psychological problems
- National Institute on Alcohol Abuse and Alcoholism criteria for “at-risk” drinking: men: >14 drinks a week or >4 per occasion; women: >7 drinks a week or >3 per occasion
- Women experience harmful effects at lower levels of alcohol consumption and are less likely to report problems related to drinking.
- System(s) affected: nervous, gastrointestinal (GI)
- Synonym(s): alcoholism, alcohol abuse, alcohol dependence

Geriatric Considerations

- Common and underdiagnosed in elderly; less likely to report problem; may exacerbate normal age-related cognitive deficits and disabilities
- Multiple drug interactions
- Signs and symptoms may be different or attributed to chronic medical
problem or dementia.
- Common assessment tools may be inappropriate.

**Pediatric Considerations**
- Children of alcoholics are at increased risk for problem drinking.
- 2.5% of adolescents ages 12 to 17 years has alcohol use disorder (AUD); 13.4% of youth age 12 to 20 years report binge drinking in the past month (2015: National Survey on Drug Use and Health [NSDUH]); negative effect on maturation and normal brain development
- Early onset drinkers (those who start drinking before age 21 years) are 4 times more likely to develop a problem than those who begin after age 21 years.
- Depression, suicidal or disorderly behavior, family disruption, violence or destruction of property, poor school or work performance, sexual promiscuity, social immaturity, lack of interests, isolation, moodiness

**Pregnancy Considerations**
- Women should abstain during conception and throughout pregnancy.
- 10–50% of children born to women who are heavy drinkers will have fetal alcohol syndrome.

**EPIDEMIOLOGY**
- Predominant age: 18 to 25 years, but all ages affected
- Predominant sex: male > female (3:1)

**Prevalence**
- 27% of Americans age 18 years or older reported they engaged in binge drinking in the past month; 7% reported they engaged in heavy alcohol use in the past month.
- 15 million adults (6%) age >18 years has AUD.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Multifactorial: genetic, environment, psychosocial
- Alcohol is a CNS depressant, facilitating γ-aminobutyric acid (GABA) inhibition and blocking N-methyl-D-aspartate receptors.

**Genetics**
- 50–60% of risk is genetic.
**RISK FACTORS**
- Family history
- Depression (40% with comorbid alcohol abuse)
- Anxiety
- Tobacco use; other substance abuse
- Male gender; lower socioeconomic status
- Unemployment
- Poor self-esteem—seeking peer/social approval
- Family dysfunction or childhood trauma
- Posttraumatic stress disorder
- Antisocial personality disorder
- Bipolar disorder
- Eating disorders
- Criminal behavior

**GENERAL PREVENTION**
Counsel with family history and risk factors.

**COMMONLY ASSOCIATED CONDITIONS**
- Cardiomyopathy, atrial fibrillation
- Hypertension
- Peptic ulcer disease/gastritis
- Cirrhosis, fatty liver, cholelithiasis
- Hepatitis
- Diabetes mellitus
- Pancreatitis
- Malnutrition
- Upper GI malignancies
- Peripheral neuropathy, seizures
- Abuse and violence
- Trauma (falls, motor vehicle accidents [MVAs])
- Behavioral disorders (depression, bipolar, schizophrenia): >50% of patients with these disorders have a comorbid substance abuse problem.

**DIAGNOSIS HISTORY**
Thorough behavioral history
- Anxiety, depression, insomnia
- Psychological and social dysfunction, marital, or relationship problems
- Social isolation/withdrawal
- Domestic violence
- Alcohol-related legal problems
- Repeated attempts to stop/reduce drinking
- Loss of interest in nondrinking activities
- Employment problems (tardiness, absenteeism, decreased productivity, interpersonal problems, frequent job loss)
- Blackouts
- Complaints about alcohol-related behavior
- Frequent trauma, MVAs, ED visits

Physical symptoms
- Anorexia
- Nausea, vomiting, abdominal pain
- Palpitations
- Headache
- Impotence
- Menstrual irregularities
- Infertility

PHYSICAL EXAM
- Physical exam may be completely normal.
- General: fever, agitation, diaphoresis
- Head/eyes/ears/nose/throat: plethoric face, rhinophyma, poor oral hygiene, oropharyngeal malignancies
- Cardiovascular: hypertension, dilated cardiomyopathy, tachycardia, arrhythmias
- Respiratory: aspiration pneumonia
- GI: stigmata of chronic liver disease, peptic ulcer disease, pancreatitis, esophageal malignancies, esophageal varices
- Genitourinary: testicular atrophy
- Musculoskeletal: poorly healed fractures, myopathy, osteopenia, osteoporosis, bone marrow suppression
- Neurologic: tremors, cognitive deficits (e.g., memory impairment), peripheral neuropathy, Wernicke-Korsakoff syndrome (from severe acute deficiency of thiamine: Korsakoff psychosis is a chronic neurologic sequela of Wernicke encephalopathy)
- Endocrine/metabolic: hyperlipidemias, cushingoid appearance, gynecomastia
- Dermatologic: burns (e.g., cigarettes), bruises, poor hygiene, palmar erythema, spider telangiectasias, caput medusae, jaundice

**DIFFERENTIAL DIAGNOSIS**
- Other substance use disorders
- Depression, dementia
- Cerebellar ataxia; cerebrovascular accident (CVA)
- Benign essential tremor; seizure disorder
- Hypoglycemia; diabetic ketoacidosis
- Viral hepatitis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Screening:**
- **CAGE Questionnaire:** (Cut down, Annoyed, Guilty, and Eye opener): >2 “yes” answers is 74–89% sensitive, 79–95% specific for AUD; less sensitive for white women, college students, elderly; not an appropriate tool for less severe forms of alcohol abuse (1)[A]
- Single question for unhealthy use: “How many times in the last year have you had X or more drinks in 1 day?” (X = 5 for men, 4 for women); 81.8% sensitive, 79% specific for AUDs (2)[C]
- **Alcohol Use Disorders Identification Test (AUDIT):** 10 items, if >4: 70–92% sensitive, better in populations with low incidence of alcoholism:
  [http://www.nams.sg/addictions/Alcohol/Pages/Self-Assessment-Tool.aspx](http://www.nams.sg/addictions/Alcohol/Pages/Self-Assessment-Tool.aspx)

**Initial Tests (lab, imaging):**
- CBC; liver function tests (LFTs); electrolytes; BUN/creatinine; lipid panel; thiamine; folate; hepatitis A, B, and C serology
- Amylase, lipase (if GI symptoms present)
- Serum levels increased in chronic abuse:
  - AST/ALT ratio >2.0
  - γ-Glutamyl transferase (GGT)
  - Carbohydrate-deficient transferrin
  - Elevated mean corpuscular volume (MCV)
  - ↑ Prothrombin time
  - Uric acid
  - ↑ Triglycerides and cholesterol (total)
- Often decreased
– Calcium, magnesium, potassium, phosphorus
– BUN
– Hemoglobin, hematocrit, platelet count
– Serum protein, albumin
– Thiamine, folate

**Blood alcohol concentration**
– >100 mg/dL in outpatient setting
– >150 mg/dL without obvious signs of intoxication
– >300 mg/dL at any time

**CAT scan or MRI of brain:** cortical atrophy, lesions in thalamic nucleus, and basal forebrain

**Abdominal ultrasound (US):** ascites, periportal fibrosis, fatty infiltration, inflammation

**Test Interpretation**

- Liver: inflammation or fatty infiltration (alcoholic hepatitis), periportal fibrosis (alcoholic cirrhosis occurs in only 10–20% of alcoholics)
- Gastric mucosa: inflammation, ulceration
- Pancreas: inflammation, liquefaction necrosis
- Heart: dilated cardiomyopathy
- Immune system: decreased granulocytes
- Endocrine organs: elevated cortisol levels, testicular atrophy, decreased female hormones
- Brain: cortical atrophy, enlarged ventricles

**TREATMENT**

- For management of acute withdrawal, please see “Alcohol Withdrawal.”

**GENERAL MEASURES**

- Brief interventions and counseling by clinicians have proven efficacy for problem drinking (3)[B].
- Treat comorbid problems (sleep, anxiety, etc.), but do not prescribe medications with cross tolerance to alcohol (benzodiazepine).
- Group programs and/or 12-step programs may have benefit in helping patients accept treatment.
- Consider referring patients with alcohol dependence to an addiction specialist
or treatment program.

MEDICATION

First Line
- Adjuncts to withdrawal regimens:
  - Naltrexone: 50 to 100 mg/day PO or 380 mg IM once every 4 weeks; opiate antagonist reduces craving and likelihood of relapse, decreases number of heavy drinking days in recalcitrant alcohol abusers (IM route may enhance compliance and efficacy) (4,5)[B].
  - Acamprosate (Campral): 666 mg PO TID after withdrawal completed; reduces relapse risk. If helpful, use for 1 year (5)[B].
  - Topiramate (Topamax): 25 to 300 mg/day PO or divided BID; may enhance abstinence (5,6)[B] (off-label FDA use)

- Supplements to all
  - Thiamine: 100 mg/day (first dose IV prior to glucose to avoid Wernicke encephalopathy)
  - Folic acid: 1 mg/day
  - Multivitamin: daily

- Contraindications
  - Naltrexone: pregnancy, acute hepatitis, hepatic failure
  - Monitor LFTs.

- Precautions: organic pain, organic brain syndromes
- Significant possible interactions: alcohol, sedatives, hypnotics, naltrexone, and narcotics

ALERT
Treat acute symptoms if in alcohol withdrawal; give thiamine 100 mg/day with first dose prior to glucose.

Second Line
- Disulfiram: 250 to 500 mg/day PO; unproven efficacy; may provide psychological deterrent; most effective if used with close supervision (4)[A]
- Selective serotonin reuptake inhibitors may be beneficial if comorbid depression exists (4)[A].

ISSUES FOR REFERRAL
Addiction specialist, 12-step or long-term program, psychiatrist
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Assess medical and psychiatric condition.
  - (CIWA > 8: a 10-item scale used in the assessment and management of alcohol withdrawal)
- Correct electrolyte imbalances, acidosis, hypovolemia (treat if in alcohol withdrawal).
- Thiamine: 100 mg IM, followed by 100 mg PO; folic acid: 1 mg/day
- Benzodiazepines used to lower risk of alcohol withdrawal, seizures

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Outpatient detoxification: daily visits (not recommended for patients with heavy alcohol abuse)
- Early outpatient rehabilitation: weekly visits
- Detoxification alone is not sufficient.

PATIENT EDUCATION

- American Council on Alcoholism: (800) 527-5344 or http://www.aca-usa.com/ (treatment facility locator, educational information)
- National Clearinghouse for Alcohol and Drug Information: (800) 729-6686 or http://www.health.org/
- Center for Substance Abuse Treatment: (800) 662-HELP or http://www.samhsa.gov/about-us/who-we-are/offices-centers/csat
- Alcoholics Anonymous: http://www.aa.org/
- Rational Recovery: https://rational.org/index.php?id=1
- Secular Organizations for Sobriety: http://www.centerforinquiry.net/sos
- http://www.alcoholanswers.org/: an evidence-based website for those seeking credible information on alcohol dependence and online support forums

PROGNOSIS

- Chronic relapsing disease; mortality rate more than twice general population, death 10 to 15 years earlier
- Abstinence benefits survival, mental health, family, employment.
12-step programs, cognitive behavior, and motivational therapies are often effective during 1st year following treatment.

COMPLICATIONS

- Psychosocial complications (family, employment, etc.)
- Cirrhosis (women sooner than men)
- GI malignancies
- Neuropathy, dementia, Wernicke-Korsakoff syndrome
- Stroke; ketoacidosis; infections
- Adult respiratory distress syndrome
- Depression; suicide; trauma

CODES

ICD10

- F10.10 Alcohol abuse, uncomplicated
- F10.20 Alcohol dependence, uncomplicated
- F10.239 Alcohol dependence with withdrawal, unspecified

CLINICAL PEARLS

- CAGE Questionnaire: >2 “yes” answers is 74–89% sensitive, 79–95% specific for AUD; less sensitive for white women, college students, elderly; not an appropriate tool for less severe forms of alcohol abuse
- Single question for unhealthy use screening: “How many times in the last year have you had X or more drinks in 1 day?” (X = 5 for men, 4 for women); 81.8% sensitive, 79% specific for AUDs
- National Institute on Alcohol Abuse and Alcoholism criteria for “at-risk” drinking: men >14 drinks a week or >4 per occasion; women: >7 drinks a week or >3 per occasion
ALCOHOL WITHDRAWAL

Sebastian T. Tong, MD, MPH

BASICS

DESCRIPTION
Alcohol withdrawal syndrome (AWS) is a spectrum of symptoms that results from abrupt cessation or reduction in alcohol intake, which has previously been heavy or prolonged. Symptoms generally start 6 to 24 hours after the last drink.

EPIDEMIOLOGY
- 16 million Americans meet diagnostic criteria for alcohol use disorder (AUD). Approximately 50% of those with AUD have experienced AWS in their lifetime.
- 8% of those admitted to the hospital are at risk for AWS.
- Higher prevalence in men, whites, Native Americans, younger and unmarried adults, and those with lower socioeconomic status

ETIOLOGY AND PATHOPHYSIOLOGY
- Consumption of alcohol potentiates the effect of the inhibitory neurotransmitter γ-aminobutyric acid (GABA). With chronic alcohol ingestion, this repeated stimulation downregulates the inhibitory effects of GABA.
- Concurrently, alcohol ingestion inhibits the stimulatory effect of glutamate on the CNS, with chronic alcohol use upregulating excitatory NMDA glutamate receptors.
- When alcohol is abruptly stopped, the combined effect of a downregulated inhibitory neurotransmitter system (GABA-modulated) and upregulated excitatory neurotransmitter system (glutamate-modulated) results in brain hyperexcitability when no longer suppressed by alcohol; clinically seen as AWS

Genetics
Some evidence for a genetic basis of AUD

RISK FACTORS
High tolerance, prolonged use, high quantities
Previous alcohol withdrawal episodes, detoxifications, alcohol withdrawal seizures, and delirium tremens (DTs)
Serious medical problems
Concomitant benzodiazepine (BZD) use

**Geriatric Considerations**
Elderly with AUD are more susceptible to withdrawal, and chronic comorbid conditions place them at higher risk of complications from withdrawal; use of short acting medications preferred for management

**Pregnancy Considerations**
Hospitalization or inpatient detoxification is usually required for treatment of acute alcohol withdrawal.

**GENERAL PREVENTION**
- Routinely screen all adults for alcohol misuse (1)[B].
- Screen with the CAGE or similar questionnaire.
  - Feeling the need to Cut down
  - Annoyed by criticism about alcohol use
  - Guilt about drinking/behaviors while intoxicated
  - “Eye opener” to quell withdrawal symptoms
  - Useful to detect problematic alcohol use; positive screen is ≥2 “yes” responses.
- 3-question AUDIT-C screening test is also useful to identify problem drinking.

**COMMONLY ASSOCIATED CONDITIONS**
- General: poor nutrition, electrolyte abnormalities (hyponatremia, hypomagnesemia, hypophosphatemia), thiamine deficiency, dehydration
- GI: hepatitis, cirrhosis, esophageal varices, GI bleed
- Heme: splenomegaly, thrombocytopenia, macrocytic anemia
- Cardiovascular: cardiomyopathy, hypertension, atrial fibrillation, other arrhythmias, stroke
- CNS: trauma, seizure disorder, generalized atrophy, Wernicke-Korsakoff syndrome
- Peripheral nervous system: neuropathy, myopathy
- Pulmonary: aspiration pneumonitis or pneumonia; increased risk of anaerobic
infections
- Psychiatric: depression, posttraumatic stress disorder, bipolar disease, polysubstance use disorder

**DIAGNOSIS**

*Diagnostic and Statistical Manual of Mental Disorders* AWS criteria are diagnosed when ≥2 of the following present within a few hours to several days after the cessation or reduction of heavy and prolonged alcohol ingestion (2)[C]:
- Autonomic hyperactivity (sweating, tachycardia)
- Increased hand tremor
- Insomnia
- Psychomotor agitation
- Anxiety
- Nausea or vomiting
- Generalized tonic-clonic seizures
- Transient visual, auditory, or tactile hallucinations or illusions

Criteria for DTs include ≥2 of the criteria for AWS and disturbances in orientation, memory, attention, awareness, visuospatial ability, or perception.

These should cause clinically significant distress or impair functioning and not be secondary to an underlying medical condition or mental disorder.

AWS can be divided into stages based on time of onset and severity:
- Minor withdrawal: onset 6 to 8 hours after cessation
  - Mild anxiety, restlessness, and agitation
  - Mild nausea/GI upset and decreased appetite
  - Sleep disturbance
  - Sweating
  - Mild tremulousness
  - Fluctuating tachycardia and hypertension
- Major withdrawal: onset 24 to 72 hours after cessation
  - Marked restlessness and agitation
  - Moderate tremulousness with constant eye movements
  - Diaphoresis
  - Nightmares
  - Nausea, vomiting, diarrhea, anorexia
  - Marked tachycardia and hypertension
  - Alcoholic hallucinosis (auditory, tactile, or visual) may have mild
confusion but can be reoriented.
- DTs: onset 72 to 96 hours after cessation
  o Fever
  o Severe hypertension, tachycardia
  o Delirium
  o Drenching sweats
  o Marked tremors
  o Persistent hallucinations
- Alcohol withdrawal–associated seizures are often brief, generalized tonic–clonic seizures and typically occur 6 to 48 hours after last drink.

HISTORY
Essential historical information should be as follows:
- Duration and quantity of alcohol intake, time since last drink
- Previous episodes/symptoms of alcohol withdrawal, prior admissions for medically-managed withdrawal
- Concurrent substance use
- Preexisting medical and psychiatric conditions, prior seizure activity
- Social history: living situation, social support, stressors and triggers

PHYSICAL EXAM
Should include assessment of conditions likely to complicate or that are exacerbated by AWS
- Cardiovascular: arrhythmias, heart failure, coronary artery disease
- GI: GI bleed, liver disease, pancreatitis
- Neuro: oculomotor dysfunction, gait ataxia, neuropathy
- Psych: orientation, memory (may be complicated by hepatic encephalopathy)
- General: hand tremor (6 to 8 cycles per second), infections

DIFFERENTIAL DIAGNOSIS
- Cocaine intoxication
- Opioid, marijuana, and amphetamine withdrawal
- Anticholinergic drug toxicity
- Neuroleptic malignant syndrome
- ICU delirium
- Liver failure
- Sepsis, CNS infection, or hemorrhage
- Mania, psychosis
Thyroid crisis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Blood alcohol level, urine drug screen
- CBC; comprehensive metabolic panel
- CNS imaging if acute mental status changes
- If first seizure, full neurologic workup including EEG, brain imaging, lumbar puncture

TREATMENT

GENERAL MEASURES
The goal is to prevent and treat withdrawal symptoms (e.g., seizures, DTs, cardiovascular events). This is done primarily with BZDs, which reduce the duration of symptoms and raise the seizure threshold.
- Exclude other medical and psychiatric causes.
- Provide a quiet, protective environment.
- The Clinical Institute Withdrawal Assessment for Alcohol Scale revised (CIWA-Ar) is useful for determining medication dosing and frequency of evaluation for AWS. Severity of symptoms are rated on a scale from 0 to 7, with 0 being without symptoms and 7 being the maximum score (except orientation and clouding of sensorium, scale 0 to 4).
  - Nausea and vomiting
  - Tactile disturbances
  - Tremor
  - Auditory disturbances
  - Paroxysmal sweats
  - Visual disturbances
  - Anxiety
  - Headache or fullness in head
  - Agitation
  - Orientation and clouding of sensorium
- The maximum CIWA-Ar score achievable is 67.
  - Mild withdrawal = score <8: likely resolve without medication
  - Moderate withdrawal = 8 to 14: often require management with medication
– Severe withdrawal = >15: are associated with the highest risk of seizures and development of DTs
• Frequent reevaluation with CIWA-Ar score is crucial.

**MEDICATION**

**First Line**

• BZD monotherapy remains the treatment of choice (3)[A]; it is associated with fewer complications compared with neuroleptics (4)[A].
• BZD should be chosen by the following considerations:
  – Agents with rapid onset control agitation more quickly (e.g., IV diazepam [Valium]).
  – Long-acting BZDs (diazepam, chlordiazepoxide [Librium]) are more effective at preventing breakthrough seizures and delirium management.
  – Short-acting BZDs (lorazepam [Ativan], oxazepam [Serax]) are preferable when prolonged sedation is a concern (e.g., elderly patients or other serious concomitant medical illness) and preferable when severe hepatic insufficiency may impair metabolism (4)[A].
• BZD dosages will vary by patients.
• Can use symptom-triggered or fixed-schedule regimens
  – Symptom-triggered regimens have been found to require less BZD amounts and reduce hospitalization.
  – Fixed-schedule regimens more appropriate if nursing staff do not have training for symptom-triggered; if patient with severe coronary artery disease; or if history of past withdrawal seizures
• Symptom-triggered regimen: Administer one of the following medications every hour when CIWA-Ar ≥8:
  – Chlordiazepoxide 50 to 100 mg PO
  – Diazepam 10 to 20 mg PO
  – Oxazepam 30 to 60 mg PO
  – Lorazepam 2 to 4 mg PO
• Fixed-schedule regimen: Administer one of the following medications every 6 hours:
  – Chlordiazepoxide 50 mg PO for 4 doses and then 25 mg PO for 8 doses
  – Diazepam 10 mg PO for 4 doses and then 5 mg PO for 8 doses
  – Lorazepam 2 mg PO for 4 doses and then 1 mg PO for 8 doses
• Important to monitor closely and provide additional BZDs if CIWA-Ar ≥8

**Second Line**
Thiamine: 50 to 100 mg daily IV or IM for at least 3 days (4)[C]
  - Do not administer IV glucose before giving thiamine because this may precipitate Wernicke encephalopathy and Korsakoff psychosis.

β-Blockers (e.g., atenolol or propranolol) and α₂-agonists (e.g., clonidine) help to control hypertension and tachycardia and can be used with BZDs. Not used as monotherapy, due to their inability to prevent DTs and seizures; may worsen underlying delirium.

Carbamazepine: not recommended as first-line therapy; associated with reduced incidence of seizures but more studies are needed.

If the patient exhibits significant agitation and alcoholic hallucinosis, an antipsychotic (3,5)[C] (haloperidol [Haldol]) can be used, but this requires close observation, as it lowers the seizure threshold.

Neuroleptic agents are not recommended as monotherapy due to their association with increased mortality, longer duration of delirium, and complications when compared with sedative agents (6)[A].

ADDITIONAL THERAPIES
Peripheral neuropathy and cerebellar dysfunction merit physical therapy evaluation.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Criteria for inpatient admission:

- CIWA-Ar score >15, or severe withdrawal
- Concurrent acute illness requiring inpatient care
- Laboratory abnormalities (e.g., electrolyte imbalance)
- Poor ability to follow up or no reliable social support
- Pregnancy
- History of severe withdrawal symptoms
- History of withdrawal seizures or DTs
- Concurrent psychiatric illness

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

- Managing alcohol withdrawal is only first step toward treating patient’s
underlying AUD.
- Discharge arrangements should include:
  - Development of plan to engage patient in further treatment
  - Transition to outpatient substance use counseling, peer support groups, and/or residential treatment facility
  - Prescription of available medication-assisted treatment such as acamprosate (Campral), naltrexone (ReVia, Vivitrol), or disulfiram (Antabuse)
- Acamprosate (666 mg PO TID): glutamate and GABA modulator indicated to reduce cravings
  - Contraindications: renal impairment (CrCl <30 mL/min)
- Naltrexone (50 mg/day PO; 380 mg IM every 4 weeks): opiate receptor antagonist, theorized to attenuate pleasurable effects of alcohol and reduce craving. Initiate therapy after patient is opioid-free for at least 7 days.
  - Contraindications: acute hepatitis/liver failure, concomitant opioid therapy
- Disulfiram (250 mg/day PO): irreversibly inhibits aldehyde dehydrogenase, blocking alcohol metabolism, leading to an accumulation of acetaldehyde
  - Second-line option due to limited evidence of efficacy for relapse prevention
  - Contraindications: concomitant use of metronidazole and ethanol-containing products, psychosis, severe myocardial disease, and coronary occlusion

**Patient Monitoring**
Frequent follow-up to monitor for relapse

**PATIENT EDUCATION**
- FamilyDoctor.Org: alcoholism (Spanish resources available)

**PROGNOSIS**
Mortality from severe withdrawal (DTs) is 1–5%.

**COMPLICATIONS**
Occurs more frequently in individuals who have prior episodes of withdrawal or
concomitant illnesses

SEE ALSO

Substance Use Disorders

CODES
ICD10

- F10.239 Alcohol dependence with withdrawal, unspecified
- F10.230 Alcohol dependence with withdrawal, uncomplicated
- F10.231 Alcohol dependence with withdrawal delirium

CLINICAL PEARLS

- Any BZD dose should be patient-specific, sufficient to achieve and maintain a “light somnolence” (e.g., sleeping but easily arousable), and should be tapered off carefully even after AWS resolves to prevent BZD withdrawal.
- Administer thiamine before patient receives glucose, so as not to precipitate Wernicke encephalopathy.
- Avoid administering diazepam and lorazepam intramuscularly because of erratic absorption.
- Managing AWS is the first step toward treating AUD. Ensure patient has outpatient follow-up to continue treatment.
ALOPECIA

Anastasia N. Gevas, DO • Kelli M. Gevas, MD

BASICS

DESCRIPTION

• Alopecia: absence of hair from areas where it normally grows
  – Anagen phase: growing hairs, 90% scalp hair follicles at any time, lasts 2 to 6 years
  – Catagen phase: regression of follicle, <1% follicles, lasts 3 weeks
  – Telogen phase: Resting phase lasts 2 to 3 months, 50 to 150 telogen hairs shed per day.

• Classified as scarring (cicatricial), nonscarring, or structural

• Scarring (cicatricial) alopecia
  – Inflammatory disorders leading to permanent hair loss and follicle destruction
  – Includes lymphocytic, neutrophilic, and mixed subtypes

• Nonscarring alopecia
  – Lack of inflammation, no destruction of follicle
  – Includes focal, patterned, and diffuse hair loss such as androgenic alopecia, alopecia areata (AA), telogen effluvium, anagen effluvium, syphilitic hair loss

• Structural hair disorders
  – Brittle or fragile hair from abnormal hair formation or external insult

EPIDEMIOLOGY

• Androgenic alopecia: onset in males between 20 and 25 years of age; onset in females prior to 40 years of age, affecting as many as 70% of women >65 years of age

• AA: onset usually prior to 30 years of age; men and women are equally affected; well-documented genetic predisposition

Incidence

Incidence greatest in Caucasians, followed by Asians, African Americans, and Native Americans; in females, 13% premenopausal, with as many as 70% females >65 years of age
Prevalence
- Androgenic alopecia: in males, 30% Caucasian by 30 years of age, 50% by 50 years of age, and 80% by 70 years of age
- AA: 1/1,000 with lifetime risk of 1–2%
- Scarring alopecia: rare, 3–7% of all hair disorder patients

ETIOLOGY AND PATHOPHYSIOLOGY
- Scarring (cicatricial) alopecia
  - Slick smooth scalp without follicles evident
  - Inflammatory disorders leading to permanent destruction of the follicle; it is not known what causes inflammation to develop.
  - Three major subtypes based on type of inflammation: lymphocytic, neutrophilic, and mixed
  - Primary scarring includes discoid lupus, lichen planopilaris, dissecting cellulitis of scalp, primary fibrosing, among others.
  - Secondary scarring from infection, neoplasm, radiation, surgery, and other physical trauma, including tinea capitis
  - Central centrifugal cicatricial alopecia most common form of scarring hair loss in African American women; etiology unknown but likely secondary to hair care practices
- Nonscarring alopecia
  - Focal alopecia
  - AA
    - Patchy hair loss, usually autoimmune in etiology, T cell–mediated inflammation resulting in premature transition to catagen then telogen phases
    - May occur with hair loss in other areas of the body (alopecia totalis [entire scalp]), alopecia universalis (rapid loss of all body hair)
    - Nail disease frequently seen
    - High psychiatric comorbidity (1)
  - Alopecia syphilitica: “moth-eaten” appearance, secondary syphilis
  - Postoperative, pressure-induced alopecia: from long periods of pressure on one area of scalp
  - Temporal triangular alopecia: congenital patch of hair loss in temporal area, unilateral or bilateral
  - Traction alopecia: patchy, due to physical stressor of braids, ponytails, hair weaves
- Pattern hair loss
– Androgenic alopecia: hair transitions from terminal to vellus hairs
– Male pattern hair loss: androgen-mediated hair loss in specific distribution; bitemporal, vertex occurs where androgen sensitive hairs are located on scalp. This is a predominantly hereditary condition (2).
  o Increased androgen receptors, increased 5-α reductase leads to increased testosterone conversion in follicle to dihydrotestosterone (DHT). This leads to decreased follicle size and vellus hair (2).
  o Norwood Hamilton classification type I to VII
  o Female pattern hair loss: thinning on frontal and vertex areas (Ludwig classification, grade I to III). Females with low levels of aromatase have more testosterone available for conversion to DHT (3). This carries an unclear inheritance pattern (2).
  o Polycystic ovarian syndrome, adrenal hyperplasia, and pituitary hyperplasia all lead to androgen changes and can result in alopecia.
– Drugs (testosterone, progesterone, danazol, adrenocorticosteroids, anabolic steroids)
  ● Trichotillomania: intentional pulling of hair from scalp; may present in variety of patterns
  ● Diffuse alopecia
    – Telogen effluvium: sudden shift of many follicles from anagen to telogen phase resulting in decreased hair density but not bald areas
      o May follow major stressors, including childbirth, injury, illness; occurs 2 to 3 months after event
      o Can be chronic with ongoing illness, including SLE, renal failure, IBS, HIV, thyroid disease, pituitary dysfunction
      o Adding or changing medications (oral contraceptives, anticoagulants, anticonvulsants, SSRIs, retinoids, β-blockers, ACE inhibitors, colchicine, cholesterol-lowering medications, etc.)
      o Malnutrition from malabsorption, eating disorders; poor diet can contribute.
    – Anagen effluvium
      o Interruption of the anagen phase without transition to telogen phase; days to weeks after inciting event
      o Chemotherapy is most common trigger.
      o Radiation, poisoning, and medications can also trigger.
  ● Structural hair disorders
    – Multiple inherited hair disorders including Menkes disease, monilethrix, and so forth. These result in the formation of abnormal hairs that are weakened.
– May also result from chemical or heat damaging from hair processing treatments

**Genetics**
- Family history of early patterned hair loss is common in androgenic alopecia, also in AA.
- Rare structural hair disorders may be inherited.

**RISK FACTORS**
- Genetic predisposition
- Chronic illness including autoimmune disease, infections, cancer
- Physiologic stress including pregnancy and childbirth
- Poor nutrition
- Medication, chemotherapy, radiation
- Hair chemical treatments, braids, weaves/extensions

**GENERAL PREVENTION**
Minimize risk factors where possible.

**COMMONLY ASSOCIATED CONDITIONS**
- See “Etiology and Pathophysiology.”
- Vitiligo—4.1% patients with AA, may be the result of similar autoimmune pathways (4)

**DIAGNOSIS**

**HISTORY**
- Description of hair loss problem: rate of loss, duration, location, degree of hair loss, other symptoms including pruritus, infection, hair care, and treatments
- Medications
- Medical illness including chronic disease, recent illness, surgeries, pregnancy, thyroid disorder, iron deficiency, poisonings, exposures
- Psychological stress
- Dietary history and weight changes
- Family history of hair loss or autoimmune disorders

**PHYSICAL EXAM**
- Pattern of hair loss
  - Generalized, patterned, focal
  - Assess hair density, vellus versus terminal hairs, broken hair.
- Scalp scaling, inflammation, papules, pustules
- Presence of follicular ostia to determine class of alopecia
- Hair pull test
  - Pinch 25 to 50 hairs between thumb and forefinger and exert slow, gentle traction while sliding fingers up.
    - Normal: 1 to 2 dislodge
    - Abnormal: ≥6 hairs dislodged
    - Broken hairs (structural disorder)
      - Broken-off hair at the borders patch that are easily removable (in AA)
- Hair loss at other sites, nail disorders, skin changes
- Clinical signs of thyroid disease, lupus, or other diseases
- Clinical signs of virilization: acne, hirsutism, acanthosis nigricans, truncal obesity

**DIFFERENTIAL DIAGNOSIS**
Search for type of alopecia and then for reversible causes.

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- No testing may be indicated depending on clinical appearance.
- Nonandrogenic alopecia
  - TSH, CBC, ferritin
  - Consider: LFT, BMP, zinc, VDRL, ANA, prolactin all depending on clinical history and exam
- Androgenic alopecia: especially in females
  - Consider free testosterone and dehydroepiandrosterone sulfate.

*Diagnostic Procedures/Other*
- Light hair-pull test: Pull on 25 to 50 hairs; ≥6 hairs dislodged is consistent with shedding (effluvium, AA).
- Direct microscopic exam of the hair shaft
  - Anagen hairs: elongated, distorted bulb with root sheath attached
  - Telogen hairs: rounded bulb, no root sheath
  - Exclamation point hairs: club-shaped root with thinner proximal shaft (AA)
  - Broken and distorted hairs may be associated with multiple hair
dystrophies.
- Biopsy: most important in scarring alopecia
- Ultraviolet light fluorescence and potassium hydroxide prep (to rule out tinea capitis)

TREATMENT

GENERAL MEASURES
- Consider potential harms and benefits to the patient prior to treatment. Many will gain an improved quality of life that is of benefit (2)[A].
- Stop any possible medication causes if possible; this will often resolve telogen effluvium (5)[C].
- Treat underlying medical causes (e.g., thyroid disorder, syphilis).
- Traction alopecia: Change hair care practices; education
- Trichotillomania: often requires psychological intervention to induce behavior change

MEDICATION
- Nonscarring
- Androgenic alopecia: Treatment must be continued indefinitely; can use in combination
  - Minoxidil (Rogaine): 2% topical solution (1 mL BID) for women, 5% topical solution (1 mL BID) or foam (daily) for men; works in 60% of cases (3)[A]
    - Unclear mechanism of action; appears to prolong anagen phase
    - Adverse effects: skin irritation, hypertrichosis of face/hands, tachycardia; category C in pregnancy (3)[A]
  - Finasteride (Propecia): 1 mg/day for men and women (off-label) (6)[A]; 30–50% improvement in males, poor data in females (2)[A]
    - 5-α reductase inhibitor, reduces DHT in system, increases total and anagen hairs, slows transition of terminal to vellus hairs
    - Works best on vertex, least in anterior, temporal areas
    - Adverse effects: loss of libido, gynecomastia, depression. Caution in liver disease; absolutely no use or contact during pregnancy, category X, reliable contraception required in female use (6)[A]
  - Spironolactone (Aldactone): 100 to 200 mg/day (off-label) (3)[C]
    - Aldosterone antagonist, antiandrogen; blocks the effect of androgens,
decreasing testosterone production
  o Adverse effects: dose-dependent, hyperkalemia, menstrual irregularity, fatigue; category D in pregnancy
  - Ketoconazole: decreases DHT levels at follicle, works best with minoxidil in female androgenic alopecia (6)[A]
  - Combination: Finasteride + minoxidil has superior efficacy to monotherapy (2)[A].

- AA: no FDA-approved treatment; high rate of spontaneous remission in patchy AA. Treatments all focus on symptom management rather than etiology.
- Intralesional steroids
  - Triamcinolone: 2.5 to 5.0 mg/mL (3)[C]
    o First line if <50% scalp involved
    o Inject 0.1 mL into deep dermal layer at 0.5 to 1.0 cm intervals with 1/2 in 30-gauge needle, every 4 to 6 weeks; maximum 20 mg/session (1)[C]
    o Adverse effects: local burning, pruritus, skin atrophy
  - Topical steroids: very limited evidence for efficacy
    - Betamethasone: 0.1% foam shows limited hair regrowth (1)[C].
      o Adverse effects: folliculitis, high relapse rate after discontinuation
  - Systemic glucocorticoids: Use in extensive, multifocal AA; may induce regrowth but requires long-term monthly treatment to maintain growth (1)[B]
    o Adverse effects: hyperglycemia, adrenal insufficiency, osteoporosis, cataracts, obesity
    o Psychiatric: SSRIs, psychiatric care, support groups
  - PUVA light therapy + prednisone: moderate effectiveness in diffuse AA
  - Tinea capitis: See “Tinea (Capitis, Corporis, Cruris).”

SURGERY/OTHER PROCEDURES
- Hair transplantation
- Wigs, hairpieces, extensions
- Surgical: graft transplantation, flap transplantation, or excision of the scarred area; used primarily in scarring alopecia
- Platelet-rich plasma: has been shown to restore dormant hair follicles and stimulate new hair growth
- Laser therapies to promote growth: lacks evidence

COMPLEMENTARY & ALTERNATIVE
MEDICINE
- Many herbal medications are available; no clear evidence at this time
- Volumizing shampoos can help remaining hair look fuller.

ONGOING CARE

DIET
If nutritional deficit noted, supplementation may be necessary.

PATIENT EDUCATION
National Alopecia Areata Foundation: www.naaf.org

PROGNOSIS
- **Androgenic alopecia**: Prognosis depends on response to treatment.
- **AA**: often regrows within 1 year even without treatment. Recurrence common. 10% have severe, chronic form; poor prognosis more likely with long duration, extensive hair loss, autoimmune disease, nail involvement, and young age
- **Telogen effluvium**: maximum shedding 3 months after the inciting event and recovery following correction of the cause. Usually subsides in 3 to 6 months but takes 12 to 18 months for cosmetically significant regrowth; rarely, permanent hair loss, usually with long-term illness
- **Anagen effluvium**: Shedding begins days to a few weeks after the inciting event, with recovery following correction of the cause; rarely, permanent hair loss
- **Traction alopecia**: excellent prognosis with behavior modification
- **Cicatricial alopecia**: hair follicles permanently damaged; prognosis depends on type of alopecia and available treatments.
- **Tinea capitis**: excellent prognosis with treatment

**SEE ALSO**

- Hyperthyroidism; Lichen Planus; Lupus Erythematosus, Systemic (SLE); Polycystic Ovarian Syndrome (PCOS); Syphilis; Tinea (Capitis, Corporis, Cruris)
- Algorithm: Alopecia

**CODES**

**ICD10**

- L65.9 Nonscarring hair loss, unspecified
- L64.9 Androgenic alopecia, unspecified
- L63.9 Alopecia areata, unspecified

**CLINICAL PEARLS**

- History and physical are necessary in determining type of alopecia for appropriate treatment.
- Treatment of underlying medical condition or removal of triggering medication will often resolve hair loss.
- Educating the patient about the nature of the condition and expectations is key to care.
- Alopecia can affect the psychological condition of the patient, and it may be
necessary to address this in any type of hair loss.
ALTITUDE ILLNESS

Douglas J. Bosin, DO • Phillip R. Hendley, MD • William S. Ellis, DO

BASICS

DESCRIPTION

- A spectrum of medical problems ranging from mild discomfort to fatal illness that occur on ascent to higher altitudes as a direct result of inadequate acclimatization
- Categories of altitude: intermediate, 1,520 to 2,440 m; high, 2,440 to 4,270 m; very high, 4,270 to 5,490 m; and extreme, >5,490 m
- Altitude illness can affect anyone, including experienced and fit individuals. For most, it is an unpleasant but self-limiting syndrome that will not require medical intervention (1).
- Acute mountain sickness (AMS): Symptoms associated with a physiologic response to a hypobaric, hypoxic environment. Onset usually occurs within 6 to 12 hours after ascending >2,500 m. Neurologic symptoms predominate, ranging from mild/moderate headache and malaise to severe impairment.
- High-altitude pulmonary edema (HAPE): noncardiogenic pulmonary edema; typically after 2 or more days at altitudes >3,000 m, rare between 2,500 and 3,000 m
- High-altitude cerebral edema (HACE): a potentially fatal neurologic syndrome considered to be the end stage of AMS; onset after at least 2 days at altitudes >4,000 m
- System(s) affected: nervous/pulmonary (2)
- Synonym(s): mountain sickness

Geriatric Considerations

- Risk does not increase with age.
- Age alone should not preclude travel to high altitude; allow extra time to acclimatize.
- Worsening of preexisting medical problems referred to as altitude-exacerbated conditions

Pediatric Considerations
Altitude illness seems to have the same incidence in children as in adults; diagnosis may be delayed in younger children.
Any child who experiences behavioral symptoms after recent ascent should be presumed to be suffering from altitude illness.

**Pregnancy Considerations**
- The risk during pregnancy is unknown.
- No evidence suggests that exposure to high altitudes (1,500 to 3,500 m) poses a risk to a pregnancy.
- It may be prudent to advise a low-altitude dwelling for any pregnant woman experiencing complications.

**EPIDEMIOLOGY**
Most epidemiologic studies are limited to relatively homogeneous male populations.

**Incidence**
- AMS: 10–25% of unacclimatized persons who ascend to 2,500 m; 50–85% at altitudes of 4,500 to 5,500 m
- HAPE/HACE: 0.5–1.0% of unacclimatized persons with 2 or more days of exposure at altitudes exceeding 3,000 m. Risk increases with rate of ascent (2).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Individuals with a prior history of AMS, HACE, or HAPE are at a higher risk of recurrent AMS.
- Hypobaric hypoxia and hypoxemia are the pathophysiologic precursors to altitude illness.
- Symptoms of AMS may be the result of cerebral swelling, either through vasodilatation induced by hypoxia or through cerebral edema.
- Other mechanisms include impaired cerebral autoregulation, release of vasogenic mediators, and alteration of the blood–brain barrier.
- HAPE is a noncardiogenic pulmonary edema characterized by exaggerated pulmonary hypertension leading to vascular leakage through overperfusion, stress failure, or both.

**RISK FACTORS**
- Failure to acclimatize at a lower altitude
Ascent rate >300 to 500 m/day
Extreme altitude
Increased duration at high altitude
Higher altitude during sleep cycle
Prior history of altitude illness
Cardiac congenital abnormalities
Female gender
History of migraines (3)
Younger age (<46 years)

GENERAL PREVENTION

General guidelines
- Preacclimatization protects against altitude illness.
- >2,500 m, do not ascend faster than 500 m/day; rest every 3 to 4 days (2).
- Lower sleeping elevation: “Climb high and sleep low” for anyone going >3,500 m.
- Avoid heavy exertion for the first 1 to 3 days at altitude.
- Avoid respiratory depressants (alcohol and sedatives).
- Preascent physical conditioning is not preventive but does increase odds of summiting.

Drug prophylaxis
- Acetazolamide, dexamethasone, and ibuprofen (see “Treatment”)
- For prevention of HAPE only (if at risk):
  o Consider nifedipine, β-agonists, and tadalafil (see “Treatment”).

DIAGNOSIS

HISTORY

AMS, mild to moderate symptoms
- Headache, plus at least one of:
  o Anorexia
  o Nausea or vomiting
  o Dizziness or light-headedness
  o Insomnia

AMS, severe symptoms
- Increased headache
- Irritability
– Marked fatigue
– Dyspnea with exertion
– Nausea and vomiting
– HAPE (Lake Louise diagnostic criteria)
  o At least two of the following: dyspnea at rest, cough, weakness, decreased exercise performance, chest tightness, congestion
  o AND at least two of crackles or wheezing in at least one lung field, central cyanosis, tachycardia, tachypnea (Note: Fatigue may be a sign of pulmonary edema.)
– HACE symptoms: mental status changes (irrational behavior, lethargy, obtundation, coma)
  o May progress to ataxia and confusion (2)

PHYSICAL EXAM

● HAPE
  – Lung crackles or wheezing
  – Central cyanosis
  – Tachycardia
  – Tachypnea

● HACE
  – Abnormal mental status exam (behavioral change, lethargy, obtundation, coma)
  – Truncal ataxia
  – Papilledema, retinal hemorrhage, cranial nerve palsies
  – Focal neurologic deficits (rare)

DIFFERENTIAL DIAGNOSIS

● Onset of symptoms >3 days at a given altitude, the absence of headache, or the lack of rapid response to oxygen or descent suggests an alternative diagnosis.

● AMS/HACE
  – Subarachnoid hemorrhage, CNS mass, cerebrovascular accident
  – Migraine headache
  – Dehydration
  – Ingestion of toxins, drugs, or alcohol
  – Carbon monoxide exposure
  – CNS infection
  – Acute psychosis

● HAPE
- Pneumonia
- Cardiogenic pulmonary edema
- Spontaneous pneumothorax
- Pulmonary embolism
- Asthma
- Bronchitis
- Myocardial infarction
- Hyperventilation syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- AMS: Laboratory studies are nonspecific and rarely required for diagnosis.
- HAPE: severe hypoxemia demonstrated with oximetry or blood gas analysis
- Chest radiographs usually show patchy infiltrates. Clear lung fields suggest an alternate diagnosis.
- ECG may show sinus tachycardia or right-sided heart strain (1).

**TREATMENT**

**GENERAL MEASURES**

- Individuals without previous altitude exposure should adhere to acclimatization guidelines.
- Early recognition is important.
- Stop ascent, acclimatize at the same altitude, and/or descend if symptoms do not abate over 24 hours. Definitive treatment is to descend to a lower altitude. Dramatic improvement accompanies even modest reductions in altitude.
- Oxygen helps relieve symptoms. Give continuously by cannula or mask, and titrate to \( \text{SaO}_2 > 90\% \) (1).
- Given that most high-altitude travel is recreational and acetazolamide has side effects, prophylaxis is not generally recommended in children (4).
- AMS
  - Acetazolamide reduces mild to moderate symptoms of AMS (see “Medication”).
  - Dexamethasone may also be effective in treating moderate AMS (see “Medication”).
- HAPE
  - Oxygen therapy
– Minimize exertion and keep patient warm.
– Immediate descent or evacuation to a lower altitude
– Portable hyperbaric therapy (2 to 15 psi using Gamow bag or Chamberlite) is an effective and practical alternative when descent is not possible.
– Nifedipine (see “Medication”)

**HACE**
– Immediate descent
– Supplemental oxygen (highest flow available; maintain SaO₂ >90%)
– Dexamethasone (see “Medication”)
– Portable hyperbaric therapy if available and unable to descend

**MEDICATION**

**First Line**

– Oxygen: 2 to 15 L/min to maintain SaO₂ >90% until symptoms improve
– Acetazolamide: If patient has a history of problems at altitude and/or plans to ascend >500 m/day above 2,500 m, consider therapy for primary prevention. Avoid in patients with a sulfonamide allergy.
  – Primary prevention of AMS: 125 to 250 mg PO BID starting 8 to 24 hours before ascent and continued for 2 days at a stable altitude; not recommended for children as a preventive medication (5)[A]
  – Treatment of AMS: 250 mg PO BID until symptoms resolve; pediatric dose: 2.5 mg/kg q12h (4)

– Dexamethasone: may significantly reduce the incidence and severity of AMS. Adverse side effects are rare (5)[A].
  – Prevention of AMS: 2 mg PO q6h or 4 mg PO q12h, starting 1 day before ascent and discontinued cautiously after 2 days at maximum altitude. Do not use for pediatric prevention (4).
  – Treatment of AMS: 4 mg PO/IV/IM q6h; pediatric dose: 0.15 mg/kg dose q6h (4)
  – Treatment of HACE: 8 mg PO/IV/IM initially and then 4 mg q6h; pediatric dose: 0.15 mg/kg dose q6h (4)

– Nifedipine (reduces pulmonary arterial pressure) (1)
  – Prevention of HAPE: 30 mg extended-release PO BID starting 1 day prior to ascent and continued for 2 days at maximum altitude
  – Treatment of HAPE: 30 mg extended-release PO q12h (likely unnecessary if oxygen is available)

– Tadalafil: Consider for the prevention of HAPE (1).
  – Prevention HAPE: 10 mg PO BID 1 day prior to ascent in HAPE
susceptible individual

- Adjunct therapy
  - Salmeterol
    - Prevention and possible treatment of HAPE: 125 µg inhaled BID starting 1 day before ascent and continued for 2 days at maximum altitude
    - Recommended as adjunct to nifedipine
  - NSAIDs: possible benefit in AMS prevention and treatment of headache
    - Aspirin: 325 mg PO q4h for total 3 doses
    - Ibuprofen: 400 to 600 mg PO q8h
  - Antiemetics
    - Prochlorperazine: 10 mg PO/IM q6–8h
    - Promethazine: 25 to 50 mg PO/IM/PR q6h
- Other trialed therapies
  - Furosemide: previously studied for treatment of AMS or HACE, 20 to 80 mg PO/IV q12h for a total of 2 doses. Currently out of favor; not recommended for prophylaxis; not established for use in HAPE
  - Hypertonic saline/mannitol: No evidence supports use.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Outpatient treatment for mild cases

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- For mild cases, no follow-up is needed.
- For more severe cases, follow until symptoms subside.

PATIENT EDUCATION
Counsel patients about the risks of high-altitude travel and how to recognize symptoms of high-altitude illness.

PROGNOSIS
Most cases of mild to moderate AMS are self-limiting and do not require medical intervention. Patients may resume ascent once the symptoms subside.
HAPE and HACE respond well to descent, evacuation, and/or pharmacologic treatment if identified early.

COMPLICATIONS
High-altitude retinal hemorrhage, can cause visual changes, is usually asymptomatic.

REFERENCES

ADDITIONAL READING

CODES
ICD10
- T70.20XA Unspecified effects of high altitude, initial encounter
- T70.20XD Unspecified effects of high altitude, subsequent encounter
- T70.20XS Unspecified effects of high altitude, sequela
CLINICAL PEARLS

- Slow ascent and timely descent are important in the prevention and treatment of high-altitude illnesses.
- Lack of symptom resolution with appropriate descent suggests an alternative diagnosis.
- High-flow oxygen, followed by oxygen titrated to maintain $\text{SaO}_2 > 90\%$, is the first-line treatment for all patients with more than mild altitude illness.
ALZHEIMER DISEASE
Jill A. Grimes, MD, FAAFP

BASICS
DESCRIPTION
- Alzheimer disease (AD) is the most common cause of dementia in the elderly.
- Degenerative neurologic disease with progressive impairment in ≥2 years:
  - Memory, executive function, attention, language, or visuospatial skills
  - With significant interference in ability to function in work, home, or social interactions
- New diagnostic criteria released in 2011 emphasize full spectrum of disease (1)[A]:
  - Preclinical AD (research purposes only: biomarkers present; subtle decline evident to patient but cognitive tests in “normal” range)
  - Mild cognitive impairment (MCI): Social, occupational, and functional skills are preserved despite significant decline in cognition.
  - Alzheimer dementia
- System(s) affected: nervous
- Synonym(s): presenile dementia; senile dementia of the Alzheimer type

Geriatric Considerations
Asymptomatic screening is not recommended.

EPIDEMIOLOGY
- Predominant age: >65 years
- 2/3 females, 1/3 males in United States

Incidence
1 in 8 Americans age >65 years (13%); ~50% at >85 years

Prevalence
>5.2 million in United States; >36 million worldwide
- 200,000 younger onset (<65 years)

ETIOLOGY AND PATHOPHYSIOLOGY
● Unknown but involves amyloid beta accumulation initially, then synaptic
dysfunction, neurodegeneration, and eventual neuronal loss
● Age, genetics, systemic disease, behaviors (smoking), and other host factors
may influence the response to amyloid beta and/or the pace of progression
toward the clinical manifestations of AD.

**Genetics**
● Positive family history in 50%, but 90% of AD is sporadic:
  – APOE4 increases risk but full unclear
● Familial/autosomal dominant AD accounts for <5% AD:
  – Amyloid precursor protein (APP), presenilin-1 (PS-1), and presenilin-2
    (PS-2)

**RISK FACTORS**
● Aging, family history, APOE4, Down syndrome
● HTN, cardiovascular, and carotid artery disease
● Smoking (2- to 4-fold increase)
● Head trauma

**GENERAL PREVENTION**
● NSAIDs, estrogen, and vitamin E do NOT delay AD; insufficient evidence for
  statins (2)[A]
● Intellectual challenge (puzzles) and regular physical exercise may offer
  preventive benefit.
● Control vascular risk factors (e.g., hypertension); lowering cholesterol may
  retard pathogenesis of AD.
● Ginkgo biloba may be beneficial for cognition but not activities of daily
  living.
● Physical activities and omega-3 fatty acids may help to prevent or delay
  cognitive decline.
● Ultrasound (US) may help to identify asymptomatic patients at increased risk
  with chronic brain hypoperfusion secondary to cardiovascular or carotid
  artery pathology.

**COMMONLY ASSOCIATED CONDITIONS**
● Down syndrome
● Depression
DIAGNOSIS

Degenerative neurologic disease with progressive impairment in ≥2 areas:
- Memory, executive function, attention, language, or visuospatial skills AND
- Significant interference in ability to function in work, home, or social interactions

HISTORY
- Include family members in interview (for accuracy and for behavioral assessment).
- Progressive and disruptive memory loss
- Depression, anhedonia, or apathy
- Intellectual decline, difficulty with calculations, multiple missed appointments
- Loss of interest, social withdrawal
- Date or time confusion
- Occupational dysfunction or personality change
- Restlessness and sleep disturbances

PHYSICAL EXAM
- Neurologic exam to rule out other causes
- Folstein Mini-Mental State Exam (MMSE): copyrighted but available (http://www.aafp.org/afp/20010215/703.html)
- Counting coins test: “If I gave you a nickel, quarter, dime, and penny, how much is that?”
- No focal neurologic signs
- Short-term memory loss
- Acalculia (e.g., cannot balance checkbook)
- Agnosia: inability to recognize objects
- Apraxia: inability to carry out movements
- Confabulation
- Delusions
- Impaired abstraction
- Decreased attention to hygiene
- Visuospatial distortion
- Late signs: psychotic features, mutism

DIFFERENTIAL DIAGNOSIS
- Depression
- Vascular dementia, multi-infarct dementia
- Lewy body disease
- Dementia associated with Parkinson disease
- Normal pressure hydrocephalus
- Creutzfeldt-Jakob disease
- End-stage multiple sclerosis
- Brain tumor: primary or metastatic
- Subdural hematoma
- Progressive multifocal leukoencephalopathy
- Metabolic dementia (hypothyroidism)
- Drug reactions, alcoholism, other addictions
- Dementia pugilistica
- Toxicity from liver and kidney failure
- Vitamin and other nutritional deficiencies
- Vasculitis
- Neurosyphilis

**DIAGNOSTIC TESTS & INTERPRETATION**

Neuropsychological testing: Order if clinical picture is confusing or to help determine level of independence for skills such as balancing checkbooks, driving, or managing medicines.

**Initial Tests (lab, imaging)**

- To help rule out other causes of dementia
  - CBC, ESR
  - Chemistry panel
  - Thyroid-stimulating hormone
  - Folate and B<sub>12</sub> levels
  - Venereal disease reaction level (VDRL) or rapid plasma reagin (RPR)
  - HIV antibody (selected cases)
  - APOE4 or biomarker testing *is not routine*.

**Imaging**: Controversy exists; may identify moderate cortical atrophy or ventricular enlargement

- Consider MRI or CT scan if
  - Cognitive decline is recent and rapid; age <60 years; history of stroke; gait disturbance or focal neurologic signs
  - Cancer, urinary incontinence, bleeding disorder, or current use of anticoagulants
– Single-photon emission computed tomography (SPECT) and positron emission tomography (PET): only if diagnostic uncertainty after CT or MRI; 

*insufficient evidence to use alone*

– Medicare pays for PET to distinguish AD from frontotemporal dementia under specific requirements; *this should not be routine.*

**Follow-Up Tests & Special Considerations**

Genetic testing for APOE4 or for familial AD types; discuss with genetic counselor.

**Test Interpretation**

- **Gross:** diffuse cerebral atrophy in hippocampus, amygdala, and some subcortical nuclei
- **Microscopic**
  - Neuritic senile plaques
  - Neurofibrillary tangles
  - Pyramidal cell loss
  - Decreased cholinergic innervation (other neurotransmitters variably decreased)
  - Degeneration of locus ceruleus and basal forebrain nuclei of Meynert; amyloid angiopathy

**TREATMENT**

**GENERAL MEASURES**

- Optimize treatment of associated comorbid conditions (including hearing and vision loss).
- Analyze environment for safety and security and avoid sudden changes in environment.
- High-fat (70%) diet found to be as effective in slowing progression as medications in small trials.
- Assess spouse/caregiver burnout.
- Advance directives, living will, power of attorney

**MEDICATION**

**First Line**

2014 meta-analysis shows cholinesterase inhibitors (ChEIs) and memantine are
“able to stabilize or slow decline in cognition, function, behavior, and global change” (3)[A].

- Debate continues regarding the clinical significance and cost-effectiveness of AD medication.
- ChEIs
  - Equally effective; all have potential for GI side effects; monitor for bradycardia/syncope; associated with abnormal dreams
  - When used for at least 6 months, provide mild benefit in cognition, ADL, and behavior. (No deterioration for 6 months is evidence of efficacy.)
  - Shown to reduce nursing home placement by 20% after 25 months of treatment
  - Best in mild to moderate disease (MMSE 10 to 24); may be effective in Lewy body dementia
  - Donepezil (Aricept): Start at 5 mg/day PO; may increase to 10 mg/day after 1 month.
  - Tablets disintegrating tablets; generic available
  - Caution with digoxin or β-blockers (as donepezil may prolong PR interval).
  - Aricept 23-mg tablet approved in 2010
  - Rivastigmine (Exelon): Start at 1.5 mg PO BID, increase by 1.5 mg BID every 2 weeks; maintenance 6 to 12 mg/day total
  - Capsule, solution, or patch (patch greatly reduces side effects)
  - Indicated for both AD and Parkinson dementia
  - Galantamine (Razadyne): Start at 4 mg BID for 4 weeks, then increase by 4 mg BID every month with goal of 16 to 24 mg/day dose.
  - Tablets, solution, extended-release (ER) capsule, and transdermal formulations (ER and transdermal have daily dosing)
- N-methyl-D-aspartate (NMDA) receptor antagonists (for moderate to severe AD; MMSE 5 to 14)
  - Monotherapy or in combination with acetylcholinesterase inhibitors (Combination shows some benefit on neuropsychiatric symptoms and behavioral problems in moderate-to-severe AD, although additional financial cost/benefit unclear.) (4)[A]
  - Memantine (Namenda): 5 mg/day; titrate to target dose of 10 mg BID after 4 weeks.
  - Often improves behavioral issues
  - Beneficial for cognition and physician’s global impression; increases risk of somnolence, weight gain, confusion, hypertension, nervous system disorders, and falling (5)[A]

mebooksfree.com
For depression (occurs in 1/3 of patients), SSRIs preferred first line

Insomnia
- Trazodone 25 to 100 mg at bedtime, zolpidem (Ambien) 5 mg at bedtime, zaleplon (Sonata) 5 to 10 mg at bedtime, ramelteon (Rozerem) 8 mg at bedtime
- Avoid diphenhydramine in elderly due to negative cognitive effects and risk of urinary retention (males).

Moderate anxiety/restlessness: Consider low-dose, short-acting benzodiazepines, buspirone, or SSRIs (efficacy unproven).

Severe aggressive agitation
- Behavioral techniques and environmental modification help more than medications for wandering, restlessness, uncooperativeness, hoarding, and irritability:
  - Consider changing environment, rewards, behavioral redirection, hearing aids, and bright light therapy.
- Memantine (Namenda): Start at 5 mg/day, with starter pack titrating to target dose of 10 mg BID after 4 weeks.

Antipsychotics (both conventional and atypical) are associated with increased mortality and acute care hospital admissions in elderly patients with dementia.

Antiepileptic agents (carbamazepine valproate, lamotrigine) have been used for their mood stabilizing properties.

Precautions
- Avoid anticholinergic drugs, such as tricyclic antidepressants and antihistamines.
- Ginkgo biloba: Avoid anticoagulants and aspirin.
- Benzodiazepines may produce paradoxical excitation or daytime drowsiness.
- Triazolam (Halcion) can produce confusion, memory loss, and psychotic behavior.
- Benzodiazepines may increase serum phenytoin concentration.
- Cimetidine may increase benzodiazepine concentration.
- Donepezil (Aricept): Use with caution with anticholinergic medication, in sick sinus syndrome, or history of peptic ulcers.
- Paroxetine increases donepezil levels.

Second Line
- Estrogen, and NSAIDs should not be routinely recommended due to lack of evidence and safety concerns (1)[A]. Although statins have been postulated to prevent cognitive decline, there is no evidence to support routine use of statins
to treat dementia, and there is good evidence that statins do not prevent cognitive decline or dementia when given to people with history or risk of vascular disease (2)[A].

- Vitamin E—no evidence for prevention of dementia, but one study shows moderate quality evidence that it may slow functional decline in AD (6)[A].
- Bexarotene (a lymphoma drug) may reduce brain amyloid; research trials are in progress.

**ISSUES FOR REFERRAL**
- Assess driving safety (vision, spatial relations, hearing, judgment):
- Support groups for patient and family: Alzheimer Association:
  http://www.alz.org/

**ADDITIONAL THERAPIES**
- Exercise to reduce restlessness.
- Cognitive challenge; traditional and computerized training both effective
- Occupational, music, aroma, and pet therapy

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Huperzine A 400 mg (herbal ChEIs) may improve cognition with minimal side effects.
- Ginkgo biloba extracts (120 mg/day) show conflicting efficacy in treatment of AD but may be beneficial.
- Coenzyme Q10 is not effective.
- Acupuncture continues to be assessed and may enhance effectiveness of Alzheimer medications.
- Omega-3 fatty acids—no strong evidence of benefit

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Schedule regular follow-up (3 months) to assess medical complications,
provide support for family, and assess need for placement.

- Serial mental status testing is potentially helpful, but bedside tests (Folstein MMSE) offer wide variability and lack of sensitivity.

PATIENT EDUCATION

- Alzheimer Association: http://www.alz.org/
- Explain progressive nature of the disease and start advance directives planning as early as possible.

PROGNOSIS

Poor: Average survival from diagnosis is 4 to 8 years (diagnosis is often delayed).

COMPLICATIONS

- Behavioral: hostility, agitation, wandering, falls
- Metabolic: infection, dehydration, drug toxicity
- “Sundowning” (increase full-spectrum lights), depression (1/3 of patients), suicide

REFERENCES

ADDITIONAL READING

SEE ALSO

Depression; Hypothyroidism, Adult; Substance Use Disorders

CODES

ICD10

- G30.9 Alzheimer’s disease, unspecified
- G30.0 Alzheimer’s disease with early onset
- G30.1 Alzheimer’s disease with late onset

CLINICAL PEARLS

- Daily intellectual stimulation, such as puzzles, and moderate physical exercise may help prevent AD.
- Imaging studies have low yield in patients with a history typical of AD.
- Encourage families to join a chapter of the Alzheimer Association and to pursue advanced directive planning early in the course of the disease.
- Atypical antipsychotic medications increase mortality.
AMENORRHEA

Thomas A. Waller, MD • Sally-Ann L. Pantin, MD, FAAFP

BASICS

DESCRIPTION

- Primary amenorrhea
  - No menses by age 13 years with absence of secondary sexual characteristics OR
  - No menses by age 15 years with normal secondary characteristics
- Secondary amenorrhea: cessation of menses for 3 months if previously normal menstruation or 6 months if a history of irregular cycles
- System(s) affected: endocrine/metabolic; reproductive

Pregnancy Considerations

Pregnancy is by far the most common cause of secondary amenorrhea.

EPIDEMIOLOGY

Prevalence

- Primary amenorrhea: <1% of female population
- Secondary amenorrhea: 3–5% of female population
- No evidence for race and ethnicity affecting prevalence

ETIOLOGY AND PATHOPHYSIOLOGY

Absence of menses that can be temporary or permanent due to dysfunction of the hypothalamus, pituitary, uterus, ovaries, or vagina

ETIOLOGY

- Primary amenorrhea
  - Gonadal dysgenesis (e.g., Turner syndrome [45,X]) or failure (e.g., autoimmune, idiopathic)
  - Anatomic abnormalities (e.g., müllerian agenesis, imperforate hymen, transverse vaginal septum)
  - Hypothalamic–pituitary abnormalities
- Functional hypothalamic amenorrhea (reduced GnRH secretion, e.g., weight loss/anorexia nervosa)
- Constitutional delay of puberty
- Central lesions (tumors, hypophysitis, granulomas)
- Pituitary dysfunction (hyperprolactinemia, abnormal follicle-stimulating hormone [FSH], luteinizing hormone [LH], or GnRH)
- Thyroid dysfunction
  - Polycystic ovarian syndrome (PCOS)
  - Androgen insensitivity syndrome
- Secondary amenorrhea
  - Pregnancy
  - Hypothalamic dysfunction (reduced GnRH secretion)
    - Functional hypothalamic amenorrhea (stress, anorexia nervosa, and/or excessive exercise)
    - Hypothalamic tumors
    - Severe systemic illness (e.g., diabetes mellitus type 1 or celiac disease)
- Pituitary disease (e.g., hyperprolactinemia, Sheehan syndrome, Cushing syndrome)
- Thyroid disease
- PCOS
- Ovarian disorders (e.g., premature ovarian failure [due to chemotherapy, radiation, Fragile X syndrome] or ovarian tumors)
- Uterine disorders (e.g., intrauterine adhesions [Asherman syndrome])
- Pathophysiology varies, depending on etiology.

**Genetics**
May occur with Turner syndrome or testicular feminization

**RISK FACTORS**
- Obesity
- Excessive exercise (commonly associated “female athlete triad”)
- Eating disorders
- Malnutrition
- Anovulatory disorders
- Stress
- Treatment with antipsychotic medications

**GENERAL PREVENTION**
Maintenance of proper body mass index (BMI) and healthy lifestyle with respect to food and exercise

COMMONLY ASSOCIATED CONDITIONS
- Premature ovarian failure may be associated with autoimmune abnormalities (autoimmune thyroiditis, type 1 diabetes).
- PCOS is associated with insulin resistance and obesity.
- Decreased exposure to estrogen may increase risk for osteopenia or osteoporosis.

DIAGNOSIS

HISTORY
- Review of systems including weight change, symptoms of pregnancy or menopause, virilizing changes, cyclic pelvic pain, galactorrhea, headaches, vision changes, fatigue, palpitations, polyuria/polydipsia
- Growth and pubertal development history, including age of breast development, pubertal growth spurt, and adrenarche (early sexual maturation)
- History of chronic illness, trauma, surgery, medications, prior chemotherapy or radiation
- Psychiatric history
- Social history, including diet and exercise history, drug abuse, and sexual history
- Family history of delayed or absent puberty

PHYSICAL EXAM
- General appearance
- Vital signs, height, weight, growth percentile and BMI, hypotension, bradycardia, hypothermia (anorexia nervosa)
- HEENT exam: evidence of dental erosions, trauma to palate (bulimia), visual field defect, funduscopic changes, cranial nerve findings (prolactinoma), webbed neck (Turner syndrome), thyromegaly
- Skin exam: evidence of androgen excess (acne, hirsutism), acanthosis nigricans (PCOS), fine downy hair on body (anorexia nervosa), striae
- Breast: state of development, evidence of galactorrhea (prolactinoma), shield chest (Turner syndrome)
- Pelvic exam: presence or absence of pubic hair (if sparse: androgen
insensitivity or deficiency); clitoromegaly (androgen excess); distention or bulging of external vagina (imperforate hymen); thin, pale vaginal mucosa without rugae (estrogen deficiency and ovarian failure); presence of cervical mucus (evidence for estrogen production); blind vaginal pouch (müllerian agenesis, androgen insensitivity syndrome); ovarian enlargement (tumors, PCOS, autoimmune oophoritis)

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- **Primary amenorrhea**
  - Serum human chorionic gonadotropin (hCG), prolactin (PRL), thyroid-stimulating hormone (TSH) and FSH
  - If no breast development:
    - FSH low suggests primary hypothalamic or pituitary etiology.
    - FSH elevated suggests gonadal failure, and karyotype analysis should be performed.
  - If breast development has occurred, evaluate for anatomic abnormalities. If uterus is absent or abnormal, perform karyotype analysis, testosterone level, and dehydroepiandrosterone sulfate (DHEA-S).

- **Secondary amenorrhea**
  - Serum hCG, PRL, TSH, and FSH
    - If PRL >100 ng/mL suggests empty sella syndrome or pituitary adenoma; perform MRI for evaluation.
    - If PRL <100 ng/mL: Evaluate for other etiologies, of which medications are most common.
    - To determine endogenous estrogen production, perform a progestin challenge (see “Treatment”): If withdrawal bleed, likely chronic anovulation (most commonly PCOS). If no withdrawal bleed, perform estrogen and progestin challenge (see “Treatment”):
      - If no bleed: Consider outflow tract obstruction.
      - If bleed occurs: Check FSH/LH: elevated in premature ovarian failure; decreased in pituitary tumors, eating disorders, chronic illness
  - If there is evidence for hyperandrogenism, measure total testosterone, DHEA-S, and 17-OH progesterone levels. Initiate evaluation for androgen-secreting tumor if testosterone >200 ng/dL.
  - Imaging is not generally indicated as a first approach.
  - US may show ovarian cysts (PCOS), presence or absence of uterus, and endometrial thickness (consider MRI if unable to tolerate US probe).
Follow-Up Tests & Special Considerations

- Women <30 years with ovarian failure (see below) should have karyotype analysis and be investigated for premutations of FMR1 gene (fragile X syndrome) and for adrenal antibodies.
- If absence of uterus or foreshortened vagina, karyotype analysis should also be performed.
- Laparoscopy: diagnosis of streak ovaries (Turner syndrome) or polycystic ovaries
- Hysterosalpingogram: Rule out Asherman syndrome and other etiologies of outflow obstruction.

Diagnostic Procedures/Other

- If constitutional delay is suspected, obtain bone age.
- If hypothalamic amenorrhea from functional suppression is suspected, consider dual energy x-ray absorptiometry (DEXA) scan to assess bone loss (1).

TREATMENT

GENERAL MEASURES
Identify and correct underlying pathology if possible.

MEDICATION

- Progesterone challenge and replacement: medroxyprogesterone (Provera): 10 mg/day for 10 days will result in withdrawal bleed within 7 days of last dose if hypothalamic–pituitary–gonadal axis is intact (i.e., amenorrhea is a consequence of anovulation and lack of progesterone) although experts disagree (2).
- Estrogen replacement: Cycling with a combination oral contraceptive (containing 35 or 50 μg of estrogen) or conjugated estrogen (Premarin) 0.625 mg for 25 days with progesterone added as above for the last 10 days will result in a withdrawal bleed if the uterus and lower genital tract are normal (hypothalamic-pituitary axis pathologic).
- Use of hormonal therapies will not correct the underlying problem. Other drugs might be required to treat specific conditions (e.g., bromocriptine for hyperprolactinemia).
- Use of hormonal replacement therapy is not recommended for long-term
management of amenorrhea in older women.
– May be safe for symptom management in young women
– Give to maintain secondary sex characteristics and to prevent osteoporosis in adolescents and young women (3)[A].
• Combination estrogen/progesterone contraceptives (oral contraceptive pills [OCPs], patch, ring) replace estrogen and prevent pregnancy.
– Have a positive effect on bone mineral density in oligo-/amenorrheic women but not in functional hypothalamic amenorrhea (4)[A]
– Can decrease hirsutism in PCOS
• Calcium supplementation: 1,500 mg/day if cause is hypoestrogenism
• Because PCOS is related to insulin resistance, metformin (Glucophage) has been used (start at 500 mg BID) to correct metabolic abnormalities, improve ovulation, and restore normal menstrual patterns. Of note, treatment with metformin has shown an increase in clinical pregnancy rates but not in live birth rates (5)[A].
• Functional hypothalamic amenorrhea appears to improve with administration of exogenous leptin (still under investigation) (6)[C].
• Contraindications to estrogen administration
  – Pregnancy, thromboembolic disease, previous myocardial infarct or cerebrovascular accident, estrogen-dependent malignancy, severe hepatic impairment or disease
• Precautions
  – Patients with amenorrhea who desire pregnancy should not be given hormone replacement therapy but should receive treatment for infertility based on the specific cause.

ISSUES FOR REFERRAL
Many causes of amenorrhea require referral to specialists in ob/gyn, endocrine, surgery, and/or psychiatry.

SURGERY/OTHER PROCEDURES
• Hymenectomy for primary amenorrhea if due to imperforate hymen
• Lysis of adhesions in Asherman syndrome is often effective in restoring regular menses and fertility.
• If karyotype is XY, gonads must be removed due to increased risk of tumors.
• Patients with congenital short vagina can undergo surgery to create a functioning vagina.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
If excessive exercise is suspected, activity level should be reduced by 25–50%.

Patient Monitoring
- Depends on the cause and treatment chosen
- If hormonal replacement is used, discontinue after 6 months to assess spontaneous resumption of menses.

DIET
- Correct overweight or underweight by dietary management and behavior modification.
- If PCOS is the etiology, a weight-loss diet will help restore ovulation.

PATIENT EDUCATION
- Educate on the circumstances and complications of her condition and its underlying etiology.
- Specific educational resources are helpful (e.g., prenatal classes and menopause support groups).
- Discuss the expected duration of amenorrhea (temporary or permanent), effect on fertility, and the long-term sequelae of untreated amenorrhea (e.g., osteoporosis, vaginal dryness).
- Appropriate contraceptive advice should be given because fertility returns before menses.
- Additional support may be needed if the amenorrhea is associated with a reduction in, or loss of, fertility.

PROGNOSIS
Reflects the underlying cause. In functional hypothalamic amenorrhea, one study demonstrated 83% reversal rate in presence of obvious contributing factor.

COMPLICATIONS
- Estrogen-deficiency symptoms (e.g., hot flashes, vaginal dryness) and osteoporosis in prolonged hypoestrogenic amenorrhea
- Increased risk of endometrial cancer in patients whose amenorrhea is secondary to anovulation with estrogen excess (obesity, PCOS)
• Premature ovarian failure may increase cardiovascular risk.

ADDITIONAL READING

SEE ALSO

• Hyperthyroidism; Hypothyroidism, Adult; Osteoporosis and Osteopenia
• Algorithms: Amenorrhea, Primary (Absence of Menarche by Age 16); Amenorrhea, Secondary; Delayed Puberty

CODES
ICD10
- N91.2 Amenorrhea, unspecified
- N91.0 Primary amenorrhea
- N91.1 Secondary amenorrhea

CLINICAL PEARLS
- First evaluate whether amenorrhea is primary or secondary and exclude pregnancy. TSH and PRL are usual first blood tests.
- Progestin challenge may cause withdrawal bleed in women with intact hypothalamic–pituitary–gonadal axis.
ANAL FISSURE
Anne Walsh, ANP-BC • Kasyap Trivedi, MD

BASICS

DESCRIPTION
Anal fissure (fissure in ano): longitudinal tear in the lining of the anal canal distal to the dentate line, most commonly at the posterior midline; characterized by a knifelike tearing sensation on defecation, often associated with bright red blood per rectum. This common benign anorectal condition is often confused with hemorrhoids; may be acute (<8 weeks) or chronic (>8 weeks) in duration.

EPIDEMIOLOGY
- Affects all ages. Common in infants 6 to 24 months; not common in older children, suspect abuse, or trauma; elderly less common due to lower resting pressure in the anal canal.
- Sex: male = female; women more likely to get anterior midline fissures (25%) versus men (8%).

Incidence
Exact incidence is unknown (1). Patients often treat with home remedies and do not seek medical care.

Prevalence
- 80% of infants, usually self-limited
- 10–20% of adults, most of whom do not seek medical advice.

ALERT
- Lateral fissure: Rule out infectious disease.
- Atypical fissure: Rule out Crohn disease.

ETIOLOGY AND PATHOPHYSIOLOGY
High-resting pressure within the anal canal (usually as a result of constipation/straining) leads to ischemia of the anoderm, resulting in splitting of the anal mucosa during defecation and spasm of the exposed internal sphincter.
**Genetics**
None known

**RISK FACTORS**
- Constipation (25% of patients)
- Diarrhea (6% of patients)
- Passage of hard or large-caliber stool
- High-resting pressure of internal anal sphincter (prolonged sitting, obesity)
- Trauma (sexual activity or abuse, foreign body, childbirth, mountain biking)
- Prior anal surgery with scarring/stenosis
- Inflammatory bowel disease (Crohn disease)
- Infection (chlamydia, syphilis, herpes, tuberculosis)

**GENERAL PREVENTION**
All measures to prevent constipation; avoid straining and prolonged sitting on toilet.

**COMMONLY ASSOCIATED CONDITIONS**
Constipation, irritable bowel syndrome, Crohn disease, tuberculosis, leukemia, and HIV

**DIAGNOSIS**

**HISTORY**
- Severe, sharp rectal pain, often with and following defecation but can be continuous; some patients will see bright red blood on the stool or when wiping.
- Occasionally, anal pruritus or perianal irritation

**PHYSICAL EXAM**
- Gentle spreading of the buttocks with close inspection of the anal verge will reveal a smooth-edged tear in the anodermal tissue, typically posterior midline, occasionally anterior midline, rarely eccentric to midline. Digital rectal exam and anoscopy are painful and can be deferred if inspection confirms the diagnosis.
- Minimal edema, erythema, or bleeding may be seen.
- Chronic fissures may demonstrate rolled edges, exposed muscle fibers,
hypertrophic papillae at proximal end, and a sentinel pile (tag) at distal end.

**DIFFERENTIAL DIAGNOSIS**
- Thrombosed external hemorrhoid: swollen, painful mass at anal verge
- Perirectal abscess: tender, warm erythematous induration or fluctuance
- Perianal fistula: abnormal communication between rectum and perianal epithelium with feculent or purulent drainage
- Pruritus ani: shallow excoriations rather than true fissure

**DIAGNOSTIC TESTS & INTERPRETATION**

*Diagnostic Procedures/Other*
- Avoid anoscopy/sigmoidoscopy initially unless necessary for other diagnoses or for chronic fissures.
- Due to pain, some patients may require exam under anesthesia in order to confirm the diagnosis.

**TREATMENT**

The goal of treatment is to avoid repeated tearing of the anal mucosa with resultant spasm of the internal anal sphincter by decreasing the patient’s high sphincter tone and addressing its underlying cause.

**GENERAL MEASURES**
- Wash area gently with warm water; consume high-fiber diet, increase fluids, add daily fiber supplement; avoid constipation, maintain healthy weight.
- Medical therapy for chronic fissures usually initiated in a stepwise manner: nitrates, calcium channel blockers, botulinum toxin

**MEDICATION**

*First Line*

Acute fissures—50% heal spontaneously with supportive measures (1)[B].
- Stool softeners (docusate) daily
- Osmotic laxatives as needed (polyethylene glycol)
- Fiber supplements (e.g., psyllium, methylcellulose, inulin) daily and increase fluid intake
- Topical analgesics (2% lidocaine gel or 3% cream) 2 to 3 times daily for pain
control

- Topical lubricants/emollients (Balneol cream, petroleum jelly) for comfort with defecation
- Topical hydrocortisone 1% cream short-term for inflammation/pruritus
- Sitz baths (sit in plain warm water bath for 10 to 20 minutes) 2 to 3 times daily after bowel movements

**Second Line**

Chronic fissures—will not heal without treatment (2)[A]:

- Chemical sphincterotomy
  - Topical nitroglycerin 0.2–0.4% ointment applied BID; nitroglycerin 0.4% ointment available commercially (Rectiv): marginally but significantly better than placebo in healing (48.6% vs. 37%); late recurrence common (50%) (2)[A]; reduces resting anal pressure through the release of nitric oxide. Headache, hypotension, dizziness are major side effects (20–30%).
  - Topical calcium channel blockers (nifedipine 0.2–0.3% gel, diltiazem 2% ointment), applied 2 to 4 times per day, relax the internal sphincter muscle, thereby reducing the resting anal pressure no better than nitrates for healing but fewer side effects consider as first-line treatment (1)[A]. Oral calcium channel blockers confer lower healing rates, more side effects, and equal rates of recurrence (3[A]).
  - Botulinum toxin 4 mL (20 units) injected into the internal sphincter muscle: no better than topical nitrates for healing but fewer side effects; inhibits the release of acetylcholine from nerve endings to inhibit muscle spasm (4)[B]

**ISSUES FOR REFERRAL**

- Late recurrence is common (50%) particularly if the underlying issue remains untreated (constipation, irritable bowel).
- Medical therapy usually tried for 90 to 120 days prior to colorectal surgery referral. Select patients with chronic fissure may be referred directly for surgical therapy due to proven superior healing rates (1)[A].

**ADDITIONAL THERAPIES**

Anococcygeal support (modified toilet seat) may offer some advantage in chronic fissures to avoid surgery.

**SURGERY/OTHER PROCEDURES**

- Surgery typically reserved for failure of medical therapy
**Lateral internal sphincterectomy (LIS)** involves division of the internal sphincter muscle and is the surgical procedure of choice (95% healing) (1)[A].

- Risk for fecal or flatus incontinence: up to 45% short term, up to 6–8% long term
- Open and closed techniques have similar results and are equally acceptable (1)[A].
- May be repeated for recurrent fissures with similar outcomes (1)[C]
- Not typically performed on women of childbearing potential due to increased risk of fecal incontinence with or without subsequent obstetrical injury (1)

**Anocutaneous flap** safe alternative to LIS with less incontinence but lower healing rates (1)[B]

**Botulinum toxin** injections also first-line treatment; less effective (60–80% healing) than surgery but fewer complications (4)[C]

- Risk for fecal or flatus incontinence: 18% short term, no long term
- May be repeated as needed with same efficacy; lower doses as effective as higher doses with lower rates of complications including incontinence and recurrence (5)[A]

- Higher doses combined with fissurectomy may be as effective as surgical sphincterotomy (6)[C].

**Controlled pneumatic balloon dilation** may be used by gastroenterologists if surgical referral not available; should not be used first line as benefits are not well documented. Uncontrolled manual dilation is no longer recommended (5)[C].

---

**ONGOING CARE**

**DIET**

High fiber (>25 g/day; augment with daily fiber supplements); increase fluid intake, decrease caffeine.

**PATIENT EDUCATION**

- Avoid prolonged sitting or straining during bowel movements; drink plenty of fluids; avoid constipation; lose weight if obese.
- Avoid use of triple antibiotic ointment and long-term use of steroid creams to anal area.
- Use a finger cot or glove when applying nitroglycerin ointment, and apply...
first dose before bedtime to minimize side effects.
- Topical medications should be applied directly to anal verge; no need to insert rectally
- Alternative medicine therapies (hibiscus extract, clove oil, anal self-massage) need further study before they can be recommended as first-line treatment.

PROGNOSIS
Most acute fissures heal within 6 weeks with conservative therapy. Medical therapy is less likely to be successful for chronic anal fissures (40% failure rate).

COMPLICATIONS
- Chronic fissure is a complication of nonhealing acute fissure.
- Recurrence is a common complication especially when underlying cause is not addressed.
- Abscess and fistula formation are less common complications.
- Fecal and flatus incontinence are primarily associated with surgery (5–45% postop), which may become permanent (up to 8% long term, primarily to flatus).

REFERENCES
ADDITIONAL READING

CODES

**ICD10**
- K60.2 Anal fissure, unspecified
- K60.0 Acute anal fissure
- K60.1 Chronic anal fissure

CLINICAL PEARLS

- Avoid anoscopy or sigmoidoscopy initially unless necessary for other diagnoses.
- Best chance to prevent recurrence is to treat the underlying cause (e.g., chronic constipation).
- No medical therapy approaches the cure rate of surgery for chronic fissure.
ANEMIA, APLASTIC

Muthalagu Ramanathan, MD • Jan Cerny, MD, PhD

BASICS

DESCRIPTION

- Pancytopenia due to hypocellular bone marrow without the presence of infiltrates or fibrosis; classified as acquired (much more common) and congenital
- Acquired aplastic anemia: insidious onset; due to exogenous insult triggering an autoimmune reaction; often responsive to immunosuppression
- Congenital forms: rare, mostly present in childhood (exception is atypical presentation of Fanconi syndrome in adults; 30s for males and 40s for females)
- The occurrence of specific mutations in genes of the telomere complex in acquired aplastic anemia has blurred the distinction between the congenital and acquired forms.
- System(s) affected: heme/lymphatic/immunologic
- Synonym(s): hypoplastic anemia; panmyelophthisis; refractory anemia; aleukia hemorrhagica; toxic paralytic anemia

ALERT

- Early intervention for aplastic anemia greatly improves the chances of treatment success.
- Hematopoietic growth factors require close monitoring in newly diagnosed patients.

Geriatric Considerations

The elderly are often exposed to large numbers of drugs and therefore may be more susceptible to acquired aplastic anemia.

Pediatric Considerations

- Congenital forms of aplastic anemia require different treatment regimens than acquired forms.
- Acquired aplastic anemia is seen in children exposed to ionizing radiation or treated with cytotoxic chemotherapeutic agents.
**Pregnancy Considerations**
- Pregnancy is a real but rare cause of aplastic anemia. Symptoms may resolve after delivery and with termination.
- Complications in pregnancy can occur from low platelet counts and paroxysmal nocturnal hemoglobinuria–associated aplastic anemia.

**EPIDEMIOLOGY**
- Predominant age: biphasic 15 to 25 years (more common) and >60 years
- Predominant sex: male = female

**Incidence**
- 2 to 3 new cases per million per year in Europe and North America
- The incidence is 3-fold higher in Thailand and China versus the Western world.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Idiopathic (~70% of the cases)
- Drugs: phenylbutazone, chloramphenicol, sulfonamides, gold, cytotoxic drugs, antiepileptics (felbamate, carbamazepine, valproic acid, phenytoin)
- Viral: HIV, Epstein-Barr virus (EBV), nontypeable postinfectious hepatitis (not A, B, or C), parvovirus B19 (mostly in the immunocompromised), atypical mycobacterium
- Toxic exposure (benzene, pesticides, arsenic)
- Radiation exposure
- Immune disorders (systemic lupus erythematosus, eosinophilic fasciitis, graft versus host disease)
- Pregnancy (rare)
- Congenital (Fanconi anemia, dyskeratosis congenita, Shwachman-Diamond syndrome, amegakaryocytic thrombocytopenia)

  The immune hypothesis: activation of T cells with associated cytokine production leading to destruction or injury of hematopoietic stem cells. This leads to a hypocellular bone marrow without marrow fibrosis (2).
- The activation of T cells likely occurs because of both genetic and environmental factors. Exposure to specific environmental precipitants, diverse host, genetic risk factors, and individual differences in characteristics of immune response likely account for variations in its clinical manifestations and patterns of responsiveness to treatment.
- Telomerase deficiency leads to short telomeres. This leads to impaired
regenerative capacity and hence a reduction in marrow progenitors and qualitative deficiency in the repair capacity of hematopoietic tissue.

- Reduction of natural killer cells in the bone marrow

**Genetics**

- Telomerase mutations found in a small number of patients with acquired and congenital forms. These mutations render carriers more susceptible to environmental insults.
- Mutations in genes called TERC and TERT were found in pedigrees of adults with acquired aplastic anemia who lacked the physical abnormalities or a family history typical of inherited forms of bone marrow failure. These genes encode for the RNA component of telomerase.
- HLA-DR2 incidence in aplastic anemia is twice that in the normal population.

**RISK FACTORS**

- Treatment with high-dose radiation or chemotherapy
- Exposure to toxic chemicals
- Use of certain medications
- Certain blood diseases, autoimmune disorders, and serious infections
- Tumors of thymus (red cell aplasia)
- Pregnancy, rarely

**GENERAL PREVENTION**

- Avoid possible toxic industrial agents.
- Use safety measures when working with radiation.

**DIAGNOSIS**

**HISTORY**

- Solvent and radiation history; family, environmental, travel, and infectious disease history
- Patients are often asymptomatic but may have frequent infections, fatigue, shortness of breath, headache, or bleeding/bruising.

**PHYSICAL EXAM**

- Mucosal hemorrhage, petechiae
- Pallor
- Fever
- Hemorrhage, menorrhagia, occult stool blood, melena, epistaxis
- Dyspnea
- Palpitations
- Progressive weakness
- Retinal flame hemorrhages
- Systolic ejection murmur
- Weight loss
- Signs of congenital aplastic anemia
  - Short stature
  - Microcephaly
  - Nail dystrophy
  - Abnormal thumbs
  - Oral leukoplakia
  - Hyperpigmentation (café au lait spots) or hypopigmentation

**DIFFERENTIAL DIAGNOSIS**
Includes other causes of bone marrow failure and pancytopenia

- Hypoplastic MDS
- Marrow replacement
  - Acute lymphoblastic leukemia
  - Lymphoma
  - Hairy cell leukemia (increased reticulin and infiltration of hairy cells)
  - Large granular lymphocyte leukemia
  - Fibrosis
- Megaloblastic hematopoiesis
  - Folate deficiency
  - Vitamin $B_{12}$ deficiency
- Paroxysmal nocturnal hemoglobinuria, hemolytic anemia (dark urine), pancytopenia, and venous thrombosis (classically hepatic veins)
- Systemic lupus erythematosus
- Prolonged starvation or anorexia nervosa (bone marrow is gelatinous with loss of fat cells and increased ground substance)
- Transient erythroblastopenia of childhood
- Drug-induced agranulocytosis that may be reversible on withdrawal of drug
- Overwhelming infection
  - HIV with myelodysplasia
  - Viral hemophagocytic syndrome
DIAGNOSTIC TESTS & INTERPRETATION

Screening tests to exclude other etiologies
- CBC and absolute reticulocyte count
- Blood smear exam
- Cytogenetic studies to exclude MDS and of peripheral lymphocytes if <35 years of age to exclude Fanconi anemia
- Liver function test
- Viral serology: hepatitis A, B, C; EBV; cytomegalovirus (CMV); HIV
- Vitamin B₁₂ and folate levels
- Autoantibody screening antinuclear antibody (ANA) and anti-DNA
- Flow cytometry looking for glycosylphosphatidylinositol (GPI), negative neutrophils and RBCs for detecting paroxysmal nocturnal hemoglobinuria
- Fetal hemoglobin in children
- Red cell adenosine deaminase (pure red cell aplasia)
- Cytogenetic analysis of bone marrow

Initial Tests (lab, imaging)
- CBC: pancytopenia, anemia (usually normocytic), leukopenia, neutropenia, thrombocytopenia
- Decreased absolute number of reticulocytes
- Increased serum iron secondary to transfusion
- Normal total iron-binding capacity (TIBC)
- High mean corpuscular volume (MCV) >104
- CD 34+ cells decreased in blood and marrow
- Urinalysis: hematuria
- Abnormal liver function tests (hepatitis)
- Increased fetal hemoglobin (Fanconi)
- Increased chromosomal breaks under specialized conditions (Fanconi)
- Molecular determination of abnormal gene (Fanconi)
- CT of thymus region if thymoma-associated RBC aplasia suspected
- Radiographs of radius and thumbs (if congenital anemia suspected)
- Renal ultrasound (to rule out congenital anemia or malignant hematologic disorder)
- Chest x-ray to exclude infections such as mycobacterial infection

Diagnostic Procedures/Other
Bone marrow aspiration and biopsy
Test Interpretation

- Normochromic RBC
- Bone marrow
  - Decreased cellularity (<10%): no fibrosis, no malignant cells or dysplastic cells seen
  - Decreased megakaryocytes
  - Decreased myeloid precursors
  - Decreased erythroid precursors
  - Prominent fat spaces and marrow stroma, polyclonal plasma cells

TREATMENT

Early treatment increases the chance of success. Two major options: immunosuppressive therapy (3) and hematopoietic stem cell transplantation. Treatment decisions are based on age of the patient, severity of disease, and availability of a human leukocyte antigen (HLA)–matched sibling donor for transplantation.

GENERAL MEASURES

- Supportive measures: RBC and platelet transfusions. Use only irradiated leukocyte-reduced or CMV-negative blood especially if patient is a candidate for hematopoietic stem cell transplantation.
- Antibiotics, antifungals, antivirals when appropriate, especially if ANC <200 cells/μL
- Oxygen therapy for severe anemia
- Good oral hygiene
- Control menorrhagia with norethisterone or oral contraceptive pills.
- Avoid/discontinue causative agents/isolation if necessary.
- HLA testing on all patients and their immediate families
- Transfusion support (judiciously prescribed RBCs for severe anemia; platelets for severe thrombocytopenia)
  - Transfuse when
    - Hb <8 g/dL or if Hb <9 g/dL and symptomatic ± congestive heart failure (CHF)
    - Platelet count is <10 × 10⁹ or if <20 × 10⁹ with fever

MEDICATION
**First Line**

- Corticosteroids (methylprednisolone) are often given with immunosuppressive regimens.
- Immunosuppressive therapy (3)
  - A combination of antithymocyte globulin (ATG) plus cyclosporine. ATG eliminates lymphocytes, and cyclosporine blocks T-cell function.
- ATG
  - Horse serum containing polyclonal antibodies against human T cells
  - First-choice treatment for patients >40 years of age and for younger patients without a compatible donor. Consider in patients 30 to 40 years of age.
  - May be used as a single agent but has better response in combination with cyclosporine
- Cyclosporine following initial ATG therapy for minimum of 6 months (3)
  - Monitor through blood levels. Normal values for assays vary.
- Granulocyte-colony stimulating factor (G-CSF)
  - May be used in conjunction with ATG and cyclosporine
  - Shows faster neutrophil recovery, but survival is not improved.
  - Treatment is costly and is disputed in two randomized trials.
  - Note: Relapses may occur after the initial response to the immunosuppressive therapy if cyclosporine is discontinued too early.
  - Restarting cyclosporine can lead to a response in up to 25% of patients.
- Stem cell transplant: matched sibling allogeneic stem cell transplant for age <20 years and absolute neutrophil count (ANC) <500 or age 20 to 40 years and ANC <200

**Second Line**

- Rabbit ATG + cyclosporine
- Campath
- Androgen such as Danazol (4) can be used in a subset of patients who have anemia as a predominant feature.
- Matched unrelated donor stem cell transplant
- Eltrombopag (5)
- In trials: thrombopoietin (TPO) receptor agonists (5)

**SURGERY/OTHER PROCEDURES**

- First-line hematopoietic stem cell transplantation is recommended for patients with an HLA-identical donor and severe aplastic anemia when age <20 years and ANC <500 or age 20 to 40 years and ANC <200. Consider in patients 40
to 50 years of age in good general medical condition.
- Patients >40 years of age have higher rates of graft versus host disease and graft rejection.
- Unrelated donor transplants should be considered for patients age <40 years without HLA-matched sibling donor who fail first-line immunosuppressive therapy.
- Thymectomy for thymoma

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
If neutropenic, use antiseptic mouthwash such as chlorhexidine.

**ONGOING CARE**

**DIET**
If neutropenic, avoid foods that can expose patient to bacteria, such as uncooked foods. [https://www.lls.org/managing-your-cancer/diet-guidelines-for-immunosuppressed-patients](https://www.lls.org/managing-your-cancer/diet-guidelines-for-immunosuppressed-patients)

**PATIENT EDUCATION**
- Stay away from people who are sick; avoid large crowds.
- Wash your hands often.
- Brush and floss your teeth; get regular dental care to reduce risk of infections.
- Pneumonia vaccine and annual flu shot

**PROGNOSIS**
- Hematopoietic stem cell transplantation with HLA-matched sibling
  - Age <16 years, 91% at 5 years
  - Age >16 years, 70–80% at 5 years
- Immunosuppressive therapy using ATG and cyclosporine: overall survival of 75%; 90% among responders at 5 years

**COMPLICATIONS**
- Infection (fungal, sepsis)
Graft versus host disease in bone marrow transplant recipients (acute 18%; chronic 26%)
- Side effects of immunosuppressant medications
- Hemorrhage
- Transfusion hemosiderosis
- Transfusion hepatitis
- Heart failure
- Development of secondary cancer: leukemia or myelodysplasia (15–19% risk at 6 to 10 years)
- Refractory pancytopenia

CODES
ICD10
- D61.9 Aplastic anemia, unspecified
- D61.89 Oth aplastic anemias and other bone marrow failure syndromes
- D61.01 Constitutional (pure) red blood cell aplasia
CLINICAL PEARLS

- Acquired aplastic anemia has an insidious onset and is caused by an exogenous insult triggering an autoimmune reaction. This form is usually responsive to immunosuppressive therapy.
- Immunosuppressive therapy using ATG and cyclosporine: overall survival of 75%; 90% among responders at 5 years
ANEMIA, CHRONIC DISEASE
Christopher Lin-Brande, MD • Jason C. McCarthy, MD

BASICS
DESCRIPTION
- Otherwise known as anemia of chronic inflammation
- During chronic systemic infection, inflammation, or malignancy, the production of proinflammatory mediators causes inhibition of erythropoiesis as well as the imbalance in iron homeostasis (1).
- Anemia of chronic disease (ACD) is characterized as a normocytic, normochromic, hypoproliferative anemia and classically has low serum iron levels, elevated ferritin levels, and elevated total iron-binding capacity (TIBC) (1,2).
- Anemia is typically mild to moderate with hemoglobin (Hgb) rarely <8 g/dL.

EPIDEMIOLOGY
Prevalence
ACD is the second most common anemia after iron deficiency anemia (IDA) due to the aging population and the high prevalence of chronic infections and inflammatory disorders in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY
- Production of red blood cells is decreased as a result of functional iron deficiency.
- In general, the severity of the anemia will correspond with the severity of the underlying disease (1).
- Proinflammatory cytokines such as interleukins (IL), tumor necrosis factor (TNF), bone morphogenic proteins (BMP), and interferons (IFN) create changes in iron homeostasis in several ways (1):
  - Dysregulating iron homeostasis
  - Diminishing proliferation as well as differentiation of red blood cell progenitor cells
  - Blunting the erythropoietic response
  - Increasing erythrocyte phagocytosis and apoptosis
- Iron overload and the proinflammatory cytokines IL-1, IL-6, and BMP6
increase the production of the iron-regulating hormone hepcidin in hepatocytes, macrophages, and enterocytes (1).
- Hepcidin binds to ferroportin causing internalization and degradation, preventing efflux of iron from stores in macrophages and hepatocytes, stopping iron absorption by duodenal enterocytes.
  - This results in low serum iron levels and inhibited erythropoiesis known as iron-restricted erythropoiesis.
- As a result, iron delivery to erythroid progenitor cells within bone marrow is reduced and erythropoiesis is diminished, causing anemia.

- Erythropoietin (EPO) production and the response to EPO by erythroid bone marrow is suppressed by proinflammatory cytokines such as IL-1, TNF-α, and IFN-γ (1).
- Inflammatory cytokines may also cause erythrophagocytosis and oxidative damage, reducing RBC survival.

COMMONLY ASSOCIATED CONDITIONS
- Chronic systemic diseases
  - Rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), sarcoidosis, temporal arteritis, inflammatory bowel disease (IBD), systemic inflammatory response syndrome (SIRS)
- Hepatic disease or failure
- Congestive heart failure or coronary artery disease
- Chronic kidney disease (CKD)
- Acute or chronic infections
  - Viral
    - HIV, HCV
  - Bacterial
    - Abscess, subacute bacterial endocarditis, tuberculosis, osteomyelitis
  - Fungal
  - Parasitic
- Malignancies
- Cytokine dysregulation (anemia of aging)
- Hypometabolic states
  - Protein malnutrition, thyroid disease, panhypopituitarism, diabetes mellitus, Addison disease

DIAGNOSIS
HISTORY
- ACD is often discovered incidentally on routine CBC with differential.
- ACD presents with the underlying causative infectious, inflammatory, or malignant process without any source of occult bleeding; often, patients will have mild and vague anemia symptoms, such as fatigue, light-headedness, and palpitations (1).
- Those with a cardiovascular condition may experience symptoms of angina, shortness of breath, and reduced exercise capacity with even a moderate Hgb level (10 to 11 g/dL).

PHYSICAL EXAM
Physical exam findings are associated with the underlying condition.

DIFFERENTIAL DIAGNOSIS
- IDA
- Anemia of CKD
- Drug-induced marrow suppression or hemolysis
- Endocrine disorders
- Thalassemia
- Sideroblastic anemia
- Dilutional anemia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Hgb/Hct, mean corpuscular volume (MCV), reticulocyte count, ferritin, B₁₂/folate, serum iron, TIBC
- Hgb (1)
  - Typically, <13 g/dL in males or <12 g/dL in females
  - An Hgb of <8 g/dL suggests a concurrent secondary cause for the anemia.
- MCV
  - Usually normal (80 to 100 fL), but microcytosis may be present with concurrent iron deficiency or long-standing disease (<25% of cases)
- RBC morphology
  - Normocytic and normochromic
  - Increased protoporphyrin levels
- Serum ferritin
  - Nonspecific acute phase reactant
– Normal or slightly elevated (30 to 200 μg/L)
– In CKD, ferritin can reach 800 μg/L.
– Serum ferritin levels <30 μg/L suggests coexisting iron deficiency.

- **Serum iron levels**
  – Low due to increased retention and decreased release from stores
  – <50

- **TIBC**
  – Extremely low
  – <300

- **Absolute reticulocyte count**
  – Inappropriately low (reticulocyte index, 20,000 to 25,000/mL) due to reduced erythropoiesis

- **Serum B₁₂ and folate**
  – Diminished due to decreased absorption or lacking in diet

**Diagnostic Procedures/Other**

- Traditional gold standard: bone marrow biopsy with Prussian blue stainable iron combined with anemia, hypoferrremia, and low TSAT (1)
  – Staining is qualitative and may not be accurate.

- **Reticulocyte Hgb concentration <28 pg (2)**

- **Soluble transferrin receptor (sTfR) and the sTfR/log ferritin index**
  – Ratio reflects erythropoiesis within bone marrow and differentiates among ACD, IDA, and ACD + IDA.
  – However, sTfR alone may have greater clinical value than the sTfR index because transferrin is not affected by chronic disease/inflammation, unlike ferritin.

- **Functional test: supplemental iron increase H/H in IDA and little effect on ACD**

- **Although a known cause of anemia may be present, iron, B₁₂, and folate**
deficiencies should be ruled out.

**TREATMENT**

**GENERAL MEASURES**

- Primary management should focus on the underlying cause of ACD (1).
  - Treatment of the primary disease will generally restore Hgb back to baseline.
- In cases where primary treatment is not possible (e.g., terminal cancer, end-stage renal disease), additional treatment can be considered.
  - The two main forms of treatment are erythropoietin-stimulating agents (ESAs) and transfusions.
  - ACD is frequently responsive to ESAs (epoetin-α, darbepoetin) in pharmacologic doses (3).
  - Replete iron to maximize ESA effectiveness.
  - Transfusion should only be initiated in severe anemia or acute symptoms.
- Currently, no target Hgb exists, but treatment to Hgb >13 g/dL is associated with adverse outcomes (1).
- Coexisting B₁₂ or folate deficiency should be considered and corrected in severe cases of anemia.
  - Reduced dietary intake of nutrients is common among patients who are chronically ill.
  - Patients who regularly undergo hemodialysis will often lose these during treatment.

**MEDICATION**

- ESAs
  - Specifically approved for CKD, but there is evidence that they may also have applications in RA, IBD, HIV, and cancer
  - Indication for ESA therapy is an Hgb <10 g/dL (3)[C].
  - ESAs do not improve symptoms or outcomes in mild anemia of CHF.
  - Do not use in certain cancers: breast, cervical, head and neck, lymphoid, and non–small cell lung cancers. Do not administer to patients with active malignancy not receiving curative therapy.
- Epoetin-α (1,3,4)
  - Indications
    - Hgb <10 g/dL
Fatigue or exertional intolerance
- CKD (eGFR <60 mL/min)
- Anemia due to IBD, RA, hepatitis C
- Chemotherapy in patients with specific malignancies (palliative therapy)
  - Dosing and schedule
    - Lowest effective dose to maintain an Hgb level generally between 10 and 12 g/dL (1,3,4)
    - CKD associated: Start 50 to 100 U/kg SC/IV 3 times per week.
  - Patients with cancer who are undergoing chemotherapy: 150 U/kg SQ 3 times per week or 40,000 U once a week
  - Adverse effects:
    - Increased risk of cardiovascular complications, mortality, and thromboembolism
    - Pure red cell aplasia (decrease in Hgb, low reticulocyte count, normal WBC and platelets)
    - Risk of tumor progression in certain cancer patients
- Darbepoetin-α
  - Long-acting, molecularly modified EPO preparation with a half-life 3 to 4 times longer than recombinant human EPO, reducing the frequency of injections to weekly or biweekly
  - Dosing and schedule
    - Administer SC/IV q1–2wk; hold if Hgb >12 g/dL; IV route is preferred in hemodialysis patients.
  - Adverse effects
    - Similar to EPO
- Epoetin-α or darbepoetin-α dose adjustments
  - Follow FDA-approved labeling.
  - Treatment beyond 6 to 8 weeks without appropriate rise of Hgb (>1 to 2 g/dL) is not recommended.

**ADDITIONAL THERAPIES**
- Iron (3)
  - Indications
    - Coexisting iron deficiency
    - Resistance to EPO
  - Forms
    - Oral: ferrous sulfate. Poorly tolerated (GI side effects); incomplete absorption (due to hepcidin)
    - Intravenous: ferric gluconate, iron sucrose, iron dextran (potential allergic
and anaphylactoid reactions), ferumoxytol

- **Adverse effects**
  - May stimulate hepcidin production and exacerbate iron restriction

- **Benefits**
  - Relatively safe
  - Inexpensive
  - May decrease ESA requirements (DRIVE study)

- **Transfusions**
  - 1 to 2 U packed red blood cells (1)
  - **Indications**
    - Life-threatening/severe anemia: A “restrictive threshold” of Hgb 7 to 8 g/dL to guide transfusion in asymptomatic patients should be used (5)[A].
    - Patients with underlying cardiac or pulmonary disease, active ACS, elderly patients, or patients with acute bleeding or hemorrhagic shock may require transfusion at Hgb of higher threshold (>10 g/dL).
    - Symptomatic anemia (chest pain, SOB, reduced exercise capacity) and/or ECG changes
    - Lack of response to medical therapy
  - **Possible adverse effects**
    - Infection (HIV, hepatitis)
    - Volume overload
    - Transfusion reaction
  - **Specific benefits**
    - Rapid correction of anemia
  - When an infection occurs during EPO therapy, it is best to cease EPO therapy and rely on transfusion therapy instead until the infection is properly treated.

- **Future directions (1)**
  - Antihepcidin antibodies, hepcidin-production inhibitors
  - Anti-BMP, anti–IL-6 antibodies
  - Ferroportin stabilizers
  - Vitamin D (lowers hepcidin)
  - Heparin (impairs hepcidin transcription)

---

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Referral to a hematologist is not always warranted.

**Patient Monitoring**
- Hgb should not be increased >11 to 12 g/dL because normalization of Hgb has been associated with higher mortality (4).
- Baseline and periodic monitoring of transferrin saturation and ferritin levels every 3 months may be of value (3).

**PATIENT EDUCATION**
Patients receiving medical therapy should be advised about the following possible risks:
- Mortality, cardiovascular complications, thromboembolism, progression of cancer

**PROGNOSIS**
ACD does not typically progress.

**COMPLICATIONS**
- Adverse effects of ACD:
  - Mortality
  - Cardiovascular complications
  - Symptoms affecting daily life
- Adverse effects of ESAs:
  - Heightened risk of mortality and/or cardiovascular complications in CKD patients
  - Heightened risk of mortality and/or tumor progression in cancer patients
  - Elevated risk of thromboembolism

**REFERENCES**

**CODES**

**ICD10**

- D63.8 Anemia in other chronic diseases classified elsewhere
- D63.0 Anemia in neoplastic disease
- D63.1 Anemia in chronic kidney disease
CLINICAL PEARLS

- ACD is the second most common anemia seen clinically.
- One of the most common diagnostic problems is making the distinction between ACD, IDA, and combined ACD + IDA.
  - Iron level is usually nondiagnostic.
  - Use markers such as transferrin/TIBC, TSAT, and ferritin to distinguish.
    New markers are under development (hepcidin, sTfR, sTfR index).
- IV iron should be given to all patients treated with ESAs.
- Hgb should be kept in low to normal range.
ANEMIA, IRON DEFICIENCY
Deborah R. Erlich, MD, MMEdEd, FAAFP

BASICS

DESCRIPTION
- Low serum iron associated with low hemoglobin (Hgb) or microcytic, hypochromic red blood cells (RBCs)
- Because normal Hgb varies with age and sex, anemia is defined as Hgb level 2 standard deviations below normal for age and sex (1).
- Onset acute (rapid blood loss) or chronic (slow blood loss, deficient iron intake or absorption)
- Both low Hgb per RBC and fewer RBC in total lead to blood oxygen deficiency, which can have serious systemic consequences.
- System(s) affected: hematologic, lymphatic, immunologic, cardiac, gastrointestinal

Geriatric Considerations
Iron deficiency anemia (IDA) is associated with increased hospitalization and mortality in older adults (2).

Pediatric Considerations
Risks for IDA in children include low birth weight, history of prematurity, lead exposure, low income status, and immigrant status. Additionally, infants who drink cow’s milk before 12 months of age have a higher risk for IDA. USPSTF did not find sufficient evidence for screening low-risk infants; the CDC recommends screening high-risk infants at 6 to 12 months, and the AAP recommends universal screening at 12 months (1)[B].

Pregnancy Considerations
USPSTF recommends screening all pregnant women for IDA. Iron supplements are recommended during pregnancy to improve maternal hematologic indexes, although significant clinical outcomes have not yet been proven (3)[A].

Epidemiology
- Iron deficiency is the most common nutritional deficiency in the world (4,5),
and IDA is the most common cause of anemia (50%) (4).

- Predominant age: all ages but especially toddlers and menstruating and pregnant women
- Predominant sex: female
- Predominant race: Mexican American and black females (4)
- Common in both developing and developed countries

**Incidence**

- Adults: men 2%, women 15–20% annually
- Infants and toddlers: 3–5% annually
- Pregnant patients: may be as high as 20% (1)

**Prevalence**

2 billion people worldwide (5)

- Infants and children age <12 years: 4–7%
- Men: 2–5%
- Menstruating women: 30% (5)

**ETIOLOGY AND PATHOPHYSIOLOGY**

Depletion of iron stores leads to decrease in both reticulocyte count and production of Hgb. Causes:

- Blood loss (menses, GI bleeding, trauma)
- Poor iron intake
- Poor iron absorption (e.g., atrophic gastritis, postgastrectomy, celiac disease)
- Increased demand for iron (e.g., infancy, adolescence, pregnancy, breastfeeding)

**RISK FACTORS**

- Premenopausal woman
- Frequent blood donor
- Pregnancy/lactation, young maternal age
- Strict vegan diet
- Use of NSAIDs
- Hospitalized with frequent blood draws
- Living in or visiting countries with endemic hookworm infection

**GENERAL PREVENTION**

- Screen asymptomatic pregnant women and high-risk children at 1 year of age
Supplementation in asymptomatic children aged 6 to 12 months if at risk for IDA (e.g., malnutrition, abuse, cow’s milk <12 months) (1,3)

- Iron- and vitamin C-rich diet for menstruating women
- Iron 30 mg/day for asymptomatic pregnant women (3)

**COMMONLY ASSOCIATED CONDITIONS**

- GI tract malignancy, peptic ulcer disease (PUD), *Helicobacter pylori* infection, irritable bowel disease
- Hookworm or other parasitic infestations
- Hypermetrorrhagia
- Pregnancy
- Obesity treated with gastric bypass surgery
- Malnutrition
- Medications such as NSAIDs or antacids

**DIAGNOSIS**

**HISTORY**

- Asymptomatic in most cases
- Weakness, fatigue, and/or malaise
- Exertional dyspnea
- Angina with coronary artery disease
- Headaches or inability to concentrate
- Melena
- Pica

**PHYSICAL EXAM**

- Pallor (skin, conjunctivae, sublingual)
- Tachycardia, tachypnea
- Cool extremities
- Brittle nails/hair
- Signs of heart failure

**DIFFERENTIAL DIAGNOSIS**

- GI bleeding (e.g., gastritis, PUD, carcinoma, varices, celiac disease)
- Chronic intravascular hemolysis (e.g., paroxysmal nocturnal hemoglobinuria,
malfunctioning prosthetic valve)
- Defective iron usage (e.g., thalassemia trait, sideroblastosis, G6PD deficiency)
- Defective iron reutilization (e.g., infection, inflammation, cancer, hypothyroid, chronic diseases)
- Hypoproliferation (e.g., decreased erythropoietin from hypothyroidism, renal failure)
- Other anemias such as anemia of chronic disease, thalassemia, lead poisoning

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Screen asymptomatic pregnant women and high-risk children at 1 year of age (1).
- Test with signs and symptoms of anemia and fully evaluate if iron deficiency is confirmed (1,5).
- **Hgb (to define anemia):**
  - <13 g in men and <12 g in women (5)
  - Hgb 2 standard deviations below normal for age and sex (1)
  - Patients with comorbidities (e.g., chronic hypoxemia, smokers, high altitudes) may be anemic at higher Hgb levels.
- **Mean corpuscular volume (MCV):** <80 Fl
  - MCV may be low normal in mild anemia or hidden by large cells (reticulocytes, macrocytes).
- **Ferritin** is most sensitive and specific for diagnosing iron deficiency as cause of anemia (5):
  - <15 μg/L diagnoses IDA (<30 μg/L likely) (1)
  - >100 μg/L rules out iron deficiency
- **Iron studies:**
  - Decreased: ferritin, serum iron, transferrin saturation
  - Increased: total iron-binding capacity (TIBC), transferrin
- **Red cell distribution width (RDW)** increases with a mixed population of cells (e.g., mixed IDA and vitamin B\(_{12}\) deficiency).
- **CBC with differential, peripheral smear, reticulocyte count, and index**
  - Peripheral smear usually shows hypochromia and microcytosis but may be normal, and reticulocyte production index is low (1).
- Consider testing for G6PD deficiency.
- Evaluate for thalassemia.
  - Very low MCV <80, elevated Hgb A2 or Hgb F, family history, and especially high or high normal RBC count
– Microcytosis with ovalocytosis and unresponsive to iron suggests the thalassemia trait.
- IgA antiendomysial antibodies (IgA anti-EmA) and/or IgA antitissue transglutaminase (IgA- anti-TTG) for celiac disease
- TSH for hypothyroidism
- An empiric trial of iron at 3 mg/kg/day may help diagnose decreased iron stores in children; reticulocytes become elevated in 7 to 10 days or Hgb increases >1 g/dL weekly, indicating iron deficiency.
- Drugs that may alter lab results:
  – Iron supplements or multivitamin–mineral preparations that contain iron
- Disorders that may alter lab results:
  – Elevated ferritin: acute inflammation, acute or chronic liver disease, Hodgkin disease, acute leukemia, solid tumors, fever, renal dialysis
  – Elevated Hgb: smoking, chronic hypoxemia, high altitude

**Diagnostic Procedures/Other**
- Stool guaiac
- Stool for ova and parasites if at risk
- Colonoscopy and endoscopy (though sequence of these not clear) to evaluate for bleeding sites and colorectal and gastric carcinoma for:
  – Premenopausal women with negative GYN workup and/or lack of response to iron
  – Men and postmenopausal women (1)[C]
- Bone marrow aspiration rarely performed

**TREATMENT**

**GENERAL MEASURES**
- Search for underlying cause and correct.
- Avoid transfusions, except in rare cases.

**MEDICATION**
- Elemental iron 100 to 200 mg/day for adults (whether pregnant or not) (3,5) [C]
- Elemental iron 3 to 6 mg/kg/day for children (5)
- Ferrous sulfate 325 mg TID or ferrous gluconate 300 mg 1 to 3 tablets BID–TID or ferrous fumarate 324 mg 1 tablet BID on an empty stomach 1 hour
before meals (1)[C]

- Constipation will occur in ~1/4 of patients. Consider a stool softener along with iron.
  - Medications that reduce gastric acid secretion such as proton pump inhibitors and H\(^2\) antagonists reduce iron absorption (1).
  - Special oral iron formulations (including enteric-coated iron) and compounds are expensive and reduce symptoms only to the degree that they reduce the delivery of iron.
- IV iron (Dextran free) is an option for patients who cannot tolerate oral replacement or for those who do not sufficiently respond to oral replacement.
- Liquid iron preparations (used for children) can also be used in adults when tablets are not absorbed or low tolerance requires a dose reduction.
  - Continued bleeding and untreated hypothyroidism are causes for “failure to respond” to iron.
  - Formula to determine elemental iron needed: Elemental iron (mg) = Dose (mL) × 0.0442 (Desired Hgb – Observed Hgb) + (0.26 × LBW)
    o Desired Hgb = target Hgb in g/dL
    o Observed Hgb = current Hgb in g/dL
    o LBW = lean body weight in kg
    o For males: LBW = 50 kg + 2.3 kg for each inch of height over 5 feet
    o For females: LBW = 45.5 kg + 2.3 kg for each inch of height over 5 feet
  - Normal Hgb (males and females)
    - >15 kg (33 lb) . . . 14.8 g/dL
    - <15 kg (33 lb) . . . 12.0 g/dL

- Relative contraindications for oral iron:
  - Tetracycline
  - Allopurinol
  - Antacids
  - Penicillamine
  - Fluoroquinolones
  - Vitamin E
- Consider parenteral iron for patients with an Hgb level <6 g/dL, malabsorption, chronic kidney disease, or failure to respond to higher oral doses with concomitant vitamin C (5).
- Issues for parenteral iron formulations:
  - Give test dose for iron dextran prior to 1st dose to avoid anaphylaxis; ferric gluconate or iron sucrose may be safer alternative. Dimercaprol increases risk of nephrotoxicity.
  - Dosing is product dependent; refer to individual product for suggested
dosing.
- Precautions
  - Iron may cause dark stools and constipation.
  - Iron overdose is highly toxic; absorption is limited to 1 to 2 mg daily (5); keep tablets and liquids out of reach of small children.
- Blood transfusion for severe acute blood loss or severely symptomatic patients (e.g., demand ischemia due to anemia). Hgb threshold varies by risk factors and clinical scenario. Pregnant women with Hgb <6 should be transfused (1) [C].

ISSUES FOR REFERRAL
- Men and postmenopausal women with IDA (test for colon cancer)
- Pregnant women with Hgb level <9 g/dL
- Men or nonpregnant women with an Hgb level <6 g/dL
- Failure to respond to a 4- to 6-week trial of oral iron therapy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Monitor patients every 3 months after Hgb normalizes for a year and then yearly (1)[C].
- Hgb increases 1 g/dL every 3 to 4 weeks.
- Iron stores may take up to 4 weeks to correct after Hgb normalizes.

DIET
- Iron-rich foods include red meat, poultry, and fish (all heme iron sources, best absorbed), and iron-fortified breads/cereals, lentils, beans, dark green vegetables, and raisins (all nonheme iron sources, less well absorbed) (6).
- Foods and beverages containing ascorbic acid (vitamin C) enhance iron absorption when taken simultaneously (5).
- Avoid milk or dairy products within 2 hours of iron tablet ingestion.
- Limit milk to 16 oz/day (adults).
- Limit tea, coffee, and caffeinated beverages.
- Increase fluid and dietary fiber to decrease likelihood of constipation.
- Limit foods with high levels of chemicals (phytates and polyphenols).
PATIENT EDUCATION

PROGNOSIS

- IDA can be resolved with iron therapy if the underlying cause is discovered and appropriately treated.
- Treat coexisting subclinical hypothyroidism and IDA together. Failure to treat hypothyroidism results in poor response to iron therapy.

COMPLICATIONS

- Hidden bleeding, particularly a bleeding malignancy
- Ischemic events or heart failure, especially in elderly
- Poor growth, failure to thrive, motor and cognitive developmental delay in children (4)

**SEE ALSO**

Algorithm: *Anemia*
CODES

ICD10
- D50.9 Iron deficiency anemia, unspecified
- D62 Acute posthemorrhagic anemia
- D50.0 Iron deficiency anemia secondary to blood loss (chronic)

CLINICAL PEARLS
- IDA due to poor dietary iron intake is the most common anemia.
- Blood loss and reduced iron stores due to malabsorption or poor utilization are major risk factors for IDA.
- Premenopausal women and children are at the greatest risk for IDA.
- Cow’s milk should not be given to any child age <12 months.
- Oral iron supplementation is the standard treatment for IDA.
ANEMIA, SICKLE CELL
Tipsuda Junsanto-Bahri, MD

BASICS
DESCRIPTION
- Hereditary, hemoglobinopathy marked by chronic hemolytic anemia, acute episodes of painful “crises,” and increased susceptibility to infections
- The heterozygous condition (Hb AS), sickle cell trait, is usually asymptomatic without anemia.
- Synonym(s): sickle cell disease (SCD); Hb SS disease

Pediatric Considerations
- Sequestration crises and hand–foot syndrome seen typically in infants/young children
- Strokes occur mainly in childhood.
- Adolescence/young adulthood
  - Frequency of complications and organ/tissue damage increases with age.
  - Psychological complications: body image, interrupted schooling, restriction of activities; stigma of disease; low self-esteem

Pregnancy Considerations
- Complicated, especially during 3rd trimester and delivery
  - Fetal mortality 35–40%. Fetal survival is >90% if the fetus reaches the 3rd trimester.
  - High prevalence of small for gestational age (SGA) babies
- Increased risk of thrombosis, preterm delivery, pain, toxemia, infection, pulmonary infarction, and phlebitis
- Partial exchange transfusion in 3rd trimester may reduce maternal morbidity and fetal mortality but is controversial.
- Chronic transfusions have been effective in diminishing pain episodes in pregnant women. However, this method should be used with caution due to risk of alloimmunization.

EPIDEMIOLOGY
Prevalence
~90,000 Americans have sickle cell anemia (SCA), and 3.5 million people in the United States have sickle cell trait.

The condition affects mainly people of African descent. Hispanic, Middle-eastern, and Asian Indian ancestry may also be affected.

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Hemoglobin S results from the substitution of the amino acid valine for glutamic acid at the sixth position of the β-globin chain.
- HbS polymerizes in the RBC in the deoxygenated state resulting in RBC sickling.
- Sickle RBCs are inflexible, causes increased blood viscosity, stasis, obstruction of small arterioles and capillaries, and ischemia.
- Chronic anemia; crises
  - Vaso-occlusive crisis: tissue ischemia and necrosis; progressive organ failure/tissue damage from repeated episodes
  - Hand–foot syndrome: Vessel occlusion/ischemia affects small blood vessels in hands or feet.
  - Aplastic crisis: suppression of RBC production by severe infection (e.g., parvoviral and other viral infections)
  - Suppression of RBC production
  - Hyperhemolytic crisis: accelerated hemolysis with reticulocytosis; increased RBC fragility/shortened lifespan
  - Sequestration crisis: splenic sequestration of blood (only in young children as spleen is later lost to autoinfarction)
- Susceptibility to infection: impaired/absent splenic function leading to decreased ability to clear infection; defect in alternate pathway of complement activation
- Increased RBC destruction causes decreased hemoglobin levels and results in anemia and fatigue.
- Sickle cells exhibit increased adhesion and decreased ability to maneuver through small vessels, leading to vaso-occlusion.

**Genetics**

- Autosomal recessive. Homozygous condition, Hb SS; heterozygous condition, Hb AS
- The heterozygote condition can also be combined with other hemoglobinopathies: Sick cell hemoglobin C (HbSC) disease and Sβ+ thalassemia are clinically similar to the heterozygous condition, whereas Sβ thalassemia is clinically similar to the homozygous condition.
RISK FACTORS

- Vaso-occlusive crisis ("painful crisis"): hypoxia, dehydration, fever, infection, acidosis, cold, anesthesia, strenuous physical exercise, smoking
- Aplastic crisis (suppression of RBC production): severe infections, human parvovirus B19 infection, folic acid deficiency
- Hyperhemolytic crisis (accelerated hemolysis with reticulocytosis): acute bacterial infections, exposure to oxidant

GENERAL PREVENTION

- Prevention of crises
  - Avoid hypoxia, dehydration, cold, infection, fever, acidosis, and anesthesia.
  - Prompt management of fever, infections, pain
  - Hydration
  - Avoid alcohol and smoking.
  - Avoid high-altitude areas.
- Minimizing trauma: Aseptic technique is imperative.

DIAGNOSIS

Diagnosis is often made by newborn screening programs.

HISTORY

- Often asymptomatic in early months of life due to presence of fetal hemoglobin
- In those >6 months of age, earliest symptoms are irritability and painful swelling of the hands and feet (hand–foot syndrome); may also see pneumococcal sepsis or meningitis, severe anemia and acute splenic enlargement (splenic sequestration), acute chest syndrome, pallor, jaundice, or splenomegaly
- Manifestations in older children include anemia, severe or recurrent musculoskeletal or abdominal pain, aplastic crisis, acute chest syndrome, splenomegaly or splenic sequestration, and cholelithiasis.
- Painful crises in bones, joints, abdomen, back, and viscera account for 90% of all hospital admissions.
- Acute chest syndrome: tachycardia, fever, bilateral infiltrates caused by pulmonary infarctions
PHYSICAL EXAM
Fever, pale skin and nail beds, mild jaundice

DIFFERENTIAL DIAGNOSIS
Anemia: other hemoglobinopathies

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Screening test: Sickledex test/Hb electrophoresis (diagnostic test of choice); SCA (FS pattern)
  - 80–100% Hb S, variable amounts of Hb F, and no Hb A1
  - Sickle cell trait (FS pattern): 30–45% Hb S, 50–70% Hb A1, minimal Hb F
- Hemoglobin ~5 to 10 g/dL; RBC indices: mean corpuscular volume (MCV) normal to increased; mean corpuscular hemoglobin concentration (MCHC) increased; reticulocytes 3–15%
- Leukocytosis; bands in absence of infection, platelets elevated; peripheral smear: sickled RBCs, nucleated RBCs, Howell-Jolly bodies
- Serum bilirubin mildly elevated (2 to 4 mg/dL); ferritin very elevated in multiply transfused patients; serum lactate dehydrogenase (LDH) elevated
- Fecal/urinary urobilinogen high
- Haptoglobin absent or very low
- Urine analysis: hemoglobinuria, hematuria (sickle cell trait may have painless hematuria), increased albuminuria (monitor for progressive kidney disease)
- Imaging depends on clinical circumstances.
  - Bone scan to rule out osteomyelitis
  - CT/MRI to rule out CVA; high index of suspicion required for any acute neurologic symptoms other than mild headache
  - Chest x-ray: may show enlarged heart; diffuse alveolar infiltrates in acute chest syndrome
  - Transcranial Doppler: Start at age 2 years; repeat yearly. Transcranial Doppler ultrasound identifies children age 2 to 16 years at higher risk of stroke; may be normal in clinically silent strokes
  - ECG to detect pulmonary hypertension and echocardiogram every other year from age 15 years and older

Test Interpretation
Hyposplenism due to autosplenectomy is common; hypoxia/infarction in
multiple organs

TREATMENT

GENERAL MEASURES

- Painful crises: hydration, analgesics; oxygen regardless of whether the patient is hypoxic
- Retinal evaluation starting at school age to detect proliferative sickle retinopathy (1)[A]
- Occupational therapy, cognitive and behavioral therapies, support groups
- All standard childhood vaccinations should be administered accordingly.
- Special immunizations
  - Influenza vaccine yearly
  - Conjugated pneumococcal vaccine (PCV13) at ages 2, 4, and 6 months; booster at 12 to 15 months
  - Patients <5 years of age with incomplete vaccination history should receive catch-up doses accordingly.
  - Adults age ≥19 years who have functional asplenia and have not received pneumococcal vaccination should receive 1 dose PCV13, followed by administration of PPSV23 at least 8 weeks later (1)[A].
- Meningococcal vaccine:
  - 6 weeks old: Hib-MenCY at ages 2, 4, 6, and 12 months
  - 9 months old: 2 doses of MCV4 separated by 3 months
  - ≥2 years of age: 2 doses of MCV4-D-CRM separated by 2 months; boosters recommended every 5 years

MEDICATION

**First Line**

- Prophylactic penicillins indicated in infants and children starting at 2 months: A dose of 125 mg BID is recommended for children <5 years. A dose of 250 mg BID is recommended for children >5 years. Amoxicillin 20 mg/kg/day is an alternative to penicillin; if high risk remains, continue until puberty (2)[A].
- Supplemental oxygen
- Painful crises (mild, outpatient)
  - Nonopioid analgesics (ibuprofen)
- Painful crises (severe, hospitalized)
  - Parenteral opioids (e.g., morphine on fixed schedule); patient-controlled
analgesia (PCA) pump may be useful (1)[A].

- Hydroxyurea for prevention of painful acute chest syndrome, vaso-occlusive episodes, and very severe anemia. Increases fetal hemoglobin concentration. Adults: Start 15 mg/kg/day single daily dose; children: 20 mg/kg/day; titrate upward every 8 weeks (max dose of 35 mg/kg/day). Monitor blood counts (avoid severe neutropenia, thrombocytopenia) (1)[A].
- Acute chest syndrome: Patients may deteriorate quickly; monitor patients with vaso-occlusive crisis with incentive spirometry. Treat with aggressive management with oxygen, analgesics, antibiotics, simple or exchange transfusion (1)[A].
- Empiric antibiotics to cover *Mycoplasma pneumoniae* and *Chlamydia pneumoniae* (cephalosporins or azithromycin) (1)[A]. If osteomyelitis, cover for *Staphylococcus aureus* and *Salmonella* (e.g., ciprofloxacin).
- Precautions: Avoid high-dose estrogen oral contraceptives; consider Depo-Provera. G-CSF use is contraindicated as it may lead to vaso-occlusive episodes and multiorgan failure.

**Second Line**

Folic acid: 0 to 6 months: 0.1 mg/day; 6 to 12 months: 0.25 mg/day; 1 to 2 years: 0.5 mg/day; >2 years of age: 1 mg/day

**ADDITIONAL THERAPIES**

Transfusions and additional therapies (3)[A]

- Transfusion for aplastic crises, severe complications (i.e., CVA), prophylactically before surgery, and treatment for acute chest syndrome; prophylactic transfusions for primary or secondary stroke prevention in children
- Preoperative transfusions have been shown to reduce the risk of perioperative complications.
- Avoid blood hyperviscosity.
- Consider chelation with deferasirox, an oral agent, if the patient is multiply transfused (after age 2 years). Red cell exchange transfusion minimizes risk of iron overload.

**SURGERY/OTHER PROCEDURES**

- Targeted fetal hemoglobin induction treatment (4)[A]
- Hematopoietic stem cell transplant (HSCT) (5)[A]: curative, but with significant morbidity and mortality; limited to individuals <16 years old
Gene therapy, where autologous hematopoietic cells treated with lentiviral vector encoding a therapeutic HBB gene, may be considered in the future (6) [C].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Admission criteria/initial stabilization: severe pain, suspected infection or sepsis, evidence of acute chest syndrome
- The preferred maintenance IV fluid is 1/2 NS, as NS may theoretically increase the risk of sickling.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Treat infections early. Parents/patients: Any temperature of ≥101°F (38.3°C) requires immediate medical attention.
- Monitor for hepatitis C and hemosiderosis in patients who receive chronic transfusions.
- Periodic eye evaluations: starting age 10 years to detect proliferative sickle retinopathy; rescreen 1 to 2 year intervals (2)[A].
- Biannual examination for hepatic, renal, and pulmonary dysfunction
- Neuroimaging screening for risk of stroke: transcranial Doppler beginning at age 2 years and continuing up to age 16 years
- Baseline pulmonary evaluation at each visit to assess for wheezing, shortness of breath, or cough (indicators of disease severity and pulmonary hypertension). Echocardiography for symptomatic patients; right heart catheterization for diagnosis
- Consider venous thromboembolism (VTE) prophylaxis as there is an increased incidence of thromboembolism.

**DIET**

- Folic acid supplementation; avoid alcohol (leads to dehydration); maintain hydration.
- Multivitamin without iron is recommended as there is high incidence of vitamin D deficiency and decreased bone marrow density in SCD patients.
PATIENT EDUCATION

- SickleCellKids.org—Education Web site for children with sickle cell anemia: http://www.sicklecelldisease.org
- American Sickle Cell Anemia Association: http://www.ascaa.org

PROGNOSIS

- Anemia occurs in infancy; sickle cell crises at 1 to 2 years of age; some children die in their 1st year.
- In adulthood, fewer crises but more complications. Median age of death is 42 years for men and 48 years for women. Complications are mentioned below.

COMPlications

- Alloimmunization, bone infarct and osteomyelitis, aseptic necrosis of femoral head
- CVA (peak age 6 to 7 years), impaired mental development, even without history of stroke
- Cholelithiasis/abnormal liver function
- Chronic leg ulcers, poor wound healing
- Impotence, priapism, hematuria/hyposthenuria, renal complications (proteinuria)
- Retinopathy, splenic infarction (by age 10 years)
- Acute chest syndrome (infection/infarction) leading to chronic pulmonary disease
- Infections (pneumonia, osteomyelitis, meningitis, pyelonephritis); sepsis (leading cause of morbidity and mortality)
- Hemosiderosis (secondary to multiple transfusions)
- Substance abuse related to chronic opioid use

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Anemia

**CODES**

**ICD10**

- D57.1 Sickle-cell disease without crisis
- D57.3 Sickle-cell trait
- D57.00 Hb-SS disease with crisis, unspecified

**CLINICAL PEARLS**

- Over 90,000 Americans have SCA (~1 in 375 African Americans).
- The preferred maintenance IV fluid is 1/2 NS, as NS may theoretically increase the risk of sickling.
- Painful crises in bones, joints, abdomen, back, and viscera account for 90% of all hospital admissions.
- Acute chest syndrome: tachycardia, fever, bilateral infiltrates caused by pulmonary infarctions
ANEURYSM OF THE ABDOMINAL AORTA

Katyayini Aribindi, MD • Adrian DaSilva-DeAbreu, MD • Raymundo A. Quintana, MD

BASICS

DESCRIPTION
- There are two types of aneurysms: true and false. A true aneurysm involves all three vessel wall layers. False aneurysms or pseudoaneurysms occur when the intimal and medial layers are disrupted, and the dilated segment is surrounded by the adventitia only, and possibly a perivascular clot. Ruptures are usually higher with false aneurysms due to poor support of the aneurysmal wall.
- Abdominal aortic aneurysm (AAA) is the most common true aneurysm. False aneurysms of the abdominal aorta are usually due to trauma or infection.
- The average diameter of the infrarenal aorta is 2.0 cm, an aortic diameter of >3.0 cm is considered aneurysmal.
- In men, AAA diameters are predictive of clinical events. In women, aneurysms are still >3.0 cm, but the aortic scaling index (ASI; diameter [cm]/body surface area [m²]) is more predictive of clinical events.
- System(s) affected: cardiovascular; neurologic; heme/lymphatic/imunologic
- Synonym(s): aortic aneurysms; AAA

Geriatric Considerations
Incidence of AAA, risk of rupture, and operative morbidity and mortality all rise with age.

Pediatric Considerations
Rare in children; may be associated with umbilical artery catheters, connective tissue diseases, arteritides, or congenital abnormalities

EPIDEMIOLOGY
- Estimated prevalence of AAA in developed countries is 2–8%. Age-related increase is seen more with men than women.
- Ultrasound studies show that 4–8% of older men have an occult AAA.
90% of all AAA >4 cm are related to atherosclerotic disease, with the vast majority located infrarenally. 

Predominant sex: male > female

**Incidence**
- >10,000 deaths per year in United States (1)
- 3.9–7.2% males >50 years (1)
- 1.0–1.3% females >50 years (1)

**Prevalence**
- Roughly 1 million U.S. individuals have an AAA (1), with the prevalence increasing in age for men and women.
- The prevalence of AAA-associated mortality has decreased by 50% since the 1990s, likely due to the decline in cigarette smoking, increased screening for AAA detection, and early interventions.
- With the increasing life expectancy in developed countries, the prevalence of AAA is expected to increase, but the decreased prevalence of smoking will have the opposite effect (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- AAAs are caused by degradations of abnormal production of elastin and collagen, the structural components of the aortic wall (2).
- There are many causes of aortic aneurysms: inflammation, degenerative disorders, vasculitis, infections, and trauma. However, the vast majority of AAA are caused by inflammation with atherosclerosis as the inciting factor (2).
- B-cell and T-cell lymphocytes, macrophages, inflammatory cytokines, and matrix metalloproteinases degrade elastin and collagen, thus decreasing the aortic wall strength, leading to a decreased ability to accommodate the pulsatile flow (2).
- Histopathology shows elastin and collagen destruction, decreased vascular smooth muscle, in-growth of new blood vessels and subsequent inflammation (2).
- Although most aortic aneurysms are caused by inflammatory or degenerative destruction of elastin and collagen, infections, trauma, and connective tissues disorders can also degrade elastin and collagen leading to similar presentations.
**Genetics**
- Familial aggregations exist: Aneurysms may develop at an earlier age.
- ~10% of AAA are familial, with a prevalence of 13% among affected families (2).
- Marfan syndrome
- Ehlers-Danlos syndrome
- Polycystic kidney disease
- Tuberous sclerosis
- Gene associations (2):
  - ANRIL: antisense RNA regulating cyclin-dependent kinase inhibitors
  - DAB2: cell growth and survival inhibitor
  - LRP1: low-density lipoprotein receptor-related protein 1, plasma receptor in vascular smooth muscle and macrophage endocytosis
  - IL-6R and IL-1RN: part of the interleukin family contributing to IL-1 inhibition

**RISK FACTORS**
Older age, male sex, Caucasian race, family history, smoking, hypertension (HTN), hyperlipidemia, atherosclerosis, peripheral aneurysms, obesity

**GENERAL PREVENTION**
- Address cardiovascular disease risk factors.
- Follow screening guidelines: U.S. screening for detection of AAA in male patients, 65 to 75 years, who have ever smoked.

**COMMONLY ASSOCIATED CONDITIONS**
- HTN, myocardial infarction (MI), heart failure, carotid artery atherosclerosis, and/or lower extremity peripheral arterial disease
- Screening for thoracic aneurysm should also be considered.
- 20% of patients with AAA have concurrent thoracic aneurysm (3).

**DIAGNOSIS**
- Asymptomatic AAA (majority)
  - USPSTF recommends a one-time screen for an AAA by abdominal ultrasonography for men aged 65 to 75 years with a smoking history (4)[A].
  - Selective screening for AAAs in nonsmoker men aged 65 to 75 years can
be offered based on personal or family history and patient’s preferences (4) [A].

– Current recommendations are against routine screening for women, regardless of smoking history.

**ALERT**

- Symptomatic: The triad of shock, pulsatile mass, and abdominal pain always suggest rupture of AAA, and immediate surgical evaluation is recommended (3)[A].
  – Hemodynamically stable patients (shock is absent as the rupture is contained) may undergo a CT abdomen with IV contrast for evaluation of an AAA.
  – Unstable patients (rupture is uncontained) undergo a focused bedside ultrasound and surgical repair if AAA is present.
- Unusual presentations:
  – Primary aortoenteric fistula: erosion/rupture of AAA into duodenum
  – Aortocaval fistula: erosion/rupture of AAA into vena cava or left renal vein: 3–6%
  – Inflammatory aneurysm: encasement by thick inflammatory rind; can cause chronic abdominal pain, weight loss, and elevated ESR. Surrounding viscera may be densely adherent.

**HISTORY**

- Abdominal, back pain, or flank pain; AAA risk factors, hypotension if presenting in an emergency situation
- Found on routine screening if presenting in an outpatient setting

**PHYSICAL EXAM**

- Pulsatile supraumbilical mass
- In one study, sensitivity varied based on abdominal girth and size of aneurysm. However, the sensitivity was 100% of aneurysms >5.0 cm when the girth was <100 cm. The sensitivity and specificity varied from 23% to 68% and 75% to 91%, respectively (5).
- Encroachment by aneurysm
  – Vertebral body erosion, gastric outlet obstruction, ureteral obstruction
  – Lower extremity ischemia secondary to embolization of mural thrombus
- Rupture leads to tachycardia, hypotension, evidence of shock and anemia, possible flank contusion (Grey Turner sign).
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- If rupturing AAA is considered: complete blood chemistry (chemistries, PT/INR, PTT, type and cross), ECG
- Ultrasound: simplest and least expensive diagnostic procedure with a high sensitivity (94–100%) and specificity (98–100%) (3)[A]
- Surveillance of asymptomatic aneurysm
  - 2.6 to 2.9 cm: Screen at 5-year intervals.
  - 3.0 to 3.9 cm: Screen at 3-year intervals.
  - 4.0 to 5.4 cm: Screen every 6 to 12 months.
- CT scans are preferred preoperative study (caution with IV contrast in renal failure) (3).
- MRI/MRA can visualize AAA but is often not possible in emergent situations.
- Aortography does not define outer dimensions of aneurysm.
- Abdominal x-rays can be diagnostic if calcifications exist; not a diagnostic tool of choice (3)

Follow-Up Tests & Special Considerations

- Evaluation for coronary artery disease is appropriate prior to elective AAA repair including stress test, echocardiography, and ECG if appropriate.
- If AAA was discovered at any location, then full assessment of entire aorta including thoracic aorta and aortic valve is recommended (3)[C].

Diagnostic Procedures/Other

ALERT
Use clinical judgment: Patients with known AAA having abdominal or back pain symptoms may be rupturing despite a negative CT scan.

DIFFERENTIAL DIAGNOSIS

- Other abdominal masses
- Other causes of abdominal or back pain (e.g., peptic ulcer disease, renal colic, diverticulitis, appendicitis, incarcerated hernia, bowel obstruction, GI hemorrhage, arthritis, metastatic disease, MI)

TREATMENT
GENERAL MEASURES

- Treat atherosclerotic risk factors: HTN, dyslipidemia, diabetes mellitus, and smoking (4)[A].
- Smoking was associated with a 0.35 mm/year AAA growth, twice as fast as AAA growth in nonsmokers, and is the most important AAA outcome predictor (3).
- Emergent treatment in unstable or symptomatic patients requires immediate vascular surgery consultation, adequate IV access and resuscitation, type and cross for multiple units, and rapid bedside ultrasound (3).
- Less acute treatment of AAA/prevention of rupture is elective repair and risk factor modification.

MEDICATION

- β-Blockers, aspirin, and statins theoretically reduce the rate of growth of AAAs, by decreasing shear wall stress, inflammation, and prevention of an intraluminal mural thrombus. However, there are conflicting RCT and meta-analysis trials. Because concomitant atherosclerosis is often a precipitating factor in AAAs, their use is recommended for reduced mortality in patients with coronary artery disease or its equivalence (6)[A].
- The use of ACE inhibitors has shown to be inconclusive with regard to growth of AAA; however, studies do indicate a decreased rate of AAA rupture (6)[A].
- Doxycycline and roxithromycin, previously theorized to decreased wall inflammation, has not been shown to have any effect on AAA (7).

SURGERY/OTHER PROCEDURES

Current recommendations are the following:

- Elective
  - 5.5-cm diameter is threshold for repair in “average” patient (3)[A].
  - Younger, low-risk patients with long life expectancy may prefer early repair.
  - Women or AAA with high risk of rupture: Consider elective repair at 4.5 to 5 cm.
    - Consider delayed repair in high-risk patients.
    - 5% perioperative mortality for open elective repair (3)
- High risk of rupture
  - Expansion >0.5 cm/year
  - Smoking/COPD severe/steroids
  - Family history; multiple relatives
– HTN if poorly controlled
– Shape nonfusiform

• High-risk patients for elective repair
  – Risk factors for open repair include age >75 years, COPD, chronic kidney disease with Cr >1.75, suprarenal clamp site.
  – The leading cause of early mortality after AAA repair is coronary artery disease, with open AAA repair being much higher risk than endovascular AAA repair (3)[A].
  – The RCT IMPROVE trial showed a similar 30-day mortality for patients with ruptured AAA who underwent endovascular repair versus open repair (35.4% vs. 37.4%). One-year follow-up all cause mortality between the two groups (41.1% vs. 45.1%) (7)[A].
  – Although difficult to quantify, perioperative morbidity rates are lower for EVAR, suggesting that an EVAR is preferable in patients with a ruptured AAA with poor prognostic factors for an open repair, such as SBP<80, age >80, Cr >1.3 on admission, ischemic heart disease, female sex, and hemoglobin <9.0 on admission) (4,7)[A].
  – Contraindications for AAA endovascular repair are an aortic neck >32 mm and a ruptured AAA with aortic neck length <7 mm. In these patients, an open AAA repair is performed due to anatomical constrictions.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Risk of abdominal compartment syndrome after repair, 4–12%; usually associated with large fluid resuscitation

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*
• May do a CT scan 5 years after an open repair for possible late aortic dilatation or pseudoaneurysm (4)[C]
• Follow-up imaging should be tailored to patient. Once renal function stabilizes postoperatively, a CT can be performed to evaluate the endograft (4) [C].
• Aggressive risk factor modification always recommended postoperatively (4)
DIET
Low-fat, low-salt, and low-caffeine diet; nutrition optimized prior to elective repair

PATIENT EDUCATION
Smoking cessation, aerobic exercise

PROGNOSIS
- Naturally progressive disorder, expands at an average rate of 0.3 to 0.4 cm per year. A fast expansion is considered >0.6 cm per year and should be evaluated for operative management.
- Possibility of rupture increases with an aneurysm diameter of >5.5 cm or a fast rate of expansion (>0.5 cm over a 6-month period), continued cigarette use, female sex, recent surgery, uncontrolled HTN, and aneurysm contour.

COMPLICATIONS
- Emergent AAA repair and elective AAA repair have similar complications, with a higher incidence in emergent AAA repair.
- Complications include MI, respiratory failure, and acute kidney injury in the early period.
- Late complications such as aortic graft infection, aortoenteric fistula, and graft occlusion have similar rates between emergent and elective repair.
- Ischemic bowel and abdominal compartment syndrome are complications usually after a ruptured open AAA repair given the massive blood loss, increased operative time, magnitude of fluid resuscitation.

### SEE ALSO

Aortic Dissection; *Arteritis, Temporal*; Ehlers-Danlos Syndrome; Marfan Syndrome; *Polyarteritis Nodosa*; Turner Syndrome

### CODES

#### ICD10

- I71.4 Abdominal aortic aneurysm, without rupture
- I71.3 Abdominal aortic aneurysm, ruptured
CLINICAL PEARLS

- Males with a smoking history aged 65 to 75 years should undergo a one-time screening abdominal ultrasound to evaluate for an AAA.
- Larger AAAs should be screened more often, with elective repair with AAA >5.5 cm or an expansion of >0.5 cm every 6 months.
- Patients with a ruptured AAA present in shock, with abdominal pain and a pulsatile mass. A bedside ultrasound should be done quickly to evaluate for an AAA, or an emergent CT scan can be performed if the patient is hemodynamically stable.
- AAA are treated either open or endovascularly as an elective or emergent procedure. 30-day and 1-year mortality between the two methods remain the same, however, there is increased mortality with an emergent AAA repair.
- Patients require aggressive risk factor modification, especially smoking cessation.
ANGIOEDEMA

Michelle T. Martin, PharmD, FCCP, BCPS, BCACP • Jamie L. Berkes, MD

BASICS

DESCRIPTION

- Angioedema (AE) is acute, localized swelling of skin, mucosa, and submucosa caused by extravasation of fluid into the affected tissues. It often resolves in hours to days but can be life-threatening if the upper airway is involved.
- Hereditary AE (HAE) and acquired AE (AAE) are diseases of the complement cascade that result in recurrent episodes of AE of the skin, upper airway, and GI tract.
- Synonym(s): angioneurotic edema; Quincke edema

EPIDEMIOLOGY

- Predominant age
  - Allergen, medication, or other triggers can affect all ages.
  - HAE: infancy to 2nd decade of life
  - AAE: often patients >40 years
- Predominant gender: male = female (except type III HAE; affects more women than men)

Prevalence

- AE occurs in 15% of the population over a lifetime.
- AE: 0.1–2.2% of patients receiving ACE inhibitors: African Americans have a 4 to 5 times greater risk of ACE inhibitor–induced AE than Caucasians.
- HAE: 1:10,000 to 50,000 population in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

- Idiopathic
- Medication-induced
  - ACE inhibitors cause 10–25% of AE cases, mostly occurring within the 1st month of use. However, onset may be delayed by years.
  - Angiotensin-receptor blockers (ARBs) also can cause AE but more rarely
than ACE inhibitors.

- **Allergic triggers**
  - Food allergens such as shellfish, nuts, eggs, milk, wheat, soy
  - Medications such as aspirin, NSAIDs, antibiotics, narcotics, and oral contraceptives
  - Latex, venom

- **Physically induced:** cold, heat, pressure, vibration, trauma, emotional stress, ultraviolet light

- **Hereditary or acquired C1 INH deficiency**
- **Thyroid autoimmune disease–associated AE**
- **Type I hypersensitivity reaction**
- **Increase in vascular permeability secondary to IgE-mediated mast cell–stimulated histamine release or from activation of the complement system and an elevation in bradykinin (HAE)**

- **HAE attacks are triggered by prolonged mechanical pressure, cold, heat, trauma, emotional stress, menses, illness, and inflammation:**
  - Type I HAE, the most common form, caused by decreased production of C1 esterase inhibitor (C1 INH), has autosomal dominant inheritance.
  - Type II HAE has functionally impaired C1 INH and autosomal dominant inheritance.
  - Type III (HAE-FXII) involves mutations in coagulation factor XII gene (occurs more frequently in women, often estrogen-dependent, associated with estrogen administration); also, type III HAE-unknown exists.

- **AAE is a rare condition:**
  - Type I is associated with lymphoproliferative diseases or paraneoplastic diseases.
  - Type II is due to autoimmune disorders (anti-C1 INH antibody).
  - Affected patients have circulating antibodies directed either against specific immunoglobulins expressed on B cells (type I) or against C1 INH (type II).
  - AAE typically presents later in life (>40 years), and patients lack family history of AE.

**Genetics**

- HAE types I and II are autosomal dominant, whereas type III is dominant X-linked.
- HAE occurs in 25% of patients as a result of spontaneous genetic mutations.

**RISK FACTORS**

- Consuming medications and foods that can cause allergic reactions
Preexisting diagnosis of HAE or AAE

**GENERAL PREVENTION**
- Avoid known triggers.
- Do not use ACE inhibitors in patients with C1 INH deficiency.

**COMMONLY ASSOCIATED CONDITIONS**
- Quincke disease (AE of the uvula)
- Urticaria

**DIAGNOSIS**

**HISTORY**
- Identify potential triggers, including medication history, recent exposure to allergens, physical elements, or trauma.
- In comparison with urticaria, AE typically is nonpruritic, but it can cause a burning sensation.
- Family history

**PHYSICAL EXAM**
- Acute onset of asymmetric localized swelling, usually of the face (eyelids, lips, ears, nose), tongue, larynx; less often of the extremities or genitalia
- GI tract involvement may manifest as intermittent unexplained abdominal pain.

**ALERT**
10–35% of patients present with severe respiratory compromise requiring endotracheal intubation.

**DIFFERENTIAL DIAGNOSIS**
Urticaria (with AE in 40–50% of patients); allergic contact dermatitis; connective tissue disease: lupus, dermatomyositis; anaphylaxis; cellulitis, erysipelas; lymphedema; diffuse SC infiltrative process

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- If AE with urticaria and/or anaphylaxis, check for allergen-specific IgE to
verify suspected trigger (1)[C].

- Serum tryptase can be elevated with histamine-mediated anaphylaxis (2)[C].
- Without a clear etiology and recurrence in AE and urticaria, check CBC and ESR:
  - Macrocytosis implies a pernicious anemia.
  - Eosinophilia may imply atopy or, rarely, a parasitic infection.
  - Elevated ESR may imply systemic disorders (1)[C].
- In recurrent AE without a clear etiology and without urticaria, consider ordering serum C4 level:
  - Low serum C4 is a sensitive but nonspecific screening test for hereditary and acquired C1 INH deficiency.
  - If C4 is normal, determine C1 INH level and function and recheck C4 during an acute attack.
  - If C4 level and C1 INH level and function are still normal, consider other causes (i.e., medications or HAE type III) for AE (2)[C].
  - If C4 level, C1 INH level, and C1 INH function are low, this indicates HAE type I.
  - HAE type II is characterized by low C4 and low C1 INH function, but C1 INH level can be normal or elevated (2)[C].
- C1q is decreased in most AAE but is usually normal in HAE (2)[C].
- Abdominal radiographs and CT scan can demonstrate GI AE or ileus.
- C1 INH deficiency may occur in association with internal malignancy, so AE rarely can be a paraneoplastic disease. Imaging (CT scan, radiography, etc.) would be done as part of a neoplastic workup for patients with AAE.

Follow-Up Tests & Special Considerations

If C4 and C1q are low (as in AAE), neoplastic and autoimmune workup is warranted. CBC, a peripheral smear, protein electrophoresis, immunophenotyping of lymphocytes, and imaging studies are often undertaken to rule out hematologic malignancies or cancer (1)[C].

Diagnostic Procedures/Other

Skin biopsy (may be nonspecific)

Test Interpretation

- Edema of deep dermis and SC tissue
- Variable perivascular and interstitial infiltrate
TREATMENT

GENERAL MEASURES
Intubation if airway is threatened

MEDICATION

First Line
- Acute allergic AE (with airway compromise)
  - Epinephrine 1:1,000; 0.3 mL IM or SC (1)[C]
  - Glucocorticoids (hydrocortisone 200 mg IV or methylprednisolone 40 mg IV) (1)[C]
  - Diphenhydramine 50 mg IV
  - If medication induced, stop the causative agent.
- Idiopathic recurrent AE
  - 1st-generation antihistamines for acute AE (cause drowsiness)
  - Older children and adults: hydroxyzine (Vistaril) 5 mg/5 mL, 25-mg tablets 10 to 25 mg TID, or diphenhydramine (Benadryl) 25 to 50 mg q6h (3)[C]
  - Children <6 years of age: diphenhydramine 12.5 mg (elixir) q6–8h (5 mg/kg/day) (3)[C]
  - 2nd-generation H1 blockers: fexofenadine (Allegra) 180 mg/day BID, cetirizine (Zyrtec) 10 mg/day, desloratadine (Clarinex) 5 mg/day (4)[C]; use with caution in pregnancy and in the elderly.
- HAE chronic prophylaxis
  - A nanofiltered plasma-derived (pd) C1 INH (pdC1 INH) concentrate (Cinryze) dosed at 1,000 units/10 mL IV, rate of 1 mL/min (for 10 minutes) q3–4d. Administration setting options include clinic, home health care, and after proper training, home self-administration; risk of thromboembolic events (2)[C]
  - Human pdC1 INH concentrate (Haegarda) dosed at 60 IU/kg SC twice weekly for home administration. Side effects include injections site reactions, hypersensitivity, nasopharyngitis, dizziness (5)[B].
  - Attenuated androgens increase hepatic production of C1 INH: PO danazol 50 to 200 mg/day or PO stanozolol 2 mg/day; use lowest effective dose. Side effects include, but are not limited to, headache, weight gain, liver dysfunction, hirsutism, and menstrual disturbances. Monitor CBC, liver function tests, creatinine kinase, lactic dehydrogenase, fasting lipid profile, and urinalysis at baseline and q6mo. Abdominal US to be performed
annually or q6mo if dose of danazol >200 mg/day. Danazol is not to be used in children, during the first 2 trimesters of pregnancy, during lactation, and in patients with hepatitis or cancer (4)[C].

- **HAE short-term prophylaxis**
  - Minor procedures (dental work): If C1 INH is available, no prophylaxis; otherwise, danazol 2.5 to 10 mg/kg/day (max 600 mg/day) and stanozolol 4 to 6 mg/day for 5 days prior to and 2 to 5 days after event (4)[C].
  - Major procedures (including intubation): C1 INH 1 (max 6) hour prior with additional dose on hand during procedure. If unavailable, danazol 2.5 to 10 mg/kg/day (max 600 mg/day) and solvent/detergent-treated plasma (SDP). If SDP unavailable, use fresh frozen plasma (FFP) 10 mL/kg; 2 to 4 units (400 to 800 mL) for an adult 1 to 6 hours prior.

- **Acute HAE treatment**
  - Recombinant human C1 INH isolated from the milk of transgenic rabbits (Ruconest—formerly Rhucin) was approved for acute HAE attacks. Trained patients ≥18 years may self-administer 50 IU/kg if <84 kg and 4,200 IU if ≥84 kg IV over 5 minutes. No >2 doses may be administered over 24 hours. Headache, nausea, and diarrhea may occur, and thromboembolic events or anaphylaxis (rabbit-allergic patients) are possible (2)[C].
  - Pasteurized human pdC1 INH (Berinert), dosed at 20 units/kg (available in 500 units/10 mL, max infusion rate of 4 mL/min IV via peripheral vein in patients ≥12 years (2)[C]; DO NOT SHAKE (will denature the protein). Worsening of HAE pain and anaphylaxis are potential adverse events.
  - Historically, C1 INH concentrate IV, dosed at 1,000 units if <50 kg; 1,500 units if 50 to 100 kg; 2,000 units if >100 kg (4)[C]
  - Ecallantide (Kalbitor), a kallikrein inhibitor, is dosed in patients aged ≥12 years at 30 mg SC with three separate 10 mg/mL injections in the abdomen, thigh, or upper arm, and a second 30-mg dose may be repeated within 24 hours if needed (2)[C]. Injection-site rotation is not necessary but must be 2 inches away from attack site. Black box warning of anaphylaxis (potential adverse event) mandates administration in health care setting.
  - Icatibant (Firazyr), a bradykinin receptor-2 antagonist, is dosed at 30 mg SC over at least 30 seconds in the abdomen, thigh, or upper arm in patients aged ≥18 years and supplied in a prefilled 10 mg/mL (3 mL) syringe for home administration. Subsequent doses of 30 mg may be repeated in 6-hour intervals (max 90 mg/24 hours). Injection site reactions can occur (2)[C].
  - Antihistamines and glucocorticoids typically do not benefit patients with HAE. Epinephrine can offer transient stabilization/improvement in laryngeal AE but is not sufficient for full treatment and does not alter the
course of attack.

- Acute AAE treatment
  - C1 INH concentrate and FFP
  - Treatment of underlying lymphoproliferative disease is often curative in AAE type I.
  - Immunosuppressive therapy to suppress antibody production

**Second Line**

- HAE chronic prophylaxis: If pdC1 INH is unavailable and if patient cannot tolerate attenuated androgens, antifibrinolytic agents (plasmin inhibitors) such as tranexamic acid (not approved by the FDA in United States) 25 to 50 mg/kg/day divided BID or TID (3 to 6 g/day max) or ε-aminocaproic acid could be used. They are less effective than attenuated androgens and have many side effects. On rare occasions, they have been linked to (but not proven to cause) thrombophlebitis, embolism, or myositis (4)[C].
- Acute HAE: FFP if C1 INH concentrate is not available, but it can potentially worsen attack.
- Idiopathic AE: PO doxepin (Sinequan) may be effective for AE (10 to 25 mg at bedtime).
- H2RA: PO ranitidine (Zantac) 150 mg/day BID

**SURGERY/OTHER PROCEDURES**

Tracheostomy if progressive laryngeal edema prevents endotracheal intubation

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Ensure patent airway. If anaphylaxis, epinephrine (1:1,000) SC 0.3 to 0.5 mg q10–15min
- IV fluids given if needed to stabilize patient

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Diagnostic workup if symptoms are severe, persistent, or recurrent
- Protect airway if mouth, tongue, or throat is involved.
DIET
Avoid known dietary allergens.

PATIENT EDUCATION
Educate on avoidance of triggers (i.e., food, medication, other physical stimuli), types of treatment, when to seek emergency care, and wearing Medic Alert bracelet.

PROGNOSIS
- AE symptoms often resolve in hours to 2 to 4 days. If airway is compromised, AE can be life-threatening.
- Patients with HAE have an average of 20 attacks/year; each may last 3 to 5 days. Prophylaxis can decrease the frequency of events and number of missed days of school or work.

COMPLICATIONS
Anaphylaxis

REFERENCES

ADDITIONAL READING

**SEE ALSO**
Anaphylaxis; *Urticaria*

**CODES**

**ICD10**
- T78.3XXA Angioneurotic edema, initial encounter
- D84.1 Defects in the complement system

**CLINICAL PEARLS**
- AE is an acute, localized swelling of skin, mucosa, and submucosa caused by extravasation of fluid into the affected tissues. It often resolves in hours to days, but it can be life-threatening if the upper airway is involved.
- HAE and AAE are diseases of the complement cascade that result in recurrent episodes of AE of the skin, upper airway, and GI tract.
- Trigger identification and avoidance are key in the prevention of AE.
- Patients with a history of allergies and AE should be prescribed an
epinephrine autoinjector.
ANKLE FRACTURES
Jeffrey P. Feden, MD, FACEP

BASICS
- Bones: tibia, fibula, talus
- Mortise: tibial plafond, medial and lateral malleolus
- Ligaments: syndesmotic, lateral collateral, and medial collateral (deltoid) ligament

DESCRIPTION
- Two common classification systems help describe fractures (but do not always predict fracture stability).
  - Danis-Weber system: based on level of the fibular fracture in relationship to the ankle joint
    - Type A (30%): below ankle joint; usually stable
    - Type B (63%): at the level of the ankle joint; may be stable or unstable
    - Type C (7%): above ankle joint; usually unstable
  - Lauge-Hansen (LH): based on foot position and direction of applied force relative to the tibia
    - Supination-adduction (SA)
    - Supination-external rotation (SER): most common (40–75% of fractures)
    - Pronation-abduction (PA)
    - Pronation-external rotation (PER)
- Stability-based classification
  - Stable
    - Isolated lateral malleolar fractures (Weber A/B) without talar shift and with negative stress test
    - Isolated nondisplaced medial malleolar fractures
  - Unstable
    - Bi- or trimalleolar fractures
    - High fibular fractures (Weber C) or lateral malleolar fracture with medial injury and positive stress test
    - Lateral malleolar fracture with talar shift/tilt (bimalleolar equivalent)
    - Displaced medial malleolar fractures
- Pilon fracture: tibial plafond fracture due to axial loading (unstable)
- Maisonneuve: fracture of proximal 1/3 of fibula associated with ankle fracture
(unstable); high risk of peroneal nerve injury

**Pediatric Considerations**
- Ankle fractures are more common than sprains in children compared to adults because ligaments are stronger than physis.
- Talar dome: osteochondral fracture of talar dome; suspect in child with nonhealing ankle “sprain” or recurrent effusions.
- Tillaux: isolated Salter-Harris III of distal tibia with growth plate involvement
- Triplane fracture: Salter-Harris IV with fracture lines oriented in multiple planes: 2-, 3-, and 4-part variants

**Epidemiology**
- Ankle fractures are responsible for 9% of all adult and 5% of all pediatric fractures.
- Peak incidence: females 45 to 64 years; males 8 to 15 years (average is 46 years)

**Incidence**
107 to 184 per 100,000 people per year

**Etiology and Pathophysiology**
- Most common: falls (38%), inversion injury (32%), sports-related (10%)
- Plantar flexion (joint less stable in this position)
- Axial loading: tibial plafond or pilon fracture

**Risk Factors**
- Age, fall, fracture history, polypharmacy, intoxication
- Obesity, sedentary lifestyle
- Sports, physical activity
- History of smoking or diabetes
- Alcohol or slippery surfaces

**General Prevention**
- Nonslip, flat, protective shoes
- Fall precautions in elderly

**Commonly Associated Conditions**
- Most ankle fractures are isolated injuries, but 5% have associated fractures,
usually in ipsilateral lower limb.
- Ligamentous or cartilage injury (sprains)
- Ankle or subtalar dislocation
- Other axial loading or shearing injuries (i.e., vertebral compression or contralateral pelvic fractures)

**DIAGNOSIS**

**HISTORY**
- Location of pain, timing, and mechanism of injury (key historical element is exact mechanism)
- Weight-bearing status after injury
- History of ankle injury or surgery
- Tetanus status
- Assess for safety and fall risk (especially in elderly).

**PHYSICAL EXAM**
- Examine skin integrity (open vs. closed fracture).
- Assess point of maximal tenderness.
- Assess neurovascular status and ability to bear weight.
- Consider associated injuries.
- Assess ankle stability: anterior drawer test for the anterior talofibular ligament (ATFL), talar tilt test for lateral and medial ligaments, squeeze test and external rotation stress test for the tibiofibular syndesmosis

**DIFFERENTIAL DIAGNOSIS**
- Ankle sprain
- Other fractures: talus, 5th metatarsal, calcaneus

**DIAGNOSTIC TESTS & INTERPRETATION**
- Plain radiographs: first line for suspected fractures
- Ottawa ankle rules (OAR): Overall sensitivity of 98% in adults increases to 99.6% if applied within the first 48 hours after trauma (1)[A].
- OAR suggest films in patients aged 18 to 55 years if:
  - Tenderness at the posterior edge or tip of the medial malleolus, or
  - Tenderness at the posterior edge or tip of the lateral malleolus, or
  - Inability to bear weight both immediately and in the ED for four steps, or
- Tenderness at navicular or 5th metatarsal (Ottawa Foot Rules)
- If symptoms persist past 48 to 72 hours, obtain x-rays.
- In children >1 year old, OAR sensitivity is 98.5%.
- OAR not valid for intoxicated patients, those with multiple injuries, or sensory deficits (neuropathy)
- Three standard views
  - Anteroposterior (AP)
  - Lateral: Talar dome/distal tibia incongruity indicates instability.
  - Mortise (15- to 25-degree internal rotation view): symmetry of mortise; space between the medial malleolus and talus should be ≤4 mm.
  - Additional stress view may demonstrate instability: increased medial clear space with manual external rotation

**Pediatric Considerations**
- Consider tenderness over distal fibula with normal films as Salter-Harris I.
- Stress views unnecessary in children and may cause physeal damage.
- Salter-Harris V often missed, diagnosed when leg length discrepancy or angular deformity after Salter-Harris I; rare, 1% of fractures

**Follow-Up Tests & Special Considerations**
- CT recommended for operative planning in trimalleolar, Tillaux, triplane, pilon fractures, or fractures with intra-articular involvement
- MRI not routinely indicated; does not increase sensitivity for detecting complex ankle fractures
  - MRI useful for chronic instability, osteochondral lesions, occult fractures, and unexpected stiffness in children

**Diagnostic Procedures/Other**
- Ultrasound for soft tissue injury associated with displaced fractures
- Bone scan or MRI for stress fracture

**TREATMENT**

**GENERAL MEASURES**
- Immobilize in temporary cast/splint and protect with crutches/non–weight bearing
  - 1 to 2 weeks to allow decreased swelling, if not open or irreducible fracture
Ice and elevate the extremity; pain due to swelling best controlled with elevation
  - Compression stockings offer no benefit for swelling (3)[A].

Closed ankle fractures—must determine stability
  - Stable = nonoperative
  - Unstable = surgery
  - Lateral shift of talus ≥2 mm or displacement of either malleolus by 2 to 3 mm = surgery (2)[C]
  - In adults with displaced fractures: insufficient evidence if surgery or nonoperative management produces superior long-term outcomes (4)[A]

Stable syndesmosis injury = nonoperative

Fracture dislocations: urgent reduction
  - Do not wait for imaging if neurovascular compromise or obvious deformity.
  - Flex hip and knee 90 degrees for easier reduction.
  - Post reduction: neurovascular exam and x-rays

**MEDICATION**

*First Line*
- NSAIDs and/or acetaminophen for pain
- Initial IM pain injection (i.e., ketorolac, ≥50 kg adult: 60 mg or 30 mg q6h, max 120 mg daily; children 2 to 16 years old, <50 kg or age of ≥65 years: 1 mg/kg, 30 mg, or 15 mg q6h, max 60 mg daily)
- For suspected open fractures: tetanus booster, broad-spectrum cephalosporin and aminoglycoside within 3 hours post injury (2)[C]
- Intra-articular or hematoma block

*Second Line*
Opioid analgesics as adjunctive therapy

**ISSUES FOR REFERRAL**
- Consultation for neurovascular compromise, tenting of skin or open fracture, displaced or unstable fracture, compartment syndrome
- All other fractures: Follow up within 1 week and remain non–weight bearing. Consult orthopedics if not comfortable with routine fracture management.

**ADDITIONAL THERAPIES**
- Nonoperative = cast immobilization
– No difference in type of immobilization (Air-Stirrup, cast, orthosis) (3)[A]
– Initially non–weight bearing with crutches, and then advance to 50% with crutches; full weight bearing after 6 weeks post injury
– If removable cast, gentle range of motion exercises at 4 weeks

- Open ankle fractures (2%)
  - Remove gross debris/contamination in ED.
  - Duration of optimal antibiotic therapy controversial
  - Surgical emergency; best if repaired within 24 hours

**SURGERY/OTHER PROCEDURES**

- Surgical options
  - Open reduction internal fixation (ORIF); preferred in athletes and unstable fractures
  - External fixation may be preferred in extreme tissue injury or comminuted fractures; may have more malunion compared to ORIF but no difference in wound complications

- Timing of surgery
  - Immediately if neurovascular compromise, open fracture, unsuccessful reduction, tissue necrosis (2)[C]
  - Otherwise delay >5 days post injury because inflammation can affect wound healing (2)[C].

- Length of recovery is usually 6 to 8 weeks.

**Pediatric Considerations**

- Salter-Harris I and II = nonoperative
  - Distal tibia: long leg cast for 4 to 6 weeks and then short leg cast for 2 to 3 weeks (5)[C]
  - Distal fibula: posterior splint or ankle brace 3 to 4 weeks, weight bearing; if displaced, then short leg cast 4 to 6 weeks, non–weight bearing (5)[C]
  - Limit reduction attempts because of potential injury to growth plate (5,6)[C].
  - Reduction not recommended if presenting ≥1 week post injury (5)[C]
  - Intra-articular displacement of ≥2 mm in child with >2 years growth remaining = ORIF (6)[C]

- Salter-Harris III and IV:
  - Distal tibia: if >2 mm displacement = ORIF (6)[C]
  - Distal fibula: rare, usually stable after tibial reduction (6)[C]
  - Tillaux and triplane: ORIF if displaced ≥2 mm (5,6)[C]
**Geriatric Considerations**

- Higher surgical risk due to age/comorbidities
- Osteoporosis increases risk of implant/fixation failure (4)[A].
- Risks from surgery/anesthesia: wound healing problems, pulmonary embolism, mortality, amputation, reoperation

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Admit if:
  - Emergency surgery required
  - Patient nonadherent, lacks social support, unable to maintain non–weight-bearing status or has significant associated injuries
  - Concerning mechanism of injury (i.e., syncope, myocardial infarction, head injury)
- Nursing: non–weight bearing; maintain splint/cast; apply ice; keep leg elevated; pain control; assist ADLs.
- Discharge criteria:
  - Ambulates with walker or crutches
  - Medical workup (if needed) completed
  - Orthopedic follow-up arranged

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Orthopedic follow-up: serial x-rays
  - In children, sclerotic lines on x-ray (Parker-Harris growth arrest lines) indicate growth disturbance (5)[C].
- Immobilize for 4 to 6 weeks and then progressive activity, weight bearing, with removable splint or boot (3)[A]
- Physical therapy referral: no difference in outcomes between stretching, manual therapy, exercise program (3)[A]

**DIET**

NPO if surgery is being considered
PATIENT EDUCATION
• Ice and elevate for 2 to 3 weeks; use crutches/cane as instructed; splint/cast care (avoid getting wet, etc.)
• Notify physician if swelling increases, paresthesias, pain, or change in color of extremity.

PROGNOSIS
• Good results can be achieved without surgery if fracture is stable.
  – Most return to activity within 3 to 4 months.
• Most athletes return to preinjury activity levels.
• Increasing age, not injury severity, associated with worsening mobility after fracture

COMPLICATIONS
• Displaced fracture or instability
• Delayed union, malunion, or nonunion (0.9–1.9%)
• Postsurgical wound problems: loss of fixation, further surgery, amputation
• Deep venous thrombosis
• Complex regional pain syndrome, extensor retinaculum syndrome in children
  (5)[C]
• Infection (osteomyelitis)
• Posttraumatic arthritis, degenerative joint disease, growth arrest in children

REFERENCES
CODES

ICD10
- S82.899A Oth fracture of unsp lower leg, init for clos fx
- S82.899B Oth fracture of unsp lower leg, init for opn fx type I/2
- S82.56XA Nondisp fx of medial malleolus of unsp tibia, init

CLINICAL PEARLS
- OAR are nearly 100% sensitive in determining the need for x-rays.
- Assess neurovascular status, ability to bear weight, associated injuries.
- Assess joint above/below (i.e., Maisonneuve).
- Normal x-rays with point tenderness indicate Salter-Harris type I fractures in children.
- Assessment of fracture stability (classification systems are helpful) often dictates conservative versus operative management.
ANKYLOSING SPONDYLITIS
Benjamin J. Slocum, DO • Virginia J. Van Duyne, MD

BASICS
DESCRIPTION
- Ankylosing spondylitis (AS) is an axial inflammatory spondyloarthropathy (axSpA) characterized by evidence of sacroiliitis on plain radiography.
- System(s) affected: musculoskeletal; eyes; cardiac; neurologic; pulmonary
- Synonym(s): Marie–Strümpell disease; “bamboo spine”

EPIDEMIOLOGY
- Onset usually in early 20s; rarely occurs after age 40 years
- Male > female (approximately 2 to 3:1)

Incidence
Age- and gender-adjusted rate of 6.3 to 7.3/100,000 person-years

Prevalence
~0.55% for AS and ~1.4% for all axSpA in the United States (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Autoinflammation at sites of bacterial exposure (e.g., intestines) or mechanical stress in genetically susceptible individuals (2)
- Inflammation at the insertion of tendons, ligaments, and fasciae to bone (enthesopathy) causes erosion, remodeling, and new bone formation.
- Inflammation-independent pathways of bony changes have also been hypothesized (2).

Genetics
- 80–90% of patients with AS are HLA-B27–positive.
- Other genetic associations include endoplasmic reticulum aminopeptidase 1 (ERAP1), interleukin-23 receptor (IL23R), and gene deserts on chromosome 2p15 and 21q22 (2).

RISK FACTORS
• HLA-B27
  – 1–8% of HLA-B27–positive adults have AS.
• Positive family history
  – HLA-B27–positive child of a parent with AS has a 10–30% risk of developing the disease.

COMMONLY ASSOCIATED CONDITIONS
• Peripheral arthritis (30%)
• Enthesopathy (29%): Achilles tendonitis, plantar fasciitis
• Uveitis (23%)
• Psoriasis (10%)
• Dactylitis “sausage digit” (6%)
• Inflammatory bowel disease “IBD” (4%) [A]
• Peripheral spondyloarthritis (SpA): psoriatic arthritis, reactive arthritis, IBD-related arthritis, juvenile idiopathic arthritis
• Aortitis and cardiac conduction defects

DIAGNOSIS

HISTORY
• Inflammatory back pain
  – Insidious onset
  – Duration >3 months
  – Morning stiffness in spine lasting >1 hour
  – Nighttime awakenings secondary to back pain
  – Pain and stiffness increase at rest and improve with activity.
• Alternating buttock/hip pain is common.
• Constitutional symptoms (fatigue, weight loss, low-grade fever) are common.
• Inspirational chest pain due to enthesitis at costochondral junction and diminished chest wall expansion
• Other symptoms associated with enthesopathy (Achilles pain, plantar fascia pain), dactylitis (oligoarthritis), iritis (painful red eye, photophobia, vision changes)

PHYSICAL EXAM
• Sacroiliac joint tenderness, loss of lumbar lordosis, and cervical spine rotation
• Diminished range of motion in the lumbar spine in all three planes of motion
Modified Wright-Schober test for lumbar spine flexion:
- Mark patient’s back over the L5 spinous process (or at dimples of Venus) and measure 10 cm above and 5 cm below this point. Normal is at least 5 cm of expansion between these two marks on maximal forward flexion.

Thoracocervical kyphosis (usually after at least 10 years of symptoms)
Occiput–wall distance increased (distance between occiput and wall when standing with back flat against a vertical surface; zero is normal)
Respiratory excursion of chest wall
- Normal is >5 cm of maximal respiratory excursion of chest wall measured at 4th intercostal space; <2.5 cm is consistent with AS.

Tenderness of insertional sites—Achilles, plantar fascia
Peripheral oligoarthritis/dactylitis seen mostly with peripheral SpA
Cauda equina syndrome rarely occurs in late disease.
Extra-articular manifestations: uveitis, psoriasis, IBD
Aortic regurgitation murmur (1%)

DIFFERENTIAL DIAGNOSIS
- Nonradiographic axSpA (features of AS with evidence of sacroiliitis on MRI but not on plain radiographs—can progress to AS); other SpA
- Osteoarthritis of the axial spine
- Diffuse idiopathic skeletal hyperostosis (DISH)
- Osteitis condensans ilii: benign sclerotic changes in the iliac portion of the SI joint after pregnancy
- Infectious arthritis or discitis, unilateral sacroiliitis: tuberculosis, brucellosis, bacterial infection (particularly in IV drug users)

DIAGNOSTIC TESTS & INTERPRETATION
- Up to 10% of Caucasian population and 4% of African American population are HLA-B27–positive. Genetic testing is not necessary as part of initial evaluation, particularly with a consistent history and exam.
- ESR and C-reactive protein (CRP) may be mildly elevated or normal; if high, correlates with disease activity and prognosis
- Absence of rheumatoid factor
- Mild normochromic anemia (15%)
- Synovial fluid: mild leukocytosis
- SI joints: Oblique projection is preferred.
  - X-ray changes may not be apparent for up to 10 years after disease onset. MRI is more sensitive; increased signal from the bone and bone marrow suggests osteitis and edema.
Sequential radiographic changes over time: widening of SI joint, erosions, sclerosis on both sides of joint not extending >1 cm from articular surface, and (lastly) ankyloses

- Spine: lateral view preferred
  - Early plain radiograph changes: “shiny corners” due to osteitis and sclerosis at site of annulus fibrosus attachments to the corners of vertebral bodies with “squaring” due to erosion and remodeling of vertebral body; contrast-enhanced MRI is more sensitive for detecting early changes.
  - Late changes: ossification of annulus fibrosis resulting in bony bridging between vertebral bodies (syndesmophytes) giving classic “bamboo spine” appearance; ankylosis of apophyseal joints, ossification of spinal ligaments, and/or spondylodiscitis also occurs.

- Peripheral joints
  - Asymmetric pericapsular ossification, sclerosis, loss of joint space, and erosions may occur.

Diagnostic Procedures/Other
Screening for cardiac conduction defects with ECG and for valvular heart disease with echocardiograms not recommended but may consider if symptomatic

Test Interpretation
- Erosive changes and new bone formation at bony attachment of the tendons and ligaments result in ossification of periarticular soft tissues.
- Synovial hypertrophy and pannus formation, mononuclear cell infiltrate into subsynovium and subchondral bone marrow inflammation in the SI joint with erosions, followed by granulation tissue formation, and finally obliteration of joint space by fusion of joint and sclerosis of para-articular bone.

TREATMENT
GENERAL MEASURES
- Symptom control, maintaining spinal flexibility and normal posture, reducing functional limitations, maintain work ability, and decreased disease complications are primary treatment goals.
- Aggressive physical therapy is the most important nonpharmacologic management.
Posture training and spinal range-of-motion exercises are essential.
Firm bed; sleep in supine position without a pillow.
Breathing exercises 2 to 3 times per day
Smoking cessation

MEDICATION

First Line
- Nonsteroidal anti-inflammatory drugs (NSAIDs) are first-line pharmacologic agent for pain and stiffness in AS (4)[A].
- NSAIDs provide rapid and dramatic symptomatic relief, which may aid in diagnosis. No single NSAID preferred. Higher doses tend to be more efficacious.
- NSAIDS may be effective in slowing radiographic disease progression, and this may be best achieved by continuous rather than on demand use (4)[A].

Precautions
- Consider CVD, GI, and renal risks of NSAIDs. Use with caution in patients with a bleeding diathesis or on anticoagulants.
- Consider GI prophylaxis (PPIs or misoprostol) while on NSAIDs in patients with hx of PUD, gastritis, or age >60 years.
- Injection of intra-articular corticosteroids into SI joints and prostheses can provide transient relief, but systemic corticosteroids are not recommended (5)[C].

Pregnancy Considerations
Infants exposed to NSAIDs in 1st trimester may have a higher incidence of cardiac malformations.

Second Line
- Biologic agents: tumor necrosis factor (TNF)-α antagonists
  - Recommended for active disease after lack of response to at least two different NSAIDs over 1 month (5)[C]
  - FDA-approved agents for AS include etanercept (recombinant TNF receptor fusion protein), infliximab (chimeric monoclonal IgG1 antibody to TNF-α), adalimumab (fully humanized IgG1 monoclonal antibody to TNF-α), and golimumab (human IgG1 kappa monoclonal antibody to TNF-α).
  - Approved agents improve pain, function, and symptoms of AS as compared to placebo (6)[A].
  - No definitive evidence for TNF-α blockers with regard to disease
remission, prevention of radiologic progression, or prevention of extra-articular manifestations
- Monoclonal TNF-α blockers are preferred when IBD is involved (5)[C].
- Further investigation as to the effectiveness of TNF blocker therapy with NSAIDs is needed.

- Precautions with TNF-α blockers
  - Anti-TNFs increase the risk of serious bacterial, mycobacterial, fungal, opportunistic, and viral infections. Screen for tuberculosis and hepatitis B.
  - Monitor for reactivation of tuberculosis and invasive fungal infections, such as histoplasmosis, in all patients, especially those who travel to (or residents in) endemic areas.
  - Lymphomas, nonmelanoma skin cancers, and other malignancies have been reported in patients receiving anti-TNFs.
  - Immunizations (especially live vaccines) should be updated before initiating anti-TNFs; live vaccines are contraindicated once patients receive anti-TNFs.

- Disease-modifying antirheumatic drugs (DMARDs), such as methotrexate and sulfasalazine, are ineffective for axial disease; sulfasalazine may be effective for peripheral arthritis; this class may be considered in patients with contraindications to TNF agents (5)[C].

**ISSUES FOR REFERRAL**
- Physical therapy can assist with treatment plan (including home regimens).
- Coordinate care with a rheumatologist for diagnosis, monitoring, and management (anti-TNF therapy).
- Management of aortic regurgitation, uveitis, spinal fractures, pulmonary fibrosis, hip joint involvement, renal amyloidosis, and cauda equina syndrome may require referral to appropriate specialty.

**ADDITIONAL THERAPIES**
Bisphosphonate medications if osteopenia or osteoporosis is present

**SURGERY/OTHER PROCEDURES**
- Evaluate for C-spine ankylosis/instability before intubation in patients with AS undergoing surgery.
- Total hip replacement with advanced hip arthritis (5)[C]
- Vertebral osteotomy can improve posture for patients with severe cervical or thoracolumbar flexion.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Monitor posture and range of motion with 6- to 12-month visits; increase frequency if higher disease activity.
- Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) or Ankylosing Spondylitis Disease Activity Score (ASDAS) can be used to measure disease activity.
- Fall prevention/evaluation
- Regular-interval monitoring of CRP or ESR
- Screening for osteopenia/osteoporosis with dual energy x-ray absorptiometry scan

PATIENT EDUCATION
- Maintain physical activity and posture.
- Swimming, tai chi, and walking are excellent activities.
- Avoid trauma/contact sports.
- Appropriate ergonomic modification of workplace
- Counsel about risk of spinal fracture.
- MedicAlert bracelet (helpful if intubation required)
- Arthritis Foundation: http://www.arthritis.org
- Spondylitis Association of America: http://www.spondylitis.org

PROGNOSIS
- Extent and rapidity of progression of ankylosis are highly variable.
- Progressive limitation of spinal mobility necessitates lifestyle modification.

COMPLICATIONS
- MSK/spine
  - Osteoporosis (13%); 10% higher risk of nonvertebral fracture in AS patients
  - Spinal fusion causing kyphosis
  - Cervical spine fracture or subluxation carries high mortality rate; fracture can occur at any level of ankylosed spine.
  - Cauda equina syndrome (rare)
- Pulmonary: restrictive lung disease, upper lobe fibrosis (rare)
Cardiac: conduction defects at atrioventricular (AV) node, aortic insufficiency, aortitis, pericarditis (extremely rare)
Eye: uveitis and cataracts
Renal: IgA nephropathy, amyloidosis (<1%)
GI: microscopic, subclinical ileal, and colonic mucosal ulcerations in up to 50% of patients, mostly asymptomatic

REFERENCES

ADDITIONAL READING
- Sieper J. Treatment challenges in axial spondylarthritis and future directions.

**SEE ALSO**

Arthritis, Psoriatic; Arthritis, Rheumatoid (RA); Crohn Disease; Reactive Arthritis (Reiter Syndrome); Ulcerative Colitis

**CODES**

**ICD10**

- M45.9 Ankylosing spondylitis of unspecified sites in spine
- M08.1 Juvenile ankylosing spondylitis
- M45.8 Ankylosing spondylitis sacral and sacrococcygeal region

**CLINICAL PEARLS**

- Diagnosis of AS is suggested by a history of inflammatory back pain, pain when supine and lasting over an hour on movement, evidence of limited chest wall expansion, restricted spinal movements in all planes, radiographic evidence of sacroiliitis, and a therapeutic response to NSAIDs.
- HLA-B27 testing supports the diagnosis if clinical features are not definitive.
- MRI is more sensitive at detecting SI joint inflammation than plain radiography.
- Physical therapy is important in helping to maintain posture and mobility.
- NSAIDs and TNF-α blockers are the mainstays of pharmacologic treatment of AS.
ANOREXIA NERVOSA

Umer Farooq, MD • Saeed Ahmed, MD

BASICS

DESCRIPTION

- Restriction of energy intake leading to significantly low weight in the context of age, sex, developmental trajectory, and physical health, with intense fear of weight gain and body image disturbance. Significantly low weight is defined as weight that is less than minimally normal/expected.

- *Diagnostic and Statistical Manual of Mental Disorders*, 5th edition (*DSM-5*), divides anorexia into two types:
  - Restricting type: not engaged in binge eating or purging behaviors for last 3 months
  - Binge eating/purging type: regularly engages in binge eating or purging behaviors (last 3 months)

- System(s) affected: cardiovascular, endocrine, metabolic, gastrointestinal, nervous, reproductive

- Severity of anorexia nervosa (AN) is based on BMI (per *DSM-5*):
  - Mild: BMI ≥17 kg/m²
  - Moderate: BMI 16.00 to 16.99 kg/m²
  - Severe: BMI 15.00 to 15.99 kg/m²
  - Extreme: BMI <15 kg/m²

EPIDEMIOLOGY

- Predominant age: 13 to 20 years
- Predominant sex: female > male (10:1 female-to-male ratio)

*Incidence*

8 to 19 women/2 men per 100,000 per year

*Prevalence*

- 0.4% in women
- Less is known; however, an estimate suggests 0.3% in men (higher in gay and bisexual men).
ETIOLOGY AND PATHOPHYSIOLOGY
- Complex relationship among genetic, biologic, environmental, psychological, and social factors that result in the development of this disorder
- Subsequent malnutrition may lead to multiorgan damage.
- Serotonin, norepinephrine, and dopamine neuronal systems are implicated.

Genetics
- Underlying genetic vulnerability is likely but not well understood; some evidence of higher concordance rates in monozygotic twins than in dizygotic
- First-degree female relative with eating disorder increases risk 6- to 10-fold.

RISK FACTORS
- Female gender
- Adolescence
- Body dissatisfaction
- Perfectionism
- Negative self-evaluation
- Academic pressure
- Severe life stressors
- Participation in sports or artistic activities that emphasize leanness or involve subjective scoring: ballet, running, wrestling, figure skating, gymnastics, cheerleading, weight lifting
- Type 1 diabetes mellitus
- Family history of substance abuse, affective disorders, or eating disorder

GENERAL PREVENTION
Prevention programs can reduce risk factors and future onset of eating disorders.
- Target adolescents and young women 15 years of age or older.
- Encourage realistic and healthy weight management strategies and attitudes.
- Promote self-esteem.
- Reduce focus on thin as ideal.
- Decrease co-occurring anxiety/depressive symptoms and improve stress management.

COMMONLY ASSOCIATED CONDITIONS
- Mood disorder (major depression)
- Social phobia, obsessive-compulsive disorder
- Substance abuse disorder
- High rates of cluster C personality disorders

**DIAGNOSIS**

**HISTORY**
- Onset may be insidious or stress-related.
- Patient unlikely to self-identify problem (lack of insight into the illness); corroborate with parent/relative.
- Restriction of energy intake relative to requirement, leading to significantly low body weight in the context of age, sex, developmental trajectory, and physical health
- Fear of weight gain and/or distorted body image
- Report feeling fat even when emaciated.
- Preoccupation with body size, weight control
- Elaborate food preparation and eating rituals
- Other possible signs and symptoms:
  - Extensive exercise
  - Amenorrhea (primary or secondary)
  - Weakness, fatigue, cognitive impairment
  - Cold intolerance
  - Constipation, bloating, early satiety
  - Growth arrest, delayed puberty
  - History of fractures (decreased bone density)
- Screening
  - Clinician-administered eating disorder screen for primary care to identify patients with eating disorders
    - Are you satisfied with your eating patterns? (No is abnormal.)
    - Do you ever eat in secret? (Yes is abnormal.)
    - Does your weight affect the way you feel about yourself? (Yes is abnormal.)
    - Have any members of your family suffered with an eating disorder? (Yes is abnormal.)
    - Do you currently suffer with or have you ever suffered in the past with an eating disorder? (Yes is abnormal.)

**PHYSICAL EXAM**
- May be normal
Abnormal vital signs: hypothermia, bradycardia, orthostatic hypotension
Body weight <85% of expected
Cardiac: dysrhythmias, midsystolic click of mitral valve prolapse
Skin/extremities: dry skin; lanugo hair on extremities, face, and trunk; hair loss; edema
Neurologic and abdominal exams: to rule out other causes of weight loss and vomiting

DIFFERENTIAL DIAGNOSIS
- Hyperthyroidism, adrenal insufficiency
- Inflammatory bowel disease, malabsorption
- Immunodeficiency, chronic infections
- Diabetes
- CNS lesion
- Bulimia, body dysmorphic disorder
- Depressive disorders with loss of appetite
- Anxiety disorder, food phobia
- Conversion disorder

DIAGNOSTIC TESTS & INTERPRETATION
- Psychological self-report screening tests may be helpful, but diagnosis is based on meeting the DSM-5 criteria.
- Most findings are related directly to starvation and/or dehydration. All findings may be within normal limits.
- Screening tools:
  - SCOFF questionnaire (1)[B]
  - Eating Disorder Screen for Primary Care

Initial Tests (lab, imaging)
- CBC: anemia, leukopenia, thrombocytopenia
- Low serum luteinizing hormone, follicle-stimulating hormone; low serum testosterone in men
- Thyroid function tests: low thyroid-stimulating hormone with normal $T_3/T_4$
- Liver function tests: abnormal liver enzymes
- Chem 7: altered BUN, creatinine clearance; electrolyte disturbances
- Hypoglycemia, hypercholesterolemia, hypercortisolemia, hypophosphatemia
- Low sedimentation rate
- 12-Lead electrocardiogram to assess for prolonged QT interval
● Dual-energy x-ray absorptiometry of bone to assess for diminished bone density, only if underweight for >6 months

**Test Interpretation**

● Osteoporosis/osteopenia, pathologic fractures
● Sick euthyroid syndrome
● Cardiac impairment

**ALERT**

AN may exist concurrently with chronic medical disorders such as diabetes and cystic fibrosis.

**TREATMENT**

**GENERAL MEASURES**

● Initial treatment goal geared to weight restoration; most managed as outpatients (OPs)
● OP treatment:
  – Interdisciplinary team (primary care physician, mental health provider, dietitian)
  – Average weekly weight gain goal: 0.5 to 1.0 kg, with stepwise increase in calories
  – Cognitive-behavioral therapy (CBT), interpersonal psychotherapy, motivational interviewing, family-based therapy
  – Focus on health, not weight gain alone.
  – Build trust and a treatment alliance.
  – Involve the patient in establishing diet and exercise goals.
  – Challenge fear of uncontrolled weight gain; help the patient to recognize feelings that lead to disordered eating.
  – In chronic cases, goal may be to achieve a safe weight rather than a healthy weight.
● Inpatient treatment:
  – If possible, admit to a specialized eating disorders unit.
  – Assess risk for refeeding syndrome (metabolic shift from a catabolic to anabolic state).
  – Monitor vital signs, electrolytes, cardiac function, edema, and weight gain.
  – Initial supervised meals may be necessary.
– Stepwise increase in activity
– Tube feeding or total parenteral nutrition is used only as a last resort.
– Supportive symptomatic care as needed

- Most patients should be treated as OPs using an interdisciplinary team.
- Behavioral therapies (e.g., cognitive-behavioral, interpersonal, or family therapy) should be offered (2,3)[A].
- CBT has demonstrated effectiveness as a means of improving treatment adherence and minimizing dropout among patients with AN (4)[A].

MEDICATION

**First Line**

- No medications are available that effectively treat patients with AN, but pharmacotherapy may be used as an adjuvant to CBTs (5)[A].
- If medications are used, start with low doses due to increased risk for adverse effects.
- SSRIs may:
  – Help to prevent relapse after weight gain
  – Treat comorbid depression or obsessive-compulsive disorder
  – Use of atypical antipsychotics is being studied with mixed findings to date. Olanzapine is potentially beneficial as an adjuvant treatment of underweight individuals in the inpatient settings.
- Attend to black box warnings concerning antidepressants.
- The antidepressant bupropion should be avoided because it is associated with a higher incidence of seizures.

**Second Line**

- Management of osteopenia:
  – Primary treatment is weight gain.
  – Elemental calcium 1,200 to 1,500 mg/day plus vitamin D 800 IU/day
  – No indication for bisphosphonates in AN
  – Weak evidence for use of hormone-replacement therapy
- Psyllium (Metamucil) preparations to prevent constipation

**ISSUES FOR REFERRAL**

Patients with AN require an interdisciplinary team (primary care physician, mental health provider, nutritionist). An important step in management is to arrange OP mental health therapist.
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Suggested physiologic values: heart rate <40 beats/min, BP <90/60 mm Hg, symptomatic hypoglycemia, temperature <97.0°F (36.1°C), dehydration, other cardiovascular abnormalities, weight <75% of expected, rapid weight loss, lack of improvement while in OP therapy
- Suggested psychological indications: poor motivation/insight, lack of cooperation with OP treatment, inability to eat, need for nasogastric feeding, suicidal intent or plan, severe coexisting psychiatric disease, problematic family environment
- Suggested lab indications: potassium <3 mmol/L, prolonged QTC (>0.499 msec), urine specific gravity >1.03 or <1.01

Pediatric Considerations

- Children often present with nausea, abdominal pain, fullness, and inability to swallow.
- Additional indications for hospitalization: heart rate <50 beats/min, orthostatic BP, hypokalemia or hypophosphatemia, rapid weight loss even if weight not <75% below normal
- Children and adolescents should be offered family-based treatment.

Geriatric Considerations

Late-onset AN (>50 years of age) may be long-term disease or triggered by death of loved one, marital discord, or divorce.
- Discharge when medically stable. Arrange OP appointment with mental health provider and primary care provider.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Close follow-up until patient demonstrates forward progress in care plan
- Family and individual therapy is extremely important for the long-term benefits/outcomes.
- CBT is very helpful for the treatment of AN and may be helpful for the prevention of relapse.
- Emphasize importance of moderate activity for health, not thinness.
**Patient Monitoring**
- Level of exercise activity
- Weigh weekly until stable and then monthly.
- Depression, suicidal ideation

**DIET**
- Dietary consultation while patient is hospitalized
- Nutritional education programs

**PATIENT EDUCATION**
- Provide patients and families with information about the diagnosis and its natural history, health risks, and treatment strategies.
- [http://www.mayoclinic.org/diseases-conditions/anorexia/home/ovc-20179508](http://www.mayoclinic.org/diseases-conditions/anorexia/home/ovc-20179508)

**PROGNOSIS**
- Prognosis: ~50% recover, 30% improve, 20% are chronically ill.
- Outcomes in men are likely better than in women.
- Mortality: 3%
- High risk of suicide in patients suffering from AN (6)[A]

**COMPLICATIONS**
- Refeeding syndrome
- Cardiac arrhythmia, cardiac arrest
- Cardiomyopathy, congestive heart failure
- Delayed gastric emptying, necrotizing colitis
- Seizures, Wernicke encephalopathy, peripheral neuropathy, cognitive deficits
- Osteopenia, osteoporosis

**Pregnancy Considerations**
- Fertility may be affected.
- Behaviors may persist, decrease, or recur during pregnancy and the postpartum interval.
- Increased risk for preterm labor, operative delivery, and infants with low birth weight; anemia, genitourinary infections, and labor induction should be managed as high risk.

- Amenorrhea; Bulimia Nervosa; Osteoporosis and Osteopenia
- Algorithm: Weight Loss, Unintentional

CODES
ICD10
- F50.00 Anorexia nervosa, unspecified
- F50.01 Anorexia nervosa, restricting type
- F50.02 Anorexia nervosa, binge eating/purging type

CLINICAL PEARLS
- “Are you satisfied with your eating patterns?” and/or “Do you worry that you have lost control over how you eat?” may help to screen those with an eating problem.
- Studies have shown patients with AN will not accept medications unless combined with psychotherapy.
- To care for a patient with AN, an interdisciplinary team that includes a medical provider, a dietitian, and a behavioral health professional is the most accepted approach.
- Family analysis is necessary for the patients with AN to determine what kind of therapy would be most helpful.
- 3 months amenorrhea is no longer the criteria needed for the diagnosis of AN.
ANTIPHOSPHOLIPID ANTIBODY SYNDROME

Edwin Seelye, DO • Troy Sterk, DO

BASICS

DESCRIPTION

Antiphospholipid antibody syndrome (APS) is an autoantibody-mediated thrombophilic disorder characterized by recurrent arterial or venous thrombosis and/or recurrent fetal loss in the presence of antiphospholipid antibodies (APAs). The APAs enhance clot formation by interacting with phospholipid-binding plasma proteins. The resulting APS can cause morbidity and mortality in both pregnant and nonpregnant individuals:

- Types of APS (based on clinical presentation)
  - Primary: occurs without associated underlying disease
  - Secondary: associated with autoimmune diseases (systemic lupus erythematosus [SLE] is most common); transient APAs linked to certain infections, drugs, and malignancies.
  - Catastrophic APS (CAPS) a.k.a. Asherson syndrome (<1%)
    - Most severe form of disease; characterized by thrombotic microangiopathy and associated with multiorgan failure
    - High mortality if treatment is delayed
    - Severe thrombocytopenia, hemolytic anemia, and DIC are additional features.
  - Associated clinical manifestations: livedo reticularis, cardiac valvular disease, thrombocytopenia, nephropathy, hemolytic anemia, coronary artery disease, and cognitive impairment

Pregnancy Considerations

- Complications include maternal thrombosis (stroke, venous thromboembolism [VTE]), fetal death, preeclampsia and placental insufficiency, fetal growth retardation, and preterm birth.
- Low-dose aspirin and low-molecular-weight heparin (LMWH) or unfractionated heparin are the drugs of choice in pregnancy.
- Prophylactic-dose heparin is recommended in the postpartum period (unless
patient is on therapeutic anticoagulation) given high risk of thrombosis during this time. With adequate treatment, >70% of patients with APS deliver viable infants.

**EPIDEMIOLOGY**
- The prevalence of APAs increases with age but is not necessarily associated with a higher risk of thrombosis.
- For APS, female > male

**Incidence**
- In patients with positive APAs without prior risk of thrombosis, the annual incident risk of thrombosis is 0–3.8%. This risk is up to 5.3% in those with triple positivity (anticardiolipin antibodies, lupus anticoagulant [LAC], and anti–β2-glycoprotein-1 (GP1) antibodies positive).
- 10–15% of recurrent abortions are attributable to APS.

**Prevalence**
APAs are present in 1–5% of the general population and in ~40% of those with SLE. A higher prevalence is seen in those with VTE and stroke.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Anti–β2-GP1 antibodies play a central role in the pathogenesis of APS. The procoagulant effect is mediated by various possible mechanisms:
  - Endothelial effects: inhibition of prostacyclin production and loss of annexin V cellular shield
  - Platelet activation resulting in adhesion and aggregation
  - Interference of innate anticoagulant pathways (such as inhibition of protein C)
  - Complement activation
- Pregnancy-related complications are also a result of autoantibody-mediated effects:
  - Interference with expression of trophoblastic adhesion molecules resulting in abnormal placentation and placental thrombosis
- Proposed mechanisms: excess production of natural antibodies, molecular mimicry due to infections, exposure of phospholipid antigens during platelet activation, cardioliopin peroxidation, and genetic predisposition
- A “second hit” by environmental factors may be required to produce thrombosis.
**Genetics**
Most cases of APS are acquired. There are a few studies of familial occurrence of anticardiolipin antibodies and LAC. A valine 247/leucine polymorphism in β2-GP1 could be a genetic risk for the presence of anti–β2-GP1 antibodies and APS.

**RISK FACTORS**
- Age >55 years in males, >65 years in females
- Cardiovascular risk factors (hypertension, diabetes, obesity, smoking, combined oral contraceptive use)
- Underlying autoimmune disease (SLE, rheumatoid arthritis, collagen vascular disease, Sjögren syndrome, idiopathic thrombocytopenic purpura, Behçet syndrome)
- Surgery, immobilization, pregnancy

**GENERAL PREVENTION**
Risk factor modification: Control HTN and diabetes; smoking cessation; avoidance of oral contraceptives in high-risk patients; start thromboprophylaxis in established cases.

**COMMONLY ASSOCIATED CONDITIONS**
- Autoimmune diseases: SLE (most common), scleroderma, Sjögren syndrome, dermatomyositis, and rheumatoid arthritis
- Malignancy
- Infections: viral, bacterial, parasitic, and rickettsial
- Certain drugs associated with APA production without increased risk of thrombosis: phenothiazines, hydralazine, procainamide, and phenytoin
- Hemolysis, elevated liver enzymes, and low platelet count in association with pregnancy (HELLP) syndrome
- Sneddon syndrome (APS variant syndrome with livedo reticularis, HTN, and stroke)

**DIAGNOSIS**
Sapporo criteria, revised 2006:
- At least one of the following clinical criteria:
  - Vascular thrombosis
- ≥1 clinical episodes of arterial, venous, or small vessel thrombosis, occurring within any tissue or organ and confirmed by unequivocal imaging studies or histopathology
- Superficial venous thrombosis does not meet the criteria for APS.
  - Complications of pregnancy (any one of the following):
    - ≥3 consecutive spontaneous abortions before the 10th week of pregnancy, unexplained by maternal/paternal chromosomal abnormalities or maternal anatomic/hormonal causes
    - ≥1 unexplained deaths of morphologically normal fetuses (documented by ultrasonography or by direct examination) at ≥10th week of gestation
    - ≥1 premature births of morphologically normal newborn babies at ≤34th week of pregnancy due to severe preeclampsia, eclampsia, or placental insufficiency
- AND the presence of at least one of three laboratory findings (confirmed on ≥2 occasions at least 12 weeks apart):
  - LAC detected in blood
  - Anticardiolipin IgG and/or IgM antibodies present at moderate or high levels in the blood (>40 GPL or MPL or >99th percentile) via a standardized ELISA
  - Anti–β2-GP1 IgG and/or IgM antibodies in blood at a titer >99th percentile by standardized ELISA

**HISTORY**
- History of VTE or arterial thrombosis (stroke, MI)
- History of fetal loss or other obstetric complications
- Bleeding from thrombocytopenia if severe or acquired factor II deficiency
- Personal or family history of autoimmune disease

**PHYSICAL EXAM**
- Signs of venous thrombosis in extremities
- Skin manifestations, including a vasculitic rash in the form of palpable purpura or livedo reticularis or lower extremity ulcers
- Livedo reticularis
- Cardiac murmurs
- Focal neurologic or cognitive deficits

**DIFFERENTIAL DIAGNOSIS**
- Thrombophilic conditions
– Acquired: neoplastic and myeloproliferative disorders, hyperviscosity syndromes, nephrotic syndrome
  • Embolic disease secondary to atrial fibrillation, LV dysfunction, endocarditis, cholesterol emboli
  • Heparin-induced thrombocytopenia
  • Atherosclerosis
  • CAPS: hemolytic-uremic syndrome, TTP, or malignant hypertension

**DIAGNOSTIC TESTS & INTERPRETATION**

- LAC assay and IgG and IGM anticardiolipin antibodies by ELISA and anti–β2-GP1 IgG and IgM antibodies are diagnostic tests of choice.
- The LAC assay combines at least two out of three screening tests (prolongation of aPTT, dilute Russell viper venom time [dRVVT], and kaolin clotting) with two confirmatory tests.
- A weakly positive LAC result should be considered clinically important (1).
- Anti–β2-GP1 antibodies are important in the pathogenesis of thrombosis. A positive LAC assay recognizes antibodies against β2-GP1 and prothrombin.
- Although testing for antibodies to phosphatidylserine and prothrombin can help to assess the risk of thrombosis, routine evaluation for prothrombin antibodies is not recommended.
- The clinical significance of other autoantibodies (annexin V, phosphatidic acid, and phosphatidylinositol) remains unclear.
- The utility of β2-GP1 anti-domain I antibodies is being evaluated thoroughly for its diagnostic and risk stratification value.

**Initial Tests (lab, imaging)**

- CBC, PT/INR, aPTT, LAC, anticardiolipin antibodies, anti–β2-GP1 antibodies (2)[B]
- Further testing for secondary causes such as SLE when clinically suspected
- Imaging is based on clinical picture, suspected sites of thrombosis, and organ involvement.

**Follow-Up Tests & Special Considerations**

- The results of LAC are difficult to interpret in patients treated with warfarin. Unfractionated heparin or LMWH and fondaparinux do not affect the LAC assay.
Repeat testing at 12 weeks for persistence of APA.

**Diagnostic Procedures/Other**
Biopsy of the affected organ system may be necessary to distinguish from vasculitis.

**Test Interpretation**
Usual finding is thrombosis and minimal vascular or perivascular inflammation:
- Acute changes: capillary congestion and noninflammatory fibrin thrombi
- Chronic changes: ischemic hypoperfusion, atrophy, and fibrosis

**TREATMENT**

**MEDICATION**

**First Line**
- Primary thromboprophylaxis: Low-dose aspirin is indicated in asymptomatic carriers of APAs with SLE and in pregnancy. It may be considered in other asymptomatic carriers. Hydroxychloroquine is recommended in all antiphospholipid-positive SLE patients.
- Secondary thromboprophylaxis: All symptomatic, nonpregnant patients with APS need indefinite anticoagulation. The target INR depends on the severity and type of thrombosis:
  - Venous thrombosis (first episode): warfarin with target INR of 2.0 to 3.0
  - Arterial thrombosis or recurrent venous thrombosis despite anticoagulation: warfarin with target INR 3.0 to 4.0
  - LMWH and fondaparinux are alternatives.
- New oral anticoagulants such as rivaroxaban, apixaban, and dabigatran; all have been approved for treatment of DVT/PE; studies in APS are lacking; a prospective randomized controlled trial of warfarin versus rivaroxaban in patients with thrombotic APS and with a target INR of 2.5 is underway.
  - Rituximab may be an option in severe cases, possibly in those with hematologic and microthrombotic/microangiopathic manifestations (3,4) [B].
- Danaparoid, fondaparinux, and argatroban can be considered in APS patients with heparin-induced thrombocytopenia.
- Newer oral anticoagulants (dabigatran, apixaban, and rivaroxaban) may be
alternatives to warfarin with few drug interactions and no need for monitoring. The presence of APA interferes with hemostatic mechanisms and can interfere with anticoagulants. Ongoing clinical trials at various phases will help evaluate the role of new oral anticoagulants.

- Statins can decrease proinflammatory and prothrombotic state in APS. They are not recommended in the absence of hyperlipidemia; some APA-positive patients with recurrent thrombosis although adequately anticoagulated may benefit from statin therapy.
- B-cell inhibition may help in recalcitrant APS cases.
- Complement inhibition may be useful in refractory cases, but utility is being unclear.
- Peptide therapy may be a future treatment for APA-positive patients.
- Autologous hematopoietic stem cell transplantation may be an effective option for patients with concurrent complicated SLE and APS (5).
- Vitamin D deficiency/insufficiency should be corrected in all APA-positive patients, but its role in APS needs further study.
- Low-dose aspirin is superior to low-dose aspirin with low-dose warfarin due to decreased bleeding risk with no differences in number of thrombosis (6).
- CAPS: Anticoagulants and high-dose steroids may suffice in less severe cases. Aggressive treatment with either IVIG or plasmapheresis is often required in this life-threatening condition. These measures have improved survival to 66%.
- Treatment in pregnancy:
  - For women with no prior history of thrombosis and ≥2 early miscarriages, either 81 mg ASA alone or in combination with unfractionated heparin (5,000 to 10,000 units SC q12h) or LMWH (prophylactic dose). In those with a previous late pregnancy loss (>10 weeks’ gestation) or preterm (<34 weeks) delivery due to severe preeclampsia, a combination of ASA and heparin is recommended.
  - In those with a history of thrombosis, low-dose ASA plus either therapeutic low-dose heparin (dosed every 8 to 12 hours to maintain mid-interval aPTT or factor Xa levels) or LMWH (therapeutic dose)
  - Refractory cases: Up to 30% of patients have recurrent pregnancy loss despite the use of ASA and heparin. There is no role for warfarin due to risk of teratogenicity (early pregnancy) and fetal bleeding (late pregnancy). Such cases are best managed in consultation with a maternal–fetal medicine specialist.

**SURGERY/OTHER PROCEDURES**
Patients with thrombosis may require thrombectomy or an IVC filter (depending on site) when anticoagulation is contraindicated.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Standard guidelines for monitoring to maintain INR at goal with warfarin therapy
- Close monitoring is required during pregnancy.

**DIET**
Heart-healthy diet. Patients on warfarin should avoid foods rich in vitamin K (kale, spinach, sprouts, greens).

**PATIENT EDUCATION**
- Compliance with warfarin therapy to keep INR at goal
- Awareness of drug and diet interactions with warfarin
- Avoid oral hormonal contraceptives.

**PROGNOSIS**
- Pulmonary HTN, neurologic involvement, myocardial ischemia, nephropathy, gangrene of extremities, and CAPS are associated with a worse prognosis.
- 30% risk of recurrent thrombosis in the absence of adequate anticoagulation

**COMPLICATIONS**
- Pregnancy complications and pulmonary HTN are associated with higher morbidity and mortality.
- Thrombotic complications are the most common cause of death.

**REFERENCES**

2. Giannakopoulos B, Passam F, Ioannou Y, et al. How we diagnose the

**ADDITIONAL READING**

**CODES**

**ICD10**

- D68.61 Antiphospholipid syndrome
- D68.69 Other thrombophilia
- D68.62 Lupus anticoagulant syndrome

**CLINICAL PEARLS**

- APS can be either primary, secondary, or present as a severe microvascular disease known as CAPS.
Both clinical and laboratory criteria are required for diagnosis. The latter must be confirmed on two separate occasions at least 12 weeks apart.

Thrombotic manifestations of APS can be either venous or arterial. Patients require lifelong anticoagulation.
ANXIETY (GENERALIZED ANXIETY DISORDER)

Jay A. Brieler, MD • Betsy Wan, MD

BASICS

DESCRIPTION

- A condition characterized by persistent, excessive, and difficult-to-control worry associated with significant symptoms of motor tension, autonomic hyperactivity, and/or disturbances of sleep or concentration
- System(s) affected: nervous (increased sympathetic tone and catecholamine release); secondary effects on other symptoms such as cardiac (tachycardia), pulmonary (dyspnea), and GI (nausea, irregular bowels)

EPIDEMIOLOGY

Prevalence

- 12-month prevalence rate: 1.8%
- Lifetime prevalence rate: 3.7%
- More common in high- versus low-income countries: 5% versus 1.6%
- Elderly prevalence as high as 7–10%
- Onset can occur any time in life but is typically during adulthood; median age of onset in the United States is 31 years.
- Predominant sex: female > male (2:1)
- Generally recurrent and chronic in nature; gradual in onset; fluctuates in severity; complete remission less likely

ETIOLOGY AND PATHOPHYSIOLOGY

- May be mediated by abnormalities of neurotransmitter systems (i.e., serotonin, norepinephrine, and γ-aminobutyric acid [GABA])
- Associated with altered regional brain function (increased activity in the amygdala and prefrontal cortex)

Genetics

- Strongly linked to depression in heritability studies
- A variant of the serotonin transporter gene (5HT1A) or other genes may
contribute to both conditions.

**RISK FACTORS**
- Caucasian race
- Adverse life events
- Family history
- Lack of social support
- Obesity
- Comorbid psychiatric disorders (2)

**GENERAL PREVENTION**
- Physical activity and cardiorespiratory fitness are associated with decreased generalized anxiety and depression.
- Cognitive-behavioral therapy (CBT) and parental intervention in children with early anxiety may protect against the development of GAD (2).

**COMMONLY ASSOCIATED CONDITIONS**
- Major depressive disorder (>60%), dysthymia, bipolar disorder, schizophrenia
- Alcohol/drug abuse
- Cigarette smoking in adolescence
- Panic disorder, agoraphobia, simple phobia, social anxiety disorder, anorexia nervosa, posttraumatic stress disorder (PTSD), obsessive-compulsive disorder (OCD), ADHD
- Somatoform and pain disorders

**DIAGNOSIS**
**HISTORY**
- Diagnosis is primarily made through history taking. Pathologic anxiety must be distinguished from normal anxiety reactions.
- DSM-5 criteria are as follows:
  - Symptoms of excessive anxiety and worry must occur more often than not for at least 6 months.
  - Patient finds it difficult to control the worry.
  - At least three additional criteria are required for diagnosis of GAD in adults; only one is required in children.
    - Restlessness or feeling keyed up or on edge
- Easily fatigued
- Difficulty concentrating or mind going blank
- Irritability
- Muscle tension
- Sleep disturbances (difficulty falling or staying asleep)
  - Persistent worry must cause significant distress or impairment in social, occupational, or other areas of functioning.
  - Focus of anxiety and worry is not consistent with or limited to the occurrence of other types of psychiatric disorders and is not directly related to PTSD.
  - Symptoms are not the result of a substance, another medical condition, or other DSM-5 diagnosis.

**PHYSICAL EXAM**
Useful for identifying other differential diagnosis (see below). No specific physical findings in GAD, but patient may exhibit irritability, bitten nails, tremor, or clammy hands.

**DIFFERENTIAL DIAGNOSIS**
- Cardiovascular: ischemic heart disease, valvular heart disease (mitral valve prolapse), cardiomyopathies, arrhythmias, congestive heart failure
- Respiratory: asthma, chronic obstructive pulmonary disease, pulmonary embolism
- CNS: stroke, seizures, dementia, migraine, vestibular dysfunction, neoplasms
- Metabolic and hormonal: hyper- or hypothyroidism, pheochromocytoma, adrenal insufficiency, Cushing syndrome, hypokalemia, hypoglycemia, hyperparathyroidism
- Drug-induced anxiety: alcohol, sympathomimetics (cocaine, amphetamine, caffeine), corticosteroids, herbals (ginseng)
- Withdrawal: alcohol, sedative-hypnotics
- Psychiatric: other disorders (e.g., panic disorder, OCD, PTSD, social phobia, adjustment disorder, and somatization disorder)

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Laboratory tests are normal. Initial tests may include thyroid-stimulating hormone, CBC, basic metabolic panel, urine drug screen, and ECG.
- GAD-2: two-question self-reporting scale (22% positive predictive value
[PPV]/78% negative predictive value [NPV])
- PHQ-4 provides a very brief screen for both anxiety and depression (2).

**Diagnostic Procedures/Other**

Psychological testing
- GAD-7: five additional questions; provides more detailed information for treatment (29% PPV/71% NPV); also may be indicative of panic disorder (GAD-7: 29% PPV/71% NPV)
- Hamilton Anxiety Scale (HAM-A), Anxiety Disorders Interview Schedule (ADIS-IV)
- In pediatric populations: ADIS-IV Parent and Child Version, Multidimensional Anxiety Scale for Children (MASC), Screen for Child Anxiety Related Emotional Disorders (SCARED)

**TREATMENT**

**GENERAL MEASURES**
- Assess for suicidality given increased risk.
- Identify and treat coexisting substance abuse and other psychiatric conditions.
- Psychoeducation recommended for all patients in addition to physical exercise and mindfulness-based stress reduction approaches
- Start early as delayed treatment may result in poorer clinical outcomes compared with patients treated within 1 year of symptom onset.
- Consider utilizing self-reported measures at each visit to quantify the level of anxiety as well as to track severity and treatment response (i.e., GAD-7).
- Remission may not occur until 4 to 6 months into treatment. Treat for at least 12 months.
- Persistence with therapy necessary to achieve maximum benefit and ensure sustained improvement

Psychotherapeutic approaches
- Psychological treatments are effective in treating GAD: number needed to treat (NNT) = 2 (3)[A].
- CBT: most well-studied psychological treatment; may improve comorbid conditions such as depression; treatment of choice when available (2)[A]
- Relaxation/mindfulness training (2)[A]
- Psychodynamic psychotherapy: Treatment is focused on patient discovering and verbalizing unconscious conflicts (2)[C].

mebooksfree.com
Insufficient evidence to compare efficacy of the various treatment types at this time (3)[A]

MEDICATION

First Line

SSRI and SNRI antidepressants have demonstrated efficacy, are well-tolerated, do not cause abuse/dependence, and treat comorbid depression. Data to compare between agents are limited (4)[A].

In general, with SSRIs/SNRIs, start at the lowest available dose, up-titrate every 2 to 4 weeks, and use highest tolerated FDA-approved dose for at least 2 weeks before deeming ineffective. Then, consider switching to a different SSRI/SNRI.

Switching between medications without adequate dose or duration of therapy can lead to ineffective treatment.

Most common adverse effects of serotonergic drugs include nausea, agitation or sedation, and sexual side effects (decreased libido, delayed orgasm).

SNRIs may elevate blood pressures.

SSRIs

– Paroxetine (Paxil): initially 10 to 20 mg/day; may titrate by 10 mg/day qwk to a maximum of 50 mg/day (no added benefit >20 mg/day)
– Escitalopram (Lexapro): initially 10 mg/day; may titrate to a maximum of 20 mg/day after 1 week
– Sertraline (Zoloft): initially 25 mg/day; may titrate by 25 to 50 mg/day qwk to a maximum of 200 mg/day
– Fluoxetine (Prozac) and citalopram (Celexa) likely have efficacy for GAD but do not have FDA indications.

SNRIs

– Duloxetine (Cymbalta): initially 30 mg/day; may titrate by 30 mg/day qwk to a maximum of 120 mg/day; doses >60 mg/day rarely more effective
– Venlafaxine XR (Effexor XR): initially 37.5 to 75 mg; may titrate up by 75 mg every 4 days to a maximum of 225 mg/day

Second Line

Benzodiazepines: efficacious in the short term but less effective long term, risk for dependence and abuse (4)[A]

– Clonazepam (Klonopin): 0.25 mg BID; may increase to 4 mg/day divided BID
– Diazepam (Valium): 2 to 5 mg BID–QID; may increase to a maximum of 40 mg/day
– Lorazepam (Ativan): 0.5 mg BID–TID; may increase to 6 mg/day divided TID
– Alprazolam (Xanax): 0.25 mg TID; may increase to 4 mg/day

**Hydroxyzine (Vistaril, Atarax):** CNS depressant, antihistamine, anticholinergic; decreased risk of dependence compared with benzodiazepines: usual dose: 50 to 100 mg PO QID; limit use in the elderly (3)[B].

**Azapirones:** buspirone (BuSpar): less risk of dependence, although may be less effective; 15 mg/day divided BID–TID initially; maximum of 60 mg/day divided BID–TID (4)[A]

**Pregabalin (Lyrica):** decreases anxiety scores and reduces relapse at 75 to 300 mg BID; may cause less sexual dysfunction and sleep disruption than SSRIs. Taper to discontinue; has rapid onset of action (4)[A]

**Quetiapine (Seroquel):** optimal dose 150 mg/day. 2nd-generation antipsychotic. Efficacious but less well-tolerated than SSRIs (5)[A]. Consider using as augmentation.

**Bupropion (Wellbutrin):** Single small pilot double-blind randomized trial showed comparable efficacy of Wellbutrin XL to escitalopram; 150 to 300 mg/day, maximum of 400 mg/day

### Geriatric Considerations

- Avoid TCAs and long-acting benzodiazepines; benzodiazepines may cause delirium.
- Pregabalin may cause dizziness and somnolence.

### Pediatric Considerations

- Black box warning (SSRIs): Antidepressants increase the risk of suicidal thinking and behavior in children, adolescents, and young adults.
- However, studies have also shown increase in suicide attempts in adolescents after SSRI discontinuation.
- Sertraline, fluoxetine, and fluvoxamine have all been shown to be effective in pediatric populations.
- Medications other than SSRIs have not been well tested in pediatric populations.
- Anxiety and ADHD often co-occur. Treat the more debilitating first and consider using nonstimulating medications.
**Pregnancy Considerations**

- **Buspirone:** Category B: secreted in breast milk; inadequate studies to assess risk
- **Benzodiazepines:** Category D: may cause lethargy and weight loss in nursing infants; avoid breastfeeding if the mother is taking chronically or in high doses.
- **SSRIs:** If possible, taper and discontinue. After 20 weeks’ gestation, there is increased risk of pulmonary hypertension; mild transient neonatal syndrome of CNS; and motor, respiratory, and GI signs. Studies regarding risk of autism show mixed results. Most are Category C, with the exception of:
  - **Paroxetine:** Category D: conflicting evidence regarding the risk of congenital cardiac defects and other congenital anomalies in the 1st trimester
  - **Hydroxyzine:** Category C: Case reports of neonatal withdrawal exist.

**ALERT**

Precautions

- **Benzodiazepines:** age >65 years, respiratory disease/sleep apnea, contraindicated with narrow-angle glaucoma, precaution with open-angle glaucoma; sudden discontinuation increases seizure risk. Long-term use has potential for tolerance and dependence; use with caution in patients with history of substance abuse.
- **Buspirone:** hepatic and/or renal dysfunction; monoamine oxidase inhibitor (MAOI) treatment
- **SSRIs:** Use caution in those with comorbid bipolar disorder; may increase risk of serotonin syndrome, especially in combination with other serotonergic drugs

**ISSUES FOR REFERRAL**

Concomitant depression, refractory anxiety, or other comorbidities may warrant a psychiatric evaluation in light of increased suicide risk.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Patients frequently engage in complementary and alternative medicine (CAM); providers should be familiar with common therapies.
- Probable benefit but more study needed on several complementary therapies
including acupuncture, yoga, massage, tai chi, and aromatherapy (5)[A]

- Kava: some evidence for benefit over placebo in mild to moderate anxiety, but concern regarding potential hepatotoxicity. Safety is potentially affected by manufacturing quality, plant part used, dose, and interactions with other substances (5)[A].
- Strong evidence to support regular physical activity to relieve anxiety symptoms (5)[A]
- Small study showed possible benefit from repetitive transcranial magnetic stimulation (rTMS) to the right dorsal lateral prefrontal cortex for pharmacotherapy treatment refractory patients.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Patients at risk for suicide should be treated as inpatients; may be considered as well for patients with substantial interference in daily function.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Follow up within 2 to 4 weeks from starting new medications.
- Medications should be continued past the initial period of response and probably for at least 6 months.
- Monitor mental status on benzodiazepines and avoid drug dependence or abrupt discontinuation.
- Monitor all patients for suicidal ideation but especially those on SSRIs and SNRIs.

**DIET**

- Limit caffeine intake.
- Avoid alcohol (drug interactions, high rate of abuse, potential for increased anxiety) and nicotine.

**PATIENT EDUCATION**

- Regular exercise, especially yoga, may be beneficial for both anxiety and comorbid conditions.
Psychoeducation regarding normal versus pathologic anxiety, the fight or flight response, and the physiology of anxiety can be extremely helpful.

PROGNOSIS
- Probability of recovery is approximately 40–60%, but relapse is common.
- Comorbid psychiatric disorders and poor relationships with spouse or family make relapse more likely.

REFERENCES

SEE ALSO
- Algorithms: Anxiety; Depressive Episode, Major

CODES
**ICD10**
- F41.9 Anxiety disorder, unspecified
- F41.1 Generalized anxiety disorder
- F41.8 Other specified anxiety disorders
CLINICAL PEARLS

- Psychiatric comorbidities, especially depression, are extremely common with GAD; patients are at increased risk for suicidality.
- CBT and SSRIs (possibly in combination) are the treatments of choice.
- Starting antidepressant medication at low doses, with careful titration to full therapeutic dosing, helps minimize side effects while maximizing efficacy.
- Benzodiazepines may be used initially but should be tapered and withdrawn if possible.
- CAM use is common, and certain therapies may be effective.
AORTIC VALVULAR STENOSIS

Michael T. Tanoue, MD • Parag Goyal, MD, MSc • James M. Horowitz, MD, FACC

 BASICS

DESCRIPTION
Aortic stenosis (AS) is a narrowing of the aortic valve area causing obstruction to left ventricular (LV) outflow. The disease has a long asymptomatic latency period, but development of severe obstruction or onset of symptoms such as syncope, angina, and congestive heart failure (CHF) are associated with a high mortality rate without surgical intervention.

EPIDEMIOLOGY

- Most common cause of LV outflow obstruction in both children and adults
- Predominant age
  - <30 years: congenital
  - 30 to 65 years: congenital or rheumatic fever (RF)
  - >65 years: degenerative calcification of aortic valve

Prevalence
- Affects 1.3% of population 65 to 74 years old, 2.4% 75 to 84 years old, 4% >84 years old (1)
- Bicuspid aortic valve: 1–2% of population. Bicuspid aortic valve predisposes to development of AS at an earlier age (1).

ETIOLOGY AND PATHOPHYSIOLOGY

- Progressive aortic leaflet thickening and calcification results in LV outflow obstruction. Obstruction causes increased afterload and, over time, decreased cardiac output.
- Increase in LV systolic pressure is required to preserve cardiac output; this leads to development of concentric LV hypertrophy (LVH). The compensatory LVH preserves ejection fraction but adversely affects heart functioning.
  - LVH impairs coronary blood flow during diastole by compression of coronary arteries and reduced capillary ingrowth into hypertrophied muscle.
  - LVH results in diastolic dysfunction by reducing ventricular compliance.
Diastolic dysfunction necessitates stronger left atrial (LA) contraction to augment preload and maintain stroke volume. Loss of LA contraction by atrial fibrillation can induce acute deterioration.
Diastolic dysfunction may persist after relief of AS due to the presence of interstitial fibrosis.
Angina: increased myocardial demand due to higher LV pressure. Myocardial supply is compromised due to LVH.
Syncope (exertional): can be multifactorial from inability to augment cardiac output due to the fixed obstruction to LV outflow; arrhythmias; or most commonly, abnormal baroreceptor response resulting in failure to appropriately augment blood pressure.
Heart failure: Eventually, LVH cannot compensate for increasing afterload resulting in high LV pressure and volume, which are accompanied by an increase in LA and pulmonary pressures.
Degenerative calcific changes to aortic valve (2)
– Mechanism involves mechanical stress to valve leaflets as well as atherosclerotic changes to the valve tissue. Bicuspid valves are at higher risk for mechanical stress.
– Early lesions: subendothelial accumulation of oxidized LDL and macrophages and T lymphocytes (inflammatory response)
– Disease progression: Fibroblasts undergo transformation into osteoblasts; protein production of osteopontin, osteocalcin, and bone morphogenic protein-2 (BMP-2), which modulates calcification of leaflets
Congenital: unicuspid valve, bicuspid valve, tricuspid valve with fusion of commissures, hypoplastic annulus
RF: chronic scarring with fusion of commissures

RISK FACTORS
Congenital unicommissural valve or bicuspid valve (1)
– Unicommissural valve: Most cases were detected during childhood.
– Bicuspid valve: predisposes to the development of AS earlier in adulthood (4th to 5th decade) compared to tricuspid valve (6th to 8th decade)
RF (1)
– Prevalence of chronic rheumatic valvular disease has declined significantly in the United States.
– Most cases are associated with mitral valve disease.
Degenerative calcific changes
– Most common cause of acquired AS in the United States
– Risk factors are similar to that of coronary artery disease (CAD) and
include the following: hypercholesterolemia, hypertension, smoking, male gender, age, and diabetes mellitus.

COMMONLY ASSOCIATED CONDITIONS
- CAD (50% of patients)
- Hypertension (40% of patients): results in “double-loaded” left ventricle (dual source of increased afterload as a result of obstruction from AS and hypertension)
- Aortic insufficiency (common in calcified bicuspid valves and rheumatic disease)
- Mitral valve disease: 95% of patients with AS from RF also have mitral valve disease.
- LV dysfunction and CHF
- Acquired von Willebrand disease: Impaired platelet function and decreased vWF results in bleeding (ecchymosis and epistaxis) in 20% of AS patients. Severity of coagulopathy is directly related to severity of AS.
- Gastrointestinal arteriovenous malformations (AVMs)
- Cerebral or systemic embolic events due to calcium emboli

DIAGNOSIS

HISTORY
- Primary symptoms: angina, syncope, and heart failure (3). Angina is the most frequent symptom. Syncope is often exertional. Heart failure symptoms include fatigue, exertional dyspnea, orthopnea, paroxysmal nocturnal dyspnea, and shortness of breath.
- Palpitations
- Neurologic events (transient ischemic attack or cerebrovascular accident) secondary to embolization
- Geriatric patients may have subtle symptoms such as fatigue and exertional dyspnea.
- Note: Symptoms do not always correlate with valve area (severity of AS) but most commonly occur when aortic valve area is <1 cm², jet velocity is >4.0 m/s, or the mean transvalvular gradient is ≥40 mm Hg.

PHYSICAL EXAM
- Auscultation (3)
– Harsh, systolic crescendo–decrescendo murmur is best heard at 2nd right sternal border and radiates into the carotid arteries. Peak of murmur correlates with severity of stenosis; later peaking murmur suggests greater severity.
– High-pitched blowing diastolic murmur suggests associated aortic insufficiency.
– Paradoxically split S2 or absent A2. Note: Normally split S2 reliably excludes severe AS.
– S4 due to stiffening of the left ventricle

• Other associated signs (3) include Pulsus parvus et tardus: decreased and delayed carotid upstroke. LV heave; findings of CHF: pulmonary and/or lower extremity edema

DIFFERENTIAL DIAGNOSIS
• Mitral regurgitation: high-frequency, pansystolic murmur, best heard at the apex, often radiates to the axilla
• Hypertrophic obstructive cardiomyopathy: also systolic crescendo–decrescendo murmur but best heard at left sternal border and may radiate into axilla. Murmur intensity increases by changing from squatting to standing and/or by Valsalva maneuver.
• Discrete fixed subaortic stenosis: 50–65% has associated cardiac deformity (patent ductus arteriosus [PDA], ventricular septal defect [VSD], aortic coarctation).
• Aortic supravalvular stenosis: Williams syndrome, homozygous familial hypercholesterolemia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

• Chest x-ray (CXR) (1)
  – May be normal in compensated, isolated valvular AS
  – Boot-shaped heart reflective of concentric hypertrophy
  – Poststenotic dilatation of ascending aorta and calcification of aortic valve (seen on lateral PA CXR)
• ECG: often normal ECG (ECG is nondiagnostic), or may show LVH, LA enlargement, and nonspecific ST- and T-wave abnormalities
• Echo indications
  – Initial workup
    o Doppler echocardiogram: primary test in the diagnosis and evaluation of
AS
- Assesses valve anatomy and severity of disease
- Assesses LV wall thickness, size, and function, and pulmonary artery pressure
  - In known AS and changing signs/symptoms
  - In known AS and pregnancy due to hemodynamic changes of pregnancy
- Echo findings
  - Aortic valve thickening, calcification
  - Decreased aortic valve excursion
  - Reduced aortic valve area
  - Transvalvular gradient across aortic valve
  - LVH and diastolic dysfunction
  - LV ejection fraction
  - Wall-motion abnormalities suggesting CAD
  - Evaluate for concomitant aortic insufficiency or mitral valve disease.
- AS severity based on echo values (4)
  - Stage A (at risk): bicuspid aortic valve, sclerosis, or other congenital abnormality; mean pressure gradient: 0 mm Hg; jet vel. <2 m/s
  - Stage B (progressive): bicuspid or trileaflet valve
    - Mild: mean pressure gradient: <20 mmHg; jet vel. 2.0 to 2.9 m/s
    - Moderate: mean pressure gradient: 20 to 40 mm Hg; jet vel. 3.0 to 3.9 m/s
  - Stage C (asymptomatic severe AS):
    - C1 (without LV dysfunction): AVA ≤1.0 or AVAi ≤0.6 cm²/m²; mean pressure gradient: 40 to 60 mm Hg; jet vel. ≥4 to 5 m/s
    - C2 (with LV dysfunction): AVA ≤1.0 or AVAi ≤0.6 cm²/m²; mean pressure gradient: ≥40 mm Hg; jet vel. ≥4 m/s
  - Stage D (symptomatic severe AS):
    - D1 (high-gradient): AVA ≤1.0 cm²; mean pressure gradient: >40 mm Hg; jet vel. >4 m/s
    - D2 (low-flow/low-gradient with reduced EF <50%): AVA ≤1.0 cm²; mean pressure gradient: <40 mm Hg; jet vel. <4 m/s
    - D3 (low-gradient, normal EF ≥50% or paradoxical low-flow severe AS): AVA ≤1.0 cm²; AVAi ≤0.6 cm²/m² and stroke volume index <35 mL/m²; mean pressure gradient: <40 mm Hg; jet vel. <4 m/s

**Diagnostic Procedures/Other**
- Exercise stress testing
– Asymptomatic patients with severe AS (5)[B]: helpful to uncover subtle symptoms or changes, abnormal BP (increase <20 mm Hg), and ECG changes (ST depressions). 1/3 of patients develop symptoms with exercise testing; STOP testing at this point.
– Symptomatic patients (5)[B]: DO NOT perform exercise stress testing, as it may induce hypotension or ventricular tachycardia.
– CHF patients (5)[B]: Dobutamine stress echocardiography is reasonable to evaluate patients with low-flow/low-gradient AS and LV dysfunction.

● Cardiac catheterization
– Perform prior to aortic valve replacement (AVR) in patients with suspected CAD (5)[B]. Determines need for coronary artery bypass graft (CABG). If unambiguous diagnosis of AS, perform only coronary angiography.
– Can also use if noninvasive testing is inconclusive or if there is discrepancy between severity of symptoms and findings on echo
– Measures transvalvular flow and transvalvular pressure gradient, which facilitates calculation of effective valve area
– Hemodynamic measurements with infusion of dobutamine can be useful for evaluation of patients with low-flow/low-gradient AS and LV dysfunction.

Test Interpretation
● Aortic valve: nodular calcification on valve cusps (initially at bases), cusp rigidity, cusp thickening, and fibrosis
● LVH, myocardial interstitial fibrosis
● 50% incidence of concomitant CAD

MEASUREMENTS

TREATMENT

MEDICATION
● No effective medical therapy for severe or symptomatic AS
● Prevention: currently no recommended medical therapy. Statins have been thought to slow progression if initiated during mild disease. However, this has not been supported by large, randomized controlled trials.
● Antibiotic prophylaxis against recurrent RF is indicated for patients with rheumatic AS (penicillin G 1,200,000 U IM q4wk; duration varies with age and history of carditis).
● Antibiotic prophylaxis is no longer indicated for prevention of infective endocarditis (5).
Comorbidities: hypertension: angiotensin-converting enzyme (ACE) inhibitors, start with low dose and increase cautiously. Be cautious of vasodilators, which may cause hypotension.

SURGERY/OTHER PROCEDURES

The only proven treatment for AS is valve replacement.

Indications for AVR surgery:
- Symptomatic and severe high-gradient AS by history or exercise testing (4) [B] when surgical risk is low or intermediate
- Asymptomatic, severe AS and LVEF <50% (4)[B]
- Severe AS (stage C or D) when undergoing other cardiac surgery (4)[B]

AVR surgery is reasonable in patients who are:
- Asymptomatic with severe AS (C1) with jet vel. ≥5 m/s and low surgical risk, decreased exercise tolerance, or have an exercise fall in blood pressure (4)[B]
- Symptomatic stage D2, with a low-dose dobutamine stress with jet vel. ≥4.0 m/s or mean pressure gradient ≥40 mm Hg with ≤1.0 cm² at any dobutamine dose (4)[B]
- Symptomatic stage D3 with LVEF >50% if clinical and hemodynamic data support valve obstruction as likely cause of symptoms (4)[C]
- Stage B who are undergoing other cardiac surgery, or asymptomatic stage C1 with rapid disease progression and low surgical risk (4)[C]

ALERT

Note: If the aortic valve area is >1.5 cm² and the gradient is <15 mm Hg, there is no benefit from AVR.

- Transcatheter AVR (TAVR) offers a less invasive option for some patients (6).
  - For those who are high at surgical risk and considered inoperable, TAVR has demonstrated superiority to medical therapy.
  - For those who are high at surgical risk, TAVR has demonstrated noninferiority to surgical AVR (6).
  - For those who are intermediate at surgical risk, TAVR may emerge as a reasonable alternative to surgical risk, although this indication has not yet been approved in the United States.
  - Valve-in-valve TAVR can be considered in high-risk patients with failed surgically implanted bioprosthetic valves.
- Percutaneous balloon valvuloplasty may have role in palliation or as a bridge to valve replacement in hemodynamically unstable or high-risk patients (5)[C]
but is not recommended as an alternative to valve replacement.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Advise patients to immediately report symptoms referable to AS.
- Asymptomatic patients: yearly history and physical (5)[C]
- Serial ECHO: yearly for severe AS, every 1 to 2 years for moderate AS, every 3 to 5 years for mild AS (5)[B]

**PATIENT EDUCATION**

Physical activity limitations

- Asymptomatic mild AS: no restrictions
- Asymptomatic moderate to severe AS: Avoid strenuous exercise. Consider exercise stress test prior to starting exercise program.

**PROGNOSIS**

- 25% mortality/year in symptomatic patients who do not undergo valve replacement; average survival is 2 to 3 years without AVR surgery.
- Median survival in symptomatic AS (3): heart failure: 2 years; syncope: 3 years; angina: 5 years
- Perisurgical mortality: AVR surgery has 4% mortality rate; AVR + CABG has 6.8% mortality rate.
- Adverse postoperative prognostic factors: age, heart failure New York Heart Association (NYHA) class III/IV, cerebrovascular disease, renal dysfunction, CAD

**REFERENCES**

**CODES**

**ICD10**
- I35.0 Nonrheumatic aortic (valve) stenosis
- I06.0 Rheumatic aortic stenosis
- Q23.0 Congenital stenosis of aortic valve

**CLINICAL PEARLS**
- AS is diagnosed on physical exam by a systolic crescendo–decrescendo murmur and delayed and diminished pulses.
- Symptomatic AS most commonly presents as angina, syncope, and heart failure.
- Symptomatic AS has a very poor prognosis, unless treated with surgical intervention.
APPENDICITIS, ACUTE
Sarah S. Dolbear, MD • John M. Doan, DO

BASICS

DESCRIPTION
- Acute inflammation of the vermiform appendix
- Arising from the base of the cecum in right lower quadrant (RLQ), the appendix can be anterior, posterior, medial, lateral to the cecum as well as in the pelvis. Vascular supply provided by appendicular artery, a branch of the ileocolic artery; nerve supply derived from the superior mesenteric plexus
- Most common cause of acute surgical abdomen

EPIDEMIOLOGY
- Predominant age: 10 to 30 years; rare in infancy
- Predominant sex: slight male predominance
  - Ages 10 to 30 years: male > female (3:2)
  - Age >30 years: male = female

Incidence
- 1 case per 1,000 people per year
- Lifetime incidence 1 in every 15 people (7%)

Pregnancy Considerations
- Most common extrauterine surgical emergency
- Incidence similar in pregnancy
- Higher rate of perforation; more likely to present with peritonitis

ETIOLOGY AND PATHOPHYSIOLOGY
Obstruction of the appendiceal lumen is thought to lead to distention, ischemia, and bacterial overgrowth. Without intervention, appendicitis can lead to perforation and subsequent abscess formation or generalized peritonitis. Causes of obstruction:
- Fecaliths (most common)
- Lymphoid tissue hyperplasia (in children)
- Vegetable, fruit seeds, and other foreign bodies
Intestinal worms (ascarids)
Strictures, fibrosis, neoplasms

Genetics
First-degree relative with history of appendicitis increases risk; no direct genetic link has been found.

RISK FACTORS
Adolescent males, familial tendency, intra-abdominal tumors

DIAGNOSIS
Diagnosis relies on history and physical examination with supporting laboratory studies and imaging.

Scoring systems
- Supplement MASS in female patients with additional investigations (e.g., abdominal ultrasound or laparoscopy).
- A MASS score >7 suggests appendicitis without the need for further imaging.

A cutoff point of 6 for the MASS score yields higher sensitivity but is also associated with a higher negative appendectomy rate (normal appendix).

Pediatric Appendicitis Score—helps predict the likelihood of acute appendicitis (diagnosis is still clinical)

HISTORY
Classic history is vague periumbilical pain, followed by anorexia, nausea, and vomiting. Over the next 4 to 48 hours, pain migrates to the RLQ.
Only 50% of patients present with a classic history.
Pain before vomiting (~100% sensitive), abdominal pain (~100%), pain migration (50%)
Anorexia (~100%), nausea (90%), vomiting (75%), obstipation
Atypical symptoms and pain suggest a retrocecal or pelvic appendix.

PHYSICAL EXAM
Fever; temperature >100.4°F (may be absent); tachycardia
• RLQ tenderness; maximal tenderness at McBurney point (1/3 the distance from the anterior superior iliac spine to the umbilicus)
• Voluntary and involuntary guarding
• Rovsing sign: RLQ pain with palpation of left lower quadrant
• Psoas sign: pain with right thigh extension (retrocecal appendix)
• Obturator sign: pain with internal rotation of flexed right thigh (pelvic appendix); local and suprapubic pain on rectal exam (pelvic appendix)
• Pelvic and rectal exams are helpful to assess other causes of lower abdominal pain (e.g., pelvic inflammatory disease, prostatitis).
• Serial exams can be useful in indeterminate cases.

DIFFERENTIAL DIAGNOSIS

• GI
  – Gastroenteritis, inflammatory bowel disease
  – Diverticulitis, ileitis
  – Cholecystitis, pancreatitis
  – Intussusception, volvulus
• Gynecologic
  – Pelvic inflammatory disease, ectopic pregnancy
  – Ovarian cyst, ovarian torsion, tubo-ovarian abscess
  – Endometriosis
  – Ruptured Graafian follicle
• Urologic
  – Testicular torsion, epididymitis
  – Kidney stones, prostatitis, cystitis, pyelonephritis
• Systemic
  – Diabetic ketoacidosis
  – Henoch-Schönlein purpura
  – Sickle cell crisis
  – Porphyria
• Other
  – Acute mesenteric lymphadenitis
  – No organic pathologic condition
  – Hernias
  – Psoas abscess
  – Rectus sheath hematoma
  – Epiploic appendagitis
  – Pneumonia (basilar)
**Pediatric Considerations**
- Decreased diagnostic accuracy of history and physical exam
- Higher fever; more vomiting and diarrhea

**Pregnancy Considerations**
- Appendicitis is a more difficult diagnosis in pregnancy.
- Normal inflammatory response is suppressed.
- Appendix displaced out of pelvis by gravid uterus

**Geriatric Considerations**
Decreased diagnostic accuracy, more likely to be atypical presentation

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- **Leukocytosis**: WBC $>10,000/mm^3$ (70%)
- **Polymorphonuclear predominance** or “left shift” ($>90%$)
- **Urinalysis**: hematuria, pyuria (30%)
- **Human chorionic gonadotropin** (hCG) (if positive, rule out ectopic pregnancy)
- **C-reactive protein**: nonspecific inflammatory marker; when paired with an elevated WBC increases predictive value for appendicitis
- **Drugs may alter lab results**: antibiotics, steroids.
- **Imaging used when the diagnosis is not clear**: is helpful to detect complications (abscess, perforation)
- **Plain films**: very little utility, nonspecific findings, may visualize fecalith
- **CT with contrast**: sensitivity 91–98%; specificity 95–99%; imaging modality of choice. Consider radiation dose, particularly in young patients (1)[A].
- **Ultrasound**: alternative in pregnancy, children, and women with suspected gynecologic pathology. Sensitivity and specificity vary by report, and accuracy depends on the skill of the ultrasonographer. Can rule in appendicitis but cannot reliably exclude the diagnosis. Start with ultrasound and, if negative, obtain a CT scan as an effective strategy (2)[B].
- **MRI**: Increasing use in pregnant patients. Also may help in patients with contrast allergies and/or patients with renal failure. Limitations include cost, availability, and time required to complete study.
- **Radioisotope-labeled WBC scans**: may be used in patients with indeterminate CT scans and suspected appendicitis as an alternative to observation or surgery. Limitations include availability and time required to complete study.
**Diagnostic Procedures/Other**

Exploratory laparotomy/laparoscopy: Acceptable nontherapeutic appendectomy rates vary based on age and gender and may be higher for females of childbearing age than males.

**Test Interpretation**

- Acute appendiceal inflammation, local vascular congestion, obstruction
- Gangrene, perforation with abscess (15–30%)
- Fecalith

**TREATMENT**

**GENERAL MEASURES**

- Surgery (appendectomy) has been the standard of care for acute, uncomplicated appendicitis. There is growing evidence for medical management in select cases—this strategy involves antibiotic therapy, with appendectomy reserved for those who do not respond to treatment or become complicated (3).

**MEDICATION**

**First Line**

- Uncomplicated acute appendicitis: perioperative dose of antibiotic: single dose of cefoxitin or ampicillin/sulbactam (Unasyn) or cefazolin plus metronidazole
- Gangrenous or perforating appendicitis
  - Broadened antibiotic coverage for aerobic and anaerobic enteric pathogens
  - Piperacillin and tazobactam (Zosyn) or ticarcillin and clavulanate (Timentin) or a 3rd-generation cephalosporin plus metronidazole are initial options.
  - Adjust dosage and choice of antibiotic based on intraoperative cultures.
  - Continue antibiotics for at least 7 days postoperatively or until patient becomes afebrile with normal WBC count.

**Second Line**

- Uncomplicated acute appendicitis: clindamycin plus one of the following: ciprofloxacin, levofloxacin, gentamicin, or aztreonam
In the case of acute appendicitis complicated by abscess formation or phlegmon in pediatric patients, some studies show initial conservative management with antibiotics alone to carry fewer risks and complications than emergent appendectomy (4)[A].

Gangrenous or perforated appendicitis: ciprofloxacin or levofloxacin plus metronidazole or monotherapy with a carbapenem (imipenem and cilastatin, meropenem, ertapenem)

ISSUES FOR REFERRAL
All cases of appendicitis require emergent surgical consultation.

SURGERY/OTHER PROCEDURES
- Inpatient surgery is indicated.
- The American College of Surgeons, Society for Surgery of the Alimentary Tract, and others recommend surgery as the treatment of choice.
- Antibiotic treatment might be used as an alternative in specific patients or if surgery is contraindicated.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admit all patients with appendicitis.
- Fluid resuscitation with normal saline (NS) or lactated Ringer (LR) solution
- Correct fluid and electrolyte deficits.
- Discharge when tolerating oral intake; return of bowel function; afebrile; normal WBC

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Return to work in 1 to 2 weeks is typically following most cases of uncomplicated appendicitis.
- Restrict activity for 4 to 6 weeks after surgery: no heavy lifting (>10 lb) or strenuous physical activity.

PATIENT EDUCATION
Postoperative warning signs:
• Anorexia, nausea, vomiting
• Abdominal pain, fever, chills
• Signs/symptoms of wound infection

PROGNOSIS
• Generally uncomplicated course in young adults with unruptured appendicitis
• Extremes of age and appendiceal rupture increase morbidity and mortality.
• Morbidity rates
  – Nonperforated appendicitis: 3%
  – Perforated appendicitis: 47%
• Mortality rates
  – Unruptured appendicitis: 0.1%
  – Ruptured appendicitis: 3%
  – Patients >60 years of age make up 50% of total deaths from appendicitis.
  – Older patients with ruptured appendix: 15%

Pediatric Considerations
• Rupture earlier
• Rupture rate: 15–60%

Pregnancy Considerations
• Rupture rate: 40%
• Fetal mortality rate: 2–8.5%

Geriatric Considerations
Rupture rate: 67–90%

COMPLICATIONS
• Wound infection, intra-abdominal abscess; lower rate with antibiotic prophylaxis (5)[A], intestinal fistulas
• Intestinal obstruction, paralytic ileus, incisional hernia
• Liver abscess (rare), pyelophlebitis

Algorithm: Abdominal Rigidity

**CODES**

**ICD10**

- K35.80 Unspecified acute appendicitis
- K35.2 Acute appendicitis with generalized peritonitis
- K35.3 Acute appendicitis with localized peritonitis
CLINICAL PEARLS

- Anorexia with periumbilical pain localizing to RLQ is the classic history for acute appendicitis.
- Diagnosis is more challenging in children, pregnant patients, and the elderly due to varying symptoms and signs.
- In equivocal cases, CT is the diagnostic test of choice. Ultrasound and MRI are alternatives.
- Acute appendicitis is the most common surgical emergency during pregnancy.
**APPROACH TO TRAVEL MEDICINE COUNSELING**

*Melissa Jefferis, MD, FAAFP*

**BASICS**

**DESCRIPTION**

Pretravel consultations assess trip plans to determine potential health hazards, discuss risks and methods for prevention, provide immunizations for vaccine-preventable disease and medications for prophylaxis and/or self-treatment, and educate the traveler to mitigate risks associated with international travel.

**EPIDEMIOLOGY**

*Incidence*

Illness and injury are common during travel.

**RISK FACTORS**

Risks vary by destination, length of the trip, planned activities, age, and health status of the traveler.

- **Traveler details**
  - Past medical history (age, gender, medical conditions, allergies, medications)
  - Special conditions (pregnancy, breastfeeding, disability or handicap, immunocompromised state, older age)
  - Immunization history
  - Prior travel experience (previous malaria prophylaxis, experience with altitude, illnesses related to prior travel)

- **Trip details**
  - Itinerary (countries and specific regions, rural or urban)
  - Timing (length of trip, season of travel, time until departure)
  - Reason for travel
  - Special activities (disaster relief, medical care, high altitude or climbing, diving, cruise ship, rafting, cycling, extreme sports)

**GENERAL PREVENTION**

mebooksfree.com
Routine vaccinations
- *Haemophilus influenzae* type b
- Hepatitis B
- Influenza
- Measles, mumps, rubella—more common in countries without routine childhood immunizations
- Meningococcal—outbreaks common in sub-Saharan Africa especially during the dry season (December through June). Saudi Arabia requires the quadrivalent vaccine for Hajj pilgrims (1).
- Pneumococcal
- Polio
- Rotavirus—common in developing countries
- Tetanus, diphtheria, pertussis
- Varicella—more common in countries without routine childhood immunizations
- Zoster—stress may trigger reactivation.
- Human papillomavirus (HPV)—sexual activity during travel may lead to HPV infection.

Travel-specific vaccinations (destination dependent)
- Cholera (not available in the United States)
- Hepatitis A—often recommended regardless of destination
- Japanese encephalitis
- Rabies—if immunoglobulin would be difficult to obtain, consider vaccination to simplify postexposure prophylaxis.
- Tickborne encephalitis (not available in United States)
- Typhoid—highest risk in India, Pakistan, and Bangladesh. Do not give oral vaccine to immunocompromised patients or those who have taken antibiotics in the previous 72 hours (1).
- Yellow fever—highest risk in sub-Saharan Africa and the Amazonian regions of South America. Vaccination is not considered valid until 10 days after administration (1).

Malaria prophylaxis
- Based on destination, types of planned activities, and patient preferences. CDC has up-to-date recommendations.
- Personal protective measures
  - Wear appropriate clothing.
  - Bed nets
  - Insecticides and repellants
    - DEET
- Picaridin
- Oil of lemon eucalyptus
- IR3535

- Chloroquine-sensitive malaria (1,2)
  - Chloroquine—begin 1 to 2 weeks prior to travel, continue for 4 weeks after leaving malaria-endemic area; may increase QTc interval (particularly if given with other QTc-prolonging agents)
    - Adult dose: 300 mg base (500 mg salt) orally once weekly
    - Pediatric dose: 5 mg/kg base (8.3 mg/kg salt) orally once weekly (up to 300 mg base per dose)
  - Hydroxychloroquine—begin 1 to 2 weeks prior to travel, continue for 4 weeks after leaving malaria-endemic area; dosed weekly
    - Adult dose: 310 mg base (400 mg salt) orally once weekly
    - Pediatric dose: 5 mg/kg base (6.5 mg/kg salt) orally once weekly (up to 310 mg base per dose)

- Chloroquine-resistant malaria (1,2)
  - Atovaquone/proguanil—begin 1 to 2 days before travel and continue for 1 week after leaving malaria-endemic area.
    - Adult dose: 250 mg/100 mg atovaquone/proguanil PO daily
    - Pediatric dose: Tablets contain 62.5 mg/25 mg atovaquone/proguanil hydrochloride.
      - 5 to 8 kg: 1/2 pediatric tablet daily
      - 8 to 10 kg: 3/4 pediatric tablet daily
      - 10 to 20 kg: 1 pediatric tablet daily
      - 20 to 30 kg: 2 pediatric tablets daily
      - 30 to 40 kg: 3 pediatric tablets daily
      - >40 kg: 1 adult tablet daily
  - Doxycycline—begin 1 to 2 days before travel and continue for 4 weeks after leaving malaria-endemic area.
    - Adult dose: 100 mg orally daily
    - Pediatric dose: ≥8 years old 2.2 mg/kg up to adult dose of 100 mg daily
  - Mefloquine—begin ≥2 weeks before travel and continue for 4 weeks after leaving malaria-endemic area; has a number of drug interactions
    - Adult dose: 228 mg base (250 mg salt) orally once weekly
    - Pediatric dose
      - ≤9 kg: 4.6 mg/kg base (5 mg/kg salt) orally once weekly
      - >9 to 19 kg: ¼ tablet once weekly
      - >19 to 30 kg: ½ tablet once weekly
• Traveler’s diarrhea
  – Symptoms range from mild abdominal cramping and urgent loose stools to severe abdominal pain, fever, vomiting, and bloody diarrhea.
  – Length—bacterial causes last 3 to 7 days if untreated. Viral lasts 2 to 3 days. Protozoal can last weeks to months if not treated.
  – High-risk areas include Asia, Middle East, Africa, Mexico, and Central and South America (1).
  – Intermediate-risk areas include countries in Eastern Europe, South Africa, and some of the Caribbean islands (1).
  – Strategies to minimize diarrhea (1)
    o Wash hands or use sanitizer prior to eating.
    o Avoid raw or undercooked meat, fish, or shellfish, salads, uncooked vegetables, unpasteurized fruit juices, or unpasteurized milk or milk products.
    o Avoid unpeeled raw fruit. Peel fruit yourself if possible.
    o Tap water may be unsafe for drinking, making ice, preparing food, washing dishes, or brushing teeth; use sealed bottled water if possible.
  – For high-risk patients—bismuth subsalicylate reduces incidence of travelers’ diarrhea by 50%; 2 oz of liquid or two chewable tablets 4 times per day (not recommended for children <3 years) (1)
  – Antibiotic options for diarrhea self-treatment
    o Ciprofloxacin 500 mg q12h × 2 doses
    o Azithromycin 500 mg daily for 1 to 3 days
  – Adjunct medications
    o Loperamide
      ■ 4 mg initially followed by 2 mg after each loose stool (max 16 mg/day)
      ■ Pediatric dose
      ■ Not recommended for children <6 years
      ■ 6 to 8 years—2 mg initial dose, followed by 1 mg after each loose stool (max 4 mg/day)
      ■ 9 to 11 years—2 mg after initial dose, followed by 1 mg after each loose stool (max 6 mg/day)
      ■ ≥12 years: Refer to adult dosing.
    o Diphenoxylate
      ■ 5 mg (2 tablets) 3 or 4 times per day until control achieved (max 20 mg/day)
- Pediatric dose: not recommended for children <2 years; 0.3 to 0.4 mg/kg/day in 4 divided doses

- Altitude illness
  - Acute mountain sickness (AMS)—most common. Typically presents with headache starting 2 to 12 hours after arrival. Other symptoms include fatigue, loss of appetite, nausea, and vomiting. Usually resolves within 24 to 48 hours of acclimatization (1).
  - High-altitude cerebral edema (HACE)—severe progression of AMS. Lethargy, drowsiness, confusion, and ataxia; requires immediate descent (1)
  - High-altitude pulmonary edema (HAPE)—can occur by itself or with AMS and HACE. Symptoms begin with shortness of breath on exertion and progress to shortness of breath at rest, weakness, and cough. Supplemental oxygen and immediate descent. HACE and HAPE can be fatal (1).

- Preventive measures
  - Ascend gradually—from low altitude to <9,000 feet in 1 day. >9,000 feet, don’t climb >1,600 feet per day. Plan an extra day for acclimatization every 3,300 feet (1).
  - In first 48 hours, avoid alcohol and only perform mild exercise.

- Preventive medications
  - Recommended for those at high risk for AMS (based on rate of ascent or history of HACE or HAPE): Consider for those at moderate risk.
  - Acetazolamide—dose: 125 mg BID (250 mg BID if >100 kg); pediatric dose: 2.5 mg/kg q12h (1)
  - Dexamethasone—can be used for prevention although usually reserved for treatment; dose: 2 mg q6h or 4 mg q12h; should not be used for prophylaxis in pediatric patients (1)
  - Nifedipine—useful for prevention of HAPE only; dose: 30 mg SR version q12h or 20 mg SR version q8h (1)
  - Tadalafil—useful for prevention of HAPE only; dose: 10 mg BID (1)

- Jet lag
  - Before travel, adjust sleep cycle (and possibly meal times) 1 to 2 hours earlier or later (depending on direction of travel) for several days prior to departure.
  - Drink plenty of water to remain hydrated.
  - Optimize sunlight exposure to destination.
  - Nonaddictive sedative hypnotics (non-benzodiazepine), such as zolpidem, can be useful to increase sleep.
  - If using benzodiazepines, use short-acting agents, such as temazepam.

- Motion sickness
– High-risk individuals
  o Children ages 2 to 12 years
  o Women, especially when pregnant, menstruating, or on hormones
  o People who get migraines, especially during a migraine
  o Some medications
– Prevention strategies
  o Avoidance of known triggers
  o Strategic positioning (front of car, overwing of aircraft)
  o Treatment
    ■ Dimenhydrinate dose: pediatric dose: 1.0 to 1.5 mg/kg 1 hour before travel and every 6 hours during the trip
    ■ Diphenhydramine: pediatric dose: 0.5 to 1.0 mg/kg per dose up to 25 mg 1 hour before travel and every 6 hours during the trip
    ■ Scopolamine—transdermal patch to hairless area behind ear at least 4 hours prior to exposure and every 3 days as needed
– Environmental hazards
  – Avoid walking barefoot (parasites can enter skin).
  – Avoid swimming in freshwater where there is a risk for schistosomiasis or leptospirosis.
  – Use sunscreen.
  – If scuba diving, avoid flying or altitude exposure >2,000 feet (1).
    o ≥12 hours after surfacing from no-depression dive
    o ≥18 hours after repetitive dives or multiple days of diving
    o 24 to 28 hours after a dive that required decompression stops
– Other information
  – Consider travel insurance (including coverage for evacuation).
  – Hand carry medications and supplies.
  – Include medications to manage exacerbations or complications of existing chronic diseases.
  – The Department of State’s Smart Traveler Enrollment Program provides destination-specific travel alerts.

CODES

ICD10

- Z71.9 Counseling, unspecified
- Z71.89 Other specified counseling

CLINICAL PEARLS

- The CDC Travelers’ Health website is a useful point-of-care tool for destination-specific travel advice (https://wwwnc.cdc.gov/travel/).
- To allow adequate time for vaccine response and necessary pretrip medications, patients should seek advice several weeks prior to anticipated travel.
ARTERITIS, TEMPORAL

Jason P. Assalita, DO • Karl T. Clebak, MD, FAAFP • Munima Nasir, MD

BASICS

DESCRIPTION

- Technically termed giant cell arteritis (GCA)
- A chronic, generalized, cellular, and humoral immune-mediated vasculitis of large- and medium-sized vessels, predominantly affecting the cranial arteries originating from the aortic arch, although vascular involvement may be widespread. Inflammation of the aorta is observed in 50% of cases.
- Frequent features include fatigue, headaches, jaw claudication, loss of vision, scalp tenderness, polymyalgia rheumatica (PMR), and aortic arch syndrome (decreased or absent peripheral pulses, discrepancies of blood pressure, arterial bruits).

EPIDEMIOLOGY

- Typically occurs ages 70 to 80 years (80% of cases)
- Women are affected about 2 times as often as men.
- Most common vasculitis in individuals of Northern European descent (Scandinavian countries)
- Rare in Asians and African Americans

Incidence

- Prevalence in individuals >50 years: 1 in 500
- Cyclic incidence: peaking every 5 to 7 years

ETIOLOGY AND PATHOPHYSIOLOGY

- The exact etiology of GCA remains unknown, although current theory suggests that advanced age, ethnicity, and specific genetic predisposition lead to a maladaptive response to endothelial injury, intimal hyperplasia, and ultimately vascular stenosis.
- Temporal arteritis (TA) is a chronic, systemic vasculitis primarily affecting the elastic lamina of medium- and large-sized arteries. Histopathology of affected arteries is marked by transmural inflammation of the intima, media, and
adventitia, as well as patchy infiltration by lymphocytes, macrophages, and multinucleated giant cells. Mural hyperplasia can result in arterial luminal narrowing, resulting in subsequent distal ischemia.

- Current theory regarding the etiology of TA is that a maladaptive response to endothelial injury leads to an inappropriate activation of T-cell–mediated immunity via immature antigen-presenting cells. The subsequent release of cytokines within the arterial vessel wall can attract macrophages and multinucleated giant cells, which form granulomatous infiltrates and give diseased vessels their characteristic histology. This also leads to an oligoclonal expansion of T-cells directed against antigens in or near the elastic lamina. Ultimately, this cascade results in vessel wall damage, intimal hyperplasia, and eventual stenotic occlusion.

- In recent years, GCA and PMR have increasingly been considered to be closely related conditions.

**Genetics**
The gene for *HLA-DRB1–04* has been identified as a risk factor for TA, and polymorphisms of *ICAM-1* have also been implicated.

**RISK FACTORS**
- Increasing age >70 years is the greatest risk factor.
- Genetic predisposition
- Environmental factors influence susceptibility.
- Heavy smoking and atherosclerotic disease are risk factors for females but not for males.

**COMMONLY ASSOCIATED CONDITIONS**
PMR may develop either before or after the arteritis (1).

**DIAGNOSIS**

**HISTORY**
- Most common presenting symptom is headache (2/3 of patients).
- Constitutional symptoms (fever, fatigue, weight loss)
- Any visual disturbances (amaurosis fugax, diplopia)
- Vision loss (20% of patients); unilateral is most common, often proceeds to bilateral if untreated.
- Jaw claudication (presence of symptom significantly increases likelihood of a positive biopsy)
- Scalp tenderness or sensitivity
- Claudication of upper extremities or tongue
- Symptoms of PMR (shoulder and hip girdle pain and stiffness)
- Distal extremity swelling/edema
- Upper respiratory symptoms

PHYSICAL EXAM
- Temporal artery abnormalities (beading, prominence, tenderness)
- Typically appear “ill”
- Decreased peripheral pulses in the presence of large vessel diseases
- Funduscopic exam shows pale and edema of the optic disk, scattered cotton wool patches, and small hemorrhages.
- Unlike other forms of vasculitis, GCA rarely involves the skin, kidneys, and lungs.
- Bruits supraclavicular, axillary, supra-orbital

DIFFERENTIAL DIAGNOSIS
- Migraines
- Herpes zoster
- Other vasculitis (Wegners, PAN)
- American College of Rheumatology Classification criteria are as follows:
  - Age >70 years
  - New localized headache
  - Temporal artery abnormality (tenderness to palpation, decreased or absent pulses)
  - ESR >50 mm/hr
  - Abnormal temporal artery biopsy showing vasculitis with predominance of mononuclear cell infiltration or granulomatous inflammation
- ACR criteria may lack sensitivity.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- ESR >50 mm/hr (86% sensitivity), although nonspecific (27%); infrequently, may be normal
- C-reactive protein (CRP) >2.45 mg/dL is a more sensitive marker of inflammation (97% sensitivity) and is associated with increased odds of a
positive biopsy result.

- A normal ESR and/or CRP renders the diagnosis of GCA unlikely.
- Platelet count $>400 \times 10^3$
- Acute-phase reactants (fibrinogen, interleukin-6) are frequently elevated, but very nonspecific, and reserved for diagnostically difficult cases.
- Mild anemia: very nonspecific but may be associated with a lower rate of ischemic complications
- Color Doppler US of the temporal artery may identify vascular occlusion, stenosis, or edema (“halo sign”); it is low cost and noninvasive but also very operator dependent and does not significantly improve on the clinical exam. It may aid in the diagnosis of larger vessel involvement.
- MRI and MRA may be beneficial in diagnosis (78% sensitive, 90% specific) if performed within 5 days of steroids.
- Positron emission tomography (PET), like MRI/MRA and color Doppler, may be useful in diagnostically difficult cases to quantify the inflammatory burden and early in the course of disease, as the metabolic changes occur prior to structural vascular damage, but it also lacks studies to support its use.

**Follow-Up Tests & Special Considerations**

- Development of aortic aneurysms (late and potentially serious complication of GCA) can lead to aortic dissection.
- Due to the risk of irreversible vision loss, treatment with high-dose steroids should be started on strong clinical suspicion of TA, prior to the temporal biopsy being done.

**Diagnostic Procedures/Other**

- Gold standard diagnostic study: histopathologic examination of the temporal artery biopsy specimen
- Overall sensitivity is 87%.
- The temporal artery is chosen because of its accessibility in the systemic disease; alternatively, facial artery or other cranial arteries may be used.
- Length of biopsy specimen should be at least 2 cm to avoid false-negative results, as skip lesions may occur.
- Diagnostic yield of biopsy may be increased if procedure is coupled with imaging (high-resolution MRI or color Doppler US).
- Bilateral temporal artery biopsy should not be performed unless the initial histopathology is negative and the suspicion for GCA remains high.
- May be negative in up to 42% of patients with GCA, especially in large vessel
disease, and a negative biopsy alone should not dictate treatment

- Biopsy results are not affected by prior glucocorticoids, so treatment should not be delayed.

**Test Interpretation**

- Inflammation of the arterial wall, with fragmentation and disruption of the internal elastic lamina
- Multinucleated giant cells are found in <50% of cases and are not specific for the disease.
- TA occurs in three histologic patterns: classic, atypical, and healed.

![TREATMENT]

**MEDICATION**

### First Line

Glucocorticoids:

- The typical dose of prednisone is between 40 and 60 mg/day (or 1 mg/kg/day), and the dose may be titrated up to relieve symptoms. Steroids should not be in the form of alternate day therapy, as this is more likely to lead to a relapse of vasculitis (1)[A].

- IV steroids indicated if vision loss has been noted, otherwise PO steroids are equally as effective (1)[C].

- Given risk of irreversible vision loss, immediate steroid therapy should be initiated prior to confirmation by biopsy.

- The initial dose of steroids is continued for 2 to 4 weeks and slowly tapered over 9 to 12 months. Tapering may require ≥2 years (1)[A].

- Tocilizumab 162 mg SQ weekly or biweekly in addition to prednisone may be superior to prednisone alone (2)[B].

- It has been suggested that low-dose aspirin might be effective for patients with GCA (3)[B].

### Second Line

- Methotrexate as an adjunct to glucocorticoid therapy may have a modest effect in decreasing the relapse rate of TA (4)[A].

- Cyclophosphamide have shown some benefit in patients who have not adequately responded to glucocorticoids (5)[A].
Therapies directed at TNF as adjunct to steroids have not shown significant benefit (1)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Sun avoidance and protection of the head and the face from photodamage may eventually prove to be important preventive measures for TA.

Patient Monitoring

- TA is typically self-limited and lasts several months or years.
- Overall, TA does not seem to decrease longevity. Nevertheless, it may lead to serious complications such as visual loss, which occurs in about 15–20% of patients.
- Another complication of GCA is the development of aortic aneurysms, usually affecting the ascending aorta. Yearly, chest x-rays may be useful to identify this problem (6)[C].
- About 50% of the patients with GCA will eventually develop PMR (stiffness of shoulder and hip girdle).

DIET

Calcium (due to steroid therapy) and vitamin D supplementation

PATIENT EDUCATION

- Consequences of discontinuing steroids abruptly (adrenal insufficiency, disease relapse)
- Risks of long-term steroid use (infection, hyperglycemia, weight gain, impaired wound healing, osteoporosis, hypertension)
- Possibility of relapse and importance of reporting new headaches and vision changes to provider immediately

PROGNOSIS

- Life expectancy is not affected by the disease unless severe aortitis is present.
- Once vision loss has occurred, it is unlikely to be recovered, but treatment resolves the other symptoms and prevents future vision loss and stroke.
- In most patients, glucocorticoid therapy can eventually be discontinued without complications. In a few patients, however, the disease is chronic and
prednisone must be continued for years.
- Disease relapse is a distinct possibility.

COMPLICATIONS
- Vision loss with delayed diagnosis
- Glucocorticoid-related toxicity

Depression; Fibromyalgia; Headache, Cluster; Headache, Tension; Polymyalgia Rheumatica; Polymyositis/Dermatomyositis

CODES

mebooksfree.com
ICD10
- M31.6 Other giant cell arteritis
- M31.5 Giant cell arteritis with polymyalgia rheumatica

CLINICAL PEARLS
- Due to the risk of irreversible vision loss, treatment with high-dose steroids (prednisone 60 mg/day) should be started immediately in patients suspected of TA.
- Temporal artery biopsy is the gold standard for diagnosis. Temporal artery biopsy is not likely to be affected by a few weeks of treatment.
- Treatment consists of a very slow steroid taper. Bone protection therapy and low-dose aspirin should be considered.
- Normal ESR level = value of age/2 for men and age +10/2 for women
- Patients on corticosteroids should be placed on therapy to minimize osteoporosis unless there are contraindications.
BASICS

DESCRIPTION

- Juvenile idiopathic arthritis (JIA) is the most common chronic pediatric rheumatologic disease.
- JIA is associated with significant disability.
  - Age of onset: <16 years
  - Common symptoms: joint swelling, restricted range of motion, warmth, redness, pain
  - Often ≥6 weeks of symptoms prior to diagnosis
- Seven (International League of Associations for Rheumatology [ILAR]) subtypes, determined by clinical characteristics in first 6 months of illness (1):
  - Systemic (Still disease): 10%; preceded by febrile onset of ≥2 weeks with rash, serositis, hepatosplenomegaly or lymphadenopathy (1)
  - Polyarticular rheumatoid factor (RF) (+): 2–7%; ≥5 joints involvement (1); large and small joints; RF positive on two tests ≥3 months apart (2)
  - Polyarticular RF (−): 10–30%; ≥5 (large and small) joints involved (1); RF negative (2)
  - Oligoarticular: 30–60%; involvement of 1 to 4 joints; risk for chronic uveitis in antinuclear antibodies (ANA) (+) females (1) and axial skeletal involvement in older boys (2). Types: (i) persistent (40%): knee, ankle, elbow; (ii) extended type (20%): >4 joints after first 6 months
  - Psoriatic arthritis: 5%; arthritis with psoriasis or arthritis with >2 of: dactylitis, nail changes (pitting), psoriasis in first-degree relative (1)
  - Enthesitis-related arthritis: 1–11%; arthritis and enthesis or one of them plus at least two of the following: sacroiliac or lumbosacral pain, Reiter syndrome or acute anterior uveitis in first-degree relative, acute symptomatic anterior uveitis, HLA-B27 (+), history of ankylosing spondylitis, sacroiliitis with inflammatory bowel disease, onset of arthritis in male >6 years old (1)[C]
  - Undifferentiated arthritis (11–21%): presents with overlapping symptoms in ≥2 categories above or arthritis that does not fulfill above categories (2)
- System(s) affected: musculoskeletal, hematologic, lymphatic, immunologic, dermatologic, ophthalmologic, gastrointestinal
- Synonyms: juvenile chronic arthritis; juvenile arthritis; juvenile rheumatoid arthritis (JRA); Still disease (2)

**EPIDEMIOLOGY**
- Male = female (1); onset: throughout childhood; 54% of cases occur in children 0 to 5 years.
- Polyarticular RF (+): female > male, 3:1 (2); onset: late childhood or adolescence (1)
- Polyarticular RF (−): female > male, 3:1; onset: early peak, 2 to 4 years; late peak, 6 to 12 years (2)
- Oligoarticular: female > male, 5:1; onset: 2 to 4 years (2)
- Psoriatic: female > male, 1: 0.95 (2); onset: early peak, 2 to 3 years; late peak, 10 to 12 years (1)
- Enthesitis: female > male, 1:7; onset: early peak, 2 to 4 years; late peak, 6 to 12 years (2)
- Affected patients have an increased risk of developing cancer, although short-term risk is low.

**Incidence**
2 to 20/100,000 children <16 years in developed nations

**Prevalence**
16 to 150/100,000 children <16 years in developed nations (1)

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Humoral and cellular immunodysregulation. T lymphocytes play a key role.
- Genetic predisposition; IL2RA/CD25 and VTCN1 implicated as genetic loci
- Environmental triggers, possibly infectious
  - Rubella or parvovirus B19 (3)
  - Heat shock proteins (3)
- Immunoglobulin or complement deficiency

**Genetics**
- Human leukocyte antigen (HLA) class I (A, B, C) and II (DR, DP, DQ) alleles
- HLA-A2 = early onset oligoarthritis in females
- HLA class II increases risk of systemic and oligo-JIA.
- HLA-B27 increases risk of enthesitis-related arthritis.
- HLA-DR4 is associated with polyarthritis RF (+) (3)[C].

**RISK FACTORS**
Female gender 3:1

**GENERAL PREVENTION**
None identified

**COMMONLY ASSOCIATED CONDITIONS**
Other autoimmune disorders, chronic anterior uveitis (iritocyclitis), nutritional impairment, growth issues (3)[C]

**DIAGNOSIS**
Clinical criteria: age of onset <16 years and >6 weeks duration of objective arthritis (swelling or restricted range of motion of a joint accompanied by heat, pain, or tenderness with no other form of childhood arthritis) in ≥1 joints

**HISTORY**
- Arthralgias, fever, fatigue, malaise, myalgias, weight loss, morning stiffness, rash
- Limp, if lower extremity involvement
- Arthritis for ≥6 weeks

**PHYSICAL EXAM**
- Arthritis: swelling, effusion, loss of musculoskeletal landmarks, limited range of motion, tenderness, pain with motion, warmth
- Rash, rheumatoid nodules, lymphadenopathy, hepat- or splenomegaly, enthesitis, dactylitis

**DIFFERENTIAL DIAGNOSIS**
- Legg-Calvé-Perthes, toxic synovitis, growing pains, Perthes disease
- Septic arthritis, osteomyelitis, viral infection, mycoplasmal infection, Lyme disease
- Reactive arthritis: postinfectious, rheumatic fever, Reiter syndrome
- Inflammatory bowel disease
- Hemoglobinopathies, hemarthrosis, rickets
Leukemia (particularly acute lymphocytic leukemia), bone tumors (osteoid osteoma), neuroblastoma
Vasculitis, Henoch-Schönlein purpura, Kawasaki disease
Systemic lupus erythematosus, dermatomyositis, mixed connective tissue disease, sarcoidosis, systemic sclerosis, collagen disorders
Farber disease
Accidental or nonaccidental trauma

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- CBC: Leukocyte count is normal or elevated (systemic), lymphopenia, reactive thrombocytosis, anemia; liver function test (LFT) (hepatic involvement) and renal function studies (prior to therapy with nephrotoxic drugs)
- Joint-fluid aspiration/analysis to exclude infection
- ESR and C-reactive protein typically elevated; CRP often disproportionately high
- Myeloid-related proteins (MRP 8/14) associated with flares
- ANA-positive patients have increased risk of uveitis; ANA positive in up to 70% with oligoarticular JIA
- RF (+): 2–10% (usually polyarticular); poor prognosis
- HLA-B27 positive: enthesitis-related arthritis

| Diagnostic radiography, MRI, US, and CT; no one modality has superior diagnostic value (4)[A]. |

- Radiograph of affected joint(s): *early* radiographic changes: soft tissue swelling, periosteal reaction, juxta-articular demineralization; *later* changes: joint space loss, articular surface erosions, subchondral cyst formation, sclerosis, joint fusion
- If orthopnea, obtain ECG to rule out pericarditis.
- Radionuclide scans: for infection/malignancy
- CT is best for bony abnormalities. MRI can assess synovial hypertrophy and cartilage degeneration; MRI more sensitive to monitor disease activity and clinical responsiveness to treatment in peripheral joints

**Follow-Up Tests & Special Considerations**
- RF and ANA present in mixed connective tissue disease (5)[B]
- Use pediatric (not adult) controls when interpreting results of dual energy x-ray photon absorptiometry.
**Diagnostic Procedures/Other**

**Ultrasound:** Assess for inflammation (4)[A].

**Synovial biopsy:** if synovial fluid cannot be aspirated or if infection is suspected in spite of negative synovial fluid culture

**Test Interpretation**

Synovial biopsy → synovial cells hyperplasia, hyperemia, infiltration of small lymphocytes, and mononuclear cells

---

**TREATMENT**

**GENERAL MEASURES**

- Goal is to control active disease, extraarticular manifestations, and achieve clinical remission.
- All patients require regular (every 3 to 4 months for oligo-JIA and in ANA-positive patients) ophthalmic exams to uncover asymptomatic eye disease, particularly for the first 3 years following diagnosis.
- Moist heat or electric blanket for morning stiffness
- Splints for contractures
- Aerobic exercise: weight-bearing or aquatic therapy to improve functional capacity

**MEDICATION**

**First Line**

- ≤4 joints
- NSAIDs: adequate in ~50%, symptoms often improve within days, full efficacy 2 to 3 months
- Drugs for children include:
  - Ibuprofen: 30 to 50 mg/kg/day, divided QID; max dose 2,400 mg/day
  - Naproxen: 10 mg/kg/day, divided BID; max dose 1,250 mg/day
  - Tolmetin sodium: 20 mg/kg/day, TID or QID; max dose 30 mg/kg/day
  - Diclofenac: 2 to 3 mg/kg, divided TID; max dose 50 mg TID
  - Indomethacin: 1 to 2 mg/kg/day, divided BID to QID; max dose of 4 mg/kg/day or 200 mg/day
- NSAIDs are contraindicated if known allergy.
- Precautions: may worsen bleeding diatheses; use caution in renal
insufficiency and hypovolemic states; take with food.
- Significant drug interactions: may lower serum levels of anticonvulsants and blunt the effect of loop diuretics; NSAIDs may increase serum methotrexate levels.

**Intra-articular long-acting corticosteroids:** immediately effective; improve synovitis, joint damage, contractures, and prevent leg length discrepancy (4) [B]
- Indication: patients with oligoarthritis who fail a 2-month NSAID trial or with poor prognosis (6)[C]
- Triamcinolone hexacetonide

≥5 joints
- If high disease activity or a failed 1 to 2 months NSAID trial → methotrexate (6)[C]

**Second Line**
- 30–40% of patients require addition of disease-modifying antirheumatic drugs (DMARDs): methotrexate, sulfasalazine, leflunomide, and tumor necrosis factor (TNF) antagonists (etanercept, infliximab, adalimumab); newer biologic therapies, including IL-1 and IL-6 receptor antagonists, are currently under investigation.

**Methotrexate:** 10 mg/m$^2$/wk PO or SC (5)[B]
- Plateau of efficacy reached with 15 mg/m$^2$/wk; further increase in dosage is not associated with therapeutic benefit.

**Sulfasalazine:** oligoarticular and HLA-B27 spondyloarthritis (5)[B]

**Etanercept:** 0.8 mg/kg (max of 50 mg/dose) given SC q1wk or 0.4 mg/kg SC twice a week (max of 25 mg/dose)

**Infliximab:** 5 mg/kg q6–8wk

**Adalimumab:** if weight 15 kg to <30 kg, 20 mg SC q2wk; if weight ≥30 kg, 40 mg SC q2wk

**Tocilizumab:** IL-6 antibody demonstrating efficacy in phase III open label trials; ongoing studies to evaluate efficacy and appropriate dosing (5)[B]

**Anakinra:** IL-1 receptor antibody under investigation with phase II and III clinical trials for systemic JIA (5)[B]

Begin treatment with TNF-α inhibitors in children with a history of arthritis in ≤4 joints and significant active arthritis despite treatment with methotrexate or arthritis in ≥5 joints and any active arthritis following an adequate trial of methotrexate (6)[C].

Begin treatment with anakinra in children with systemic arthritis and active
fever whose treatment requires a second medication, in addition to systemic glucocorticoids (5)[B].

- Analgesics, including narcotics for pain control

**ISSUES FOR REFERRAL**
- Pediatric rheumatologist for management of JIA
- Orthopedics as needed for articular complications
- Ophthalmology: to evaluate for uveitis
- Physical therapy to maintain range of motion, improve muscle strength, and prevent deformities
- Occupational therapy to maintain and improve appropriate age-related functional activities
- Behavioral health if difficulty coping with disease

**SURGERY/OTHER PROCEDURES**
- Total hip and/or knee replacement for severe disease
- Soft tissue release if splinting/traction unsuccessful
- Correct limb length or angular deformities
- Synovectomy is rarely performed.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admit if:
  - Patient unable to ambulate
  - Signs/symptoms of pericarditis
  - Persistent fever or diagnostic confusion to facilitate evaluation and workup
  - Need for surgery
- Discharge upon resolution of fever and swelling or serositis

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Determined by medication and disease activity
- NSAIDs: periodic CBC, urinalysis, LFTs, renal function tests
- Aspirin and/or other salicylates: transaminase and salicylate levels, weekly for
1st month and then every 3 to 4 months
- Methotrexate: monthly LFTs, CBC, BUN, creatinine

**DIET**
Regular diet. Ensure adequate calcium, iron, protein, and caloric intake.

**PATIENT EDUCATION**
- Psychosocial needs; school issues; behavioral strategies for dealing with pain and noncompliance; available health care resources; support groups

**PROGNOSIS**
- 50–60% of patients will ultimately achieve remission.
- Functional ability depends on adequacy of therapy (disease control, maintaining muscle and joint function).
- Poor prognosis: patients with active disease at 6 months; polyarticular disease; extended pauciarticular disease course; female gender; RF (+); ANA (+); persistent morning stiffness; rapid appearance of erosions; hip involvement

**COMPLICATIONS**
- Blindness, band keratopathy, glaucoma, short stature, micrognathia if temporomandibular joint involvement, debilitating joint disease, disseminated intravascular coagulation, hemolytic anemia
- NSAIDs: peptic ulcer, GI hemorrhage, CNS reactions, renal disease, leukopenia
- DMARDs: bone marrow suppression, hepatitis, renal disease, dermatitis, mouth ulcers, retinal toxicity (antimalarials; rare)
- TNF antagonists: higher risk of infection
- Osteoporosis, avascular necrosis
- Methotrexate: Folate supplementation decreases hepatic/GI symptoms; may reduce stomatitis
- Macrophage activation syndrome: decreased blood cell precursors secondary to histiocyte degradation of marrow

**REFERENCES**
2. Prince FH, Otten MH, van Suijlekom-Smit LW. Diagnosis and management

**ADDITIONAL READING**

**CODES**

**ICD10**
- M08.90 Juvenile arthritis, unspecified, unspecified site
- M08.80 Other juvenile arthritis, unspecified site
- M08.00 Unsp juvenile rheumatoid arthritis of unspecified site

**CLINICAL PEARLS**
- JIA is the most common form of arthritis in children.
- Include JIA in the differential diagnosis for a limping child.
- High-titer RF correlates with disease severity; prognosis worse if positive RF titers
- DMARDs improve JIA-associated symptoms.
ARTHRITIS, PSORIATIC

Lorena C. Dollani, MD • Nikki A. Levin, MD, PhD

BASICS

A chronic, destructive, seronegative arthropathy most common in patients with long-standing psoriasis

DESCRIPTION

- Psoriatic arthritis (PsA) is a seronegative spondyloarthropathy characterized by inflammatory arthritis and enthesitis.
- Five patterns of arthritis in PsA:
  - Asymmetric oligoarthritis: <5 joints
  - Distal interphalangeal (DIP) joint predominant: osteoarthritis-like, associated with nail psoriasis
  - Symmetric polyarthritis: may be indistinguishable from rheumatoid arthritis (RA)—typically milder
  - Spondyloarthritis: asymmetric and discontinuous, unlike ankylosing spondylitis (AS)
  - Arthritis mutilans: destructive, resorptive arthritis; produces “opera-glass” or “telescoping” digit
- Although psoriasis generally is present, it may be limited in extent.
  - Course of arthritis and extent of psoriasis do not appear to correlate.
  - Other extra-articular features, such as iritis, are less common.
  - Damaging joint disease may occur in 40–60%. Characteristic radiologic changes include “pencil-in-cup” deformity and periostitis.
- Rheumatoid factor (RF) and cyclic citrullinated peptide antibody (anti-CCP) are usually negative. HLA-B27 may be positive.

EPIDEMIOLOGY

- Peak onset age: 30 to 50 years
- Predominant gender: female = male
- Polyarthritis is more common in women.
- Spondylitis in up to 25%, more common in males
- Psoriasis precedes arthritis in most patients by an average of 12 years.
  - Arthritis preceding psoriasis occurs in up to 15% of patients, usually children.
  - Arthritis and psoriasis may present simultaneously.
Psoriasis occurs in 2–3% of the U.S. population; 6–42% will develop PsA (1).

**Prevalence**
Prevalence: 1 to 2/1,000 population (1)

**ETIOLOGY AND PATHOPHYSIOLOGY**
- CD4+/CD8+ T cells; tumor necrosis factor α (TNF-α); interleukins 1 (IL-1), 6, 8, and 10; and matrix metalloproteases present in synovial fluid
- Osteoclast precursor cell upregulation
- Unknown. Probably multifactorial: immunologic, genetic, environmental factors

**Genetics**
- 30–40% concordance in identical twins
- HLA-B27 in 15–50% with PsA (spondylitis pattern) versus 90% in AS
- Other HLA associations in PsA: HLA-B7, HLA-B38, HLA-B39, HLA-Cw6

**RISK FACTORS**
- Psoriasis
- Family history of PsA

**GENERAL PREVENTION**
No known prevention strategies; unknown whether early treatment of psoriasis prevents onset of PsA

**COMMONLY ASSOCIATED CONDITIONS**
Psoriasis

**DIAGNOSIS**
- A history of inflammatory arthritis, dactylitis, or enthesitis in patients with existing psoriasis is usually adequate to establish the diagnosis; often difficult to differentiate from other inflammatory arthropathies
- Classification of psoriatic arthritis (CASPAR) criteria (91% sensitivity; 99% specificity) are validated to screen patients for PsA. Inflammatory articular disease (joint, spine, or enthesal) with ≥3 points from the following five categories:
  - Evidence of current psoriasis, a personal or family history of psoriasis (2
points)
- Typical psoriatic nail dystrophy, including onycholysis, pitting, and hyperkeratosis (1 point)
- Negative RF (ELISA preferred) (1 point)
- Current or prior history of dactylitis (1 point)
- Radiologic evidence of new bone formation (excluding osteophyte formation) on plain radiographs of the hand or foot (1 point)

HISTORY
History and physical exam are often adequate to establish the diagnosis of PsA.
- (Generally) long-standing history of psoriasis
- Morning stiffness of hands, feet, or low back for >30 minutes
- Pain of involved joints
- Swelling or redness of peripheral joints
- Low back or buttock pain
- Ankle or heel pain
- Dactylitis or uniform swelling of an entire digit

PHYSICAL EXAM
- Affected peripheral joints may have overlying erythema, warmth, and swelling.
  - Synovitis
  - Dactylitis
  - Swelling of tendons (e.g., Achilles tendon) and tenderness at insertion sites (e.g., calcaneus)
  - Limited range of motion of axial skeleton
  - Pain with stress of the sacroiliac joint
- Well-demarcated pink-to-red erythematous plaques with a white silvery scale; common locations include scalp, ears, trunk, buttocks, elbows and forearms, knees and legs, and palms and soles.
- Nails may be dystrophic with pits, oil spots, crumbling, leukonychia, and red lunulae.

DIFFERENTIAL DIAGNOSIS
- Reactive arthritis
- Psoriasis and RA
- Psoriasis and osteoarthritis
- Psoriasis and polyarticular gout
Psoriasis and AS

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Serum RF (usually negative)
- Anti-CCP (usually negative)
- Antinuclear antibodies (usually negative)
- Acute-phase reactants (ESR and C-reactive protein) may be elevated.
- HLA-B27 is noted in 50–70% with axial disease and <15% with peripheral disease.
- Baseline plain radiographs of affected joints
- Plain radiographs may aid in the diagnosis and allow assessment of damage, disease progression, and response to therapy.
- Juxta-articular new bone formation (periostitis) and marginal joint erosions that may progress centrally to form the “pencil-in-cup” erosions are the most characteristic plain radiographic features.

Follow-Up Tests & Special Considerations
Follow-up radiographs; interval based on severity

Diagnostic Procedures/Other
Diagnosis is typically clinical.

Test Interpretation
Biopsy of skin or synovium is not usually required.

TREATMENT

GENERAL MEASURES
Physical therapy and/or occupational therapy typically benefit all stages of disease.

- Treatment algorithms for PsA are based on severity of joint symptoms, extent of structural damage, and severity of psoriasis.
- Patients with moderate to severe arthritis should be started on disease-modifying antirheumatic drugs (DMARDs) to reduce or prevent joint damage and preserve joint integrity and function.
**MEDICATION**

**First Line**
- NSAIDs for control of symptoms with mild disease. Intermittent intra-articular glucocorticoid injections may also help.
- There are no systematic trials of NSAIDs for PsA. NSAIDs doses are directed toward suppressing mild inflammation. Selection is based on patient preference and dosing convenience. Sample NSAIDs include ibuprofen 400 to 800 mg PO TID–QID, naproxen 250 to 500 mg PO BID–TID, diclofenac 100 to 150 mg QD, indomethacin 100 to 150 mg QD.
- Monotherapy is as effective as combination therapy (≥2 drugs from the following: analgesics, NSAIDs, opioids, opioid-like drugs, and neuromodulators [antidepressants, anticonvulsants, and muscle relaxants]) for adults (2)[A].

<table>
<thead>
<tr>
<th>Second Line</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recommended DMARDs include sulfasalazine, leflunomide, methotrexate; no evidence to support the use of combination DMARD therapy</td>
</tr>
<tr>
<td>Initial dosing regimens for DMARDs: sulfasalazine (2 to 3 g/day PO divided in BID dosing), leflunomide (loading dose of 100 mg/day PO for 3 days and then 20 mg/day PO), methotrexate (1 test dose of 2.5 to 5 mg PO to assess for significant bone marrow suppression and then 15 to 25 mg once weekly), azathioprine (0.5 mg/kg/day, with a max dose of 2.5 mg/kg/day if no signs of cytopenia at lower doses)</td>
</tr>
<tr>
<td>Consider anti–TNF-α therapy in patients who fail to respond to at least one standard DMARD or in patients with poor prognosis, even if they have not failed a standard DMARD (3)[A].</td>
</tr>
<tr>
<td>Dosing regimens for biologics: adalimumab (40 mg SC q2wk), etanercept (50 mg SC weekly), golimumab (50 mg SC monthly), infliximab (5 mg/kg at 0, 2, and 6 weeks, q8wk afterward); certolizumab pegol 200 mg every 2 week; for maintenance dosing or 400 mg every 4 weeks</td>
</tr>
<tr>
<td>Anti–interleukin-17 agents are increasingly available:</td>
</tr>
<tr>
<td>– Ixekizumab 80 mg q2wk (4)</td>
</tr>
<tr>
<td>– Secukinumab 150 mg weekly from 0 to 4 weeks, then monthly (4)</td>
</tr>
<tr>
<td>Anti–interleukin-12/interleukin-23 agents include:</td>
</tr>
<tr>
<td>– Ustekinumab is currently dosed at 45 or 90 mg (depending on weight) at 0, 4, and 12 weeks then q12wk thereafter.</td>
</tr>
<tr>
<td>PDE4 inhibitors include:</td>
</tr>
<tr>
<td>– Apremilast dosed at 30 mg PO BID (4)</td>
</tr>
</tbody>
</table>
With the exception of the TNF-α inhibitors, apremilast and ustekinumab, all medications described above are not FDA approved for PsA. Use is off-label.

**ALERT**

- Do not use anti-TNF agents in the setting of active infection (including TB and hepatitis B). Do not use anti-TNF agents with concurrent live vaccinations, with New York Heart Association classes III to IV congestive heart failure, with malignancy, or in patients with a history of demyelinating disease.
- Do not use ustekinumab in patients with active infection, mycobacterial or *Salmonella* infection, with concurrent live vaccinations, including Bacillus Calmette-Guérin vaccination or with history of malignancy.

**Pregnancy Considerations**

- Avoid teratogenic medications (e.g., methotrexate, leflunomide) during pregnancy.
- Adalimumab, etanercept, golimumab, infliximab, ustekinumab, and certolizumab pegol are currently listed as Category B medications.

**ISSUES FOR REFERRAL**

- Rheumatology
- Dermatology

**SURGERY/OTHER PROCEDURES**

Joint fusion or replacement for advanced destruction

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Epidemiologic data suggest a relationship between psoriasis, metabolic syndrome, myocardial infarction, and stroke. Control of weight, blood pressure, lipids, and glucose is recommended (5).

**PATIENT EDUCATION**

- PsA is not contagious.
- National Psoriasis Foundation, [http://www.psoriasis.org/i-have-psoriatic-arthritis](http://www.psoriasis.org/i-have-psoriatic-arthritis)
– Arthritis Foundation http://www.arthritis.org/about-arthritis/types/psoriatic-arthritis/
– American College of Rheumatology

PROGNOSIS

- Course is typically insidious with chronic joint disease and recurring/remitting skin disease.
- Prognosis is more favorable than for RA (except for patients who develop arthritis mutilans).

COMPLICATIONS

- Chronicity
- Disability
- Psychosocial impact of psoriasis

REFERENCES

ADDITIONAL READING

mebooksfree.com

**CODES**

**ICD10**

- L40.50 Arthropathic psoriasis, unspecified
- L40.51 Distal interphalangeal psoriatic arthropathy
- L40.53 Psoriatic spondylitis

**CLINICAL PEARLS**

- One in four patients with psoriasis will develop PsA.
- The severity of psoriasis often correlates with the likelihood of developing arthritis. The severity of psoriasis does not correlate with severity of arthritis.
- Often overlooked locations of psoriasis include scalp, ears, umbilicus, and gluteal cleft.
- Osteoarthritis and polyarticular gout may mimic or coexist with PsA.
- The polyarticular pattern of PsA mimics RA. The presence of both enthesitis and psoriasis helps differentiate PsA from RA.
- Axial skeleton involvement in PsA is asymmetric and discontinuous.
BASICS

DESCRIPTION
- Chronic systemic autoimmune inflammatory disease with symmetric polyarthritis and synovitis
- Progressive chronic inflammation leads to large and small joint destruction, deformity, decline in functional status, and premature morbidity/mortality.
- System(s) affected: musculoskeletal, skin, hematologic, lymphatic, immunologic, muscular, renal, cardiovascular, neurologic, pulmonary

Geriatric Considerations
- Increased age-related comorbidities
- Decreased medication tolerance; increased incidence of hydroxychloroquine-associated maculopathy and sulfasalazine-induced nausea/vomiting, NSAID-induced gastric ulcers, and corticosteroid-induced diabetes and osteoporosis

Pregnancy Considerations
- Use effective contraception in patients taking disease-modifying antirheumatic drugs (DMARDs).
- Methotrexate, leflunomide, cyclophosphamide, and cyclosporine are teratogenic. Sulfasalazine and hydroxychloroquine are safe to use during pregnancy and breastfeeding.
- 50–80% of patients improve during pregnancy because of immunologic tolerance. Most relapse in 6 months after delivery. First episode may occur in pregnancy or postpartum.

EPIDEMIOLOGY

Incidence
- 25 to 30/100,000 for males
- 50 to 60/100,000 for females
- Peak age at onset is 35 to 50 years.

Prevalence
1% of the U.S. population

ETIOLOGY AND PATHOPHYSIOLOGY

- An insult (e.g., infection, smoking, trauma) precipitates an autoimmune reaction activating antibody-complement complexes, resulting in endothelial activation, synovial hypertrophy, and joint inflammation/damage.
- Pathogenesis is mediated by abnormal B- and T-cell interactions and cytokine overproduction (TNF and IL-6).
- Multifactorial disease with genetic, host (hormonal, immunologic), and environmental (socioeconomic, smoking) factors

Genetics

- RA is 50% attributable to genetic causes. HLA-DR4 is a shared epitope in over 50% of cases.
- Monozygotic twin concordance is 15–20%, suggesting nongenetic factors also contribute.
- Individuals with HLA-DR4 and DRB1, and mutations in STAT4, CD40+ have increased relative risk.

RISK FACTORS

- First-degree relatives have 2- to 3-fold increased risk.
- Smokers have elevated relative risk of 1–2%. Smoking is associated with an increased risk of developing ACPA-positive antibodies.
- Pregnancy and breastfeeding for 24 months lowers risk up to 50%.
- Women affected 3:1; difference diminishes with age.

COMMONLY ASSOCIATED CONDITIONS

Accelerated atherosclerosis, pericarditis, amyloidosis, Felty syndrome (RA, splenomegaly, neutropenia), interstitial lung disease, pulmonary nodules, rheumatoid nodules, vasculitis, lymphomas, and carpal tunnel syndrome

DIAGNOSIS

HISTORY

- Symmetric polyarthritis most commonly affecting the hands and feet
- Constitutional symptoms: fatigue, malaise, weight loss, low-grade fevers

[A], (2)[C]

mebooksfree.com
Articular symptoms: tender/swollen joints, early morning stiffness (at least 60 minutes), and difficulty with activities of daily living (ADL) (1)[A],(2)[C].

Extra-articular involvement: skin, pulmonary, cardiovascular, and ocular symptoms; onset is typically insidious. Patients rarely present with abrupt onset of symptoms and extra-articular manifestations (1)[A],(2)[C].

**PHYSICAL EXAM**
- Evaluate for swollen, boggy, or tender joints with pain and decreased ROM; usually symmetric
  - Small joints: metacarpophalangeal (MCP), leading to Boutonnière and swan-neck deformities, carpal bones of wrist, 2nd to 5th metatarsophalangeal (MTP), and thumb interphalangeal (IP) joints
  - Large joints: Shoulders, elbows, hips, knees, and ankles will show evidence of effusions.
- Joint deformity, nodules, and fusion are late findings.
- Extra-articular findings:
  - Splenomegaly, lymphadenopathy, subcutaneous nodules, peripheral neuropathy, and atlantoaxial joint instability. Axial migration of dens into foramen magnum may contribute to occipital headaches.
  - Cardiovascular mortality increased with RA—evaluate rhythm, presence of murmurs (valvular dysfunction), and for pericardial effusion.
  - Pulmonary disease typically manifests as pleural effusion and fibrosis (dullness, rales).

**DIFFERENTIAL DIAGNOSIS**
Sjögren syndrome, systemic lupus erythematosus, systemic sclerosis, adult Still disease, psoriatic arthritis, polymyalgia rheumatica (older), seronegative polyarthritis, erosive osteoarthritis, crystal arthropathy, septic arthritis, chronic Lyme disease, viral-induced arthritis (parvovirus B19, Chikungunya virus, hepatitis C [with cryoglobulinemia]), occult malignancy, vasculitis (Behçet syndrome), inflammatory bowel disease, RS3PE hemochromatosis, sarcoidosis

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- CBC: Mild anemia and thrombocytosis are common and relate to disease activity (1)[A].
- ESR and C-reactive protein (CRP) are nonspecific markers used to assess disease activity (1)[A].
- Rheumatoid factor (RF): >1:80 in 70–80% of patients with RA (most commonly IgM Ab) (1)[A]
- Anticyclic citrullinated peptide antibodies (anti-CCP antibodies); specificity >90% (1)[A]
- Antinuclear antibody: present in 20–30%
- Electrolytes, creatinine, liver function, and urinalysis to assess comorbid states, establish baseline, and to assist with medication management (3)[A]
- Radiographs help establish diagnosis and monitor progression (1)[A].

Plain film radiographs are preferred for RA:
- Initial radiographs of the hands, wrists, and feet
- Hallmark is a lack of bony remodeling and symmetric joint space narrowing.
- Earliest pattern of erosions is loss of cortical distinctness, followed by dot-dash pattern of cortical bone loss. Marginal erosions at cortical bone within joint capsule not covered by cartilage result in “mouse-ear” erosions.
- MRI of hands and wrists (erosions, pannus, synovitis)
- Ultrasound can assess synovial thickening/erosions.

Diagnostic criteria: based on the 2010 ACR/EULAR Criteria (1)[A]
- ≥1 joint with definitive clinical synovitis not explained by another disease plus either:
  - Presence of ≥2 typical periarticular erosions
  - Score of ≥6 on following:
    - Joint involvement (0 to 5)
      - 1 medium to large joint: 0
      - 2 to 10 medium to large joints: 1
      - 1 to 3 small joints: 2 (DIP, 1st MCP, and 1st MTP joints are excluded from assessment)
      - 4 to 10 small joints: 3
      - >10 joints (>1 small joint): 5
    - Serology score: (0 to 3)
      - Negative RF and ACPA (anticitrullinated protein antibody): 0
      - Low positive RF or low positive ACPA: 2
      - High positive RF or high positive ACPA: 3
    - Acute-phase reactants score: (0 to 2)
      - Normal CRP and normal ESR: 0
      - Abnormal CRP or ESR: 1
    - Duration of symptoms score: (0 to 1)
      - <6 weeks: 0
      - ≥6 weeks: 1
Patients with a score of <6/10 do not meet RA criteria. Reevaluate these patients over time.

**Diagnostic Procedures/Other**
- Joint aspiration (if needed) to exclude crystal arthropathy and septic arthritis
- Synovial fluid analysis:
  - Gram stain, cell count, culture, crystal analysis, and overall appearance
  - Yellowish-white, turbid, poor viscosity in RA
  - WBC increased (3,500 to 50,000 cells/mm3)
  - Protein: ~4.2 g/dL (42 g/L)
  - Serum-synovial glucose difference ≥30 mg/dL (≥1.67 mmol/L)

**TREATMENT**

**GENERAL MEASURES**
- Goal is to achieve remission or minimize disease activity, prevent structural damage and prevent disability (4)[A].
- Early, aggressive treatment prevents structural damage and disability (4)[A].
- Periodic evaluation of disease activity and extent of synovitis can establish severity of disease (4)[A].
- Disease activity measures include the DAS 28 score and the RAPID 3 score (4)[A].
- Treatment is based on severity of disease (4)[A].

**MEDICATION**
- Early DMARD therapy to slow disease progression and induce remission is standard of care (4)[A].
- Nonbiologic DMARDs:
  - Start within 3 months of diagnosis.
  - Due to greater convenience, lower toxicity profiles, and quicker onset of action, initial therapy is a nonbiologic DMARD.
  - Methotrexate (MTX): is the first-line DMARD in patients with active RA; start with 7.5 to 25 mg/week PO. Titrate to optimal dosage within 4 to 8 weeks. DMARD with the most predictable benefit. Folic acid 1 mg PO daily reduces toxicity. Monitor CBC, renal and liver function every month for 3 months and then every 3 months; contraindicated in renal and hepatic diseases, pregnancy, and breastfeeding.
– Sulfasalazine (SSZ): 500 mg/day, increase to 2 g/day over 1 month; max: 2 to 3 g/day; 6-month trial. Monotherapy for low disease activity. Monitor CBC, liver enzymes every 2 weeks for 3 months, then every month for 3 months, and then every 3 months. Screen for G6PD deficiency.
– Leflunomide (Arava): loading dose 100 mg/day × 3 days and then 10 to 20 mg/day. GI side effects and potentially teratogenic; contraindicated in pregnancy. Monitor CBC, LFTs, and phosphate monthly for the first 6 months. Stop use if ALT >3 × upper limit normal.
– Hydroxychloroquine (Plaquenil) 400 mg QHS for 2 to 3 months and then 200 mg QHS; 6-month trial. Usually used to treat milder forms or in combination with other DMARDs. Ophthalmologic exam every 6 to 12 months due to potential maculopathy. Adjust dose in renal insufficiency.
– Minocycline (100 mg BID), antibiotic with anti-inflammatory properties; used in mild disease

**Biologic DMARDs:**
– TNF inhibitors: IV infliximab (Remicade), SC adalimumab (Humira), and SC etanercept (Enbrel). No evidence that one is superior; certolizumab pegol (Cimzia) and golimumab (Simponi), approved in moderate to severe disease
– Janus kinase (JAK) inhibitor: tofacitinib citrate (Xeljanz), used for moderate to severe disease in adults that failed methotrexate
– Interleukin-6 (IL-6) receptor antagonist: tocilizumab (Actemra) for moderate to severe active rheumatoid arthritis that failed DMARD therapy. Sarilumab (Kevzara), newly FDA approved in May 2017 for treatment of moderate to severe RA in patients who had an inadequate response or intolerance to anti-TNF therapy; need to monitor for neutropenia (5)[A]
– Abatacept (Orencia) and anakinra (Kineret) no longer considered cost-effective or efficacious treatment for RA
– Rituximab (Rituxan): A chimeric monoclonal antibody that targets CD20 on B cells. It is recommended with or without MTX for active moderate to severe RA with inadequate response to other DMARDs or failed anti-TNF agent.

**All biologics can be used in combination with a DMARD or steroids (4)[A].**
**In patients with history of lymphoproliferative disorders, rituximab is preferred to TNF inhibitor (4)[A].**
**In patients with skin cancer, DMARD are preferred to biologic agents (4)[A].**
**In patients with CHF, combo DMARD therapy, a non-TNF biologic, or tofacitinib is recommended over a TNF inhibitor (4)[A].**
**Check purified protein derivative (PPD) and screen for hepatitis prior to**
treatment.

- Ensure vaccinations (pneumococcal, HPV, hepatitis B, influenza, varicella zoster) are up-to-date prior to starting biologic agents.
- Treating flare-ups:
  - Intra-articular steroids: if disease is well controlled after ruling out intra-articular infection
  - Repository corticotropin injection, an ACTH analogue (Acthar gel)

**ADDITIONAL THERAPIES**

Symptomatic therapy in addition to DMARDs:

- NSAIDs: naproxen (500 mg BID) or ibuprofen (800 mg TID) for symptomatic relief. If poor response to initial NSAID after 2 weeks, try alternative NSAID.
- If still poor response, prednisone (5 to 30 mg/day); taper off NSAID or prednisone as soon as effective control of disease activity with DMARD is achieved.
- Capsaicin cream: 3 to 4 times/day as needed
- Physical therapy to minimize loss of function and joint damage

**SURGERY/OTHER PROCEDURES**

- Synovectomy, tendon reconstruction, joint fusion, and joint replacement may be considered to prevent disability in RA unresponsive to therapy or in advanced RA.
- Need flexion/extension films of cervical spine prior to any surgery due to high risk of atlantoaxial joint instability and subluxation

**ONGOING CARE**

The goals of comprehensive, interdisciplinary care are to inhibit the disease process, reduce pain, preserve joint function, and maximize quality of life.

**FOLLOW-UP RECOMMENDATIONS**

Encourage full activity as tolerated. Avoid heavy work or exercise during active (flare) phases. Emphasize exercise, mobility, and reduction of joint stress.

**Patient Monitoring**

Disease Activity Score (DAS28) questionnaire to monitor disease activity at
follow-up visits and Health Assessment Questionnaire (HAQ) for functional status yearly

**DIET**
Some benefits for symptom control have been found with Mediterranean diet.

**PROGNOSIS**
- Poor prognostic findings
  - Persistent moderate to severe disease; early or advanced age at disease onset
  - Many affected joints; positive MCP squeeze test, and PIP and MCP symmetric involvement
- 50% cannot function in their primary jobs within 10 years of onset.

**REFERENCES**

**CODES**

- M06.9 Rheumatoid arthritis, unspecified
- M05.60 Rheu arthritis of unsp site w involv of organs and systems
M05.30 Rheumatoid heart disease w rheumatoid arthritis of unsp site

CLINICAL PEARLS

- Plain films are the initial imaging modality of choice in RA.
- Females have more articular disease; males have more systemic manifestations.
- Early treatment with DMARDs slows disease progression and improves the chance for remission.
- Methotrexate is the first-line DMARD in patients with active RA.
ARTHRITIS, SEPTIC
Jeffrey P. Feden, MD, FACEP

BASICS

DESCRIPTION
- Infection due to bacterial invasion of the joint space
- Systems affected: musculoskeletal
- Synonyms: suppurative arthritis; infectious arthritis; pyarthrosis; pyogenic arthritis; bacterial arthritis

EPIDEMIOLOGY
- May occur at any age. Incidence is higher in very young and elderly.
- Prevalence: 27% of patients presenting with monoarticular arthritis have nongonococcal septic arthritis (1).
- Gender differences:
  - Gonococcal: female > male
  - Nongonococcal: male > female

ETIOLOGY AND PATHOPHYSIOLOGY
- Many different pathogens
- Nongonococcal:
  - *Staphylococcus aureus* (most common in adults)
    - MRSA risk increased in elderly, intravenous drug users (IVDU), postsurgical
  - *Streptococcus* spp. (second most common in adults)
  - Gram-negative rods (GNR): IVDU, trauma, extremes of age, immunosuppressed
- *Neisseria gonorrhea* (most common in young, sexually active adults)
- Other: rickettsial (e.g., Lyme), fungal, mycobacterial
- Risk by specific age (2):
  - <1 month: *Streptococcus aureus*, Group B strep (GBS), GNR
  - 1 month to 4 years: *S. aureus*, *Streptococcus pneumoniae*, *Neisseria meningitidis*
  - 16 to 40 years: *N. meningitidis*, *S. aureus*
  - >40 years: *S. aureus*
Specific high-risk groups:
- Rheumatoid arthritis: *S. aureus*
- IVDU: *S. aureus*, GNR, opportunistic pathogens
- Neonates: GBS
- Immunocompromised: gram-negative bacilli, fungi
- Trauma patients with open injuries: mixed flora

Pathogenesis:
- Hematogenous spread (most common)
- Direct inoculation by microorganisms secondary to trauma or iatrogenesis (e.g., joint surgery)
- Adjacent spread (e.g., osteomyelitis)

Pathophysiology:
- Microorganisms initially enter through synovial membrane and spread to the synovial fluid.
- Resulting inflammatory response releases cytokines and destructive proteases leading to systemic symptoms and joint damage.

**RISK FACTORS**
- Age >80 years
- Low socioeconomic status; alcoholism
- Cellulitis and skin ulcers
- Violation of joint capsule
  - Prior orthopedic surgery
  - Intra-articular steroid injection
  - Trauma
- History of previous joint disease
  - Inflammatory arthritis (rheumatoid arthritis [RA]: 10-fold increased risk)
  - Osteoarthritis
  - Crystal arthritides
- Systemic illness
  - Diabetes mellitus, liver disease, HIV, malignancy, end-stage renal disease/hemodialysis, immunosuppression, sickle cell anemia
- Risks for hematogenous spread
  - IVDU, severe sepsis/systemic infection

**GENERAL PREVENTION**
- Prompt treatment of skin and soft tissue infections
- Control risk factors.
- Immunization (*S. pneumoniae; N. meningitidis*)
DIAGNOSIS

HISTORY

- Typically presents with a combination of joint pain, swelling, warmth, and decreased range of motion
- Nongonococcal arthritis: predominantly monoarticular (80%)
  - Typically large joints (knee in 50% of cases)
  - Most patients report fever.
  - IV drug users may develop infection in axial joints (e.g., sternoclavicular joint).
  - Prosthetic joints may show minimal findings and present with draining sinus over the joint.
  - Patients on chronic immunosuppressive drugs and those receiving steroid joint injections may have atypical presentations (no fever or joint pain).
- Pediatric considerations
  - Infants may refuse to move limb (can be mistaken as neurologic problem).
  - Hip pain may present as referred knee or thigh pain.
- Gonococcal arthritis
  - Bacteremic phase: migratory polyarthritis, tenosynovitis, high fever, chills, pustules (dermatitis–arthritis syndrome)
  - Localized phase: monoarticular, low-grade fever

PHYSICAL EXAM

- Physical exam has poor sensitivity and specificity for septic arthritis.
  - Common findings include:
    - Limited range of motion
    - Joint effusion and tenderness
    - Erythema and warmth over affected joint
    - Pain with passive range of motion
- Hip and shoulder involvement may reveal severe pain with range of motion and less obvious swelling.
- Infants with septic hip arthritis maintain flexed and externally rotated hip.

DIFFERENTIAL DIAGNOSIS

- Crystal arthritis: gout, pseudogout, calcium oxalate, cholesterol
- Infectious arthritis: fungi, spirochetes, rheumatic fever, HIV, viral
- Inflammatory arthritis: RA, spondyloarthropathy, systemic lupus erythematosus, sarcoidosis

mebooksfree.com
• Osteoarthritis
• Trauma: meniscal tear, fracture, hemarthrosis
• Other: bursitis, cellulitis, tendinitis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

• Synovial fluid analysis is the gold standard:
  - Obtain prior to antibiotic therapy when possible.
  - Include Gram stain, culture, cell count/differential, and crystal analysis.
  - Use blood culture bottles to increase yield.
  - Gram stain (positive in 50%) and culture (positive in 50–70%)
  - >50,000 WBCs/HPF with >90% polymorphonuclear leukocytes is suggestive; *synovial WBC (sWBC) count alone is insufficient to rule in or rule out septic arthritis* (2)[A].
  - The presence of crystals (e.g., urate or calcium pyrophosphate) *does not exclude concurrent infectious arthritis*.
  - Prosthetic joint: WBC count is unreliable; a lower number of sWBCs may indicate infection.

• Serum tests:
  - WBC count alone is neither sensitive nor specific.
  - ESR >15 mm/hr has sensitivity up to 94% but poor specificity (3)[B].
  - CRP >20 mg/L has sensitivity of 92% (3)[B].
  - Synovial lactate is a potential biomarker (4)[A].
  - Blood cultures are positive in 50% of cases.

• Other tests:
  - Disseminated gonococcus: culture blood, cervix, urine, urethra, pharynx in addition to joint fluid
  - Suspected Lyme arthritis: Send serum titers.

• Pediatrics: No single lab test distinguishes septic arthritis from transient synovitis.
  - The combination of fever, non–weight bearing, and elevated ESR and CRP is suspicious; synovial fluid should still be obtained.

• Imaging is helpful to identify effusion but does not differentiate septic from other forms of arthritis.
  - Plain films:
    o Nondiagnostic for septic arthritis. Useful for trauma, soft tissue swelling, osteoarthritis, or osteopenia
    o May show nonspecific changes of inflammatory arthritis (i.e., erosions,
Joint destruction, or joint space loss

- Ultrasound:
  - Helps guide arthrocentesis
  - Recommended for aspiration of the hip
- MRI:
  - Highly sensitive for effusion; may be helpful to distinguish between transient synovitis and septic arthritis in children
- Other imaging techniques:
  - CT is not routinely indicated.
  - Bone scans are not performed unless there is suspicion for osteomyelitis.

**Diagnostic Procedures/Other**
Arthrocentesis in all suspected cases (prior to starting antibiotics). Avoid contaminated tissue (e.g., overlying cellulitis) when performing arthrocentesis.

**Test Interpretation**
Synovial biopsy shows polymorphonuclear leukocytes and (possibly) the causative organism.

---

**TREATMENT**

**GENERAL MEASURES**

- Admit for parenteral antibiotics and monitoring. Begin antibiotics immediately after arthrocentesis.
- Drainage of purulent material is *required* if:
  - Pediatric: Surgical drainage and irrigation is recommended if hip is involved due to high risk of avascular necrosis.
  - Prosthetic joint: antibiotics and consult with orthopedics for consideration of revision arthroplasty, resection arthroplasty, or débridement
- Treat with antibiotic therapy for a total of 4 to 6 weeks in most cases.
  - Exception: gonococcal (2 to 3 weeks)
- Intra-articular antibiotics are not recommended.

**MEDICATION**

**First Line**

- Initial antibiotic choice is guided by Gram stain or the most likely organism based on age, clinical history, and risk factors.
- Nongonococcal (5)[C]:
  - Gram-positive cocci:
    o Vancomycin 15 to 20 mg/kg 2 to 3 times daily or linezolid 600 mg twice daily
  - Gram-negative bacilli:
    o Cefepime 2 g twice daily or ceftriaxone 2 g daily or ceftazidime 2 g 3 times daily or cefotaxime 2 g 3 times daily
    o For cephalosporin allergy: Consider treatment with ciprofloxacin 400 mg 3 times daily.
  - Negative Gram stain:
    o Vancomycin 15 to 20 mg/kg 2 to 3 times daily plus 3rd-generation cephalosporin until cultures and susceptibilities return
    - Duration of therapy: typically 2 weeks of IV and an additional 2 to 4 weeks PO while monitoring therapeutic response
- Gonococcal:
  - Ceftriaxone 1 g IV/IM daily for 7 to 14 days (and at least 24 to 48 hours after symptoms resolve)
  - May require concurrent drainage of affected joint
  - Concomitant treatment for Chlamydia (doxycycline 100 mg twice daily or azithromycin 1 g daily)
- Other considerations:
  - Narrow antibiotic therapy based on culture results.
  - Consider Salmonella in pediatric patients with a history of sickle cell disease: 3rd-generation cephalosporin helpful in this instance.
  - Lyme arthritis: doxycycline 100 mg PO twice daily or amoxicillin 500 mg PO 3 times daily for 28 days if no neurologic involvement, otherwise ceftriaxone 2 g IV daily

**ISSUES FOR REFERRAL**
- Infectious disease and orthopedic consultations
- IVDU and immunosuppression merit infectious disease consultation to guide therapy; prosthetic joint infection best managed with orthopedic consultation

**SURGERY/OTHER PROCEDURES**
- Consider drainage in all cases, particularly shoulder, hip, and prosthetic joints.
- Other treatment options include repeat needle aspiration, arthroscopy, or arthrotomy.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Can monitor synovial fluid to verify decreasing WBC and sterile fluid after initial treatment
- If no improvement within 24 hours, reevaluate and consider arthroscopy.
- Follow up at 1 week and 1 month after stopping antibiotics to ensure no relapse.

PROGNOSIS

- Early treatment improves functional outcome.
- Delayed recognition/treatment is associated with higher morbidity and mortality.
- Elderly, concurrent rheumatoid arthritis, S. aureus infections, and infection of hip and shoulder also increase risk of poor outcome.

COMPLICATIONS

- Mortality estimated at 11% (1)
- Limited joint range of motion, ankylosis
- Secondary osteoarthritis
- Flail, fused, or dislocated joint
- Sepsis, septic necrosis
- Sinus formation
- Osteomyelitis, postinfectious synovitis
- Limb length discrepancy (in children)

REFERENCES

4. Carpenter CR, Schuur JD, Everett WW, et al. Evidence-based diagnostics:

**CODES**

**ICD10**

- M00.9 Pyogenic arthritis, unspecified
- M00.20 Other streptococcal arthritis, unspecified joint
- M00.00 Staphylococcal arthritis, unspecified joint

**CLINICAL PEARLS**

- Arthrocentesis and synovial fluid analysis are mandatory in cases of suspected septic arthritis.
- Gram stain has variable sensitivity in septic arthritis. Synovial WBC count is generally >50,000/HPF but is unreliable as a sole diagnostic feature.
- Early IV antibiotics and (if necessary) drainage of infected joints are critical to successful management.
- Crystalline disease may coexist with septic arthritis.
- Initial antibiotic therapy is guided by arthrocentesis results (Gram stain), age, and patient-specific risk factors.
BASICS

DESCRIPTION

- Arthropods are the largest division of the animal kingdom. Two classes, insects and arachnids, have the greatest impact on human disease.
- Arthropods affect humans by inoculating poison or irritative substances through a bite or sting, by invading tissue, or by contact allergy to their skin, hairs, or secretions.
- Transmission of infectious microorganisms during feeding is of the greatest concern.
- Sequelae of bites, stings, or contact may include:
  - Local redness with itch, pain, and swelling: common, usually immediate and transient
  - Large local reactions increasing over 24 to 48 hours
  - Systemic reactions with anaphylaxis, neurotoxicity, organ damage, or other systemic toxin effects
  - Tissue necrosis or secondary infection
  - Infectious disease transmission: Presentation may be delayed weeks to years.

EPIDEMIOLOGY

Incidence

- ~40 deaths per year in the United States from fatal anaphylactic reaction to insects but likely underreported
- Unrecognized anaphylactic reactions to Hymenoptera stings may be cause of 1/4 of sudden and unexpected deaths outdoors.

Prevalence

Widespread, with regional and seasonal variations

ETIOLOGY AND PATHOPHYSIOLOGY

- Arthropods: four medically important classes
  - Insects: Hymenoptera (bees, wasps, hornets, fire ants), mosquitoes, bed
bugs, flies, lice, fleas, beetles, caterpillars, and moths
- Arachnids: spiders, scorpions, mites, and ticks
- Chilopods (centipedes)
- Diplopods (millipedes)
- Four general categories of pathophysiologic effects: toxic, allergic, infectious, and traumatic
  - Toxic effects of venom: local (tissue inflammation or destruction) versus systemic (neurotoxic or organ damage)
  - Allergic: Antigens in saliva may cause local inflammation. Exaggerated immune responses may result in anaphylaxis or serum sickness.
  - Trauma: Mechanical injury from biting or stinging causes pain, swelling, and portal of entry for bacteria and secondary infection. Retention of arthropod parts can cause a granulomatous reaction.
  - Infection: Arthropods transmit bacterial, viral, and protozoal diseases.

Genetics
Family history of atopy may be a factor in the development of more severe allergic reactions.

RISK FACTORS
- Previous sensitization
- Although most arthropod contact is inadvertent, some activities, occupations, and travel increase risk.
- Greater risk for adverse outcome in young, elderly, immunocompromised, and those with unstable cardiac or respiratory disease
- Increased risk of anaphylaxis in patients with mastocytosis (1)

GENERAL PREVENTION
- Avoid common arthropod habitats.
- Insect repellents (not effective for bees, spiders, scorpions, caterpillars, bed bugs, fleas, ants)
  - N,N-diethyl-meta-toluamide (DEET)
    - Most effective broad-spectrum repellent against biting arthropods (2)
    - Formulations with higher concentrations (20–50%) are first-line choice in areas of endemic arthropod-borne diseases (2).
    - Concentrations >30% have longer duration of action.
    - Safe for children >6 months of age and pregnant and lactating women (2)
  - Icaridin (formerly known as picaridin)
- Concentrations <20% require more frequent applications to maintain activity.
  - P-menthane-3,8-diol (PMD-lemon eucalyptus extract)
    - Recommended alternative repellent to DEET at concentrations >20% (2)
    - May be used in children >6 months of age (2)
  - IR3535: less effective in most studies
  - Other botanical oils (citronella, etc.): less effective than DEET; not for disease-endemic areas
- Barrier methods: clothing, bed nets
  - Use of light-colored pants, long-sleeved shirts, and hats may reduce arthropod impact.
  - Permethrin: synthetic insecticide derived from chrysanthemum plant. Do not apply directly to skin. Permethrin-impregnated clothing provides good protection against arthropods.
  - Mosquito nets: Insecticide-treated nets are advised for all travelers to disease-endemic areas at risk from biting arthropods (2).
- Desensitization 75–95% effective for Hymenoptera-specific venom
  - Skin tests to determine sensitivity
  - Refer to allergist/immunologist.
- Fire ant control (but not elimination) possible
  - Baits; sprays, dusts, aerosols; biologic agents
- Risk of tick-borne diseases decreased by prompt removal of ticks within 24 hours of attachment.

**DIAGNOSIS**

**HISTORY**
- Sudden onset of pain or itching with visualization of arthropod
- Many cases unknown to patient or asymptomatic initially (bed bugs, lice, scabies, ticks). Consider in patients presenting with localized erythema, urticaria, wheals, papules, pruritus, or bullae.
- May identify insect by its habitat or by remnants brought by patient
- History of prior exposure useful but not always available or reliable
- Travel, occupational, social, and recreational history

**PHYSICAL EXAM**
- If stinger is still present in skin, remove by flicking or scraping away from
skin.

- Anaphylaxis is a clinical diagnosis. Signs and symptoms include (1,3):
  - Erythema, urticaria, angioedema
  - Itching/edema of lips, tongue, uvula; drooling
  - Persistent vomiting
  - Respiratory distress, wheeze, repetitive cough, stridor, dysphonia
  - Hypotension, dysrhythmia, syncope, chest pain

- If anaphylaxis not present, exam focuses on the sting or bite itself. Common findings include local erythema, swelling, wheals, urticaria, papules, or bullae; excoriations from scratching

- Thorough exam to look for arthropod infestation (lice, scabies) or attached ticks. Body lice usually found in seams of clothing; skin scraping to identify scabies

- Signs of secondary bacterial infection after 24 to 48 hours: increasing erythema, pain, fever, lymphangitis, or abscess

- Delayed manifestations of insect-borne diseases

**DIFFERENTIAL DIAGNOSIS**

- Urticaria and localized dermatologic reactions:
  - Contact dermatitis, drug eruption, mastocytosis, bullous diseases, dermatitis herpetiformis, tinea, eczema, vasculitis, pityriasis, erythema multiforme, viral exanthem, cellulitis, abscess, impetigo, folliculitis, erysipelas, necrotizing fasciitis

- Anaphylactic-type reactions
  - Cardiac, hemorrhagic, or septic shock; acute respiratory failure, asthma; angioedema, urticarial vasculitis; flushing syndromes (catecholamines, vasoactive peptides); panic attacks, syncope
  - Differential diagnosis of the acute abdomen should include black widow spider bite.

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

Seldom needed; basic lab parameters usually normal. Some findings may help confirm diagnosis of anaphylaxis:

- Plasma histamine levels elevated briefly after mast cell activation. Consider 24-hour urinary histamine.

| Consider baseline serum tryptase level to rule out mastocytosis in patients with suspected anaphylactic reaction to stings (1)[A]. |

mebooksfree.com
Follow-Up Tests & Special Considerations

- Severe envenomations may affect organ function and require monitoring of lab values (CBC, comprehensive metabolic panel, prothrombin time/international normalized ratio).
- Potential arthropod-borne diseases:
  - Ticks: Lyme disease, Rocky Mountain spotted fever, relapsing fever, anaplasmosis, babesiosis, tularemia; ehrlichiosis
  - Flies: tularemia, leishmaniasis, African trypanosomiasis, bartonellosis, loiasis
  - Fleas: plague, tularemia, murine typhus
  - Chigger mites: scrub typhus
  - Body lice: epidemic typhus, relapsing fever
  - Kissing bugs: Chagas disease
  - Mosquitoes: malaria, yellow fever, dengue fever, West Nile virus, equine encephalitis, chikungunya, Zika virus
- With history of anaphylaxis, significant systemic symptoms, progressively severe reactions, refer to allergist for formal testing (1,3).

Diagnostic Procedures/Other

Skin and immunologic tests available to identify specific allergens

TREATMENT

**ALERT**

- Rapid anaphylaxis is severe and potentially life-threatening. Most deaths due to anaphylaxis occur within 30 to 60 minutes of sting.
- Give Epinephrine as soon as diagnosis of anaphylaxis is suspected. Delay is associated with increasing rates of fatality (1,3).
- Antihistamines and steroids do not replace epinephrine and are never initial therapy in anaphylaxis. No direct outcome data regarding their effectiveness in anaphylaxis available (1,3).
- Airway management critical if angioedema

GENERAL MEASURES

Local wound care, ice compress, elevation, analgesics
MEDICATION

First Line

- For arthropod bites/stings with anaphylaxis
  - There are no randomized controlled trials on treatments, so the following recommendations are based on expert opinion consensus (3)[C].
  - Epinephrine: **most important:** IM injection in midanterolateral thigh (vastus lateralis muscle):
    - IM injection: epinephrine 1:1,000 (1 mg/mL): adult: 0.3 to 0.5 mg per dose; pediatric: Give 0.01 mg/kg to a maximum dose of 0.3 mg per dose, can repeat every 5 to 15 minutes to total of three injections (1,3).
  - Place patient in supine position.
  - Oxygen 6 to 8 L/min up to 100%, as needed
  - IV fluids: Establish 1 to 2 large-bore IV lines. Normal saline rapid bolus 1 to 2 L IV; repeat as needed (pediatrics 20 to 30 mL/kg).
  - H<sub>1</sub> antihistamines: diphenhydramine 25 to 50 mg IV (pediatrics 1 to 2 mg/kg)
  - β<sub>2</sub> agonists: albuterol for bronchospasm nebulized 2.5 to 5.0 mg in 3 mL
  - Emergency treatment of refractory cases: Consider epinephrine infusion, dopamine, glucagon, vasopressin (1,3).

- Arthropod bites/stings **without anaphylaxis**
  - Tetanus booster, as indicated
  - Oral antihistamines
    - Diphenhydramine
    - Cetirizine
    - H<sub>2</sub> blockers: ranitidine
  - Oral steroids: Consider short course for severe pruritus; prednisone or prednisolone 1 to 2 mg/kg once daily.
  - Topical intermediate-potency steroid cream or ointment × 3 to 5 days
    - Desoximetasone 0.05%
    - Triamcinolone 0.1%
    - Fluocinolone 0.025%
  - Wound care: antibiotics only if infection
  - Other specific therapies:
    - Scorpion stings: Treat excess catecholamine release (nitroprusside, prazosin, β-blockers). Atropine for hypersalivation (4). Only one FDA-approved scorpion antivenom in United States. Use only in consultation with toxicologist. Black widow bites: Treat muscle spasms with
benzodiazepines and opioid analgesics (4,5). Antivenom: available but should be administered in conjunction with toxicologist.

- Consult poison control for questions regarding management of envenomation. Poison Control hotline: 1-800-222-1222.
  - Fire ants: characteristically cause sterile pustules Leave intact: Do not open or drain.
  - Brown recluse spider: pain control, supportive treatment; surgical consult if débridement needed
  - Ticks: early removal
  - Pediculosis: head, pubic, and body lice
    - First line: permethrin 1% (Nix) topical lotion. Apply to affected area; wash off in 10 minutes.
    - Alternatives: pyrethrin or malathion 0.5% lotion, ivermectin (not FDA approved for pediculosis) PO
    - Repeat above treatment in 7 to 10 days.
    - For eyelash infestation: Apply ophthalmic-grade petroleum jelly BID for 10 days.
  - Sarcoptes scabiei scabies
    - Permethrin 5% cream: Apply to entire body. Wash off after 8 to 14 hours. Repeat in 1 week.
    - Ivermectin: 200 µg/kg PO once; repeat in 2 weeks (not FDA approved for this use).
    - Crotamiton 10% cream or lotion less efficacious; apply daily for 2 days after bathing.

**Second Line**
Second-line options for anaphylaxis:
- Ranitidine
- Methylprednisolone 1 mg/kg for 3 to 4 days or hydrocortisone 200 mg (3)

**ISSUES FOR REFERRAL**
Patients with history of anaphylaxis, severe systemic symptoms, or progressively severe reactions benefit from consultation with allergy/immunology.

**SURGERY/OTHER PROCEDURES**
Débridement and delayed skin grafting may be needed for severe brown recluse spider and other bites.
COMPLEMENTARY & ALTERNATIVE MEDICINE
A paste of 3 tsp of baking soda and 1 tsp water used to help salve bites.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Anaphylaxis, vascular instability, neuromuscular events, pain, GI symptoms, renal damage/failure

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Immunotherapy as recommended by allergist
- Venom immunotherapy cornerstone of treatment for Hymenoptera; 80–98% effective (1)
- Provide epinephrine for patient self-administration if history of anaphylaxis. Consider “med-alert” identifiers (1,3).

Patient Monitoring
- Monitor for delayed effects, including infectious diseases from arthropod stings and bites.
- Serum sickness reactions, vasculitis (rare)

PATIENT EDUCATION
Arthropod avoidance and preventive measures

PROGNOSIS
- Excellent for local reactions
- For systemic reactions, best response with early intervention to prevent cardiorespiratory collapse

COMPLICATIONS
- Scarring
- Secondary bacterial infection
- Arthropod-associated diseases as mentioned earlier
- Psychological effects, phobias
REFERENCES

ADDITIONAL READING

CODES

ICD10

- T63.481A Toxic effect of venom of arthropod, accidental, init
- T63.301A Toxic effect of unsp spider venom, accidental, init
- T63.484A Toxic effect of venom of oth arthropod, undetermined, init

**CLINICAL PEARLS**

- Urgent administration of epinephrine is the key to successful treatment of anaphylaxis.
- Local treatment and symptom management are sufficient in most insect bites and stings.
ASCITES

Daniel J. Stein, MD, MPH • Stephen K. Lane, MD, FAAFP

BASICS

DESCRIPTION
- Accumulation of fluid in the peritoneal cavity; may occur in conditions that cause generalized edema
- Men generally have no fluid in peritoneal cavity; women may have up to 20 mL depending on menstrual phase.

EPIDEMIOLOGY
- Children: nephrotic syndrome and malignancy most common
- Adults: cirrhosis (81%), cancer (10%), heart failure (3%), other (6%)

Incidence
~50–60% of patients with cirrhosis develop ascites within 10 years (1).

Prevalence
10% of patients with cirrhosis have ascites.

ETIOLOGY AND PATHOPHYSIOLOGY
- Portal hypertensive versus nonportal hypertensive causes
  - Cannot reliably establish/confirm etiology without paracentesis
  - Serum-ascites albumin gradient (SAAG): (serum albumin level: ascites albumin level) helps to differentiate causes
- High portal pressure (SAAG ≥1.1)
  - Cirrhosis
  - Hepatitis (alcoholic, viral, autoimmune, medications)
  - Acute liver failure
  - Liver malignancy (primary or metastatic)
  - Elevated right-sided filling pressures from heart failure or constrictive pericarditis
  - Hepatic venous thrombosis (Budd-Chiari syndrome)
  - Portal vein thrombosis
Normal portal pressure (SAAG <1.1)
- Peritoneal carcinomatosis
- Tuberculosis
- Severe hypoalbuminemia (nephrotic syndrome; severe enteropathy with protein loss)
- Meigs syndrome (ovarian cancer)
- Lymphatic leak (chylous ascites)
- Pancreatitis
- Inflammatory (vasculitis, lupus serositis, sarcoidosis)
- Other infections (parasitic, fungal)
- Hemoperitoneum (trauma or ectopic pregnancy)

Pathophysiology is best described for portal hypertensive (typically cirrhotic) ascites.
- Reduced renal and carotid perfusion activates systemic vasoconstrictors and antinatriuretic mechanisms. This stimulates the sympathetic nervous system and renin-angiotensin-aldosterone system to retain sodium and water.
- Most ascites is due to portal hypertension, with preferentially dilated splanchnic vasculature causing systemic hypotension.

**DIAGNOSIS**

**HISTORY**
- Address risk factors (e.g., EtOH use, TB exposure, prior malignancies, sexual partners, transfusion history, metabolic syndrome, increased risk of nonalcoholic steatohepatitis progressing to cirrhosis).
- Progressive abdominal distention may be painful.
- Weight gain, dyspnea/orthopnea, edema, early satiety, nausea
- Patients with spontaneous bacterial peritonitis (SBP) may present with fever, abdominal tenderness, and altered mentation.
- Individuals with underlying malignancy may present with weight loss.

**PHYSICAL EXAM**
- Abdominal distention with flank/shifting dullness is the most sensitive (83%) and specific (56%) exam finding; requires >1,500 mL of fluid to detect
- Edema (penile/scrotal, pedal), pleural effusion, rales
- Stigmata of cirrhosis (palmar erythema, spider angiomata, dilated abdominal wall collateral veins)
Other signs of advanced liver disease: jaundice, muscle wasting, gynecomastia, leukonychia
- Signs of underlying malignancy: cachexia; umbilical (Virchow) node suggests upper abdominal malignancy.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Diagnostic paracentesis for fluid analysis to determine etiology and rule out infection in all patients with ascites requiring hospital admission and in any new-onset or new-to-treatment patients (1)[C]
  - Paracentesis complication rate is 1% (despite high rates of coexisting coagulation abnormalities).
  - Routine attempts to correct platelet or coagulation defects are not needed prior to paracentesis (1)[B].
- Ascitic fluid analysis (1)[C]:
  - Cell count and differential:
    - Polymorphonuclear (PMN) leukocytes ≥250 cells/mm$^3$ suggest infection.
    - Albumin to calculate SAAG:
      - <1.1 g indicates a low portal pressure exudative process (i.e., inflammatory, biliary/pancreatic, carcinomatosis, TB).
      - ≥1.1 g indicates portal hypertensive/transudative process (cirrhosis, CHF, constrictive pericarditis, thrombosis).
    - Total protein (low in cirrhosis, nephrotic disease and high in cardiac ascites)
  - Other tests (based on clinical scenario) (1)[C]:
    - Bacterial gram stain/culture if infection suspected (Cirrhotic patients with ascites can fail to mount fever or leukocytosis.)
      - Fluid cultures are traditionally positive in 50–90% of cases of SBP.
      - Yield is improved if inoculated to blood culture bottles at bedside and if fluid is obtained before 1st dose of antibiotics.
    - Amylase (suspicion for bowel perforation, choledocholithiasis, or pancreatitis)
    - Triglyceride if fluid appears milky
    - Cytology if concern for malignancy (less sensitive in the absence of carcinomatosis)
    - Lactate dehydrogenase (LDH): An ascitic fluid–to–serum LDH ratio >1.0 can indicate infection, perforation, or tumor.
Carcinoembryonic antigen and alkaline phosphatase (elevated in viscous perforation)
- Mycobacterial culture/PCR for suspicion of TB
- BUN/creatinine, electrolytes (renal function)
  - Brain natriuretic peptide (heart failure)
  - Liver function tests and hepatitis serologies (hepatitis)
- Abdominal ultrasound (US) can confirm ascites; highly sensitive, cost-effective, involves no radiation
- Portal US Doppler can detect thrombosis or cirrhosis.
- CT scan for intra-abdominal pathology (malignancy)
- MRI preferred for evaluation of liver disease or confirmation of portal vein thrombosis

**Diagnostic Procedures/Other**
Laparoscopy: if imaging and paracentesis are nondiagnostic
- Allows for direct visualization and biopsy of peritoneum, liver, and intra-abdominal lymph nodes
- Preferred for evaluating suspected peritoneal tuberculosis or malignancies

**Test Interpretation**
Cytology may reveal malignant cells: adenocarcinoma (ovary, breast, GI tract) or primary peritoneal carcinoma (most commonly associated with ascites).

**TREATMENT**
For all patients:
- Daily weight
- Restrict dietary sodium to ≤2 g/day if the cause is due to portal hypertension (high SAAG) (1)[A].
- Water restriction (1 to 1.5 L/day) only necessary if serum sodium <120 to 125 mEq/L (1)[C]
- If creatinine >2.0 mg/dL, decrease diuretic doses.
- Avoid alcohol and ensure adequate nutrition if liver disease (1)[A].
- Baclofen may be used to reduce alcohol craving/consumption (1)[C] in EtOH cirrhosis.

**MEDICATION**
**Alert**
- Careful diuresis; aggressive diuresis can induce prerenal acute kidney injury, encephalopathy, and hyponatremia. Monitor creatinine and electrolytes closely. Serum creatinine >2 mg/dL or serum sodium <120 mmol/L warrants withdrawal of diuretics.
- Avoid NSAIDs to avoid exacerbation of oliguria/azotemia.
- ACE inhibitors and angiotensin receptor blockers (ARBs) may be harmful in patients with cirrhosis/ascites due to an increased risk of hypotension and renal failure ([1][C]). Avoid in refractory ascites ([1][B]).
- Consider discontinuing β-blockers in patients with refractory ascites, worsening hypotension, or azotemia ([1][B]).

**First Line**
- Sodium restriction and diuretics are the mainstay of treatment for patients with elevated portal pressures ([1][A]); other causes (e.g., carcinomatosis) are less likely to respond to medical therapy.
  - Spironolactone 100 to 400 mg daily PO; typical initial dose is 100 to 200 mg given in AM.
    - Diuretic of choice due to antialdosterone effects; can be used as single agent in minimal ascites. Monitor for hyperkalemia ([1][B]).
  - Furosemide 40 to 160 mg daily PO; typical initial dose is 40 mg given in AM.
    - Antinatriuretic effect helps achieve negative sodium balance.
    - Preferred in combination with spironolactone rather than as monotherapy ([1][B])
  - Most common (and preferred) regimen is spironolactone and furosemide together (maintaining a 100:40 ratio) for maximum efficacy and to maintain potassium homeostasis ([1][C]).
    - Titrate dose to desired result and monitor renal function regularly.
    - Follow daily weight.
    - Adjust ratio to maintain normal potassium.
- Diuretic-intractable ascites (10% of patients): persistent or worsening ascites despite maximum doses of spironolactone (400 mg/day) and furosemide (160 mg/day) and sodium restriction or progressive rise in creatinine to 2.0
  - Ensure compliance with dietary sodium restriction using 24-hour urine sodium excretion: In general, if <78 mEq/day, patient is compliant with 2-g dietary sodium restriction.
  - Therapeutic paracentesis or serial large-volume paracentesis (LVP) (see...
“Surgery/Other Procedures”
– Consider a trial of IV diuresis if seemingly diuretic resistant and consider alternative agents that are better absorbed (e.g., bumetanide) (1)[C].

**Second Line**
- Midodrine 7.5 mg TID can be added to diuretic-resistant or hypotensive patients and may improve survival (1)[B]. Titrate to blood pressure response.
- Alternatives to spironolactone: amiloride up to 40 mg/day; triamterene up to 200 mg/day in divided doses (1)[C]
- Alternatives to furosemide: torsemide up to 100 mg/day; bumetanide up to 4 mg/day (1)[C]
- Vaptans may have a beneficial effect on hyponatremia and ascites, but routine use in ascites is not yet supported (2)[A].

**ISSUES FOR REFERRAL**
Consider referral for liver transplant in patients with decompensated liver disease, whether or not ascites is present/controlled. Liver transplant is the definitive treatment for portal hypertension (1)[B].

**SURGERY/OTHER PROCEDURES**
- Therapeutic paracentesis
  - Initial therapy if tense ascites is present (1)[C]
  - Serial (generally every 2 weeks) paracenteses can be used as second line after diuretics in patients with elevated portal pressures.
  - Complications: infection, hemodynamic collapse, acute renal failure
  - Similar complication rate as diuretics
  - Replace albumin when removing >5 L of ascites: 5.5 to 8 g albumin for each liter removed. Albumin replacement decreases renal dysfunction, postparacentesis hyponatremia, and overall morbidity (3)[A]; likely not needed for malignant ascites
  - Continue diuretics at 1/2 previous dose if transitioning to serial paracentesis in patients who fail diuretics alone.
- Transjugular intrahepatic portosystemic shunt (TIPS)
  - Used only in patients with elevated portal pressures
  - Fluoroscopically placed conduit from portal to hepatic vein for intractable ascites (4)[A]
    - At time of placement, portal pressure should drop ≥20 mm Hg (or to <12 mm Hg), and ascites should be controllable with diuretics.
Yearly US to confirm shunt function
- 4 weeks after TIPS, urinary sodium and serum creatinine improve significantly and can normalize after 6 to 12 months in combination with diuretics (4). Shunt dilation and/or replacement may be required after 2 years.
- Encephalopathy is a primary complication.
- TIPS is superior to paracentesis for controlling ascites; no difference in mortality (4)[A]

- Peritoneovenous shunt (LeVeen or Denver shunt): drains ascites directly into the inferior vena cava
  - Clinical trials show poor long-term shunt patency, no survival advantage over medical therapy.
  - Complications include bacteremia, bowel obstruction, and variceal bleed.
  - Usually reserved for patients with refractory ascites who are not candidates for TIPS or liver transplant and who are unable to tolerate repeated paracentesis (1)[C]
- Indwelling catheters with external drainage
  - Most useful in malignant ascites as a palliative measure (can be drained at home)
  - Overall low rate of infection
- Percutaneous endoscopic gastrostomy (PEG) tube placement should be avoided in patients with ascites due to an associated high mortality rate following this procedure (1)[B].

COMPLEMENTARY & ALTERNATIVE MEDICINE
Caution about use of herbal and dietary supplements (drug interactions, hepatotoxicity, coagulopathy)

ONGOING CARE

PROGNOSIS
- Prognosis varies depending on underlying cause.
- Ascites in itself is rarely life-threatening but can signify life-threatening underlying disease (e.g., cancer, end-stage liver disease).

COMPLICATIONS
**SBP**
- Ascitic fluid PMN leukocyte count ≥250 cells/mm³ or positive culture
  - Broad-spectrum antibiotics are as follows: cefotaxime 2 g q8h or similar 3rd-generation cephalosporin is the treatment of choice for suspected SBP; covers 95% of flora (including *Escherichia coli*, *Klebsiella*, pneumococci) (1)[A]; broader coverage often required for hospital-acquired infections
  - Lifetime antibiotic prophylaxis with norfloxacin or trimethoprim-sulfamethoxazole (TMP-SMX) is indicated in some patients who survive an episode of SBP (1)[A]; reduced incidence of SBP, delayed development of hepatorenal syndrome, and improved survival in cirrhosis (5)[C]. Ciprofloxacin is often used due to lack of availability of norfloxacin.
  - Suspect primary bacterial peritonitis (PBP) due to bowel perforations when ascitic fluid. >250 cells/mm³ (often >5,000 cells/mm³) and any two of the following:
    - Ascitic fluid total protein >1 g/dL (often >3 g/dL)
    - Ascitic fluid glucose <50 mg/dL (or 2.8 mmol/L)
    - Ascitic fluid LDH that is 3-fold greater than serum LDH

**Hepatorenal syndrome:** acute worsening of renal function after excluding other causes of acute renal failure and at least 2 days of diuretic withdrawal and maximal intravascular volume expansion with albumin (see “Hepatorenal Syndrome”)

**Cellulitis** is common in obese patients with brawny edema. Treat with diuretics and antibiotics (1)[B].

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

- Cirrhosis of the Liver; Hepatorenal Syndrome
- Algorithms: Congestive Heart Failure: Differential Diagnosis; Nephrotic Syndrome

**CODES**

**ICD10**

- R18.8 Other ascites
- R18.0 Malignant ascites
- K70.31 Alcoholic cirrhosis of liver with ascites

**CLINICAL PEARLS**

- Cirrhosis is the most common cause of ascites.
- Patients with new-onset ascites or hospitalized patients with ascites should undergo diagnostic paracentesis.
- Avoid ACE inhibitors, ARBs, and β-blockers in patients with ascites.
- Most common cause of “diuretic-intractable ascites” is noncompliance with dietary sodium restriction.
- Diuretics are first-line agents in the treatment of ascites. Serial paracentesis or TIPS are second line.
- Ensure early referral of cirrhosis patients who are candidates for liver transplant.
A heterogeneous disease characterized as chronic inflammation of the airway; patients present with history of wheeze, shortness of breath (SOB), chest tightness, and cough which varies in time and intensity along with variable expiratory flow (1).

- Common triggers: exercise, allergen-irritant exposure, change in weather, laughter, or viral respiratory infections
- Patient may experience symptoms-free periods alternating with sporadic flare-up (exacerbations).
- Most common asthma phenotypes (1):
  - Allergic asthma: present since childhood and has strong family history
  - Non-allergic asthma
  - Late onset asthma: particularly in females
  - Asthma with fixed airflow limitation: due to airway remodeling
  - Asthma with obesity
- Four major classifications of asthma severity used primarily to initiate therapy (2,3):
  - Intermittent: symptoms ≤2 days/week, nighttime awakenings ≤2 times per month, short-acting β-agonist (SABA) use ≤2 days/week, no interference with normal activity, and normal forced expiratory volume in 1 second (FEV₁) between exacerbations with FEV₁ (predicted) >80% and FEV₁/FVC >80%
  - Mild persistent: symptoms >2 days/week but not daily, nighttime awakenings 3 to 4 times per month, SABA use >2 days/week but not daily, minor limitations in normal activity, and FEV₁ (predicted) >80% and FEV₁/FVC >80%
  - Moderate persistent: daily symptoms, nighttime awakenings ≥1 times per week but not nightly, daily use of SABA, some limitation in normal activity, and FEV₁ (predicted) 60–80% and FEV₁/FVC 75–80%
– Severe persistent: symptoms throughout the day, nighttime awakenings often 7 times per week, SABA use several times a day, extremely limited normal activity, and FEV₁ (predicted) <60% and FEV₁/FVC <75%

**EPIDEMIOLOGY**

**Prevalence**
Asthma affects 300 million individuals worldwide.

- 345,000 deaths every year
- Asthma affects 11.1% of children aged 13 to 14 years (2000 to 2003) in United States.
- Asthma prevalence is greater in boys than girls; however, in adult, women are more affected.
- Obesity is associated with increased prevalence and incidence of asthma, especially in woman with abdominal obesity.

**ETIOLOGY AND PATHOPHYSIOLOGY**
Airway hyperreaction begins with inflammatory cell infiltration and degranulation, subbasement fibrosis, mucus hypersecretion, epithelial injury, significant smooth muscle hypertrophy and hyperreactivity, angiogenesis that then leads to intermittent airflow obstruction due to reversible bronchospasm (3).

**Genetics**
- Genetic association with increased interleukin production and airway hyperresponsiveness leading to asthma; genome-wide association studies (GWAS) show genetic predisposition leading to increased production of IgE, which increased chances of developing the disease.
- Variation in genetic coding has also shown the different level of response to treatment, which is a key factor for controlling the disease and to decrease the rate or exacerbation.

**RISK FACTORS**
- Host factors: genetic predisposition, gender, race, BMI/obesity
- Environmental: viral infections, animal and airborne allergens, tobacco exposure
- Exercise, obesity, and emotional stress
- Aspirin or NSAIDs hypersensitivity or β-blockers
- Food allergies and asthma increased risk for fatal anaphylaxis from those
foods (1,2)

COMMONLY ASSOCIATED CONDITIONS
- Atopy: eczema, allergic conjunctivitis, allergic rhinitis
- Obesity (associated with higher asthma rates)
- Sinusitis
- Gastroesophageal reflux disease (GERD)
- Obstructive sleep apnea (OSA)
- Stress/depression/anxiety

DIAGNOSIS

HISTORY
History of variable respiratory symptoms with patterns characteristic of asthma symptoms and timing of initiation during childhood:
- More than one symptom such as wheeze, SOB, cough, chest tightness
- Symptoms worse at night, vary in time and intensity, worse with common triggers

PHYSICAL EXAM
- May be normal
- Focus on
  - General appearance: signs of respiratory distress such as use of accessory muscles
  - Upper respiratory tract: rhinitis, nasal polyps, swollen nasal turbinates
  - Lower respiratory tract: wheezing, prolonged expiratory phase. Note:
    Wheezing may be absent in severe exacerbation.
  - Skin: eczema

DIFFERENTIAL DIAGNOSIS
- In children
  - Upper airway diseases (allergic rhinitis or sinusitis)
  - Large airway obstruction (foreign body aspiration, vocal cord dysfunction, vascular ring or laryngeal web, laryngotracheomalacia, lymph nodes, or tumor)
  - Small airway obstruction (viral bronchiolitis, cystic fibrosis, bronchopulmonary dysplasia, heart disease, primary ciliary dyskinesia,
bronchiectasis)
- Other causes (recurrent cough not due to asthma, chronic upper airway cough syndrome, aspiration/GERD)

- In adults
  - Chronic obstructive pulmonary disease, bronchiectasis heart failure, pulmonary embolism, benign or malignant tumor, pulmonary infiltration with eosinophilia, Churg-Strauss syndrome, medication induced cough (ACE inhibitors), vocal cord dysfunction

### DIAGNOSTIC TESTS & INTERPRETATION

#### Initial Tests (lab, imaging)
- Blood tests are not required but may find eosinophilia or elevated serum IgE levels (allergic asthma).
- Documented variable expiratory airflow limitation (1):
  - Spirometry: Normal test does not rule out asthma; it measures the FVC and the FEV₁; a reduced predicted ratio of FEV₁/FVC with reversibility (increase of 200 mL and 12% of FEV₁/FVC from baseline) after using a short-acting bronchodilator (SABA), 10 to 15 minutes
  - Excessive variability in twice-daily; peak expiratory flow (PEF) in 2 weeks (daily diurnal PEF variability >10%)
  - Bronchial challenge test: used mainly in adults, positive when there is a fall in FEV₁ >20% with methacholine or histamine; or >15% with hypertonic saline or mannitol challenge
  - Exercise challenge test: fall in FEV₁ >10% and 200 mL from baseline
  - Significant increase in lung function after 4 weeks of anti-inflammatory treatment
- Chest x-ray is used to exclude alternative diagnoses and to evaluate patients for complicating cardiopulmonary processes.
- Pregnancy considerations: Do not use bronchial provocation test nor step down controller treatment until after delivery.
- Elderly considerations: commonly under diagnosed due to comorbidities; echocardiogram and measurement of plasma brain natriuretic peptide may also be helpful along with detailed history.

#### Follow-Up Tests & Special Considerations
- Asthma action plan: Patients monitor their own symptoms and/or peak flow measurements. Reassess action plan every 3 to 6 months.
Assess asthma symptoms control with simple screening tools like consensus-based GINA symptoms control tool or Primary Care Asthma Control Screening Tool (PACS).

**Diagnostic Procedures/Other**
- Allergy skin testing is not useful for diagnosis of asthma but may be to evaluate atopic triggers.
- Measurement of fractional concentration of exhaled nitric oxide (FENO), widely available although not useful for ruling in or ruling out diagnosis of asthma. FENO suggests eosinophilic airway inflammation which can be elevated in other conditions than asthma such as eosinophilic bronchitis.

### TREATMENT

**GENERAL MEASURES**
- Focus always on symptoms control.
- Use of holding chambers (“spacers”) improves with inhaled agents improves clinical outcomes.
- Written asthma self-management action plan (1)
- Encourage physical activity, weight loss, smoking cessation, avoidance of irritants, emotional stress.
- Avoidance of occupational exposure (1)
- Annual influenza vaccine and pneumococcal vaccination
- Patients at risk for anaphylaxis should carry an EpiPen.
- Medication categories: controllers medications, used for regular maintenance, reduce airway inflammation, control symptoms and reduce risk of exacerbations:
  - Inhale corticosteroids (ICS)
    - Beclometasone dipropionate
    - Budesonide
    - Ciclesonide
    - Fluticasone furoate or propionate
    - Mometasone furoate
    - Triamcinolone acetonide
  - Long-acting β-agonist (LABA)
    - Formoterol
    - Salmeterol
• Reliever (rescue medication) provided to all patients for as-needed relief of breakthrough symptoms
  – SABA—albuterol/levalbuterol

• Add-on therapies for patients with severe asthma, when patients persist with symptoms despite optimized treatment with high-dose controller medications (ICS + LABA)
  – Anticholinergic agent, tiotropium (long-acting muscarinic antagonist [LAMA]) (1)[B] or ipratropium (short-acting muscarinic antagonist [SAMA])
  – Anti-immunoglobulin E (anti-IgE) (omalizumab) treatment (1)[A]
  – Leukotriene receptor antagonist (LTRA) (montelukast, zafirlukast) (1)[B]
  – Chromones (nedocromil sodium + sodium cromoglicate) (1)[A]

• Initial recommended controllers by patient’s presenting symptoms (1):
  – No controller recommended (1) when:
    o Typical symptoms or need for SABA <2 times per month, no waking up from sleep in last month, no risk factor for exacerbations, no exacerbation in the past year
  – Low-dose ICS (1) when:
    o Infrequent asthma symptoms but patient has presence of >1 risk factors for exacerbation
  – Low-dose ICS (1)[B] when:
    o Typical symptoms or need for SABA 2 times per month / week or patient wakes up from sleep
  – Low-dose ICS (1)[A] when:
    o Symptoms recurs or need for SABA >2 times per week; alternative treatment—LTRA or theophylline
  – Medium- to high-dose ICS (1)[A] or low-dose ICS/LABA (1)[A] when:
    o Symptoms recurs most of the day, patient wakes up from sleep >1 a week, presence of risk factors for asthma exacerbation.
  – Short course of oral corticosteroids (OCS) plus regular controller treatment—high-dose ICS or moderate-dose ICS/LABA (budesonide/formoterol; beclomethasone/formoterol) when:
    o Severe uncontrolled asthma or acute exacerbation
  – Stepwise approach for asthma treatment (1):
    o Step 1: as needed reliever inhaler:
      ■ First: inhaled SABA (1)[A]; alternatives: second: low-dose ICS (1)[B]; third: inhaled SAMA or oral SABA or short-acting theophylline
    o Step 2: low-dose controller + as needed reliever:
First: low-dose ICS + SABA; alternative for controllers: second: LTRA; third: low-dose ICS/LABA; third sustained-release theophylline (1)[B] or cromones (1)[A]

- Step 3: one or two controller + as needed reliever:
  - First: low-dose ICS/LABA + SABA or ICS/formoterol as both controller + reliever; alternatives: second: moderate-dose ICS + SABA; third: moderate-dose ICS or low-dose ICS + LTRA versus low-dose sustained-release theophylline
- Step 4: two or more controllers + as needed reliever:
  - First: low-dose ICS/formoterol + reliever or moderate-dose ICS/LABA + as needed SABA; alternative: second: LAMA, sustained-release theophylline or LTRA as add-on therapy
- Step 5: higher level of care and add-on therapy such as LAMA, anti-IgE, anti–interleukin-5, sputum-guided therapy, low-dose OCS

**ISSUES FOR REFERRAL**
- Suspected occupational asthma
- Specialized testing (e.g., bronchoprovocation)
- Specialized treatments (e.g., immunotherapy, anti-IgE therapy)
- Poorly controlled asthma or frequent exacerbation or multiple ED visits

**Pregnancy Considerations**
- Asthma symptoms tends to worsen in 1/3 of patients, 1/3 improves, and 1/3 remains unchanged (1).
- Exacerbations are common in 2nd trimester.
- Poorly controlled asthma results in low birth weight, increased prematurity, and perinatal mortality.
- All short-acting agents (SABA) are pregnancy Category C as well as ICS.
- ICS prevents asthma exacerbation during pregnancy.
- Cessation of ICS during pregnancy is a significant risk factor for exacerbation.
- Montelukast and zafirlukast are Category B but are not studied extensively in pregnancy.

**Special Considerations**
- Exercise-induced bronchoconstriction (EIB):
  - Pharmacotherapy have shown to reduce symptoms, SABA prior exercise or LTRA/chromones.
- Athletes:
– Limit exertion in extreme cold or pollution.

- Occupational asthma if suspected, refer for consultation due to legal implications (1)[A].

**Geriatric Considerations**
Management challenges due to comorbidities (like arthritis) and due to polypharmacy

**ADDITIONAL THERAPIES**

- Allergen immunotherapy when clear relationship between symptoms and exposure to an unavoidable allergen
  - There are two types of immunotherapy: subcutaneous and sublingual.
- Bronchial thermoplasty involves treatment of the airway.
- Vitamin D supplementation in mild to moderate asthma resulted in decreased exacerbations needing steroid use, ED visits, and asthma admissions (3)[A].
- Management of acute exacerbation of asthma
  - Outpatient:
    - Mild: speak in full sentence, HR<120, oxygen saturation 90–95% and peak flow >50% of predicted can be managed as outpatient in clinic; should start SABA and prednisolone; if symptoms resolve within 1 hour, could be discharge home with close follow-up
    - Severe symptoms: not able to speak in full sentence, HR>120, oxygen sat <90%, peak flow <50% predicted, drowsy, confused or silent chest; transfer to inpatient facility.
  - Treatment for severe:
    - Oxygen: to maintain saturation 93–95%
    - SABA: within 1 hour of arrival, initially around the clock followed by on demand
    - Systemic steroids: Oral is as effective as IV. 50 mg prednisolone (morning dose) or 200 mg hydrocortisone divided in doses. Duration should be 5 to 7 days.
    - Epinephrine: only when asthma is associated with angioedema or anaphylaxis
    - Avoid sedative.
    - Careful respiratory monitoring including vital signs, pulse oximetry, response and duration of response to SABA, and when possible, an objective measure of lung function such as PEF or FEV$_1$
    - Asthma education
– Discharge criteria
  o Minimal or absent asthma symptoms
  o Hypoxia has resolved.
  o FEV₁ or PEF ≥70% predicted or personal best
  o Bronchodilator response sustained ≥60 minutes

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Identify triggers and control exposures.
- Consider stepping down treatment once symptoms are controlled for 3 months and patient is at low risk for exacerbation.

**PATIENT EDUCATION**

- American Academy of Allergy, Asthma & Immunology: 800-822-2762 or [http://www.aaaai.org/](http://www.aaaai.org/)
- American Lung Association: [www.lungusa.org](http://www.lungusa.org)
- Asthma and Allergy Foundation of America: 800-727-8462 or [http://www.aafa.org/](http://www.aafa.org/)

**PROGNOSIS**

Prognosis is good for male patients, nonsmokers, and children with mild disease.

**COMPLICATIONS**

- Atelectasis
- Pneumonia
- Air leak syndromes: pneumomediastinum, pneumothorax
- Medication-specific side effects/adverse effects/interactions
- Respiratory failure
- Death: ~50% of asthma deaths occur in the elderly (age >65 years), and mortality is increasing in that population.

**REFERENCES**

**CODES**

**ICD10**
- J45.909 Unspecified asthma, uncomplicated
- J45.901 Unspecified asthma with (acute) exacerbation
- J45.20 Mild intermittent asthma, uncomplicated

**CLINICAL PEARLS**
- SABA is the most effective rescue therapy for acute asthma symptoms.
- Holding chambers should be used by all.
- ICSs are the preferred long-term control therapy for patients of all ages.
ATELECTASIS

Jennifer Duke, MD • Adrian DaSilva-DeAbreu, MD • Raymundo A. Quintana, MD

BASICS

DESCRIPTION

- Incomplete expansion of lung tissue with resultant loss of lung volume and function, leading to impaired airway mucus clearance
- Broadly categorized as:
  - Obstructive: blockage within an airway
  - Nonobstructive: loss of contact between the parietal and visceral pleurae, replacement of lung tissue by scarring or infiltrative disease, surfactant dysfunction, and parenchymal compression
- Symptoms depend on how rapidly the occlusion occurs, the size of the lung area affected, and the presence or absence of lung disease and comorbidities.
- Reduced respiratory gas exchange can lead to hypoxemia and other pulmonary complications.

EPIDEMIOLOGY

- Affects all ages; mean age is 60 years.
- Male = female; no racial predilection

Incidence

- Round atelectasis (see “Initial Tests (lab, imaging)”) is high in asbestos workers (65–70%).
- Incidence of lobar atelectasis depends on the collateral ventilation within each individual lung lobe.

Prevalence

Postoperative atelectasis is extremely common, affecting up to 90% of surgical patients, especially after major cardiac or GI procedures.

ETIOLOGY AND PATHOPHYSIOLOGY

- Obstructive (resorptive) atelectasis is more common and is caused by intrinsic respiratory blockage.
– Due to luminal blockage (foreign body, mucus plug, asthma, cystic fibrosis, trauma, tumor) or airway wall abnormality (congenital malformation, emphysema)
– Distal to the obstruction, air is reabsorbed from the alveoli into the deoxygenated venous system, causing complete collapse of the alveolar tissue.
– There are three collateral ventilation systems in each lobe: the pores of Kohn, canals of Lambert, and fenestrations of Boren. The patency and formation of the systems depends on multiple factors including age, lung disease, and FiO₂.
– Emphysema: The fenestra of Boren in emphysematous patients often becomes enlarged; this enlargement can lead to a delay in atelectasis despite an obstructing lesion or mass.
– FiO₂: Oxygen rapidly dissociates from alveoli to deoxygenated vessels in an obstructed airway. The 79% nitrogen in atmospheric air has a slower rate of dissociation from the alveoli and thereby prevents collapse by maintaining positive pressure inside the alveoli. With increased FiO₂, the concentration of nitrogen is decreased predisposing patients to rapid development of atelectasis at the onset of obstruction.

- Nonobstructive atelectasis
  – Passive atelectasis: results from pleural membrane separation of the visceral and parietal layers
    o Pleural effusion, pneumothorax
  – Compression atelectasis: alveoli compression leading to diminished resting volume (functional residual capacity [FRC]):
    o Space-occupying lesions, lymphadenopathy, cardiomegaly, abscess, chest wall pressure
  – Adhesive atelectasis: surfactant dysfunction resulting in increased surface tension and alveoli collapse
    o Respiratory distress syndrome, acute respiratory distress syndrome (ARDS), radiation exposure, smoke inhalation, uremia
  – Cicatization: pleural or parenchymal scarring
    o Granulomatous disease, toxic inhalation, drug-induced fibrosis (e.g., amiodarone, cyclophosphamide), radiation exposure
  – Replacement atelectasis: diffuse tumor manifestation resulting in complete lobar collapse
    o Bronchioalveolar cell carcinoma
- Rounded atelectasis: distinct form of atelectasis following asbestos exposure
Others
– Hypoxemia due to pulmonary embolus
– Muscular weakness (anesthesia, neuromuscular disease)

**Pediatric Considerations**
The younger the child, the less developed the collateral ventilation, hence, the higher the risk of developing atelectasis.

**RISK FACTORS**
- General anesthesia: positive fluid balance, ≥4 units blood transfusion, use of nasogastric tube, long-acting muscle relaxants, hypothermia, postoperative epidural anesthesia, ventilator settings with high tidal volume (Vt) and plateau pressure
- Surgical procedures: cardiothoracic, upper GI, neurosurgery, oromaxillofacial, ENT, vascular
  – Often a precursor to more serious pulmonary complications postoperatively
- Patient risk factors for developing postoperative atelectasis:
  – Age >60 and <6 years, chronic obstructive pulmonary disease (COPD), obstructive sleep apnea, CHF, alcohol abuse, pulmonary hypertension, albumin <3.5 g/dL, hemoglobin <10 g/dL, BMI >27 kg/m² (weak evidence), ASA class II+ functional dependence in activities of daily living (ADLs), heart failure, smoking
- Intensive care and prolonged immobilization
- Right middle lobe syndrome (Brock syndrome): wedge-shaped density that extends inferiorly and anteriorly from the hilum of the lung. Best seen on lateral chest radiography; no consistent clinical definition

**GENERAL PREVENTION**
- Early mobilization, deep breathing exercises, coughing, and frequent changes in body position
- Preoperative physical therapy lowered rates of atelectasis, PNA, and LOS in elective cardiac surgery without improving other postoperative pulmonary complications or mortality (2)[A]. Further large RCTs are needed before conclusions can be made regarding the effect of chest physiotherapy and incentive spirometry.
- Mechanical ventilation settings with high Vt (Vt >10 mL/kg), high plateau pressures (>30 cm H₂O), and without positive end-expiratory pressure (PEEP)
are associated with postoperative pulmonary complications such as pneumonia and respiratory failure:
– Ventilator-induced lung injury can be minimized by using low Vt and plateau pressures at sufficient PEEP while maintaining lower FiO$_2$ during anesthetic induction and intraoperatively.
• Application of continuous positive airway pressure (CPAP) during anesthesia induction and reversal of anesthesia-induced atelectasis after intubation by a recruitment maneuver may decrease postoperative pulmonary complications (3)[C].

COMMONLY ASSOCIATED CONDITIONS
• COPD and asthma
• Trauma
• ARDS, neonatal respiratory distress syndrome, pulmonary edema, pulmonary embolism
• Neuromuscular disorders (muscular dystrophy, spinal muscular atrophy, spinal cord injury), cystic fibrosis
• Respiratory syncytial virus (RSV), bronchiolitis
• Bronchial stenosis, pulmonic valve disease, pulmonary hypertension
• Pneumonia, pleural effusion, pneumothorax

DIAGNOSIS

HISTORY
• Frequently asymptomatic
• Tachypnea and sudden-onset dyspnea
• Nonproductive cough
• Pleuritic pain on affected side
• History of smoking, COPD, pulmonary insufficiency, exposure to radiation, asbestos, or other air pollutants

PHYSICAL EXAM
• Signs of hypoxia or cyanosis
• Tracheal or precordial impulse displacement toward the affected side; dullness to percussion
• Bronchial breathing if airway is patent
• Wheezing or absent breath sounds if airway is occluded
Diminished chest expansion

**DIFFERENTIAL DIAGNOSIS**
See “Etiology and Pathophysiology.”

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- CBC and sputum culture if infection suspected
- ABG: Despite hypoxemia, the PaCO$_2$ level is usually normal or low.
- Chest x-ray (CXR), PA, and lateral
  - Raised diaphragm, flattened chest wall, movement of fissures and mediastinal structures toward the atelectatic region
  - Unaffected lung may show compensatory hyperinflation.
  - Wedge-shaped densities: obstructive atelectasis
  - Small, linear bands (Fleischner lines) often at lung bases: discoid (subsegmental or plate) atelectasis
  - Lobar collapse
  - Direct signs: displacement of fissures and opacification of the collapsed lobe. Right upper lobe collapse may display the inverted S sign of Golden, suggesting neoplastic shift of the minor fissure.
    - Indirect signs: displacement of the hilum, mediastinal shift toward the side of collapse, loss of volume of ipsilateral hemithorax, elevation of ipsilateral diaphragm, crowding of the ribs, compensatory hyperlucency of remaining lobes, and silhouetting of the diaphragm or heart border
  - Air bronchograms: Evidence of pleural fluid or air may indicate compressive atelectasis.
  - Adhesive atelectasis may present as a diffuse reticular granular pattern, progressing to a pulmonary edema pattern, and finally to bilateral opacification in severe cases.
  - Pleural-based round density on CXR: round atelectasis
  - Complete atelectasis of entire lung: opacification of the entire hemithorax and an ipsilateral shift of the mediastinum

*Follow-Up Tests & Special Considerations*
- Chest CT or MRI may be indicated to visualize airway and mediastinal structures and identify cause of atelectasis.
- Pulmonary function tests (PFTs) may detect restrictive disease, decreased respiratory muscle pressures, or airflow obstruction.
Low serum albumin (<3.5 g/L) is a powerful marker of increased risk for postoperative pulmonary complications, including atelectasis.

**Diagnostic Procedures/Other**
Bronchoscopy can be considered in unexplained or refractory cases.

---

**TREATMENT**

**GENERAL MEASURES**
- Prevention following surgery or general anesthesia using PEEP (3)[C]
- Treat the underlying cause.
- Ensure patient is lying on the unaffected side to promote drainage:
  - Maximize mobility and encourage frequent coughing and deep breathing.
- Incentive spirometry every hour while awake
  - Lack of evidence for incentive spirometry preventing postoperative pulmonary complications after coronary artery bypass grafting (CABG) (4)[A]
- Initiate intubation and mechanical ventilation with PEEP in severe respiratory distress or hypoxemia:
  - Lower Vt (6 mL/kg) and lower plateau pressures (<30 mm Hg) are associated with reduced mortality.
  - PEEP 15 to 20 mL may be necessary to maintain arterial O₂ saturation in surfactant-impaired states.
- Postsurgical measures include positive airway pressure, continuous or intermittent.

**MEDICATION**

**First Line**
Pharmacotherapy should be tailored to address underlying cause:
- Antibiotics for infection
- Chemo/radiation therapy for tumor
- Steroids for asthma
- Effective analgesia to permit deep inspiration and coughing
- Mucolytics can be considered to promote airway clearance (NAC and saline most commonly studied).
**Pediatric Considerations**

- Dornase alfa may be effective clearing mucinous secretions in refractory mucous plugging in children.
- Chest physiotherapy (i.e., percussion, drainage, deep insufflation, and saline lavage) is a common treatment modality in the hospital setting.
- Application of continuous distending pressure has some benefit in the treatment of preterm infants with respiratory distress syndrome and has the potential to reduce lung damage particularly if applied early (5)[A].
- In obstructive atelectasis, bronchoscopy remains controversial. In the presence of a mucus plug or cast, bronchoscopy may be beneficial.

**Second Line**

Bronchofibroscopy in aspiration of inspissated secretions to improve airway clearance has been efficacious in several studies. However, debate continues regarding its efficacy in the treatment of atelectasis.

**SURGERY/OTHER PROCEDURES**

- Appropriate surgical resection for underlying disease (e.g., tumor, severe lymphadenopathy)
- Bronchoscopy

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Ensure adequate oxygenation (may start with 100% FiO₂ then taper) and humidification.

**ALERT**

It is likely that the association between postoperative atelectasis and fever is coincidental rather than causal.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Depends on underlying cause and comorbidities
In uncomplicated cases of atelectasis associated with asthma or infection, outpatient monitoring is appropriate.

PATIENT EDUCATION
Maximize patient mobility and encourage frequent coughing and deep breathing.

PROGNOSIS
- For postoperative atelectasis, spontaneous resolution usually occurs within 24 hours but can persist for days after surgery.
- The prognosis of lobar atelectasis secondary to endobronchial obstruction depends on treatment of the underlying disease or malignancy.
- Surgical therapy is needed only for resectable causes or if chronic infection and bronchiectasis supervene.

COMPLICATIONS
- Pneumonia and pulmonary infections
- Acute atelectasis
  - Hypoxemia and respiratory failure
  - Postobstructive drowning of the lung
- Chronic atelectasis
  - Bronchiectasis
  - Pleural effusion and empyema

ADDITIONAL READING

CODES

ICD10

J98.11 Atelectasis

CLINICAL PEARLS
- No strong clinical evidence supports atelectasis as an early cause of postoperative fever.
- Anesthesia-induced atelectasis occurs in almost all anesthetized patients.
- Bronchogenic carcinoma, which may present with atelectasis, must be excluded in all patients >35 years.
- In complete atelectasis of an entire lung, the mediastinal ipsilateral shift separates atelectasis from massive pleural effusion.
- Low serum albumin is a powerful predictor of postoperative pulmonary complications, including atelectasis.
ATRIAL FIBRILLATION AND ATRIAL FLUTTER

Youhua Zhang, MD, PhD • Bianca Lee, DO, MS

BASICS

This topic covers both atrial fibrillation (AFib) and atrial flutter (AFlut).

DESCRIPTION

- **AFib:** Paroxysmal or continuous supraventricular tachyarrhythmia characterized by rapid, uncoordinated atrial electrical activity and an irregularly irregular ventricular response. In most patients, the ventricular rate is rapid because the atrioventricular (AV) node is bombarded with very frequent atrial electrical impulses (400 to 600 bpm).

- **AFlut:** Paroxysmal or continuous supraventricular tachyarrhythmia with rapid but organized atrial electrical activity. The atrial rate is typically between 250 and 350 bpm and is often manifested as “saw-tooth” flutter (F) waves on the ECG, particularly in the inferior leads and V1. AFlut commonly occurs with 2:1 or 3:1 AV block, so the ventricular response may be regular and typically at a rate of 150 bpm.

- AFib and AFlut are related arrhythmias, sometimes seen in the same patient. Distinguishing the two is important, as there may be implications for management.

- **Clinical classifications:**
  - Paroxysmal: self-terminating episodes, usually <7 days
  - Persistent: sustained >7 days, usually requiring pharmacologic or DC cardioversion to restore sinus rhythm
  - Permanent: Sinus rhythm cannot be restored or maintained. It is a shared decision between patient and clinician as to when to cease further attempts to restore and/or maintain sinus rhythm.
  - Nonvalvular AFib: absence of rheumatic mitral stenosis, a mechanical or bioprosthetic heart valve or mitral valve repair

- Lone AFib occurs in patients <60 years (with possible genetic predisposition) who have no clinical or echocardiographic evidence of cardiovascular disease, including hypertension (HTN).
EPIDEMIOLOGY

- Incidence/prevalence increases significantly with age.
- Young patients with AFib, particularly lone AFib, are most commonly males.

Incidence

- AFib: from <0.1%/year <40 years to >1.5%/year >80 years
- Lifetime risk: 25% for those ≥40 years
- AFib is less common.

Prevalence

- Estimated at 0.4–1% in general population, with 2.7 million patients in America
- Increase with age, up to 8% in those ≥80 years

ETIOLOGY AND PATHOPHYSIOLOGY

- Cardiac: HTN, ischemic heart disease, heart failure, valvular heart disease, cardiomyopathy, pericarditis, and infiltrative heart disease
- Pulmonary: pulmonary embolism (PE), chronic obstructive pulmonary disease (COPD), obstructive sleep apnea, pneumonia
- Ingestion: ethanol, caffeine
- Endocrine: hyperthyroidism, diabetes
- Obesity
- Postoperative: cardiac, pulmonary, or esophageal
- Idiopathic: lone AFib

Patients with paroxysmal episodes are usually associated with premature atrial beats and/or bursts of tachycardia, originating in pulmonary vein ostia or other sites.

Many patients with AFib are thought to have some degree of atrial fibrosis or scarring. This is often subclinical and usually not detectable with current cardiac imaging techniques but plays an important role in the pathogenesis of the arrhythmia.

- Autonomic (vagal and sympathetic) tone may play a role in triggering the arrhythmia.
- The presence of AFib is associated with electrical and structural remodeling processes that promote arrhythmia maintenance in the atria, termed “AFib begets AFib.”

Genetics
Familial forms are rare but do exist. There are ongoing efforts to identify the genetic underpinnings of such cases.

**RISK FACTORS**
Age, HTN, and obesity are the most important risk factors for both AFib and AFlut.

**GENERAL PREVENTION**
Adequate control of HTN may prevent development of AFib due to hypertensive heart disease and is the most significant modifiable risk factor for AFib. Weight reduction may decrease the risk of AFib in obese patients. Ethanol consumption may trigger AFib in some.

**COMMONLY ASSOCIATED CONDITIONS**
HTN and other cardiac diseases

---

**DIAGNOSIS**

**HISTORY**
Symptoms vary from none to mild (palpitations, light-headedness, fatigue, poor exercise capacity) to severe (angina, dyspnea, syncope).

**PHYSICAL EXAM**
- AFib: irregularly irregular heart rate and pulse, frequently tachycardiac, pulse deficit
- AFlut: similar to AFib but may have regular pulse

**DIFFERENTIAL DIAGNOSIS**
- Multifocal atrial tachycardia
- Sinus tachycardia with frequent atrial premature beats
- Paroxysmal supraventricular tachycardia (Wolff-Parkinson-White [WPW], atrioventricular nodal reentry tachycardia [AVNRT])

**DIAGNOSTIC TESTS & INTERPRETATION**
- AFib: The ECG is diagnostic, with findings of low-amplitude fibrillatory waves without discrete P waves and an irregularly irregular pattern of QRS complexes. There is often tachycardia in the absence of heart rate–controlling
medications (1).

- AFlut: The ECG is diagnostic. Saw-tooth F waves are the classic sign, generally best seen in the inferior leads, although ventricular rate may need to be slowed to see the waves. QRS complexes may be regular or irregular; there is usually tachycardia (1).

- Ambulatory rhythm monitoring (e.g., telemetry, Holter monitoring, event recorders) is helpful in diagnosing paroxysmal AFib or AFlut and monitoring for recurrence (1).[C].

**Initial Tests (lab, imaging)**

TSH, electrolytes, CBC, 2D transthoracic echocardiogram, PT/INR (if anticoagulation is contemplated); digoxin level (if appropriate)

**Follow-Up Tests & Special Considerations**

- Occasional Holter monitoring and/or exercise stress testing to assess for adequacy of rate and/or rhythm control
- Chest x-ray (CXR) for cardiopulmonary disease
- ECG for signs of cardiac hypertrophy, ischemia, and/or other arrhythmias
- Transesophageal echocardiogram to detect left atrial appendage thrombus if cardioversion is planned
- Sleep study may be useful if sleep apnea is suspected.

**Test Interpretation**

Evaluate for presence of atrial dilatation and fibrosis, atrial thrombus (especially in atrial appendage), valvular/rheumatic disease, cardiomyopathy.

**TREATMENT**

**MEDICATION**

- Two primary issues in the management of AFib and/or AFlut: decisions on heart rate control (control ventricular rate while allowing AFib to continue) or rhythm control (terminate AFib and restore normal sinus rhythm) and decision to anticoagulate or not
- Anticoagulation therapy to prevent thromboembolism (primarily stroke) reduces risk of stroke by about 2/3. Several calculators exist for estimating yearly risk of thromboembolic event (ATRIA, CHADS2, CHA2DS2VASc). If risk is sufficiently low, or risk of bleeding is high, no anticoagulation may be
indicated. Clinical judgment and patient preference remain important.
• AHA/ACC anticoagulation guidelines (the same for AFib and AFib) (1,2)[C]:
  - CHA2DS2-VASc scoring (CHF [1 point], HTN [1 point], Age ≥75 years [2 points], DM [1 point], prior Stroke or TIA [2 points], Vascular disease [1 point], Age 65 to 74 years [1 point], female Sex category [1 point]). CHA2DS2-VASc is the recommended stroke risk assessment for patients with nonvalvar AFib (1)[B].
    o In patients with nonvalvar AFib and a CHA2DS2-VASc score of 0, antithrombotic therapy may be omitted (1)[B].
    o In patients with nonvalvar AFib and a CHA2DS2-VASc score of 1, no antithrombotic therapy or oral anticoagulant or aspirin is recommended (1)[C].
  - Unless contraindicated, patients with nonvalvar AFib with any high-risk factors for stroke (prior transient ischemic attack [TIA]/cerebrovascular accident [CVA]/thromboembolism) or a CHA2DS2-VASc score ≥2 should receive oral anticoagulants. The following oral anticoagulants include warfarin with maintenance of an INR of 2.0 to 3.0 (1)[A], dabigatran (1)[B], rivaroxaban (1)[B], or apixaban (1)[B]. Patients with mechanical valves should maintain an INR of 2.0 to 3.0 or 2.5 to 3.5 dependent on the type and location of the prosthesis (1)[B]. For patients with AFib and mitral stenosis, a target INR range of 2.0 to 3.0 is recommended (2)[B].
  - Dabigatran (Pradaxa), a direct thrombin inhibitor, and apixaban (Eliquis) and rivaroxaban (Xarelto), factor Xa inhibitors, can be alternatives to warfarin for the prevention of first and recurrent stroke in patients with nonvalvar AFib (3)[C]. The selection of an antithrombotic should be individualized (1)[B]; consider the risks of each agent, cost, patient preference, and tolerability (1)[C].
    o ALERT: Renal function should be evaluated prior to initiation of direct thrombin or factor Xa inhibitors (1)[B]. Dosing of such agents may in fact need individualized adjustment.
    o Idarucizumab (Praxbind) is the first reversal agent approved specifically for Pradaxa demonstrated in the RE-VERSE AD study.
  - Anticoagulation recommendations are independent of AFib pattern (paroxysmal, persistent, and permanent) (1,2)[B] although ongoing efforts to better understand who may be at greater and lesser risk of thromboembolism continue. Four classes of medications are available to achieve ventricular rate control: β-blockers (i.e., metoprolol), nondihydropyridine calcium channel blockers (i.e., verapamil, diltiazem),
digoxin, and amiodarone. Optimal target for ventricular rate has not been firmly established, but there is evidence that aggressive control of the ventricular rate (<80 bpm) offers no benefit beyond more modest rate control (i.e., resting heart rate <110 bpm) (1)[B].

- Preventing rapid ventricular response (RVR) rates using AV nodal blocking medications is also often effective at controlling a patient’s symptoms associated with AFib or AFLut. Patients in whom rate control cannot be achieved or who continue to have persistent symptoms despite reasonable heart rate control may require attempts at restoration of sinus rhythm.
- Ventricular rate control can often be difficult to achieve in AFLut due to the more organized nature of the atrial electrical activity. For this reason, conversion to sinus rhythm is often the preferred strategy, and catheter ablation is also considered as a first-line treatment in recurrent AFLut (1).
- Restoration of sinus rhythm using electrical or pharmacologic cardioversion may significantly reduce the symptom burden of AFib or AFLut in many patients and may also be useful for controlling ventricular rate. Cardioversion does not impact the long-term risk/benefit ratio of anticoagulation:
  - Cardioversion is most often performed electrically, but may also be achieved using antiarrhythmic drug therapy in some instances, by experienced clinicians (1)[A].
  - If duration of AFib is >48 hours or unknown, anticoagulate for ≥3 weeks before cardioversion to reduce the risk of stroke. Alternatively, once anticoagulation is established, a transesophageal echo may be performed to exclude the presence of left atrial thrombus, allowing cardioversion to proceed. After cardioversion, anticoagulation should be continued for ≥4 weeks in all patients in whom duration of AFib/AFLut is >48 hours, as the postcardioversion period is a time of increased stroke risk (1,2)[B].
- Randomized clinical trials (AFFIRM and RACE) comparing the outcomes of rate versus rhythm control found no difference in morbidity, mortality, and stroke rates in patients assigned to one therapy or the other (1).
- Chronic PO antiarrhythmic therapy to suppress AFib recurrence is available for appropriately selected patients. Expert consultation is recommended owing to the complexities of safe antiarrhythmic drug selection.

**ISSUES FOR REFERRAL**

Management of AFib or AFLut refractory to standard medical therapy (i.e., unable to achieve adequate rate control with medication or development of significant bradycardia with treatment) may require the use of more aggressive treatments. These may include pacemaker implantation (to allow for more
intensive pharmacologic blocking of the AV node) or an ablation procedure. AFib in particular is often very amenable to ablation; thus, consideration should be given to early expert referral in appropriate patients. Antiarrhythmic drug therapy can often be very effective but should be prescribed by experienced practitioners.

SURGERY/OTHER PROCEDURES

- Electrophysiologic study and ablation may be considered for patients with either AFib or AFLut. In the case of AFLut, ablation is a procedure generally viewed as a first-line therapy due to its high rate of success in appropriate candidates. Ablation of AFib is a much more complex procedure with a more variable success rate. Thus, it is typically reserved for drug refractory patients.
- Cardiac surgery (e.g., the maze procedure, ligation of the left atrial appendage) may be considered in patients planning to undergo cardiac surgery for other reasons.
- A recent FDA-approved left atrial appendage closure device WATCHMAN may be useful in those at increased risk of stroke and systemic embolism that seek a nonpharmacologic approach to anticoagulation (4).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Patients with significant symptoms, RVR, AFib/AFLut triggered by an acute process (e.g., MI, CHF, PE), or in whom antiarrhythmic therapy is being started likely require admission to the hospital for a period of stabilization.
- Outpatient management is reasonable for low-risk patients with controlled ventricular rates.
- Acute therapy for symptomatic patients with AFib or AFLut:
  - IV β- or nondihydropyridine calcium channel blockers for control of ventricular rate in patients without preexcitation (1)[B]

- Commonly used therapies in the acute setting include (1):
  - Metoprolol tartrate: 2.5 to 5.0 mg IV bolus over 2 minutes; up to 3 doses
  - Diltiazem: 0.25 mg/kg IV bolus over 2 minutes, then 5 to 15 mg/hr
  - Some patients will be far more responsive to one class of agents than another. For this reason, if rate control is difficult to achieve, switching drug classes may be useful.

- Urgent cardioversion should be performed in hemodynamically unstable patients (1)[B]. It is somewhat unusual for AFib or AFLut alone to cause marked hemodynamic insult; thus, the possibility of a concurrent process
should be considered in this setting.

- Consider the initiation of PO anticoagulation therapy. Inpatients may be “bridged” with IV or SC heparin or SQ low-molecular-weight heparin (LMWH) while waiting for warfarin to become effective (1)[C].

ONGOING CARE

Many patients may benefit from elective expert consultation. In patients with no significant symptoms, if ventricular rate control or sinus rhythm is easily achieved and the choice of thromboembolic prevention is clear, management in a primary care setting may be appropriate.

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Adequate anticoagulation levels (if warfarin is employed) should be determined at least weekly during initiation and monthly when stable (1)[A]. Ventricular rate control should be assessed on a regular basis.

DIET

Patients on warfarin should attempt to consume a stable amount of vitamin K.

PROGNOSIS

Yearly risk of stroke in untreated nonvalvular AFib has declined and now lies between 4% and 5% per year.

- Anticoagulation reduces the annual embolic stroke rate by about 2/3 for most patients. AFib and AFlut may increase morbidity and mortality, but the overall prognosis is a function of underlying heart disease and adherence with therapy. Reported risk of anticoagulation varies but lies between 1% and 4% per year for major hemorrhage.

COMPLICATIONS

- Embolic stroke
- Peripheral arterial embolization
- Bleeding with anticoagulation
- Tachycardia-induced cardiomyopathy with prolonged periods of inadequate rate control
REFERENCES

CODES

ICD10

- I48.91 Unspecified atrial fibrillation
- I48.92 Unspecified atrial flutter
- I48.0 Paroxysmal atrial fibrillation

CLINICAL PEARLS

- Primary decision in persistent AFib is rate control or rhythm control. Younger patients often do better with a rhythm control strategy, whereas older patients often do well with rate control. Decision is complex.
- Whether to anticoagulate or not is based on risk of thromboembolism
regardless of AFib pattern.
ATRIAL SEPTAL DEFECT

Edlira Yzeiraj, DO, MS • Edward A. Gotfried, DO, FACOS

BASICS

DESCRIPTION

- Anatomy
  - Opening in the atrial septum allowing flow of blood between the two atria
  - Patent foramen ovale is also an open communication between the atria, but it is not considered an ASD because no septal tissue is missing.
- Types (by location in the interatrial septum) (1)
  - Classified based on their different anatomic location and abnormal embryogenesis: secundum ASD, primum ASD, sinus venosus ASD, coronary sinus ASD
  - 70%: Ostium secundum defect occurs in the fossa ovalis region.
  - 15–20%: Ostium primum defect occurs in the inferior septum; often associated with cleft mitral valve and failure of endocardial cushion development
  - 5–10%: Sinus venosus defect occurs in the superior-posterior septum near the orifice of the superior vena cava; usually associated with partial anomalous right upper pulmonary venous return
  - Less than 1%: coronary sinus defect: Part of the entire common wall between the coronary sinus and the LA is absent.
- Hemodynamic effects
  - Left-to-right shunting in late ventricular systole and early diastole
  - Degree depends on size of the defect and relative pressures of the two ventricles.
  - Causes excessive blood flow through the right-sided circulation, ultimately leading to reactive pulmonary hypertension and heart failure
- Systems affected: cardiovascular; pulmonary

Pediatric Considerations

- Most cases of ASD are detected and corrected in the pediatric population.
- The smaller the defect and the younger the child, the greater the chance of spontaneous closure.
EPIDEMIOLOGY

Incidence
- Predominant age: present from birth, may be diagnosed at any age
- Slight female predominance (2)
- No race predilection
- 2/1,000 live births

Prevalence
ASDs account for 13% of congenital heart disorders.

ETIOLOGY AND PATHOPHYSIOLOGY
- Flow across ASD usually left-to-right shunt because of higher left-sided pressures:
  - Minimal right-to-left shunting in early ventricular systole, especially during inspiration
  - Increased right-sided pressure/pulmonary hypertension can cause reversal of shunt flow (Eisenmenger syndrome) with resulting cyanosis and clubbing.
- Symptoms typically occur due to right ventricular and pulmonary vascular volume overload and right-sided heart failure.

Genetics
- Most cases are spontaneous.
- 5% with chromosomal abnormalities; other rare mutations exist.
- 25% prevalence in Down syndrome

RISK FACTORS
- Other congenital heart defects
- Family history (~7–10% recurrence)
- Thalidomide, alcohol exposure in utero, smoking, maternal age >35 years, and elevated blood glucose have been associated with increased risk (2).

COMMONLY ASSOCIATED CONDITIONS
- ASDs may occur as a component of other complex cardiac structural defects.
- Important to exclude anomalous pulmonary venous return
- Occasionally can indicate underlying genetic syndromes, for example, Holt-Oram (ASD present in 66%), Ellis-van Creveld, VACTERL syndrome, or
Noonan syndrome.
- Overall, ~70% isolated (1)

## DIAGNOSIS

### HISTORY
- Most ASDs are small and do not cause symptoms in infancy and childhood and are often found on routine physical examination when a cardiac murmur is detected incidentally.
- Infants with large ASDs may present with right-sided heart failure (more advanced, only 10% at diagnosis), recurrent respiratory infections, or failure to thrive.
- Should be considered in children with other congenital heart defects, Down syndrome
- In uncorrected defects, most people become symptomatic by age 40 years. Common symptoms in adults include atrial arrhythmias (the most frequent presenting symptom), exercise intolerance, dyspnea, and fatigue.

### PHYSICAL EXAM
- Signs vary according to extent of shunting.
- Cardiac auscultation
  - Fixed, widely split $S_2$ (key physical finding)
  - May also have
    - Systolic ejection murmur (pulmonic flow murmur)
    - Low-pitched diastolic rumble (tricuspid flow murmur)
    - Diastolic murmur (pulmonic regurgitation)
    - Systolic murmur (mitral regurgitation)
- Right ventricular heave
- Palpable pulmonary artery pulse at left upper sternal border
- If heart failure has developed, may hear a fourth heart sound (right-sided)
- Signs of Eisenmenger syndrome:
  - Cyanosis and clubbing
  - Jugular venous distention and edema

### DIFFERENTIAL DIAGNOSIS
- Other congenital heart disease
- Right bundle branch block (for widely split $S_2$)
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Echocardiography is the test of choice (1)[C].
- Generally start with transthoracic Doppler imaging of the entire atrial septum (sensitivity is ~89% for secundum, ~100% for primum, and ~44% of sinus venosus ASDs), with progression to transesophageal echocardiography (TEE) if transthoracic echocardiography (TTE) is nondiagnostic.
- Patients with right ventricular overload by TTE but an otherwise negative study should have further testing.
- Oximetry: Cyanosis may suggest Eisenmenger syndrome (right-to-left shunting).
- ECG is not typically diagnostic, but findings may include the following:
  - Right axis deviation
  - Right atrial enlargement (tall P in inferior leads)
  - Right ventricular conduction delay
  - Q wave in lead V₁
  - Right bundle branch block
  - Leftward axis, inverted P wave in lead III (sinus venosus)
  - Leftward axis (ostium primum)

Follow-Up Tests & Special Considerations
- Bubble contrast enhancement may be helpful.
- TEE may be required to define ASD morphology and to locate the pulmonary veins; often used prior to percutaneous closure. TEE has excellent sensitivity and specificity.

Diagnostic Procedures/Other
- Cardiac catheterization (1)[C]
  - Demonstrates right ventricle enlargement, location/fraction of the shunt, size of the ASD, any valvular disease, and overall anatomy
  - Used to assess pulmonary vascular resistance if pulmonary hypertension is suspected, particularly if surgery is planned
  - Generally not used in young patients for initial diagnosis, more often reserved for use when
    - Part of a planned interventional closure
    - Evaluating other disease simultaneously (e.g., coronary artery disease)
    - Visualization by other methods insufficient
• Cardiac magnetic resonance: a noninvasive follow-up to echo that allows viewing the defect/pulmonary veins and measurement of shunt fraction and right ventricular function—particularly useful for sinus venous defects (2)
• Exercise testing: useful to quantify symptoms not consistent with clinical findings or to document change over time (1)[C]
• Chest x-ray: may demonstrate right ventricular and pulmonary artery enlargement, increased pulmonary vascular markings
• Cardiac CT scans can also define ASDs but with significant radiation exposure.

![TREATMENT](image)

**GENERAL MEASURES**

• 75% of small secundum ASDs (<8 mm) will close spontaneously by 18 months of age; however, close follow-up is warranted (2).
• The likelihood of spontaneous closure is mainly determined by defect diameter: >10 mm at time of diagnosis is unlikely to spontaneously close (3).
• Primum and sinus venousus defects do not generally close and generally require surgical closure (2).

**MEDICATION**

**First Line**

• Treatment of secondary atrial fibrillation/supraventricular tachycardia with anticoagulation and cardioversion, followed by anticoagulation with maintenance of sinus rhythm if possible, or rate control if this fails (1)[A]
• Pulmonary vasodilator therapy may be considered for adults with progressive/severe pulmonary vascular disease (1)[B].
• Treatment of heart failure (diuretics, oxygen, digoxin, etc.)

**Second Line**

• Antibiotic prophylaxis is NOT recommended for unrepaired/isolated ASDs.
• The American Heart Association (AHA) recommends antibiotic prophylaxis against infective endocarditis during dental procedures for 6 months after the repair in patients whom a device or prosthetic material is used.
  – In patients with repaired ASD who have a residual defect at or adjacent to the device, prophylaxis is recommended indefinitely.
  – If prophylaxis is indicated, for dental procedures, amoxicillin 2 g (adults) or
50 mg/kg (children). Other options include cephalosporins (e.g., ceftriaxone 1 g [adults] or 50 mg/kg [children] IM or IV) or clindamycin 600 mg PO (adults) or 20 mg/kg PO (children) or azithromycin 500 mg PO (adults) or 15 mg/kg (children) in patients who are penicillin-sensitive (4)[B].

- To prevent thrombus formation after device deployment, aspirin alone or a combination of aspirin and clopidogrel 75 mg for at least 6 months is recommended (5).

SURGERY/OTHER PROCEDURES

- The majority of small secundum defects, <6 mm, close spontaneously by 2 years of age, and some as late as 5 years. Closure is generally indicated in children with:
  - Defect >8 mm (unlikely to close) in children >2 years of age (to allow time for spontaneous closure, even though uncommon)
  - Defects of any size in a child >5 years with related symptoms
- Closure for secundum defects is not recommended in asymptomatic patients before 2 years of age given the possibility of spontaneous closure.
- In adults, secundum closure via percutaneous transcatheater device or surgery to reduce subsequent morbidity and mortality, if:
  - Right side heart enlargement regardless of symptoms (1)[B]
  - Pulmonary systemic flow ratio is 2:1 (or >1.5:1 and <21 years old according to the AHA).
  - Symptoms such as documented orthodeoxia/platypnea or paradoxical embolism (1)[C]
- Surgical repair is standard for a sinus venosus, coronary sinus, or primum ASD (1,2)[B]. These defects rarely close spontaneously and are not considered amenable to percutaneous closure.
- Percutaneous closure is considered the treatment of choice of secundum ASD in adults (6)[A]. It is safe and effective with satisfactory long-term clinical follow-up. In addition, the use of closure device does not significantly affect aortic or mitral valve function (6)[B].
- Secundum ASDs that are suitable for percutaneous closure should be ~35 mm in stretched balloon diameter and should have a sufficient rim of surrounding atrial tissue.
- Closure is not indicated for patients who have developed irreversible severe pulmonary hypertension without continued shunting or those who never develop symptoms and have an ASD <5 mm (1)[B].
- Overall, closing small asymptomatic secundum ASDs is controversial and not
often done.
- Maze procedure may be considered before or after closure for patients with intermittent or chronic atrial tachyarrhythmias (1)[C].

**FOLLOW-UP RECOMMENDATIONS**
Echocardiography can be used to monitor both repaired and unrepaired ASDs.

**Patient Monitoring**
- In otherwise asymptomatic healthy children, follow up until defect has closed or become negligible in size.
- Appropriate evaluation and management for atrial tachyarrhythmias in patients with long-term follow-up (1)[C]
- If ASD repaired as an adult, periodic long-term follow-up is indicated (1)[C].
- ASDs repaired in childhood generally do not have late complications.
- In female patients with unrepaired ASD and Eisenmenger syndrome, pregnancy is not recommended due to increased risk of maternal and fetal mortality (1)[C].
- Pregnancy is well tolerated in patients with repaired ASD and small unrepaired ASDs (1)[A].
- Scuba diving and high-altitude travel must be approached with caution in patients with unrepaired ASDs; consultation is recommended.

**PATIENT EDUCATION**
For patient education materials on this topic, consult the following:
- American Heart Association: [http://www.heart.org](http://www.heart.org)

**PROGNOSIS**
- ASD closure in asymptomatic or minimally symptomatic adults reduces morbidity but not mortality (7).
- ASD closure before age 25 years in symptomatic adults reduces morbidity and likely also mortality.
- ASD repair deferred until after adolescence may not decrease long-term risk of future atrial arrhythmias.
- Up to 50% mortality by age 50 years in untreated symptomatic patients with large defects
COMPLICATIONS

- Unrepaired: congestive heart failure, stroke, pulmonary hypertension/Eisenmenger syndrome, atrial arrhythmias, increased infection risk (pulmonary, cerebral abscess, infective endocarditis)
- Surgically repaired: late-onset arrhythmias 10 to 20 years after surgery (5%), perioperative atrial tachyarrhythmias in 10–13% of patients
- Device closure: device embolization (1%), cardiac perforation, thrombus formation, endocarditis, supraventricular arrhythmias, and device erosions

REFERENCES

SEE ALSO
Aortic Valvular Stenosis; Coarctation of the Aorta; Patent Ductus Arteriosus; Pulmonary Valve Stenosis; Tetralogy of Fallot; Ventricular Septal Defect

CODES
ICD10
- Q21.1 Atrial septal defect
- Q21.2 Atrioventricular septal defect

CLINICAL PEARLS
- ASD is often missed due to subtle clinical presentation.
- Ideally, hemodynamically significant ASDs should be closed in early childhood, although some benefit from closure is present in older patients.
- Many ASDs can be treated by catheter-directed percutaneous closure rather than open-heart surgery.
- Routine endocarditis prophylaxis is not recommended for unrepaired ASDs.
- Generally, symptomatic and hemodynamically significant ASDs are repaired; management of asymptomatic small ASDs is debated.
- Patent foramen ovales, unlike large ASDs, are very common and generally require no treatment in asymptomatic individuals.
ATTENTION DEFICIT/HYPERACTIVITY DISORDER, ADULT

Amal Shine, MD • Anub G. John, MD • Hugh Peterson, MD, FACP

BASICS

- Adult attention deficit hyperactivity disorder (adult ADHD) is a psychiatric condition resulting in inattention and/or hyperactivity or impulsivity. It is typically associated with a combination of low self-esteem, dysfunctional or unstable social relationships, and impaired academic/job performance.
- Adult ADHD has been shown to affect a significant portion of the adult population; 30–60% of patients diagnosed with ADHD as a child will continue to meet criteria as adults. Some others who no longer meet strict criteria still have significant residual ADHD traits.
- During transition from pediatric to adult care, poor control of high-risk behaviors during a hiatus of ADHD treatment can lead to increased morbidity.

DESCRIPTION

- Symptoms include difficulty concentrating, impulsivity, and hyperactivity/overactivity. Impairment in executive functioning and emotional dysregulation are common features.
- The three main types of ADHD are (i) hyperactivity-impulsivity predominant, (ii) inattentive predominant, and (iii) combined.
- DSM-5 also classifies ADHD into mild, moderate, and severe based on the severity of symptoms (1).

EPIDEMIOLOGY

Prevalence
ADHD affects approximately 4.4–5.2% of adults between 18 and 44 years of age (1).

Genetics
ADHD patients often have first-degree relatives with ADHD. Twin studies based on self-rated symptoms in adult population samples show moderate heritability
estimates of 30–40%. Some genes have been correlated with ADHD, although not necessary or sufficient for diagnosis.

RISK FACTORS
History of childhood and adolescent ADHD diagnosis, particularly symptoms of hyperactivity and/or impulsivity, persisting into adulthood. ADHD is more commonly diagnosed among adult males than females, with an odds ratio of 1.6:1.0 (1); however, some studies have shown that this is due to the less overt symptoms in females.

COMMONLY ASSOCIATED CONDITIONS
- Substance use and substance abuse disorders
- Mood disorders
- Anxiety disorders
- Intellectual disabilities
- Obsessive-compulsive disorder (OCD)
- Tic disorders

DIAGNOSIS
- Diagnosis is made from patient’s history and detailing patient’s current level of functioning in at least two different settings (e.g., work and home).
- It is particularly important to gather history of patient’s childhood and school performance. Several inattentive or hyperactive-impulsive symptoms should be present prior to age 12 years.

HISTORY
- History of childhood ADHD symptoms before age 12 years
- DSM-5 criteria for adults ≥17 years include ≥5 hyperactivity/impulsivity symptoms and/or ≥5 inattentive symptoms. These symptoms must be present for ≥6 months (1).
- Symptoms must result in maladaptive behavior that impairs the patient’s function.
- There must be clear evidence of impaired function due to inattention/hyperactivity in ≥2 settings (e.g., home and work).
- These symptoms must not be related to a psychotic episode or mood disorder and must not be better explained by another DSM diagnosis. However, DSM-5 allows a comorbid diagnosis with autism spectrum disorder.
CAGE and substance abuse questions can help identify substance abuse issues but cannot determine whether substance abuse or ADHD is the primary disorder.

Personal and family history of cardiac disease or sudden death should be documented.

History of exposure to lead or other toxins

History of thyroid disease

History of medication or substances including anticonvulsants, steroids, antihistamines, nicotine, and caffeine that have side effects that impact attentiveness and mimic ADHD symptoms

PHYSICAL EXAM

Physical exam is key to ruling out other medical conditions.

Focus on thyroid and neurologic examinations; look for findings suggestive of substance abuse.

Record BP and baseline weight; monitor if starting medical treatment.

DIFFERENTIAL DIAGNOSIS

Hearing impairment; hyperthyroid/hypothyroid; sleep deprivation; sleep apnea; phenylketonuria; OCD; lead toxicity; substance abuse

DIAGNOSTIC TESTS & INTERPRETATION

Adult ADHD screening tools: Retrospective scales include the Childhood Symptom Scale and the Wender Utah Rating Scale; current symptom scales include the Adult ADHD Rating Scale IV, Adult Self Report Scale Symptom Checklist, and the Connor Adult Rating Scale. These scales can take 5 to 20 minutes to complete.

Provider/patient screening checklist

– https://med.nyu.edu/psych/sites/default/files/psych/psych_adhd_screener_0.pdf

Developments in imaging techniques have revealed structural and functional brain differences between individuals with and without ADHD but there is no evidence for clinical utility. (1)

ECG with concerns for cardiac disease in patient or family history

Record baseline blood pressure, pulse, and BMI.
**Initial Tests (lab, imaging)**
- Thyroid-stimulating hormone (TSH)
- Liver function test monitoring (with atomoxetine)
- Rapid plasma reagin (RPR) or venereal disease research laboratory (VDRL) test
- Serum lead levels (pending history)

**Follow-Up Tests & Special Considerations**
- A history of childhood behaviors is helpful, but adult patients often don’t accurately recall childhood symptomology.
- Seek the patient’s permission to speak with family/friends/prior physicians and to seek school records and results of any psychological assessments.
- Inquire about family history of ADHD, family and personal substance abuse, and tic disorders to facilitate formulation of an accurate diagnosis and recognition of high-risk behaviors.
- Caution against stimulant use in pregnancy because of high risk of low fetal birth weight and preterm birth. Risks and benefits of treatment must be discussed in detail with patient and preferably with her spouse (3)[B].
- Caution against use of stimulants in adult patients with cardiac history.

**ALERT**
Mood disorders, generalized anxiety disorders, and substance abuse can also coexist with adult ADHD; treating both the ADHD and comorbid conditions will improve the patient’s prognosis.

**TREATMENT**
- Most of the research and medication trials have been performed in children.
- There is increasing evidence that stimulants and nonstimulants used in children are also effective in adults (2) [A].

**ALERT**
Because stimulant medication may induce dependency, substance abuse, and diversion, it is necessary to do pill counts, screen urine for drugs, monitor behavior, and query prescription databases. Misuse of amphetamines may cause sudden death and serious cardiovascular adverse events.
GENERAL MEASURES
When prescribing stimulant medications for adults with ADHD, watch for misuse, abuse, and diversion of prescription medications. When substance abuse is not present, stimulants are first-line treatment for ADHD and highly efficacious. There are multiple formulations of stimulants, and patients may require trials of different dosages, formulations, and medications before an optimal response in symptoms and functions is achieved.

MEDICATION
- Psychotropic medications play a large part in the treatment of ADHD symptoms. Medications should be titrated slowly to effective dose to avoid side effects.
- Stimulants are more effective than antidepressants or nonstimulants, but up to 30% discontinue medications because of side effects.
- Stimulants can be divided into two different classes: Methylphenidate and amphetamine come in both short- and long-acting preparations. Recent evidence suggests that adherence and persistence rates improve in ADHD when using long-acting agents (vs. short-acting) (1).
- Antidepressants studied for ADHD include bupropion, which has been shown to have a medium effect compared with stimulants (3)[A].

First Line
- **Stimulants**: methylphenidate (Concerta, Ritalin), dexamethasphenidate (Focalin), dextroamphetamine/amphetamine (Adderall), dextroamphetamine (Dexedrine), lisdexamfetamine (Vyvanse)
  - Methylphenidate preparations are available in short-acting, intermediate-acting, long-acting, and patch formulations.
  - Ritalin LA may be used for patients naive to stimulants. It can be started at 20 mg daily and dose titrated by 10 mg increments weekly to symptoms response; max dose of 60 mg/day.
  - Concerta ER is another option in adults up to 65 years of age. Starting dose of 18 mg/day; adjust in increments of 18 mg weekly until symptoms improve. Max dose 72 mg/day. Concerta also has an oral osmotic release to decrease abuse potential.
  - Amphetamines also come in immediate-release preparations and sustained-release preparations.
  - Dextroamphetamine is commonly used (half-life of 4 to 6 hours) with an initial dose of 5 mg twice daily; titrate up by 5 mg weekly to maximum of
20 mg twice daily.
- Caution: Immediate-release preparations have high abuse potential.
- Dextroamphetamine/amphetamine (Adderall) is a 75%/25% mix that also comes in an extended-release form. Initial dosing can be started at 5 mg twice daily for short acting or 20 mg once daily for long acting and increased by 5 mg/week for short acting and 10 mg/week long acting to a maximum of 40 to 60 mg total daily.
- Lisdexamfetamine (Vyvanse) is an extended-release stimulant that is a prodrug requiring metabolism to active component, dextroamphetamine.
- Dextroamphetamine can be initiated at 30 mg daily and titrated by 10 to 20 mg weekly to a maximum of 30 to 70 mg daily.
- Common side effects of stimulants include hypertension (HTN), tachycardia, insomnia, weight loss, stomach upset, increased anxiety/irritability, or worsening of tics (2)[A].

**Nonstimulants:** Atomoxetine (Strattera) has been shown effective in adults with ADHD when compared to placebo (4)[B]. It may be given as a single dose or split dose and has low abuse potential, making it a better choice over a stimulant medication for patients with substance abuse history. Onset of effect may take up to 4 weeks. Atomoxetine may require dose adjustments with strong inhibitors of cytochrome P2D6 (e.g., Paxil or Prozac). Also, there are rare cases of liver damage associated with these medications. Monitor for increased suicidal thinking.
- Antidepressants: best used for those at high risk or with history of substance abuse disorder. Bupropion (Wellbutrin) is an antidepressant effective in adults with ADHD symptoms (3)[A].
- Tricyclic antidepressants (desipramine and nortriptyline) have also shown to be effective in ADHD (1).
- Alpha-2 agonists (guanfacine, clonidine) have been found to be effective in children and adolescents; however, their efficacy, safety, and tolerability have not been studied extensively in adults (5)[C].
- Combining stimulants with a nonstimulant medication such as atomoxetine, guanfacine, or clonidine has shown positive effects among patients who are resistant to stimulants alone.

**ISSUES FOR REFERRAL**
Patients with comorbid conditions may need referral for diagnosis and treatment. Consider cardiology consult for patients with known cardiac issues who may require stimulant treatment. Consider referral to obstetrician experienced in high-risk pregnancies when treating pregnant women with ADHD.
ADDITIONAL THERAPIES
Cognitive-behavioral therapy (CBT) can be useful in conjunction with medication to help patients modify and cope with symptoms. CBT helps reduce impairments resulting from executive dysfunction that is not optimally ameliorated with medication (1).

COMPLEMENTARY & ALTERNATIVE MEDICINE
Vitamin–mineral supplementation is an area of active research that holds promise for improved ADHD treatment (6)[A].

ONGOING CARE
Transfer from pediatric to adult care must be closely coordinated to avoid hiatus in treatment.

FOLLOW-UP RECOMMENDATIONS
- Close follow-up of medication as dose is titrated.
- Continue to monitor for medication side effects.
- Repeat screening checklists to quantify benefit of interventions as needed.
- Reinforce behavioral change (e.g., self-initiated through CBT), which is the essential goal of long-term management.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- F90.9 Attention-deficit hyperactivity disorder, unspecified type
- F90.1 Attn-defct hyperactivity disorder, predom hyperactive type
- F90.0 Attn-defct hyperactivity disorder, predom inattentive type

**CLINICAL PEARLS**

- Adult ADHD results in inattention, easy distractibility, hyperactivity, and impulsive behavior; it is associated with low self-esteem, problematic interpersonal relationships, and difficulty meeting academic and job expectations.
- Psychotropic medications plus cognitive-behavioral treatments are the cornerstone of management.
- Substance abuse is a common comorbidity; recommend use of nonstimulant medication in those at high risk.
ATTENTION DEFICIT/HYPERACTIVITY DISORDER, PEDIATRIC
Laura Novak, MD • Rehman Tariq, MD

BASICS

DESCRIPTION
- Attention deficit hyperactivity disorder (ADHD) is a neurodevelopmental problem that manifests in early childhood characterized by distractibility, impulsivity, hyperactivity, and/or inattention.
- Three subsets: predominantly hyperactivity impulsive (ADHD-HI), predominantly inattentive (ADHD-I), or combined (ADHD-C)
- System(s) affected: nervous
- Synonym(s): attention deficit disorder; hyperactivity

EPIDEMIOLOGY
- Predominant age: onset <12 years; lasts into adolescence and adulthood; 50% meet diagnostic criteria by age 4 years.
- Predominant sex: male > female (2:1); ADHD-I may be more common in girls.

Prevalence
11% of children 4 to 17 years old were diagnosed with ADHD as of 2011. Of those, 6.1% are receiving a medication for ADHD.

ETIOLOGY AND PATHOPHYSIOLOGY
Not definitive

Genetics
Familial pattern

RISK FACTORS
- Family history
- Medical causes (affecting brain development)
- Environmental causes (toxins such as lead, fetal alcohol, and nutritional
deficiencies)

GENERAL PREVENTION
- Children are at risk for abuse, depression, and isolation.
- Parents need regular support and advice.

COMMONLY ASSOCIATED CONDITIONS
- Depression (in up to 1/3 of cases)
- Oppositional defiant disorder
- Conduct disorder
- Anxiety disorder
- Learning disabilities

DIAGNOSIS
- American Academy of Pediatrics (AAP) guidelines recommend DSM-5 criteria to establish diagnosis (1)[C].
- DSM-5 criteria for children <17 years: ≥6 inattention criteria and/or ≥6 hyperactivity/impulsivity criteria. Symptoms must occur often, be present before age of 12 years, for >6 months, be noticed in ≥2 settings (e.g., home, school), reduce quality of social or scholastic functioning, be excessive for development level of child, and are not better explained by or occur with another mental disorder (e.g., mood, anxiety, or personality disorder) (2)[C].
- Inattention
  - Careless mistakes in tasks; difficulty sustaining attention or in organizing tasks; does not seem to listen, follow through, or finish tasks; avoids tasks that require sustained mental effort; loses things; forgetful in daily activities
- Hyperactivity/impulsivity
  - Fidgets; difficulty remaining seated; runs/climbs excessively or inappropriately; difficulty playing quietly; acts as if “driven by a motor” or seeming to always be “on the go”; talks excessively; blurts out answers before question is complete; has difficulty waiting turn; interrupts others
- Children undergoing extreme stress (parent’s divorce, illness, homelessness, abuse) may demonstrate ADHD behaviors secondary to stress (1)[C]. This can be assessed using the American Academy of Child and Adolescent Psychiatry (AACAP) screening tool.
- If diagnostic behaviors are noted in only one setting, explore the stressors in that setting.
The diagnostic behaviors are more noticeable in tasks that require concentration or boredom tolerance than in free play or office situations.

HISTORY
- Birth and development history
- Psychosocial evaluation of home environment
- School performance history and school absences
- Psychiatric history or comorbid disorder(s)
- Cardiac history

PHYSICAL EXAM
- Baseline weight for future monitoring
- Note any soft neurologic signs, such as tics, clumsiness, mixed handedness.
- Assess hearing and vision.

DIFFERENTIAL DIAGNOSIS
- Activity level appropriate for age
- Dysfunctional family situation
- Learning disability (e.g., dyslexia)
- Language or communication disorders
- Hearing/vision disorder
- Autism spectrum disorders
- Oppositional/defiant disorder or conduct disorder
- Tourette syndrome: motor and verbal tics
- Absence seizures (ADHD-I only)
- Lead poisoning
- Sequelae of central nervous system infection/trauma
- Medication (decongestant, antihistamine, phenobarbital)
- Sleep disorder

DIAGNOSTIC TESTS & INTERPRETATION
- Behavior rating scales must be completed by parents, caregivers, and teachers prior to initiation of therapy and then repeated after therapy is started to gauge treatment efficacy.
- Forms are available from the ADHD toolkit at [http://www.nichq.org/adhd.html](http://www.nichq.org/adhd.html) (Vanderbilt Assessment Scales).
- Testing for learning disability (e.g., dyslexia) through the school may be needed.
Initial Tests (lab, imaging)
Lead level if high risk, possible thyroid-stimulating hormone (TSH)

Diagnostic Procedures/Other
- EEG if symptoms are highly suggestive of absence seizure disorder
- ECG prior to starting stimulant medication if high risk

TREATMENT

GENERAL MEASURES
- Parent/school/patient education
- Work closely with teacher.
- Behavioral therapy/environmental changes

MEDICATION
- 2011 AAP guideline recommends behavioral interventions for ages 4 to 5 years and behavioral interventions plus stimulant medications as first-line treatment for ages 6 to 17 years (3)[A].
- Stimulant choice should be based on cost, formulary, convenience, and duration. A second type of stimulant should be tried if the first treatment fails. All stimulant capsules can be opened and sprinkled (note Concerta is a pill).

First Line
Stimulant:
- Methylphenidate
  - Short-acting
    - Ritalin, Methylin: initial 5 mg BID before breakfast and lunch; increase by 5 to 10 mg weekly to maximum dose of 60 mg/day (divided BID/TID).
  - Intermediate-acting
    - Ritalin SR: 20 mg once in AM; increase by 10 mg weekly up to 40 to 60 mg.
    - Metadate ER: 10 mg BID; increase by 10 mg weekly to 40 to 60 mg.
  - Long-acting
    - Metadate CD: 20 mg in AM; increase by 10 to 20 mg weekly to 40 to 60 mg.
o Quillivant XR: 20 mg in AM; increase 10 to 20 mg weekly until 40 to 60 mg.
  o Ritalin LA: 10 to 20 mg in AM; increase 10 mg weekly until 40 to 60 mg.
  o Concerta: 18 to 36 mg in AM; increase by 18 mg weekly until 54 to 72 mg.
  o Daytrana transdermal patch: 10-mg patch on (hip area) 2 hours before effect is needed; patch removed 9 hours after application; increase to next higher patch weekly until 30-mg patch if needed.

- **Dexmethylphenidate**
  - **Focalin:** initial: 2.5 mg BID; increase total daily by 2.5 to 5 mg weekly up to maximum dose of 20 mg/day.
  - **Focalin XR:** initial: 5 mg in AM; increase daily dose by 5 mg weekly up to maximum dose of 30 mg/day.

- **Dextroamphetamine**
  - Dexedrine spansule (long-acting): 5 mg BID; increase by 5 mg weekly to maximum dose of 40 mg daily.

- **Dextroamphetamine and amphetamine**
  - **Short-acting**
    - Adderall: 5 mg daily or BID; increase by 5 to 10 mg weekly to a maximum dose of 40 mg daily divided into 1 to 3 doses.
  - **Long-acting**
    - Adderall XR: 5 to 10 mg in AM; increase by 5 to 10 mg weekly until maximum dose of 30 mg/day.

- **Lisdexamfetamine**
  - Vyvanse: 30 mg in AM; increase by 10 to 20 mg weekly up to a maximum of 70 mg/day.

**ALERT**
The FDA recommends that a personal or family history of congenital heart disease or sudden death be screened with an ECG and possible cardiology consultation before beginning stimulant medication (2)[C].

- **Precautions:**
  - If not responding, check compliance and consider another diagnosis.
  - Some children experience withdrawal (tearfulness, agitation) after a missed dose or when medication wears off. A small, short-acting dose at 4 PM may help to prevent this.
  - Stimulants are drugs of abuse and should be monitored carefully.
  - Drug holidays are not recommended but may be tried in weight loss or
ADHD-I.

- Common adverse effects:
  - Anorexia, insomnia, GI effects, and headache
- Significant possible interactions: may increase levels of anticonvulsants, SSRIs, tricyclics, and warfarin
- High-caffeine energy drinks, albuterol inhalers, and decongestants may increase side effects.
- The FDA reports permanent skin discoloration with Daytrana patches.

**Pregnancy Considerations**
Medications are Category C: caution in pregnancy

**Second Line**
Nonstimulant:

- SNRI
  - Atomoxetine (Strattera):
    - ≤70 kg: 0.5 mg/kg/day initial; increase after a minimum of 3 days to target dose of 1.2 mg/kg/day; maximum of 1.4 mg/kg/day
    - >70 kg: 40 mg daily; increase after minimum of 3 days to target dose of 80 mg/day; dose may be increased to maximum of 100 mg/day after additional 2 to 4 weeks.

- α₂-Agonist
  - Modest efficacy, high side effects. Consider consultation before use.
    - Clonidine XR (Kapvay): 0.1 mg once daily at bedtime; increase by 0.1 mg weekly; doses should be taken twice daily with equal or higher split dosage given at HS; maximum of 0.4 mg/day; taper when discontinued.
    - Guanfacine XR (Intuniv): 1 mg daily; increase by 1 mg weekly until 1 to 4 mg daily; taper when discontinued.

**ALERT**
Atomoxetine carries a “black box” warning regarding potential exacerbation of suicidality (similar to SSRIs). Close follow-up is recommended.

- Associated with hepatic injury in a small number of cases; check liver enzymes if symptoms develop.
- Interacts with paroxetine (Paxil), fluoxetine (Prozac), and quinidine

**ISSUES FOR REFERRAL**
Should be considered for children <6 years old for psychological or medical
complications, developmental disorder or intellectual disability, or poor response to medication

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Surveys have shown that parents of children with ADHD use herbals and complementary treatments frequently (20–60%).
- If nutritional deficiency is suspected, assess and replace deficits.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Parent/teacher rating scales
- Office visits to monitor side effects and efficacy: End points are improved grades, rating scales, family interactions, and peer interactions.
- Monitor growth (especially weight) and BP.

**DIET**

- “Insufficient evidence to suggest that dietary interventions reduce the symptoms of ADHD” (2)[C]
- The AAP recommends that “for a child without a medical, emotional, or environmental etiology of ADHD behaviors, a trial of a preservative-free food coloring-free diet is a reasonable intervention” (3)[B].

**PATIENT EDUCATION**

- Excellent reference: [http://www.parentsmedguide.org](http://www.parentsmedguide.org)
- Key points for parents:
  - Find things the child is good at and emphasize these; reinforce good behavior; give one task at a time; stop behavior with quiet discipline; coordinate homework with teachers; have external organization tools—charts, schedules, tokens.
  - Develop an individualized education plan (IEP) with the school.
- Support groups:
  - Children and Adults with Attention Deficit Disorder (CHADD): [http://www.chadd.org](http://www.chadd.org)
– Attention Deficit Disorder Warehouse: http://www.addwarehouse.com
– National Information Center for Children and Youth with Disabilities: http://www.nichcy.org

PROGNOSIS
- May last into adulthood; plan for a transition at age 17 years.
- Relative deficits in academic and social functioning may persist into late adolescence/adulthood.
- Encourage career choices that allow autonomy and mobility.

COMPLICATIONS
- Untreated ADHD can lead to failing in school, parental abuse, social isolation, and poor self-esteem.
- Possible withdrawal when medication wears off
- Monitor growth with stimulant use. If appetite is poor, eat before the medication is given and after it wears off. Consider a shorter duration medication.
- Risk of substance abuse is controversial and seems to decrease with treatment of ADHD.
- Increased automobile accidents and injuries; decreases with medication

REFERENCES

### CODES

**ICD10**

- F90.9 Attention-deficit hyperactivity disorder, unspecified type
- F90.0 Attn-defct hyperactivity disorder, predom inattentive type
- F90.1 Attn-defct hyperactivity disorder, predom hyperactive type

### CLINICAL PEARLS

- AAP recommends behavioral interventions for age 4 to 5 years and behavioral interventions plus stimulant medications as first-line treatment for age 6 to 17 years. Children undergoing extreme stress (parent’s divorce, illness, homelessness, abuse) may demonstrate ADHD behaviors secondary to stress.
- ADHD is 2 to 8 times more common in persons who have a first-degree relative with the condition.
ATYPICAL MOLE (DYSPLASTIC NEVUS) SYNDROME
Anne R. Atalig, MD, CPT • Terin H. Blanchard, MD

BASICS
Atypical mole syndrome (AMS), also known as dysplastic nevi syndrome (DNS), B-K mole syndrome, Clark nevi syndrome, or familial atypical multiple mole melanoma (FAMMM) syndrome, is a condition characterized by a large number of pigmented nevi with architectural disorder, which arise sporadically or by inheritance and are associated with an increased risk of melanoma.

DESCRIPTION
- There is no consensus on criteria for AMS.
- Elevated total body nevi count, including clinically atypical nevi, is usually >50 and often >100.
  - Larger number in hereditary AMS versus sporadic atypical nevi (as few as <10)
- Increased risk of melanoma
  - Up to 90% occurrence by age 80 years in certain high-risk individuals
  - Earlier onset than in sporadic melanoma
  - More arise de novo than from an existing nevus
  - Higher risk for appearance at unusual sites (e.g., scalp, eyes, and sun-protected areas)
- Median age of diagnosis for melanoma in AMS is 10 to 20 years earlier than the general population, with documented cases of melanoma as early as in the 2nd and 3rd decades of life.

EPIDEMIOLOGY
Incidence
Uncertain due to phenotype variability, limited data

Prevalence
Affects between 2% and 8% of fair-skinned adults
ETIOLOGY AND PATHOPHYSIOLOGY

- Cyclin-dependent kinase inhibitor 2A (CDKN2A) mutations have been observed in familial DNS and multiple melanomas. The CDKN2A gene on 9p21 encodes for the proteins p16 and p14. p16 binds to CDK4/6 and is a negative cell-cycle regulator via inhibition of the CDK-cyclin D interaction needed for cell cycle progression from G1 to S. p14 functions by stabilizing the tumor-suppressor protein p53 in the G1 phase of the cell cycle.
- Familial cases of germline CDKN2A mutations are transmitted in an autosomal dominant fashion.
- No clear somatic mutation patterns in sporadic cases

Genetics

CDKN2A mutation observed in 25–40% of hereditary cases, with autosomal dominant inheritance but variable expressivity and incomplete penetrance

RISK FACTORS

Family history of melanoma or multiple nevi, sun exposure, neonatal blue-light phototherapy, history of painful sunburns

GENERAL PREVENTION

- Primary prevention with sun avoidance, sun protection
- Secondary prevention of melanoma with routine skin exams, biopsy of suspect lesions, and environmental risk mitigation as above

COMMONLY ASSOCIATED CONDITIONS

- Malignant melanoma, including ocular melanoma
- Ocular nevi
- Pancreatic cancer in CDKN2A mutation

DIAGNOSIS

AMS is a clinical diagnosis with various classifications schemes proposed. Although not widely accepted, diagnostic criteria, as defined by the NIH, require the three features of (i) malignant melanoma in ≥1 first- or second-degree relatives; (ii) numerous melanocytic nevi (frequently >50), some of which are clinically atypical; and (iii) nevi that have certain histologic features (1).
HISTORY
- Changing lesions: bleeding, scaling, size, texture, nonhealing, hyper- or hypopigmentation
- Large number of nevi
- Congenital nevi
- Sun exposure
- Prior skin biopsies
- Prior melanoma
- Immunosuppression (e.g., AIDS, chemotherapy, pancreatic cancer)
- First- or second-degree relatives with:
  - AMS
  - Melanoma
  - Pancreatic cancer

PHYSICAL EXAM
- Full-body skin exams
- Goal to distinguish melanoma from AMS
- ABCDE mnemonic for skin lesions concerning for melanoma: Asymmetry, Border irregularity, Color variegation, Diameter >6 mm, and Evolving lesion
  - Atypical mole (AM) is often defined as ≥5 mm and at least two other features.
  - Melanoma typically has several characteristics of ABCDEs, with increased specificity for melanoma if lesion diameter is >6 mm.
- “Ugly duckling sign” (2)[B]:
  - Melanoma screening strategy of identifying malignant nevi straying from the predominant nevus pattern when numerous atypical nevi are present
- Most common features of AM on dermoscopy include (3)[C]:
  - Atypical pigment network
  - Irregular/peripheral depigmentation areas
  - Irregular distribution of brown globules
  - Pigmentation with central heterogeneity and abrupt termination
- Dermatoscopic features more suggestive of melanoma include (4)[C]:
  - Depigmented areas
  - Whitish veil
  - Homogenous areas distributed irregularly, in multiple areas, or >25% of total lesion
  - ≥4 colors
DIFFERENTIAL DIAGNOSIS

- Common nevus: acquired or congenital
- Melanoma
- Seborrheic keratosis
- Dermatofibroma
- Lentigo
- Pigmented actinic keratosis
- Pigmented basal cell carcinoma
- Blue rubber bleb nevus syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis is first suspected with history and physical exam and then confirmed by biopsy and histopathology.

Initial Tests (lab, imaging)

- Dermoscopy can be used for more detailed exam to distinguish between benign and malignant lesions and for further classification to any of 11 subtypes.
- Genetic testing is available for CDKN2A mutations, but it is not recommended outside of research studies as results cannot be adequately used for management or surveillance (4)[C].
- When the total nevus count is high and following each nevus is impractical, total body photography may aid in the evaluation of evolving nevi as well as in documenting new nevi (5)[C].

Diagnostic Procedures/Other

- Biopsy is recommended for any lesion where melanoma cannot be excluded.
- Biopsy entails full-thickness biopsy of the entire lesion with a narrow 1- to 3-mm margin of normal skin down to fat for adequate depth assessment (6)[C].
  - Excisional biopsy, elliptical or punch excision, provides the most accurate diagnosis and should be performed when possible.
  - Scoop shave biopsy can also be used, but care must be taken to not transect the lesion.
- Reexcision of mild to moderately dysplastic nevi with positive margins may not change pathologic diagnosis, but for severely dysplastic nevi, consider reexcision, with surgical margins of 2 to 5 mm (5)[C].

Test Interpretation
“Dysplastic nevus” is a term more accurately reserved as a histologic diagnosis. Features may include melanocyte proliferation in the dermoepidermal junction extending through at least three rete ridges in a specific pattern, fusing of rete ridges, dermal fibrosis, neovascularization, and interstitial lymphocytic inflammation (5)[C].

**TREATMENT**

**MEDICATION**

No medications have been shown to treat AMS (5)[C].

**ISSUES FOR REFERRAL**

- Dermatologist for routine skin exam in patients at high risk for melanoma
- Ophthalmologic exams for ocular nevi/melanoma screening/papilledema
- Oncology or specialized genetics study group involvement if strong family predisposition to pancreatic cancer
- Cosmetic surgery consultation for cosmetically poor excision outcomes

**ADDITIONAL THERAPIES**

- Topical chemo- and immunotherapies have been unsuccessfully attempted to treat atypical moles (5)[C].
- Laser treatment should be avoided because it is both unsafe and ineffective for melanocytic nevi (5)[C].

**SURGERY/OTHER PROCEDURES**

Surgical excision of all atypical nevi is not recommended because most melanomas in AMS appear de novo on healthy skin and the procedure leads to both poor cosmetic outcomes and a false sense of security. Lesions suspicious for melanoma should be biopsied or removed surgically.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Close follow-up with a dermatologist or other experienced physician:

- Total body skin exam (including nails, scalp, genital area, and oral mucosa)
every 6 months initially, starting at puberty; may be reduced to annually once nevi are stable
- Dermoscopic evaluation for suspect lesions
- Ocular exam for those with familial AMS
- Excision of suspect lesions
- Total body photography at baseline

Patient Monitoring
Monthly self-exams of skin

PATIENT EDUCATION
For young adults with fair skin, counsel to minimize exposure to ultraviolet radiation to reduce risk of skin cancer (USPSTF Grade B)[A].
- Fair skin: light eye, hair, or skin color, freckles
- Educate on sun avoidance, proper application of sunscreen, use of protective clothing (e.g., hats), avoidance of tanning booths and sunburns.
- Teach “ABCDE” mnemonic + “ugly duckling sign” to assess nevi and identify potential melanomas.
- Provide instruction on skin self-exam techniques.
- A sample listing of patient-centric review sources on this topic are as follows:
  - American Academy of Dermatology (cancer.about.com/od/skincancermelanoma/p/abcdeskinca.pdf)
  - Skin Cancer Foundation (http://www.skincancer.org/skin-cancer-information/dysplastic-nevi)
  - Melanoma Research Foundation (http://www.melanoma.org/understand-melanoma/what-is-melanoma)

PROGNOSIS
- Most AM either regress or do not change.
- Multiple classification schemes have been developed over the years to delineate risk of melanoma in patients with AMS. Individuals with a family history of melanoma are at greatest risk. The Rigel classification system can be applied in the clinical setting. Points are assigned based on incidence of melanoma, with 1 point given for a personal history with melanoma and 2 points for each family member with melanoma (modified nuclear family consisting of first-degree relatives plus grandparents and uncles/aunts) and stratified as follows:
  - Score = 0, Rigel group 0, 6% 25-year accumulated risk for melanoma
– Score = 1, Rigel group 1, 10% risk
– Score = 2, Rigel group 2, 15% risk
– Score ≥3, Rigel group 3, 50% risk

The CDKN2A mutation has also been associated with a 60–90% risk of melanoma by age 80 years and a 17% risk for pancreatic cancer by age 75 years.

COMPLICATIONS

• Malignant melanoma
• Poor cosmetic outcomes from biopsy

REFERENCES

ADDITIONAL READING

**CODES**

mebooksfree.com
ICD10
- D22.9 Melanocytic nevi, unspecified
- D22.4 Melanocytic nevi of scalp and neck
- D22.30 Melanocytic nevi of unspecified part of face

CLINICAL PEARLS
- In describing nevi, “atypical” is a clinical term, whereas “dysplastic” is a histologic term.
- Melanoma in AMS tends to arise from healthy skin despite a large number of atypical nevi.
- ~20% of individuals with familial AMS will develop pancreatic cancer by age 75 years.
- Patients with AMS tend to produce neoplasms in unusual sites such as the scalp, eyes, and sun-protected areas (e.g., gluteal folds).
AUTISM SPECTRUM DISORDERS
Liyu Liu, DO • Holly L. Baab, MD

BASICS
DESCRIPTION

- Group of neurodevelopmental disorders of early childhood: DSM-5: umbrella term autism spectrum disorders (ASDs) which combines autistic disorder, childhood disintegrative disorder, Asperger disorder, pervasive developmental disorder not otherwise specified (PDD-NOS), early infantile autism, childhood autism, Kanner autism, high-functioning autism, and atypical autism (1)[A]
- Two symptom-driven subtypes: impairment of effective social skills and absent or impaired communication skills
- Fixed interests/repetitive behaviors
- Repetitive and/or stereotyped behaviors and interests, especially in inanimate objects (2)[A]
- Severity levels
  - Level 1: requiring support
  - Level 2: requiring substantial support
  - Level 3: requiring very substantial support
- Important to distinguish autism disorder from social (pragmatic) communication disorder. Separate DSM-5 criteria for individuals with social communication deficits but do not meet autism-spectrum criteria.

EPIDEMIOLOGY

- Predominant age: onset in early childhood
- Predominant sex: male > female (4.5:1)

Pediatric Considerations
Symptom onset seen in children <3 years of age (except for childhood disintegrative disorder)

Prevalence
- According to the Centers for Disease Control and Prevention (CDC), an estimated prevalence of 1/68
Among children aged 3 to 17 years within the United States, there was found to be a 2.2% (22.4 in 1,000) parent-reported prevalence.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- No single cause has been identified.
- General consensus: A genetic abnormality leads to altered neurologic development.
- No scientific evidence relating vaccines, such as vaccines for measles, mumps, or rubella (MMR), or thimerosal causing ASDs
- Pathophysiology is not fully understood.

**Genetics**
- High concordance in monozygotic twins
- Increased recurrence risk (2–18%) in subsequent siblings

**RISK FACTORS**
- Having an affected sibling confers 5 times greater risk of developing autism.
- Advanced parental age

**GENERAL PREVENTION**
- Early screening for early intervention means a better prognosis.
- Some ASDs are caused by genetic disorders.
- Economic costs:
  - An additional $17,000 to $21,000 is an estimated cost for raising an ASD child.
  - Due to caretaker burden, family earnings are found to be 28% less among families with ASD compared to children without health conditions.

**COMMONLY ASSOCIATED CONDITIONS**
- Mental retardation, ADHD, anxiety, depression, or obsessive behavior
- Phenylketonuria (PKU), tuberous sclerosis, fragile X syndrome, Angelman syndrome, and fetal alcohol syndrome (rare)
- Seizures (increased risk if severe mental retardation)
- Maternal use of selective serotonin reuptake inhibitors (SSRIs) during pregnancy
- Sleep issues: insomnia, circadian rhythm sleep-wake disorder, sleep-related movement disorder
**DIAGNOSIS**

**HISTORY**
- Listen to parents’ concerns and test early if they or you have suspicion of a neurodevelopmental disorder.
- Impairment in social interaction
  - Impairment in nonverbal behaviors such as eye-to-eye gaze, facial expression
  - Unable to develop peer relationships
  - Does not smile nor share emotions
  - Loss of social or emotional reciprocity
- Communication impairment
  - Delay or lack of development in language skills
  - Inability to initiate or sustain conversation
  - Stereotyped and repetitive use of language
  - Preoccupation with parts of toys or body parts
- Repetitive and stereotyped patterns of behavior
  - Excessively lines up toys or other objects
  - Unusually attached to one particular toy or object
  - Repetitive odd movements (toe walking, hand flapping)
  - Adherence to specific routines or rituals
- Prenatal, neonatal, and developmental history
- Seizure disorder
- Family history of autism, genetic disorders, learning disabilities, psychiatric illness, neurologic disorders, or mental retardation
- Commonly associated with sleep disorders

**PHYSICAL EXAM**
- Macrocephaly in 25%; head circumference growth peaks at age 6 months and begins to decline by 1 year.
- Dysmorphic features consistent with genetic disorder (fragile X syndrome)
- Hypotonia occurs in autism but should prompt imaging.
- Wood lamp skin exam to rule out tuberous sclerosis

**DIFFERENTIAL DIAGNOSIS**
- Other mental and CNS disorders
- Obsessive-compulsive disorder
- Elective mutism
• Language disorder/hearing impairment
• Intellectual disability/global developmental delay
• Stereotyped movement disorder
• Severe early deprivation/reactive attachment disorder
• Anxiety disorder
• Social communication disorder
• Developmental language disorder

**DIAGNOSTIC TESTS & INTERPRETATION**

• Modified Checklist for Autism in Toddlers (M-CHAT) to screen for ASDs 16 to 30 months of age ([https://m-chat.org/](https://m-chat.org/))
• The Pervasive Developmental Disorders Screening Test-II (PDDST-II) to screen for ASDs beginning at 18 months
• Social Communication Questionnaire (SCQ) (formerly Autism Screening Questionnaire)—used with children age 4+ years—the gold standard diagnostic interview used in research studies

**Initial Tests (lab, imaging)**

• Lead and PKU screening
• Karyotype and DNA analysis (fragile X, PKU, tuberous sclerosis, and others)
• Metabolic testing if signs of
  – Lethargy, limited endurance, unusual habits, hypotonia, recurrent vomiting and dehydration, developmental regression, or specific food intolerance
• Consider MRI if focal neurologic symptoms.

**Follow-Up Tests & Special Considerations**

• Hearing tests: audiometry and brainstem auditory evoked response (BAER)
• Comprehensive speech and language evaluation
• Evaluation by multidisciplinary team: includes a psychiatrist, neurologist, psychologist, and other autism specialists
• Intellectual level needs to be established and monitored, as it is one of the best measures of prognosis.
• Test used to follow autism are the following:
  – Autism Behavior Checklist (ABC)
  – Gilliam Autism Rating Scale (GARS)
  – Childhood Autism Rating Scale (CARS)
  – Autism Diagnostic Interview-Revised (ADI-R)
  – Autism Diagnostic Observation Schedule-Generic (ADOS-G) Imaging
Diagnostic Procedures/Other
EEG if history of seizures or spells

TREATMENT

GENERAL MEASURES
- Comprehensive structured educational programming of a sustained and intensive design, most commonly applied behavioral analysis therapy
- Core features of a successful education program
  - High staff–student ratio 1:2, or less
  - Individualized programming
  - Specialized teacher training with ongoing evaluation of teachers and programs
  - 25 hours a week minimum of specialized services
  - A structured routine environment
  - Functional analysis of behavioral problems
  - Transition planning and involvement of the family
- Currently, no cure for ASDs. Early diagnosis and initiation of multidisciplinary intervention help enhance functioning in later life.
- Early intensive behavioral intervention (EIBI) involving treatment for 20 to 40 hours per week is a well-established treatment for ASD.
- School-based special education for older children
- Some evidence indicate social skill groups can improve social competence for some children and adolescents with ASD.
- Find alternative methods of communication: sign language; picture exchange communication system.

MEDICATION
- Autism behavior issues should be managed with maximal behavioral management.
- No true first-line medical therapy; medications used to treat targeted symptoms

First Line
- Stimulants (such as methylphenidate): efficacious in treating concomitant symptoms of ADHD such as impulsiveness, hyperactivity, and inattention; however, the magnitude of response is less than in typically developing
children and adverse effects are more frequent.

- SSRIs have limited evidence for autism. It has shown help in reducing ritualistic behavior and improving mood and language skills; initial choice for anxiety and depressive mood \( (3) \)[B]
- Risperidone has shown short-term efficacy for treatment for irritability, repetitious behaviors, and social withdrawal \( (4) \)[B]. Aripiprazole has shown efficacy for treating short-term irritability, hyperactivity, and repetitive movements \( (5) \)[B].
- Melatonin used for patients with concomitant sleep disorders

**ISSUES FOR REFERRAL**

- Refer early to
  - Early learning for evaluation of behavior and language, genetic counseling, and audiology
- Consider referrals to psychiatry, ophthalmology, otolaryngology, neurology, and nutrition \( (6) \).
- Refer family members to parent support groups and respite programs.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Parent-mediated early intervention for young children with autism spectrum has sufficient evidence of benefit in child outcomes related to language understanding and severity of autism characteristics.
- No evidence to support use of auditory integration therapy or other sound therapies as an effective treatment for ASD

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Constant monitoring by caregivers
- Reevaluation every 6 to 12 months by physician for seizures, sleep and nutritional problems, and to follow prescribed medical management
- Intellectual and language testing every 2 years in childhood

**DIET**
• No current good evidence for or against any certain dietary modifications for ASD
• Limited variety of food consumed due to dietary obsessions

PROGNOSIS
• Beginning treatment at a young age (2 to 4 years) results in better outcomes.
• Prognosis is closely related to initial intellectual abilities.
• Communicative language development before 5 years is also associated with a better outcome.
• The general expected course is for a lifelong need for supervised structured care.

COMPLICATIONS
• Increasing incidents of seizure disorders in up to 1 in 4 children
• Increased risk for physical and sexual abuse
• With pica, increased risk of lead poisoning
• Increased risk for GI symptoms, including weight abnormalities and abnormal stool patterns

Algorithm: Intellectual Disability

CODES

ICD10

- F84.0 Autistic disorder
- F84.5 Asperger’s syndrome
- F84.3 Other childhood disintegrative disorder

CLINICAL PEARLS

ALARM mnemonic from the American Academy of Pediatrics (AAP)

- **ASD** is prevalent (screen ALL children between 18 and 24 months).
- **Listen** to parents when they feel something is wrong.
- **Act** early: Screen all children who fall behind in language and social developmental milestones (use early learning to help with evaluation).
- **Refer** to multidisciplinary teams (speech and language evaluation, genetic screening, social support groups).
- **Monitor** support for patient and families.
BABESIOSIS

Frederick W. Nielson, MD

BASICS

DESCRIPTION

- Rare tick-borne hemolytic disease caused by intraerythrocytic protozoan parasites of the genus Babesia
- Infrequently reported outside the United States
  - Sporadic cases have been reported from
    - France, Italy, the United Kingdom, Ireland, the former Soviet Union, Mexico (1)
    - China, Italy, and Turkey have reported a reemergence of cases.
  - In the United States, infections have been reported in many states. The most endemic areas are:
    - Islands off the coast of Massachusetts (including Nantucket and Martha’s Vineyard)
    - New York (including Long Island, Shelter Island, and Fire Island); Connecticut
    - Asymptomatic infection common in these areas (1)
- Incubation period varies from 5 to 33 days:
  - Most patients do not recall specific tick exposure.
  - After transfusion of infected blood, the incubation period can be up to 9 weeks (1).
- System(s) affected: cardiovascular, gastrointestinal, hemic/lymphatic/immunologic, musculoskeletal, nervous, pulmonary, renal/urologic

Pediatric Considerations

Transplacental and perinatal transmission rarely reported (1,2)

Geriatric Considerations

- Morbidity and mortality higher in patients >60 years
- Cases more common in patients >70 years who have medical comorbidities

EPIDEMIOLOGY
Babesiosis affects patients of all ages. Most patients present in their 40s or 50s (1).

**Incidence**
- Cases reported to the CDC appear to be on the rise from 911 in 2012 to 1,744 in 2014.
- Prevalence is difficult to estimate due to lack of surveillance and asymptomatic infections.
- Transfusion-associated babesiosis and transplacental/perinatal transmission have been reported (1).
- In patients at high risk for tick-borne diseases, seroconversion data show antibodies to *Babesia microti* in 7 of 671 individuals (1%) (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- *B. microti* (in the United States) and *Babesia divergens* and *Babesia bovis* (in Europe) cause most human infections (1). *B. divergens* and a new strain *Babesia duncani* appear to be more virulent. Other species identified in case reports. All share morphologic, antigenic, and genetic characteristics (1).
- Ixodid (hard-bodied) ticks, particularly *Ixodes dammini* (*Ixodes scapularis*: deer tick) and *Ixodes ricinus*, are the primary vectors.
- The white-footed mouse is the primary reservoir.
- Infection is passed to humans through the saliva of a nymphal-stage tick during a blood meal. Sporozoites introduced at the time of the bite enter red blood cells and form merozoites through binary fission (classic morphology on blood smear). Humans are a dead-end host for *B. microti*.

**RISK FACTORS**
- Residing in endemic areas
- Asplenia
- Immunocompromised state

**GENERAL PREVENTION**
- Avoid endemic regions during the peak transmission months of May to September (1).
- Appropriate insect repellent is advised during outdoor activities, especially in wooded or grassy areas:
  - 10–35% N,N-diethyl-meta-toluamide (DEET) provides adequate protection (1).
Early removal of ticks—daily skin checks
Examine pets for ticks; flea/tick control for pets

COMMONLY ASSOCIATED CONDITIONS
- Coinfection with *Borrelia burgdorferi* and *Babesia microti*, particularly in endemic areas (1). Coinfection rates may be as high as ~27%.
- Coinfection with *Ehrlichia* (1)

DIAGNOSIS

HISTORY
- The tick must remain attached for at least 24 hours before the transmission of *B. microti* occurs (1).
- Travel/exposure history
- Comorbidities (immunosuppression, chronic disease)
- Fever (68–89%), fatigue (78–79%), chills (39–68%), sweats (41–56%), headache (32–75%), myalgia (32–37%), anorexia (24–25%), cough (17–23%), arthralgias (17–32%), nausea (9–22%). Other symptoms reported by case reports include abdominal pain, vomiting, diarrhea, and emotional lability.

PHYSICAL EXAM
- High fever (up to 40°C [104°F])
- Hemodynamic instability (shock in extremely ill)
- Hepatomegaly and splenomegaly (mild if noted)
- Rash (uncommon)
- CNS involvement includes headache, photophobia, neck and back stiffness, altered sensorium, and emotional lability
- Jaundice and dark urine may develop later in course of illness.

DIFFERENTIAL DIAGNOSIS
- Bacterial sepsis
- Hepatitis
- Lyme disease; ehrlichiosis
- Leishmaniasis
- Malaria
- HIV; EBV
HELLP syndrome (in pregnancy)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Diagnosis requires a high index of clinical suspicion. Nonspecific laboratory clues include evidence of mild to severe hemolytic anemia, normal to slightly depressed leukocyte count (1), elevated LDH or transaminase level, elevated BUN and Cr, proteinuria with hemoglobinuria (1,2).

- Definitive diagnosis is made by blood smear.
  - Wright- or Giemsa-stained peripheral blood smear demonstrates intraerythrocytic parasites (2)[B].
  - Dividing “cross-like” tetrads of merozoites (Maltese cross) are pathognomonic (2).
  - Serial blood smears may be required (low parasite load early in the illness) (2).
  - Can be confused with *Plasmodium falciparum* on peripheral smear

- If blood smears are negative but suspicion remains, IgM serologies through indirect immunofluorescent antibody testing (IFAT) for *B. microti* antigen:
  - Positive titer results vary by lab. Titers of >1:64 or a 4-fold increase from baseline are consistent with *B. microti* infection (3). Titers may be >1:1,024 in acute infection (2)[B]. Titers often elevated 8 to 12 months and can persist for years.
  - In New England, seroprevalence is 0.5–16% (3).

- Detection of *B. microti* by polymerase chain reaction (PCR) is more sensitive and equally specific in acute cases. PCR can also be used to monitor disease progression (2)[B]. Newer real-time PCR tests have a sensitivity and specificity approaching 100%.

- If lab tests are inconclusive and infection is strongly suspected, inoculation of laboratory animals with patient blood can reveal *B. microti* organisms in the blood of the animal within 2 to 4 weeks (2).

**Follow-Up Tests & Special Considerations**

Monitoring intraerythrocytic parasitemia helps guide treatment (4)[C].

**Diagnostic Procedures/Other**

Based on blood smear, history, and epidemiologic information (2)
TREATMENT

GENERAL MEASURES

- In areas endemic for Lyme disease and ehrlichiosis, consider adding doxycycline (Vibramycin) 100 mg BID PO to empirically treat coinfection until serologic testing is complete (1)[C].
- Drug resistance has emerged in severely immunocompromised patients (2).
- Consider treating asymptomatic patients if parasitemia persists for >3 months; otherwise, do not treat in absence of symptoms (1),(4)[C].

MEDICATION

First Line

- Mild to moderate infection with *B. microti*: 7 to 10 days of atovaquone 750 mg PO BID plus azithromycin 500 to 1,000 mg/day PO on day 1, followed by 250 mg/day. Pediatrics: atovaquone 20 mg/kg (max 750 mg) BID and azithromycin 10 mg/kg (max 500 mg) on day 1 and then 5 mg/kg (max 250 mg) (4)[B]. For severe *B. microti* infection: oral quinine 650 mg TID or QID plus oral clindamycin 600 mg TID for 7 to 10 days. Pediatrics: clindamycin 7 to 10 mg/kg (max 600 mg) TID or QID and quinine 8 mg/kg (max 650 mg) TID. IV formulations can be used (4)[C].
- Persistent or relapsing babesiosis: Treat for 6 weeks, including 2 weeks after *Babesia* is no longer detected on blood smear (5)[B].

Second Line

- Combination of quinine sulfate 650 mg PO TID and clindamycin 600 mg PO TID or 1.2 g parenterally BID for 7 to 10 days is the most commonly used treatment. Pediatric: quinine 8 mg/kg (max 650 mg) every 6 to 8 hours for 7 to 10 days and clindamycin 7 to 10 mg/kg (max 600 mg) PO q6–8h for 7 to 10 days. Some experts prefer this regimen for severe infections (4)[C].
- Other drugs including tetracycline, primaquine, sulfadiazine (Microsulfon), and sulfadoxine/pyrimethamine (Fansidar) have been evaluated. Results vary. Pentamidine (Pentam) is moderately effective in diminishing symptoms and decreasing parasitemia (1)[C].

ALERT

Clindamycin can lead to *Clostridium difficile*–associated diarrhea.
ISSUES FOR REFERRAL
Severe disease: Consider consultation with hematology and infectious disease for exchange transfusion in extremely ill patients (blood parasitemia >10%, massive hemolysis, and asplenia) (2)[C].

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- If left untreated, silent babesiosis may persist for months or years (2).
- Of 139 hospitalized cases from 1982 to 1993:
  - 9 patients (7%) died.
  - 25% were admitted to the ICU.
  - 25% hospitalized for >14 days
- Alkaline phosphatase levels >125 U/L, WBC counts >5 × 10^9/L, history of cardiac abnormality, history of splenectomy, presence of heart murmur, and parasitemia of 4% or higher are associated with disease severity.

Patient Monitoring
The need for monitoring depends on disease severity. Severe infections: Follow hematocrit and parasitemia levels until clinical improvement, and parasitemia is <5%. Mild to moderate: Expect clinical improvement within 48 hours and complete resolution within 3 months (4)[C].

COMPlications
- Many remain asymptomatic.
- Complications in hospitalized patients: CHF (12%), DIC (18%), ARDS (21%), renal failure (6%), coma/lethargy (9%), death (9%)
- Other reported complications include neutropenia and myocardial infarction.
- In asplenic patients, warm autoimmune hemolytic anemia has been reported.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

B60.0 Babesiosis

**CLINICAL PEARLS**

- Ticks must remain in place for 24 hours to transmit infection—encourage daily “tick checks” if people are exposed in high-risk areas.
- Most patients do not recall tick exposure, and incubation can last up to a
Left untreated, silent babesial infection may persist for months or years.
First-line treatment for mild or moderate disease is atovaquone plus azithromycin.
Patients with mild-to-moderate disease should show clinical improvement within 48 hours after starting therapy. Symptoms should fully resolve in 3 months.
Coinfection with *B. burgdorferi* and *Ehrlichia* species is common in endemic areas. In areas endemic for Lyme disease and ehrlichiosis, consider adding doxycycline until serologic testing is completed.
BACK PAIN, LOW

Michael Maddaleni, MD • J. Herbert Stevenson, MD

BASICS

DESCRIPTION

- Low back pain (LBP) is extremely common and includes a wide range of symptoms involving the lumbosacral spine and pelvic girdle.
- Characterized by duration or associated symptoms
  - Duration (1)[A]
    - Acute (<6 weeks)
    - Subacute (>6 weeks but <3 months)
    - Chronic (>3 months)
  - Associated symptoms (1)[A]
    - Localized/nonspecific “mechanical” LBP
    - Back pain with lower extremity symptoms
    - Systemic and visceral symptoms
- A specific cause is not found for most patients with LBP. Most cases resolve in 4 to 6 weeks.
- Rule out “red” flag symptoms indicating the need for immediate intervention.
- System(s) affected: musculoskeletal, neurologic
- Synonym(s): lumbago, lumbar sprain/strain, low back syndrome

EPIDEMIOLOGY

Incidence

- 1-year incidence for first episode: 6.3–15.3% (2)[A]
- 1-year incidence for any episode: 1.5%–36% (2)
- A very common primary care complaint (1)[A]

Prevalence

- Lifetime prevalence: 84% (1)[A]
- Global point prevalence: 9% (1)[A]
- Chronic point prevalence in United States: 13.1%
- Predominant sex: male = female
- Age: The highest incidence is in the 3rd decade (20 to 29 years); overall
prevalence increases with age until age 65 years and then declines (1)[A].

**ETIOLOGY AND PATHOPHYSIOLOGY**

LBP can be commonly due to muscle spasm/tension. Estimated 39% of chronic LBP due to disc degeneration. 30% estimated to be from facet joint syndrome. Other possibilities include sacroiliac injuries/degeneration and spinal stenosis. Age-related degenerative changes of the lumbosacral spine and atrophy of supporting musculature may contribute as well (2)[A].

**RISK FACTORS**

- Age (1)[A]
- Activity (lifting, sudden twisting, bending) (1)[A]
- Obesity (1)[A]
- Sedentary lifestyle (1)[A]
- Physically strenuous work (1)[A]
- Psychosocial factors—anxiety, depression, stress (1)[A]
- Genetic factors (2)
- Heavy operating equipment (2)
- Poor flexibility (2)
- Smoking (1)[A]

**GENERAL PREVENTION**

- Maintain normal weight (1)[A].
- Adequate physical fitness and activity (1)[A]
- Stress reduction (1)[A]
- Proper lifting technique and good posture
- Smoking cessation
- There is insufficient evidence to recommend for or against routine preventive measures in adults.

**DIAGNOSIS**

**HISTORY**

- Onset of pain (sudden or gradual) (1)[A]
- Pain from spinal structures (musculature, ligaments, facet joints and disks) can refer to the thigh region but rarely below the knee. However, facet pain most commonly radiates to SI joint/PSIS region (1).
Sacroiliac pain often refers to the thigh and can also radiate below the knee (1)[A].

Irritation, impingement, or compression of lumbar nerve roots often results in more leg pain than back pain (1)[A].

Pain from the L1–L3 nerve roots radiates to the hip and/or thigh, whereas pain from the L4–S1 nerve roots radiates below the knee.

Red flags
- Recent trauma
- Neurologic deficits
  - Bowel/bladder incontinence or urinary retention
  - Saddle anesthesia
  - Weakness, falls
- Night pain, sweats, fever, weight loss
- Age >70 years with or without trauma
- Age >50 years with minor trauma
- History of cancer
- Osteoporosis
- Immunosuppression, prolonged glucocorticoid use

Yellow flags (predicting poor long-term prognosis):
- Lack of social support
- Unsupportive work environment
- Depression and/or anxiety
- Abuse of alcohol or other substances
- History of physical or sexual abuse
- Excessive mobility in spine or other joints (2)
- Fear of reinjury, movement, or pain (2)
- Low expectation of recovery (2)
- Passive coping style (2)

Pain can be provoked with motion: flexion–extension, side-bending rotation, sitting, standing, and lifting. Pain often relieved with rest.

Radicular pain may radiate to buttocks, thighs, and lower legs.

**Pediatric Considerations**
Back pain is not normal in children and must be carefully evaluated. Patients participating in gymnastics or other high-impact or hyperextension sports (such as skateboarding and cheerleading) frequently land on their feet or buttocks. These can result in a vertebral fracture and/or damage to the intervertebral discs.
PHYSICAL EXAM

- Observe gait, positioning, and facial expressions.
- Test lumbar spine range of motion.
- Evaluate for point tenderness or muscle spasm.
- Evaluate for signs of muscle atrophy.
- Complete thorough physical exam to assess for wide differential (full differential listed in subsequent section).
  - Completely evaluate reflexes, strength, pulses, sensation.
  - Slump test: Have patient sit on table and slump shoulders forward. Then have patient touch chin to chest and attempt to have them extend one leg at a time. Do this while continually reassessing for symptom reproduction; can be indicative of disc herniation.
  - Straight leg test: Raise the patient’s leg straight while the patient is lying down. Keep the knee straight. For more specificity, dorsiflex ankle while lifting leg. This can also evaluate for herniated disc.
  - Evaluate for saddle anesthesia, anal wink reflex.
  - Straight leg test
  - FABER and FADIR test of hips bilaterally
  - Evaluate for psychological distress that may be contributing.
  - Stork test: Stand on one leg with opposite hip held in flexion. Extend back. Pain in lumbosacral area is a positive test—consider spondylolisthesis versus facet OA.

DIFFERENTIAL DIAGNOSIS

- Localized/nonspecific “mechanical” LBP (87%) (1)[A]
  - Lumbar strain/sprain (70%)  
  - Disc/facet degeneration (10%)
  - Osteoporotic compression fracture (4%)
  - Spondylolisthesis (2%)
  - Severe scoliosis, kyphosis
  - Asymmetric transitional vertebrae (<1%)
  - Traumatic fracture (<1%)
- Back pain with lower extremity symptoms (7%) (1)[A]
  - Disc herniation (4%)
  - Spinal stenosis (3%)
- Systemic and visceral symptoms (1)[A]
  - Neoplasia (0.7%)
    o Multiple myeloma; metastatic carcinoma
- Lymphoma/leukemia
- Spinal cord tumors, retroperitoneal tumors
  - Infection (0.01%)
    - Osteomyelitis
    - Septic discitis
    - Paraspinal abscess; epidural abscess
    - Shingles
  - Inflammatory disease (0.03%)
    - Ankylosing spondylitis, psoriatic spondylitis
    - Reactive arthritis
    - Inflammatory bowel disease
  - Visceral disease (0.05%)
    - Prostatitis
    - Endometriosis
    - Chronic pelvic inflammatory disease
    - Nephrolithiasis, pyelonephritis
    - Perinephric abscess
    - Aortic aneurysm
    - Pancreatitis; cholecystitis
    - Penetrating ulcer
  - Other
    - Osteochondrosis
    - Paget disease
    - Cauda equina syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- No clinical benefit of routine imaging (2)
  - Imaging only recommended for progressive, severe neurologic deficits or in the setting of “red flags” (2)
  - Significant amount of false positives; evidence of possible herniated disc material seen in 20–76% of asymptomatic patients on CT, MRI, myelography (2)
- **X-ray of the lumbar spine (1,3)[A]**
  - Not recommended for initial presentation without red flags. Defer films for 6 weeks unless there is a history of acute trauma (fall, etc.) or high risk of disease.
  - Useful to evaluate bony etiology (e.g., fracture)
MRI of the lumbar spine (1,3)[A] for patients presenting with neurologic deficits, failure to improve with 6 weeks of conservative treatment, or if there is a strong suspicion of cancer or cauda equina syndrome
  – Useful for suspected herniated disc, nerve root compression, or metastatic disease
CT scan of the lumbar spine (1,3)[A]
  – Appropriate alternative to MRI for patient with pacemaker, metallic hardware, or other contraindication to MRI
Labs are unnecessary with initial presentation if no related red flags, signs, or symptoms (1,3)[A].
If infection or bone marrow neoplasm is suspected, consider (1,3)[A]
  – Complete blood count (CBC) with differential
  – Erythrocyte sedimentation rate (ESR)
  – C-reactive protein (CRP) level

Diagnostic Procedures/Other
Neurosurgical consult for acute neurologic deficits or suspected cauda equina syndrome (1)[A]

TREATMENT
The primary goal is to provide supportive care and allow return to functional activity. Patients should be aware of alarm symptoms to prompt a return visit.

First Line
- Physical therapy
- Patient education
  – Reassure patients that pain is usually self-limited; treatment should relieve pain and improve function.
  – Encouraging activity as tolerated leads to quicker recovery.
  – Early intervention with formal physical therapy (2)
- Medications (1,3)[A]
  – Acetaminophen 325 to 650 mg PO q4–6h PRN pain (max 4 g/day)
  – NSAIDs
    o Ibuprofen 400 to 600 mg PO 3 to 4 times daily (max 3,200 mg/day)
    o Naproxen 250 to 500 mg PO q12h (max 1,500 mg/day)
  – Manual medicine (4)[A], osteopathic manipulative treatments (OMT): myofascial, counterstrain, bilateral ligamentous techniques, as well as
muscle energy, if tolerated

- Obstetric considerations (5)[B]
  - Use medications cautiously in pregnancy—benefit must clearly outweigh risk.
- OMT and chiropractic care may be used in a multidisciplinary approach; may be used in the general population as well as the obstetric patient

**Second Line**

- Second-line therapy for moderate to severe pain (1,3)[A]
  - Cyclobenzaprine 5 to 10 mg PO up to TID PRN (max 30 mg/day)
  - Tizanidine 2 mg PO up to TID PRN
  - Opioid use (≤4 days, maximum) for LBP is clinical judgment; however, studies show opioids in the setting of LBP do not have a significantly better effect than NSAIDs plus placebo or placebo alone (4)[A].
- Other treatments (1,3)[A]
  - Antidepressants (1,3)[A]
    - Tricyclic antidepressants (amitriptyline, nortriptyline, desipramine) have been shown in randomized trials to provide a small pain reduction in patients. No clear evidence that SSRIs are more effective than placebo in cases of chronic LBP. Treatment of concurrent depression may have positive effect on LBP.

- Injections (5)[A]
  - Facet: Lumbar radiofrequency neurotomy, therapeutic facet joint nerve blocks in the lumbar spine, and lumbar intra-articular injections have all shown benefit.
  - Epidural: provide short-term relief of persistent pain associated with documented radicular symptoms caused by herniated disc (1,3,5)[A]

**Geriatric Considerations**

- Older persons taking nonselective NSAIDs should use a proton pump inhibitor or misoprostol for gastrointestinal protection.
- Patients taking a COX-2 selective inhibitor with aspirin should use a proton pump inhibitor or misoprostol for gastrointestinal protection.
- Age-related decline in cytochrome P450 function and polypharmacy (common in elderly patients) increases risk for adverse medication reactions.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Acupuncture is superior to no treatment, but evidence is mixed regarding the effectiveness of acupuncture over other treatment modalities (1,3)[A].
Yoga can help with chronic LBP (1,3)[A].

Patient Monitoring
- Reassurance is important. Follow up within 2 to 4 weeks of initial presentation to monitor progress. Most patients spontaneously improve.
  - Assess severity and quality of pain, range of motion, and other historical features (red flags).
- Reevaluate for organic causes if no adequate improvement.

COMPLICATIONS
- Regular NSAID use can increase risk of gastrointestinal toxicity and nephrotoxicity (1)[A].
- Acetaminophen has potential hepatotoxicity (1)[A].
- Centrally acting skeletal muscle relaxants and opioid agonists carry the risk for sedation, confusion, dependence, and abuse (1)[A].

**ADDITIONAL READING**

SEE ALSO

- Algorithm: Low Back Pain, Acute

CODES

ICD10

- M54.5 Low back pain
- G89.29 Other chronic pain
- M53.3 Sacrococcygeal disorders, not elsewhere classified

CLINICAL PEARLS

- LBP is one of the most common complaints in primary care. Most cases resolve spontaneously within 4 to 12 weeks of onset.
- Assess for red flag symptoms in every patient, such as bowel/bladder incontinence, history of cancer, or recent trauma.
- Labs and imaging studies are unnecessary for most cases of back pain if no red flag symptoms are present. Symptoms typically will resolve in 6 weeks or less.
- In the absence of red flags, physical activity as tolerated speeds recovery.
- Early intervention with formal physical therapy can reduce symptoms, strengthen musculature, and speed up recovery.
BACTERIURIA, ASYMPTOMATIC

Mony Fraer, MD, FACP, FASN • Kantima Phisitkul, MD

BASICS

DESCRIPTION

Asymptomatic bacteriuria (ASB) is diagnosed when significant bacteriuria is not accompanied by signs and symptoms attributable to urinary tract infection (UTI).

EPIDEMIOLOGY

Incidence

• General population: 3.5%
• Pregnancy: 7–10%
• Older women: 16–18%

Prevalence

• Variable, increased with age, female gender, sexual activity, and presence of genitourinary (GU) abnormalities
• Pregnancy: 2–10%
• Short- and long-term indwelling catheter 9–23% and 100%, respectively
• Long-term care residents in women 25–50% and men 15–40%

ETIOLOGY AND PATHOPHYSIOLOGY

• Microbiology is similar to that of other UTI, with bacteria originating from periurethral area, vagina, or gut.
• Organisms are less virulent in ASB than those causing UTI.
• The most common organism is *Escherichia coli*. Other common organisms are *Klebsiella pneumonia*, *Enterobacter*, *Proteus mirabilis*, *Staphylococcus aureus*, group B *Streptococcus* (GBS), and *Enterococcus*.

Genetics

Genetic variations that reduce toll-like receptor-4 function (TLR4) have been associated with ASB by lowering innate immune response and delaying bacterial clearance.
RISK FACTORS
- Older age
- Female gender
- Sexual activity, use of diaphragm with spermicide
- GU abnormalities: neurogenic bladder, urinary retention, urinary catheter use (indwelling, intermittent, or condom catheter)
- Institutionalized residents
- Diabetes mellitus
- Immunocompromised status
- Spinal cord injuries or functional impairment
- Hemodialysis
- Pregnancy (decreased peristalsis of the urinary tract)

COMMONLY ASSOCIATED CONDITIONS
Depends on the risk factors

DIAGNOSIS

HISTORY
- Asymptomatic
- Lack of symptoms attributable to UTI such as fever, acute dysuria (<1 week), new or worsening urinary urgency/frequency/incontinence, or acute gross hematuria

PHYSICAL EXAM
- Afebrile
- No suprapubic and costovertebral angle tenderness

DIFFERENTIAL DIAGNOSIS
- UTI
- Contaminated urine specimen

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Urinalysis (UA):
  - The presence of pyuria, leukocyte esterase, and nitrite in ASB is common.
Urine culture

Screening urine culture in asymptomatic patients is indicated in only two conditions:

- Pregnancy: screening between 12 and 16 weeks’ gestation or at first prenatal visit if later (1)[A]
- Prior to transurethral resection of prostate (TURP) (1)[A] or any urologic interventions when mucosal bleeding is anticipated (1)[C]

Screening for ASB in men and nonpregnant women is not recommended.

Follow-Up Tests & Special Considerations

- Noncontaminated urine specimen should be used for urine culture.
- In pregnancy, periodic screening urine culture should be done after ASB treatment (1)[A] but not required in GBS bacteriuria (2,3)[C].

Test Interpretation

- Patient with significant bacteriuria with or without pyuria and without symptoms referable to UTI should be diagnosed as ASB per Infectious Diseases Society of America.
  - Significant bacteriuria is defined based on type of urine specimen, sex, and the amount of bacteria.
  - By midstream, clean catch specimen
    - Male: >100,000 CFU/mL of single bacteria species
    - Female: the same criteria as male but needs two positive consecutive specimens
    - By catheterized specimen male and female: >100 CFU/mL of one bacterial species. Required one-time collection only

- The presence of pyuria or leukocyte esterase is common but not a marker of infection.
- Positive nitrite is an indicator of the presence of bacteriuria, but cannot differentiate UTI from ASB or poor collection technique.

TREATMENT

GENERAL MEASURES

ALERT

- Antibiotic treatment of ASB is indicated in only two conditions:
- Pregnancy (1)[A]
  - Rationale: Treatment has been shown to significantly reduce the incidence of acute pyelonephritis and low birth weight.
- Prior to urologic procedure particularly TURP (1)[A]
  - Rationale: Antibiotic treatment can effectively prevent postprocedure bacteremia and sepsis.

Treatment of ASB in other conditions (nonpregnant women, diabetic women, indwelling catheter, patients with spinal cord injury, or the elderly living in the community) does not provide any known clinical benefit, does not reduce the risk of symptomatic infection, nor improve morbidity or mortality. It increases health care cost, adverse drug side effects, development of resistant organisms, and reinfection rate (1,4).

- Inadequate evidence to guide management in nonurologic procedure and solid organ transplant (1,4)

**MEDICATION**

**Pregnancy**
- Intrapartum antibiotic prophylaxis with IV penicillin or clindamycin (penicillin allergy) is recommended for women with GBS bacteriuria occurring at any stage of pregnancy and of any colony count to prevent GBS disease in the newborn (2)[C].

- No consensus on choice of antibiotics and duration of treatment in pregnancy; however, the cure rate is higher for the 4 to 7 days of treatment than 1-day treatment (1)[A].
- Choice of antibiotics should be guided by bacterial pathogen, local resistance rate, adverse effects, and comorbidities of patients (5).
- Common oral antibiotics (FDA-B) that have been used
  - Nitrofurantoin 100 mg BID for 5 days (low level of resistance, may cause hemolysis in glucose-6-phosphate dehydrogenase deficiency)
  - Amoxicillin/clavulanate 500/125 BID for 5 to 7 days
  - Cefuroxime 250 mg BID for 5 days
  - Cephalexin 500 mg BID for 5 days
  - Fosfomycin 3 g for 1 single dose (not effective when glomerular filtration rate is <30 mL/min, may be used in highly resistant bacteria such as methicillin-resistant *Staphylococcus aureus* [MRSA], vancomycin-resistant enterococci [VRE], and extended-spectrum beta-lactamase [ESBL]-producing organism bacteria) (6)
- Avoid trimethoprim in 1st trimester and near term. Avoid sulfa after 32 weeks’ gestation.
– Contraindicated: fluoroquinolones (FDA-C), tetracyclines (FDA-D)

Prior to invasive urologic interventions

– Initiate antibiotic the night before or immediately before the procedure (1) [A].
– Antibiotic should be continued until the indwelling catheter is removed postprocedure (1)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

No consensus on screening frequency of ASB in pregnancy, but monthly screening of urine culture after ASB treatment is recommended except GBS (1,2).

Patient Monitoring

Development of any signs/symptoms of UTI should warrant antibiotic treatment.

DIET

Daily cranberry juice may reduce the frequency of ASB during pregnancy, but it has not been confirmed in large study (see “Additional Reading”).

PATIENT EDUCATION

Patient should seek medical attention when UTI symptoms develop.

COMPLICATIONS

– Late pregnancy pyelonephritis occurs in 20–35% of women with untreated bacteriuria (20- to 30-fold higher than women with negative initial screening urine cultures or in whom bacteriuria was treated). Pyelonephritis is associated with premature delivery and worse fetal outcomes (infant with group B streptococcal infections, low-birth-weight infant). Antimicrobial treatment will decrease the risk of subsequent pyelonephritis from 20–35% to 1–4% and the risk of having a low-birth-weight baby from 15% to 5%.
– If bacteriuria remains untreated in patients who undergo traumatic urologic procedures, up to 60% develop bacteremia after the procedure and 5–10% progress to severe sepsis/septic shock.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- N39.0 Urinary tract infection, site not specified
- B96.20 Unsp Escherichia coli as the cause of diseases classd elswhr
- B96.1 Klebsiella pneumoniae as the cause of diseases classd elswhr
CLINICAL PEARLS

- ASB is a common and benign disorder for which treatment is not indicated in most patients.
- The presence of pyuria, leukocyte esterase, and nitrite is common in ASB and not an indication for antimicrobial treatment.
- Antibiotic treatment is indicated for ASB in pregnancy and patients who require urologic procedure in which mucosal bleeding is anticipated.
- Treatment of ASB in other conditions does not decrease the frequency of UTI or improve outcome.
- Overtreatment of ASB may result in negative consequences such as antimicrobial resistance, adverse drug reaction, and unnecessary cost.
BALANITIS, PHIMOSIS, AND PARAPHIMOSIS

John M. Doan, DO • Sarah S. Dolbear, MD

BASICS

DESCRIPTION

- Balanitis:
  - An inflammation of the glans penis
  - Posthitis is an inflammation of the foreskin.
  - Balanitis xerotica obliterans (BXO) is lichen sclerosus of the glans penis (uncommon).

- Phimosis and paraphimosis:
  - Phimosis: tightness of the distal penile foreskin that prevents it from being drawn back from over the glans
  - Paraphimosis: constriction by foreskin of an uncircumcised penis, preventing the foreskin from returning to its position over the glans; occurs after the retracted foreskin becomes swollen and engorged; a urologic emergency

- System(s) affected: renal/urologic; reproductive; skin/exocrine

ALERT

- Recurrent infection and irritations (condom catheters) can lead to phimosis.
- Recurrent balanitis, either chemical or infectious, can lead to an acquired phimosis.
- Inappropriate forced reduction of a physiologic foreskin can lead to chronic scarring and acquired phimosis; unfortunately, many times done due to instructions from health care providers
- Paraphimosis is a pediatric emergency; if left untreated, can lead to necrosis and autoamputation

EPIDEMIOLOGY

- Balanitis: predominant age: adult; predominant gender: male only
- Phimosis/paraphimosis: predominant age: infancy and adolescence; unusual in adults; risk returns in geriatrics; predominant sex: male only
Incidence
Balanitis: will affect 3–11% of males

Prevalence
Phimosis: in the United States: 8% of boys age 6 years and 1% of men >16 years of age (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- **Balanitis:**
  - Allergic reaction (condom latex, contraceptive jelly)
  - Infections (*Candida albicans, Borrelia vincentii, streptococci, Trichomonas, HPV*)
  - Fixed-drug eruption (sulfa, tetracycline)
  - Plasma cell infiltration (Zoon balanitis)
  - Autodigestion by activated pancreatic transplant exocrine enzymes

- **Phimosis:**
  - Physiologic: present at birth; resolves spontaneously during the first 2 to 3 years of life through nocturnal erections, which slowly dilate the phimotic ring
  - Acquired: recurrent inflammation, trauma, or infections of the foreskin

- **Paraphimosis:**
  - Often iatrogenically or inadvertently induced by the foreskin not being pulled back over the glans after voiding, cleaning, cystoscopy, or catheter insertion

Geriatric Considerations
Condom catheters can predispose to balanitis.

Pediatric Considerations
Oral antibiotics predispose male infants to *Candida balanitis*. Inappropriate care of physiologic phimosis can lead to acquired phimosis by repeated forced reduction of the foreskin.

RISK FACTORS

- **Balanitis:**
  - Presence of foreskin
  - Morbid obesity
  - Poor hygiene
– Diabetes; probably most common
– Nursing home environment
– Condom catheters
– Chemical irritants
– Edematous conditions: CHF, nephrosis

• Phimosis:
  – Poor hygiene
  – Diabetes by repeated balanitis
  – Frequent diaper rash in infants
  – Recurrent posthitis

• Paraphimosis:
  – Presence of foreskin
  – Inexperienced health care provider (leaving foreskin retracted after catheter placement)
  – Poor education about care of the foreskin

**GENERAL PREVENTION**

• Balanitis:
  – Proper hygiene and avoidance of allergens
  – Circumcision

• Phimosis/paraphimosis:
  – If the patient is uncircumcised, appropriate hygiene and care of the foreskin are necessary to prevent phimosis and paraphimosis.

**DIAGNOSIS**

**HISTORY**

• Balanitis:
  – Pain
  – Drainage
  – Dysuria
  – Odor
  – Ballooning of foreskin with voiding
  – Redness

• Phimosis:
  – Painful erections
  – Recurrent balanitis
– Foreskin balloons when voiding
– Inability to retract foreskin at appropriate age

**Paraphimosis:**
– Uncircumcised
– Pain
– Drainage
– Voiding difficulty

**PHYSICAL EXAM**

**Balanitis:**
– Erythema
– Tenderness
– Edema
– Discharge
– Ulceration
– Plaque

**Phimosis:**
– Foreskin will not retract.
– Secondary balanitis
– Physiologic phimosis—preputial orifice appears normal and healthy.
– Pathologic phimosis—preputial orifice has fine white fibrous ring of scar.

**Paraphimosis:**
– Edema of prepuce and glans
– Drainage
– Ulceration

**DIFFERENTIAL DIAGNOSIS**

**Balanitis:**
– Leukoplakia
– Lichen planus
– Psoriasis
– Reiter syndrome
– Lichen sclerosus et atrophicus
– Erythroplasia of Queyrat
– BXO: atrophic changes at end of foreskin; can form band that prevents retraction

**Phimosis/paraphimosis:**
– Penile lymphedema, which can be related to insect bites, trauma, or allergic reactions
• Penile tourniquet syndrome: foreign body around penis, most commonly hair
• Anasarca

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Microbiology culture
- Wet mount
- Serology for syphilis
- Serum glucose; ESR (if concerns about Reiter syndrome)
- STD testing
- HIV testing
- Gram stain

**Diagnostic Procedures/Other**
Biopsy, if persistent

**Pathological Findings**
Plasma cells infiltration with Zoon balanitis

**TREATMENT**

**GENERAL MEASURES**
- Consider circumcision for recurrent balanitis and paraphimosis.
- Warm compresses or sitz baths
- Local hygiene

**MEDICATION**
- Balanitis:
  - Antifungal:
    - Clotrimazole (Lotrimin) 1% BID
    - Nystatin (Mycostatin) BID–QID
    - Fluconazole: 150 mg PO single dose
  - Antibacterial:
    - Bacitracin QID
    - Neomycin–polymyxin B–bacitracin (Neosporin) QID
    - If cellulitis, cephalosporin or sulfa drug PO or parenteral:
- Dermatitis: topical steroids QID
- Zoon balanitis: topical steroids QID

**Phimosis:**
- 0.05% fluticasone propionate daily for 4 to 8 weeks with gradual traction placed on foreskin (2)[B]
- 1% pimecrolimus BID for 4 to 6 weeks; not for use in children <2 years (3)[C]

**Paraphimosis:**
- Manual reduction, if possible (should be done with the patient sedated). Place the middle and index fingers of both hands on the engorged skin proximal to the glans. Place both thumbs on glans and, with gentle pressure, push on the glans and pull on the foreskin to attempt reduction. If unsuccessful, a dorsal slit will be necessary, with eventual circumcision after the edema resolves.

**Osmotic agents:** granulated sugar placed on edematous tissue for several hours to reduce edema
**Puncture technique:** Multiple punctures of foreskin with a 21-gauge needle will allow edematous fluid to escape and thus allow reduction.
**Dorsal slit:** done by surgeon or urologist
**BXO:**
- 0.05% betamethasone BID
- 0.1% tacrolimus BID

### ISSUES FOR REFERRAL
Recurrent infections or development of meatal stenosis

### SURGERY/OTHER PROCEDURES
- Balanitis and phimosis: Consider circumcision as preventive measure.
- For paraphimosis:
  - Represents a true surgical emergency to avoid necrosis of glans
  - Dorsal slit with delayed circumcision, if reduction is not possible
  - Operative exploration if the possibility of penile tourniquet syndrome cannot be eliminated. Hair removal cream can be applied if a hair is thought to be the cause of the tourniquet.

### ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization
– Uncontrolled diabetes
– Sepsis

• Appropriate hygiene if condom catheters are used
• Discharge upon resolution of problem

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Balanitis:
• Every 1 to 2 weeks until etiology has been established
• Persistent balanitis may require biopsy to rule out malignancy or BXO.
• Evaluation for resolution of phimosis

DIET
Weight reduction, if obese

PATIENT EDUCATION
• Need for appropriate hygiene
• Appropriate foreskin care
• Avoidance of known allergens
• No sexual activity for 2 to 3 weeks after circumcision

PROGNOSIS
Should resolve with appropriate treatment

COMPLICATIONS
• Meatal stenosis
• Premalignant changes from chronic irritation
• UTIs
• Acquired phimosis
• Unreducible paraphimosis can lead to gangrene.
• Posthitis (inflammation of the prepuce)

REFERENCES
1. Oster J. Further fate of the foreskin. Incidence of preputial adhesions,

**ADDITIONAL READING**

**SEE ALSO**

Reactive Arthritis (Reiter Syndrome)

**CODES**

**ICD10**

- N48.1 Balanitis
- N47.1 Phimosis
- N48.0 Leukoplakia of penis
CLINICAL PEARLS

- Balanitis is an inflammation of the glans penis. Posthitis is an inflammation of the foreskin. BXO is lichen sclerosus of the glans penis.
- With recurrent infections and a plaque, a biopsy should be done to rule out BXO or malignancy.
- If there is a true phimosis that interferes with appropriate hygiene, treat the phimosis with steroids or circumcision to help with hygiene.
BARRETT ESOPHAGUS

Eric Ji-Yuan Mao, MD • Harlan G. Rich, MD, FACP, AGAF

BASICS

DESCRIPTION
- Metaplasia of the distal esophageal mucosa from native stratified squamous epithelium to abnormal columnar (intestinalized) epithelium, likely as a consequence of chronic GERD
- Predisposes to the development of adenocarcinoma of the esophagus

EPIDEMIOLOGY
- Predominant age: >50 years
- May occur in children (rare <5 years)

Incidence
- 10–15% of patients undergoing endoscopy for evaluation of reflux symptoms
- Esophageal adenocarcinoma incidence is rising in the United States (1). From 1975 to 2001, there was ~6-fold increase, from 4 to 23 cases/million person-years.
- Attributed to changes in smoking and obesity rather than reclassification or overdiagnosis

Prevalence
- Difficult to ascertain because of different populations studied, varying definitions, and asymptomatic cases
- As many as 1.5 to 2.0 million adults in the United States (extrapolated from a 1.6% prevalence in Swedish general population)

ETIOLOGY AND PATHOPHYSIOLOGY
- Chronic gastric reflux injures the esophageal mucosa, triggering columnar metaplasia. Refluxed bile acids likely induce differentiation in gastroesophageal junction (GEJ) cells.
- Columnar cells in the esophagus have higher malignant potential than squamous cells. Activation of CDX2 gene and overexpression of HER2/neu
(ERBB2) oncogene promotes carcinogenesis.
- Elevated levels of COX-2, a mediator of inflammation and regulator of epithelial cell growth, are associated with Barrett esophagus (BE) (1).
- Classic progression: normal epithelium $\rightarrow$ esophagitis $\rightarrow$ metaplasia (BE) $\rightarrow$ dysplasia (low- or high-grade) $\rightarrow$ adenocarcinoma

**Genetics**
- Familial predisposition to GERD and BE with multiple genetic markers have been identified.
- Acquired genetic changes lead to adenocarcinoma and are being investigated as biomarkers for risk stratification and early detection.

**RISK FACTORS**
- Chronic reflux (>5 years)
- Hiatal hernia
- Age >50 years
- Male gender
- White ethnicity—incidence in white males is much higher than white women and African American men.
- Smoking history
- Intra-abdominal obesity
- Family history—at least one first-degree relative with BE or esophageal adenocarcinoma

**GENERAL PREVENTION**
Weight loss, smoking cessation, robust intake of fruits and vegetables, and moderate wine consumption may decrease risk of BE and lower progression to esophageal cancer (1)[C].

**COMMONLY ASSOCIATED CONDITIONS**
GERD, obesity, hiatal hernia

**DIAGNOSIS**

**HISTORY**
- Assess underlying risk factors.
- Common GERD symptoms: heartburn, regurgitation
- Less common symptoms include chest pain, odynophagia, chronic cough, water brash, globus sensation, laryngitis, or wheezing.
- Symptoms suggestive of complicated GERD or cancer include weight loss, anorexia, dysphagia, odynophagia, hematemesis, or melena.

**ALERT**
Up to 25% of patients with BE are asymptomatic (1).

**PHYSICAL EXAM**
No abnormal findings on physical exam are specific for BE. A general examination should include vital signs, oral examination, cardiopulmonary examination, abdominal examination, and lymph node examination.

**DIFFERENTIAL DIAGNOSIS**
- Erosive esophagitis
- GERD

**DIAGNOSTIC TESTS & INTERPRETATION**
Endoscopy with multiple biopsies demonstrating intestinal metaplasia extending ≥1 cm proximal to the GEJ are required to diagnose BE.
- Gastric cardia–type epithelium on pathology does not have clear malignant significance and may reflect sampling error.
- Specialized intestinal metaplasia at the GEJ: cancer risk difficult to assess with varying definitions of GEJ landmarks

**ALERT**
- Endoscopic screening for BE is suggested in men with chronic GERD (>5 years) and/or frequent GERD symptoms with 2 or more risk factors: age >50 years; white ethnicity; central obesity, smoking history, family history of BE or esophageal adenocarcinoma.
- Screening for BE in the general population with GERD or women with GERD is not routinely recommended. Consider in women with multiple risk factors (2)[C].

**Initial Tests (lab, imaging)**
None:
- *Helicobacter pylori* testing is not indicated. Meta-analyses show an inverse relationship between *H. pylori* infections and BE, which may be related to
decreased acid production.

- No current biomarkers are effective for diagnosis; some under investigation for risk stratification (1)[B]

**Diagnostic Procedures/Other**

- Endoscopy: visual identification of columnar (reddish, velvety appearance) replacing squamous (pale, glossy appearance) lining of the distal esophagus
- White light endoscopy (preferably high resolution) is the standard for diagnosis.
- Disease extent: long-segment (≥3 cm) versus short-segment (<3 cm)
- The Prague classification is a consensus-driven grading system used to describe BE using landmarks of the squamocolumnar junction and GEJ. C is the circumferential extent of the columnar lining. M is the maximal proximal extent of columnar mucosa.
- Advanced imaging techniques, such as narrow band imaging (NBI) and confocal laser endomicroscopy, may help identify dysplasia (not in routine use).
- Systematic endoscopic biopsies confirm diagnosis:
  - Seattle protocol: four-quadrant biopsies at regular intervals with biopsies of visible mucosal irregularities; more time-consuming but higher diagnostic yield than random biopsies (1)[A]
  - Capsule endoscopy is still developing and has lower sensitivity than conventional endoscopy.

**Test Interpretation**

- Specialized intestinal metaplasia (also called specialized columnar epithelium) is diagnostic (3)[C].
- Diagnosis of dysplasia (and grade) should be confirmed by two gastrointestinal pathologists before treatment. Benign BE is established by a single pathologist report (3)[C].
- Cardia-type columnar epithelium may predispose to malignancy (unclear risk); International Consensus Group recommends defining BE by the presence of columnar mucosa in the esophagus (noting if intestinal metaplasia is present) (3)[C].
- If screening endoscopy reveals erosive esophagitis, repeat endoscopy after 8 to 12 weeks of proton pump inhibitor (PPI) therapy to exclude underlying BE; defer biopsies until healing occurs (2)[C].
**TREATMENT**

**ALERT**
Neither suppression of gastric acid production via high-dose PPIs nor reduction in esophageal acid exposure via antireflux surgery induces regression of BE. These therapies may, however, decrease cancer risk.

**MEDICATION**
- The goal of medical therapy is to control GERD to reduce esophagitis.
- Therapy usually does not result in reversal of BE but may decrease cancer risk (1)[A], (4)[B].

**First Line**
- Unlike the stepwise management of GERD without evidence of BE, patients with BE and GERD symptoms should be treated with a once-daily PPI.
- PPIs should be dosed 30 minutes before a meal (ideally, the first meal of the day).

**ALERT**
Titrate PPI therapy to symptoms; pH monitoring is **not** recommended (1)[C].

- Chemoprevention of neoplastic progression is under active investigation.
- Case-controlled studies have shown that aspirin and NSAIDs may prevent progression to esophageal cancer due to COX-2 inhibition:
  - COX-2 selective inhibitor celecoxib use not shown to affect progression of Barrett dysplasia to adenocarcinoma (1)[A]
  - Use of aspirin and a PPI for chemoprevention of esophageal cancer is under investigation (1).
  - Consider low-dose aspirin in patients with BE and risk factors for cardiovascular disease (1)[C].

- Statins, alone or in combination with aspirin or NSAIDs, appear to be effective in chemoprevention but are not yet routinely recommended (1)[B], (5)[A].

**Second Line**
If once-daily PPI does not control symptoms, move to twice-daily dosing (2)[A].

**ISSUES FOR REFERRAL**
- Initiate PPI therapy prior to endoscopy to reduce reactive esophagitis/atypia (2)[C].
- Refer patients considering esophagectomy to a high-volume institution.

**ADDITIONAL THERAPIES**
- Any combination of endoscopic mucosal resection (EMR) followed by photodynamic therapy (PDT), and radiofrequency ablation (RFA) to eliminate BE is considered “endoscopic eradication.”
- EMR: eradication rate 86–100%, excises to submucosa, allows staging, preferred for visible irregularities
- PDT: eradication rate 77–100%; strictures in 40%
- RFA: eradication rate 54–90%, comparable efficacy to PDT, fewer adverse effects
  - Focal EMR combined with RFA of other areas is considered most effective eradication therapy (1)[B].
  - Additional studies required before cryotherapy and other ablative procedures can be recommended.
- **BE with visible lesions:**
  - EMR with ablation if high-grade dysplasia or intramucosal cancer detected (3)[C]
- **Low-grade dysplasia**: Treatment is controversial.
  - Offer treatment such as RFA for low-grade dysplasia and high-risk features (multifocality, long segment length, persistence) (3)[C]. Endoscopic eradication may prevent progression to high-grade dysplasia or esophageal adenocarcinoma (1)[B],(6)[A].
  - Endoscopic eradication therapy is recommended for **high-grade dysplasia**, without or with very limited submucosal invasion (stage T1SM1 or lower) (1,4)[B].

**ALERT**
Endoscopic eradication not recommended for BE without dysplasia. Continue surveillance in these patients.

**SURGERY/OTHER PROCEDURES**
Antireflux surgery such as fundoplication may control GERD symptoms but are not convincingly shown to reverse BE, decrease risk of cancer, or be superior to medical therapy (1)[A].

**ALERT**
Available data suggest that antireflux surgery does not decrease risk of esophageal cancer.

- Esophagectomy is definitive and should be offered as an alternative to endoscopic eradication therapy for high-grade dysplasia (1)[B]:
  - Preferred for patients with evidence of submucosal invasion (stage T1SM2 or higher), or T1a patients with poor differentiation, lymphovascular invasion, or incomplete EMR
  - Added benefit of lymph node removal
  - Mortality rate: <5% in patients with high-grade dysplasia who are otherwise healthy
  - Serious postoperative complications: 30–50%
  - Should ideally be performed by an experienced surgeon in a high-volume center (1)[A]

COMPLEMENTARY & ALTERNATIVE MEDICINE

A prospective study of 339 men and women with BE found those taking either a multivitamin, vitamin C, or vitamin E once a day were less likely to develop esophageal adenocarcinoma.

Geriatric Considerations

Surveillance or no treatment may be preferable to endoscopic eradication therapy or esophagectomy in patients who are poor operative candidates.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Surveillance (to detect high-grade dysplasia or early carcinoma), although controversial, is recommended in patients with histologically confirmed BE—especially for those in high-risk groups.
- Surveillance intervals depend on the grade of dysplasia (1)[C].
- Patients diagnosed with BE on initial exam do not require endoscopy in 1 year (2)[C].
- No dysplasia: Survey every 3 to 5 years.
  - Discontinue surveillance if life expectancy is ≤5 years (3)[C].
- Low-grade dysplasia: Survey every 6 months.
– Routine surveillance if patients have confirmed absence of low-grade dysplasia after two consecutive endoscopies (3)[C]

- Indefinite for dysplasia: Repeat after 3 to 6 months of increased acid suppression, and if unchanged, survey every 12 months (3)[C].
- High-grade dysplasia without eradication therapy: Survey every 3 months; with eradication therapy: Survey every 3 months for 4, and then every 6 months for 2, then every 12 months.

**ALERT**
Adherence to recommended surveillance protocols may improve rates of dysplasia and cancer detection.

- Continue surveillance even if the patient has had endoscopic ablation therapy, antireflux surgery, or esophagectomy.

**DIET**
Avoid foods that can trigger reflux: caffeine, alcohol, chocolate, peppermint, carbonated drinks, garlic, onions, spicy foods, fatty foods, citrus, and tomato-based products.

**PATIENT EDUCATION**
- Lifestyle modifications: smoking cessation, weight loss, avoid supine position after meals, avoid tight-fitting clothes, elevate head of bed.
- No evidence that treating GERD reverses BE or prevents esophageal cancer.

**PROGNOSIS**
Annual incidence of esophageal cancer in patients with BE is ≤0.33% per year (1)[B]:

- Low-grade dysplasia: may be transient; cancer risk 0.5–0.6% per year
- High-grade dysplasia: cancer risk 5–7% per year
- Promising areas for future research include the use of biomarkers for risk stratification, chemoprevention of neoplastic progression, capsule endoscopy for screening, and the use of vitamins and antioxidants for prevention and treatment.

**COMPLICATIONS**
Same as GERD: stricture, bleeding, ulceration

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- K22.70 Barrett’s esophagus without dysplasia
- K22.719 Barrett’s esophagus with dysplasia, unspecified
- K22.710 Barrett’s esophagus with low grade dysplasia

**CLINICAL PEARLS**

mebooksfree.com
The incidence of esophageal cancer is rising faster than any other major malignancy. BE is a precursor for esophageal carcinoma.

- The highest incidence of BE is in white males >50 years of age.
- Endoscopic eradication therapy is preferred for high-grade dysplasia with or without submucosal invasion.
- Esophagectomy offers definitive therapy: Consider for all patients with high-grade dysplasia; preferred for patients with submucosal invasion.
BASAL CELL CARCINOMA
William Farkas, DO

BASICS

DESCRIPTION
Basal cell carcinoma (BCC) is the most common cancer, originating from the basal cell layer of the skin appendages.

- Rarely metastasizes but capable of local tissue destruction

Geriatric Considerations
Greater frequency in geriatric patients (Ages 55 to 75 years have 100 times the incidence when compared with those aged <20 years.)

Pediatric Considerations
- Rare in children, but childhood radiation treatment is contributory, as are frequent or severe sunburns.
- The Centers for Disease Control and Prevention recommends against using tanning beds and lamps in their guidelines for cancer prevention in school-age children.

EPIDEMIOLOGY
Worldwide, the most common form of cancer

Incidence
- Incidence in the United States: 1.2 million cases each year; 4 to 5 times more common than squamous cell carcinoma; Australia has highest incidence in the world.
- White people have a 1 in 5 chance of developing BCC during their lifetime.
- Predominant age: generally >40 years, although incidence increasing in younger populations
- Predominant sex: male > female (2:1 ratio)

ETIOLOGY AND PATHOPHYSIOLOGY
- UV-induced inflammation and cyclooxygenase activation in skin
- In chromosome 9q22, mutation of PTCH1 (patched homolog 1), a tumor-
suppressor gene that inhibits the hedgehog signaling pathway
- UV-induced mutations of the TP53 (tumor protein 53), a tumor-suppressor gene
- Activation of BCL2, an antiapoptosis proto-oncogene

**Genetics**
- Several genetic conditions increase the risk of developing BCC:
  - Albinism (recessive alleles)
  - Xeroderma pigmentosum (autosomal recessive)
  - Bazex syndrome (rare, X-linked dominant)
  - Nevoid BCC syndrome/Gorlin syndrome (rare, autosomal dominant)
  - Cytochrome P450 CYP2D6 and glutathione S-transferase detoxifying enzyme gene mutations (especially in truncal BCC, marked by clusters of BCCs and a younger age of onset)
  - Mutations in the tumor suppressor gene Patched, or activated mutations in Smoothened, resulting in upregulation of Hedgehog pathway signaling

**RISK FACTORS**
- Chronic sun exposure (UV radiation); most common in the following phenotypes:
  - Light complexion: skin type I (burns but does not tan) and skin type II (usually burns, sometimes tans)
  - Red or blond hair
  - Blue or green eyes
- Tendency to sunburn
- Male sex, although increasing risk in women due to lifestyle changes, such as tanning beds
- History of nonmelanoma skin cancer
  - After initial diagnosis of skin cancer, 35% risk of new nonmelanoma skin cancer at 3 years and 50% at 5 years
- Family history of skin cancer
- 3 to 4 decades after chronic arsenic exposure
- 2 decades after therapeutic radiation
- Chronic immunosuppression: transplant recipients (10 times higher incidence), patients with HIV, or lymphomas
- No significant association between age and recurrence rate, according to most studies
GENERAL PREVENTION

- Use broad-spectrum sunscreens of at least SPF 30 daily and reapply after swimming or sweating.
- Avoid overexposure to the sun by seeking shade between 10 AM and 4 PM and wearing wide-brimmed hats and long-sleeved shirts.
- The American Cancer Society recommends cancer-related checkups every 3 years in patients 20 to 40 years old and yearly in patients >40 years.

COMMONLY ASSOCIATED CONDITIONS

- Cosmetic disfigurement because head and neck most often affected
- Loss of vision with orbital involvement
- Loss of nerve function due to perineural spread or extensive and deep invasion
- Ulcerating neoplasms are prone to infections.

DIAGNOSIS

HISTORY
Exposure to risk factors, family history

PHYSICAL EXAM

- 80% on face and neck, 20% on trunk and lower limbs (mostly women)
- Nodular: most common (60%); presents as pinkish, pearly papule, plaque, or nodule, often with telangiectatic vessels, ulceration, and a rolled periphery, usually on face
  - Pigmented: presents as a translucent papule with “floating pigment”; more commonly seen in darker skin types; may give a blue, brown, or black appearance and be confused with melanoma
  - Superficial: 30%; light red, scaly plaque resembling eczema or psoriasis but with raised, pearly white borders similar to the nodular subtype, usually on trunk or extremities; least invasive of BCC subtypes
- Morpheaform: 5–10%; resembles localized scleroderma; mass is ill-defined and often extends beyond visible lesion.

DIFFERENTIAL DIAGNOSIS

- Sebaceous hyperplasia
- Epidermal inclusion cyst
- Intradermal nevi (pigmented and nonpigmented)
Molluscum contagiosum
Squamous cell carcinoma (SCC)
Nummular dermatitis
Psoriasis
Melanoma (pigmented lesions)
Atypical fibroxanthoma
Rare adnexal neoplasms

**DIAGNOSTIC TESTS & INTERPRETATION**

**Diagnostic Procedures/Other**
- Clinical diagnosis and histologic subtype are confirmed through skin biopsy and pathologic examination.
- Shave biopsy is typically sufficient; however, punch biopsy is more useful to assess depth of tumor and perineural invasion.
- If a genetic disorder is suspected, additional tests may be needed to confirm it.

**Test Interpretation**
- Nodular BCC
  - Extending from the epidermis are nodular aggregates of basaloid cells.
  - Tumor cells are uniform; rarely have mitotic figures; large, oval, hyperchromatic nuclei with little cytoplasm, surrounded by a peripheral palisade
  - Early lesions are usually connected to the epidermis, unlike late lesions.
  - Increased mucin in dermal stroma
    - Cleft formation (retraction artifact) common between BCC “nests” and stroma due to mucin shrinkage during fixation and staining
- Superficial BCC
  - Appear as buds of basaloid cells attached to undersurface of epidermis
  - Peripheral palisading
- Morpheaform BCC
  - Thin cords and strands of basaloid cells; embedded in dense, fibrous, scar-like stroma
  - Less peripheral palisading and retraction, greater subclinical involvement
- Infiltrating BCC
  - Like morpheaform BCC but no scar-like stroma and thicker, more spiky, irregular strands
  - Less peripheral palisading and retraction, greater subclinical involvement
- Micronodular BCC
– Small, nodular aggregates of tumor cells
– Less retraction artifact and higher subclinical involvement than nodular BCC

**TREATMENT**

**MEDICATION**

- May be especially useful in those who cannot tolerate surgical procedures and in those who refuse to have surgery as well as for low-risk superficial and/or nodular BCC
- 5-Fluorouracil (5-FU) cream inhibits thymidylate synthetase, interrupting DNA synthesis for superficial lesions in low-risk areas; primary treatment only; 5% applied BID for 3 to 10 weeks.
- Imiquimod (Aldara) cream approved for treatment of low-risk superficial BCC; daily dosing for 6 to 12 weeks; 90% histologic cure (1,2][A]
- 5-FU is not considered appropriate primary monotherapy for infiltrative or nodular BCC (1)[A]; however, with nodular BCC, imiquimod has been shown to have 5-year clearance rates ranging between 75% and 85% (3)[A].
- Topical treatment failure may yield skip lesions that yield false-negative margins, making Mohs and excisional surgery potentially less effective (1)[A].

**Emerging therapies:**

- Vismodegib, a sonic hedgehog pathway inhibitor; for patients with advanced BCC when other options are exhausted; not considered appropriate therapy for low-risk tumors (1)[A],(4)[B]; also beneficial for multiple BCC and BCC nevus syndrome (4)[A] Demonstrated success with this has led to research on other hedgehog inhibitor compounds, including sonidegib, which is approved for treatment of locally advanced BCC or those who are not candidates for surgery or RT (3).
- Intralesional IFN-a-2B injection: some efficacy for small (<1 cm) nodular and superficial BCCs; relatively high cost and frequent side effects (1)[A]
- Ingenol mebutate (IM): derived from the plant *Euphorbia peplus*; in one trial, 63% of lesions, significant histologic cure rates were seen 85 days after treatment, but long-term studies need to be conducted (3)[A].
- Laser therapy: Evidence for monotherapy is currently lacking in randomized controlled trials, but anecdotal evidence supports treatment for superficial BCC; in one RCT in which it was used as a pretreatment to
PDT, 1-year recurrence rates ranged from 1% to 8%, depending on the laser form used (3)[A].

ADDITIONAL THERAPIES

- Radiation therapy
  - Useful for patients, typically older, who cannot or will not undergo surgery (1)[C]
  - Used following surgery, particularly if margins of tumor were not cleared
  - Cure rate is ~90%.
  - Tumors that recur in areas previously treated with radiation are harder to treat, and the area is more difficult to reconstruct.
  - Local treatment
  - Recurrence rates are 7–8%.

- Photodynamic therapy (PDT)
  - Methyl aminolevulinate and 5-aminolevulinic acid, photosensitizers, are activated by specific wavelengths of light, creating singlet oxygen radicals that destroy local tissue (no damage to surrounding or deep tissues).
  - Decades old, well studied form of treatment currently approved in Canada, Europe, Australia, and New Zealand; off-label treatment for BCC in the United States (3)
  - Useful in areas where tissue preservation is cosmetically or functionally important; considered inferior to surgical excision in terms of efficacy (2)
  - More favorable for superficial versus nodular BCC (3)[A]

SURGERY/OTHER PROCEDURES

- Surgical excision is first-line treatment (4)[A]; specific treatment selection varies with extent and location of lesion as well as tumor border demarcation.

- High-risk areas
  - Inner canthus, nasolabial sulcus, philtrum, preauricular area, retroauricular sulcus, lip, temple, “mask areas” of the face (2)[C]

- Curettage and electrodesiccation
  - If nodular lesion <1 cm, in low-risk area, not deeply invasive
  - Avoid in the hair-bearing areas due to risk of the tumor extending down follicular structures.
  - 5-year cure rate of 92%; recurrence as high as 27% for high-risk lesions

- Excision with postoperative margin assessment
  - Treatment of choice for low-risk lesions <2 cm in diameter
- Goal is 4-mm margin.
- 5-year cure rate of 98%

**Cryosurgery**
- Reserved for nodular and superficial BCC, not indicated for tumors with depth exceeding 3 mm
- Typically for tumors with low risk of recurrence
- May want pre- and posttreatment biopsies (2)[C]
- Mean recurrence rates range from 3% to 4%.

**Mohs surgery**
- Preferred microsurgically controlled surgical treatment for lesions in high-risk areas, recurrent lesions, and lesions exhibiting an aggressive growth pattern (1,2)[A]
- Gold standard for maximizing tissue sparing for functional or cosmetic reasons (1)[A]
- 5-year survival rate of 99%
- Requires referral to appropriately trained dermatologic surgeon

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Outpatient, unless extensive lesion

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Seek shade, especially between 10 AM and 4 PM.
- Oral retinoids may prevent the development of new BCCs in patients with Gorlin syndrome, renal transplant recipients, and patients with severe actinic damage.

**Patient Monitoring**
- Every 6 to 12 months for first 5 years and then annually for life
- Increased risk of other skin cancers
- Recurrence:
  - Regional: surgery and/or radiation therapy
  - Metastatic: multidisciplinary tumor board consultation
PATIENT EDUCATION
- Teach patient-appropriate sun-avoidance techniques.
- Monthly skin self-exam
- Educate patients concerning adequate vitamin D intake. Use broad-spectrum UVA/UVB sunscreen SPF 15 or higher.
- Keep newborns out of the sun. Apply sunscreen to babies 6 months or older.

PROGNOSIS
- Proper treatment yields 90–95% cure.
- Most recurrences happen within 5 years. 56% of primary high-risk BCC are reported to recur >5 years postoperatively.
- Development of new BCCs: Many patients (30–50%) will develop a new lesion within 5 years.

COMPLICATIONS
- Local recurrence and spread
- Usually, recurrences will appear within 5 years.
- Metastasis: rare (<0.1%), but metastatic disease usually fatal within 8 months.

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**

- C44.91 Basal cell carcinoma of skin, unspecified
- C44.31 Basal cell carcinoma of skin of other and unspecified parts of face
- C44.41 Basal cell carcinoma of skin of scalp and neck

**CLINICAL PEARLS**

- BCC is the most common cancer, originating from the basal cell layer of the skin appendages.
- Nodular: pearly papule, plaque, or nodule often with telangiectatic vessels, ulceration, and a rolled periphery, usually on face
- Pigmented: presents as a translucent papule with “floating pigment”; more commonly seen in darker skin types
- Superficial: scaly papule or plaque with atrophic center, ringed by translucent micropapules, usually on trunk or extremities; more common in men
- Morpheaform: firm, smooth, flesh-colored, scar-like papule or plaque with ill-defined borders
- Use diagnostic keys above to differentiate between BCC and cutaneous SCC.
SCC arises from actinic keratosis in 60% of cases and generally presents as an asymptomatic hyperkeratotic lesion. If unsure, biopsy or refer to a specialist.

- Some hyperpigmented BCCs may appear similar to melanoma. Remember the ABCDEs of melanoma recognition: **Asymmetry**, **Border** irregularities, **Color** variability, **Diameter >6 mm**, **Enlargement**. If unsure, refer to a specialist.

- The USPSTF concludes insufficient evidence and recommends for or against routine total body skin exams for melanoma, BCC, or SCC. Exams should be based on risk factors, including exposure and family and prior medical history. All patients should receive education about risks and self-exam.
BED BUGS

Fawn J. Winkelman, DO • Adam Strosberg, DNP, ARNP-BC

BASICS

DESCRIPTION

- Nocturnal obligate blood parasites residing in furniture and bedding
- 5 to 7 mm oval, reddish brown, flat, wingless

EPIDEMIOLOGY

Incidence

- Bed bug infestations increasing and difficult to treat, more so than cockroaches, termites, and ants (1)[B]
- Resurgence due to changes in pesticide increased travel, use of secondhand furniture, and high turnover rates of hotel guests.

Prevalence

- Infestations are increasing across the United States.
- Bed bugs have increased 10–30% in public places (schools, hospitals, hotels/motels, aircrafts) over the past decade (2)[B].

ETIOLOGY AND PATHOPHYSIOLOGY

- Insect family Cimicidae
- Three species bite humans: Cimex lectularius, Cimex hemipterus, and Leptocimex boueti (2)[B].
- Most prevalent species is C. lectularius (2)[B].
- Found in tropical and temperate climates
- Hide in crevices of mattresses, box springs, headboards, and baseboards
- Infestations occur in hotels/motels, hospitals, cinemas, vehicles, aircraft, and homes.
- Reactions range from an absent or minimal response to the typical pruritic, erythematous maculopapular rash. Less commonly, there is an urticarial or anaphylactoid response.
- Skin reactions are due to host immunologic response to parasite salivary
Urticarial reactions are mediated via immunoglobulin (Ig) G antibody response to salivary proteins (3)[B].
Bullous reactions caused by an IgE-mediated hypersensitivity to nitrophorin in bug saliva (3)[B]
Bugs are attracted to body warmth and exhaled carbon dioxide (4).
Bites do not transmit other known pathogens.

GENERAL PREVENTION
Traps typically use carbon dioxide and heat to attract and trap bugs but can be cost prohibitive (5)[B].
Vector control: Vacuum regularly, reduce clutter, seal cracks in walls, inspect luggage and clothing.
Launder all bedding and clothing in >130°F (50°C) for 2 hours or place in 20°F (−5°C) or cooler environment for at least 5 days.
If present in the home, eradication using professional extermination services. Some pest control companies use canines to detect live bed bugs and eggs based on pheromones from the bed bugs (5)[B].

RISK FACTORS
- Immunocompromise
- High hotel turnover
- Secondhand furniture in home

DIAGNOSIS
HISTORY
- Recent travel
- Bed bug sighting; blood specks on sheets
- New skin lesions in the morning
- Intense pruritus, pain, or burning

PHYSICAL EXAM
- Characteristic lesions are erythematous pruritic papules in an irregular linear pattern.
- Found on body surfaces exposed during sleeping such as face, neck, arms, legs, and shoulders
May appear hours to days after being bitten
Patients are usually asymptomatic but may present with papular urticaria, diffuse urticaria, bullous lesions, and/or anaphylactoid symptoms.

**DIFFERENTIAL DIAGNOSIS**
- Urticaria; insect or spider bite; scabies
- Dermatitis herpetiformis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Skin scraping with mineral oil preparation
- Skin biopsy

**Test Interpretation**
- Skin scraping is negative with mineral oil, which helps to exclude scabies.
- Skin biopsy shows nonspecific perivascular eosinophilic infiltrate consistent with arthropod bite reaction.

**TREATMENT**

**GENERAL MEASURES**
- Self-limited and resolves within 1 to 2 weeks
- Treat symptomatically.
- Avoid and control bed bugs.

**MEDICATION**

**First Line**
- Disease is self-limited; treat symptoms.
- Oral antihistamines (i.e., diphenhydramine, hydroxyzine)
- Topical antipruritics (i.e., pramoxine/calamine ointment or doxepin cream)
- Topical low- to midpotency corticosteroids for 2 weeks (i.e., hydrocortisone, triamcinolone)
- Systemic corticosteroids (severe cases)

**ADDITIONAL THERAPIES**
- If secondarily infected, use topical or oral antibiotics against *Staphylococcus*
and *Streptococcus* spp. (i.e., cephalexin, tetracycline, doxycycline, clindamycin, topical mupirocin).
- Epinephrine for anaphylaxis
- Professional extermination may be necessary.

### ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS
- Not necessary as disease is self-limited
- May need specific care in extreme cases or if anaphylactoid reactions

### PATIENT EDUCATION
- Avoid scratching to prevent superinfection.
- Inspect bedding, furniture, and luggage regularly.
- CDC: [www.cdc.gov/parasites/bedbugs/](http://www.cdc.gov/parasites/bedbugs/)
- EPA: [http://www2.epa.gov/bedbugs](http://www2.epa.gov/bedbugs)
- Myth 1: *Bed bugs are invisible*. They are nocturnal and hide during the daytime. Adult bugs are ~1/4-inch long, and eggs are the size of a pin head.
- Myth 2: *Bed bugs reproduce rapidly*. Their life cycle is 4 to 5 weeks, longer than the house fly.
- Myth 3: *Bed bugs can live without feeding*. Bugs can live 3 to 5 months without a blood meal.
- Tips to prevent and control bed bugs
  - Ensure infestation is bed bugs (not fleas, other insects, and/or ticks).
  - Regularly wash and heat-dry your clothing and bedding, especially if it touches the floor.
  - EPA tips: [https://www.epa.gov/bedbugs/top-ten-tips-prevent-or-control-bed-bugs](https://www.epa.gov/bedbugs/top-ten-tips-prevent-or-control-bed-bugs)

### COMPLICATIONS
- Bed bug dermatitis, allergic reactions, asthma exacerbations, anaphylaxis
- Significant psychological distress (insomnia, depression, anxiety, delusional parasitosis) (3)
- Secondary bacterial infections
- Transmission of blood-borne diseases (rare)

### REFERENCES

**ADDITIONAL READING**

- Lancaster Extension Education Center: [http://lancaster.unl.edu/pest/bugs.shtml](http://lancaster.unl.edu/pest/bugs.shtml)
- National Pesticide Information Center: [http://npic.orst.edu/](http://npic.orst.edu/)

**CODES**

**ICD10**

- S00.96XA Insect bite (nonvenomous) of unspecified part of head, initial encounter
- S10.96XA Insect bite of unspecified part of neck, initial encounter
- S40.269A Insect bite (nonvenomous) of unspecified shoulder, initial encounter

**CLINICAL PEARLS**

- 90% of infestations occur within 3 feet of beds.
- Wash bedding/clothing regularly in hot water and vacuum carpet daily or steam clean daily.
- Inspect furniture, bedding, and luggage regularly.
- Bed bug have become resistant to over-the-counter (OTC) products (permethrin, cyfluthrin, bifenthrin, and deltamethrin or fluvalinate and esfenvalerate).
**BASES**

**DESCRIPTION**
Behavior that disrupts at least one area of psychosocial functioning. Commonly reported behavioral problems are as follows:

- **Noncompliance**: active or passive refusal to do as requested by parent or other authority figure
- **Temper tantrums**: loss of internal control provoked by overtiredness, physical discomfort, or fear that leads to crying, whining, breath-holding, or in extreme cases, aggressive behavior
- **Sleep problems**: sleep patterns that are distressing to caregivers or child; difficulty going to sleep or staying asleep at night, nightmares, and night terrors
- **Nocturnal enuresis**: enuresis that occurs only at night in children >5 years of age with no medical problems
  - Primary: children who have never been dry at night
  - Secondary: children dry at night for at least 6 months
- **Functional enuresis**: repeated involuntary fecal soiling that is not caused by organic defect or illness
- **Problem eating**: “picky eating,” difficult mealtime behaviors
- **Normative sexual behaviors**: developmentally appropriate behaviors in children in the absence of abuse
- **Thumb-sucking**: an innate reflex that is self-soothing; may be protective against sudden infant death. If persists, past eruption of primary teeth can affect teeth alignment and mouth shape.

**EPIDEMIOLOGY**

- Noncompliance issues: may manifest as children develop autonomy; males have a modestly greater likelihood of being noncompliant; decreases with age
- Temper tantrums: 70% of 18- to 24-month-old children; 7% of 3- to 5-year-old children; in children with severe tantrums, 52% have other behavioral/emotional problems (1).
- Sleep problems
- Night waking in 25–50% of infants 6 to 12 months; bedtime refusal in 10–30% of toddlers
- Nightmares in 10–30% of preschoolers; peaks between ages 6 and 10 years
- Night terrors in 1–6.5% early childhood; peaks between ages 4 and 12 years
- Sleepwalking frequently in 3–5%; peaks between ages 5 and 8 years
  - Nocturnal enuresis
    - At least 20% of children in the 1st grade wet the bed occasionally; 4% wet ≥2 times per week.
    - At 10 years of age, 9% in boys, 3% in girls
  - Functional encopresis
    - Rare before age 3 years, most common in 5- to 10-year-olds; more common in boys
  - Problem eating
    - Prevalence peaks at 50% at 24 months of age; no relation to sex/ethnicity/income
  - Normative sexual behaviors
    - Rare in infancy, except hand to genital contact
    - Increased in 3- to 5-year-olds; less observed in >5-year-olds because more covert
  - Thumb-sucking: decreases with age; most children spontaneously stop between 2 and 4 years.

**COMMONLY ASSOCIATED CONDITIONS**

- Noncompliance: If exceeds what seems normative, rule out depression, compulsive patterns, adjustment disorder, inappropriate discipline.
- Temper tantrums: difficult child temperament, stress
- Sleep problems: often with inconsistent bedtime routine or sleep schedule, stimulating bedtime environment; can be associated with hyperactive behavior, poor impulse control, and poor attention in young children. Acute or chronic anxiety is associated with insomnia. Long-acting stimulant medications disturb sleep quality.
- Enuresis: secondary often with medical problems, especially constipation, and frequent behavior problems, especially ADHD and autism
- Functional encopresis: enuresis, UTIs, ADHD
- Normative sexual behaviors: family stressors such as separation or divorce
HISTORY

- Noncompliance: complete history from caregivers and teachers, if applicable; direct observation of child or child–caregiver interaction
  - Criteria are problematic for at least some adults, leading to difficult interactions for at least 6 months.
  - Reduces child’s ability to take part in structured activities
  - Creates stressful relationships with compliant children
  - Disrupts academic progress; places child at risk for physical injury
- Temper tantrums: history, with focus on development, family functioning, or violence; may consist of stiffening limbs and arching back, dropping to the floor, shouting, screaming, crying, pushing/pulling, stamping, hitting, kicking, throwing, or running away (1)
- Sleep disorders: screening questions about sleep during well-child visit, such as the Bedtime problems, Excessive daytime sleepiness, Awakenings during the night, Regularity and duration of sleep, and Snoring (BEARS) screen; bedtime routine (2)[C]
- Nocturnal enuresis: severity, onset, and duration; daytime wetting or any associated genitourinary symptoms; family history of enuresis; medical and psychosocial history; constipation; child and caregiver’s motivation for treatment
- Problem eating: review of child’s diet, growth curves, nutritional needs, and caregiver’s response to behavior (5)[C]
- Normative sexual behaviors: When was behavior first noticed? Any recent changes or stressors in family? Behavior solitary or with another; if with another, what age? Changes in frequency or nature of behaviors; occurs at home, daycare, school? Is behavior disruptive, intrusive, or coercive? (See “Child Sexual Behavior Inventory” in the following discussion.)

PHYSICAL EXAM

- Nocturnal enuresis
  - Physical exam of abdomen for enlarged bladder, kidneys, or fecal masses; rectal exam if history of constipation; back for spinal dysraphism seen in dimpling or hair tufts
  - Neurologic exam: Focus on lower extremities.
  - Genitourinary exam
    - Males: meatal stenosis, hypospadias, epispadias, phimosis
    - Females: vulvitis, vaginitis, labial adhesions, ureterocele at introitus; wide vaginal orifice with scar or healed laceration may be evidence of
abuse.
- Functional encopresis
  - Height and weight; abdominal exam for masses or tenderness; rectal exam for tone, size of rectal vault, fecal impaction, masses, fissures, hemorrhoids; back for signs of spinal dysraphism seen in dimpling or hair tufts (4)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- For nocturnal enuresis: urinalysis (dipstick test OK); if abnormal, consider urine culture.
  - For secondary enuresis: serum glucose, creatinine, thyrotropin
  - Urinary tract imaging and urodynamic studies if significant daytime symptoms with history or diagnosis of UTI or history of structural renal abnormalities
- For functional encopresis: tests for hypothyroidism or celiac disease if poor growth or family history; urinalysis and culture if enuresis or features of UTI (4)
  - Spine imaging if evidence of spinal dysraphism or if both encopresis and daytime enuresis; barium enema if suspect Hirschsprung disease

**Follow-Up Tests & Special Considerations**
Sleep disorders: Sleep studies may be performed in children if there is a history of snoring and daytime ADHD-type symptoms (2).

**Diagnostic Procedures/Other**
- Child Sexual Behavior Inventory: completed by female caregiver to assist with differentiation of normative versus abnormal behaviors particularly those related to sexual abuse: http://www.nctsnet.org/content/child-sexual-behavior-inventory-csbi

**TREATMENT**
• General: Educate caregiver about specific behavioral problem.
• Parent management training programs and techniques are effective for many child behavior problems.
• Noncompliance: In the case of extreme child disobedience, consider parent training programs. Child may need to be formally screened for ADHD, obsessive-compulsive disorder (OCD), oppositional defiant disorder (ODD), or conduct disorder (CD).
• Temper tantrums: Remind caregiver this is a normal aspect of early childhood.
  – Educate caregiver that tantrums are not attention seeking, although they may reveal that the child needs more attention from caregiver. This attention should be developmentally appropriate and not occur when the child is tantruming but at other times and prior to the tantrum.
  – If tantrum is set off by external factors, such as hunger or overtiredness, then correct.
  – Other methods for dealing with a tantrum include one of the following:
    o Ignore the tantrum; remove the child and place him or her in time-out (1 minute for each year of age); hold/restrain child until calmed down; provide child with clear, firm, and consistent instructions as well as enough time to obey.
• Sleep problems: Intervention consists largely of education of the caregiver who may need a roadmap for dealing with this difficult and distressing problem. Developmental stages; environmental factors and cues; caregiver emotions and reactions; and child fears, stress, and habits are all important factors in sleep onset and maintenance that should be explored and explained to the caregiver.
• Specific recommendations may also consist of other interventions including the following (2)[A]:
  – Graduated extinction: Caregiver ignores cries for specified period; can check at a fixed time or increasing intervals
  – “Fading”: gradual decrease in direct contact with the child as child falls asleep; goal is for the caregiver to exit the room and allow child to fall asleep independently.
  – Consider the “5S Intervention” for settling problems in toddlers (used to comfort infants in nurseries): swaddling, sucking, shushing, stomach/side position, and swinging.
  – If fearful, preferred routines or inert sprays or glitter spread by the child (while avoiding the eyes) may help the child feel more secure.
• Nocturnal enuresis
  – Bedwetting alarm: first-line therapy for caregivers who can overcome
objection of having their sleep disturbed; about 2/3 of children respond while using the alarm; if enuresis recurs after use, it will often resolve with a second trial.

- Decrease fluids an hour before bedtime.
- Not as effective as bedwetting alarm but evidence for other behavioral intervention, including positive reinforcement (small reward for each dry night) or responsibility training (if developmentally able, child is responsible for changing or washing sheets), encouraging daily bowel movements, and frequent bladder emptying during the day (7)[A]

- **Functional encopresis**
  - First disimpaction: PO with polyethylene glycol solution or mineral oil; if unsuccessful, manual mineral oil enemas
  - Maintenance therapy
    - Medical: osmotics, such as polyethylene glycol, fiber, lactulose; stimulants, such as senna or bisacodyl
    - Behavior modification: toileting after meals for 10 minutes 2 to 3 times a day, star charts, and rewards (4)[C]

- **Problem eating**
  - Avoid punishment, prodding, or rewards. Offer a variety of healthy foods at every meal; limit milk to 24 oz/day and decrease juice (5)[C].

- **Normative sexual behavior**: No treatment needed; caregivers may need encouragement not to punish or admonish child and to use gentle distraction to redirect behavior when in public setting.

- **Thumb-sucking**: Recommendations to caregivers include praising children when not sucking their thumb, offer alternatives that are soothing (e.g., stuffed toys), provide reminders or negative reinforcement in the form of a bandage around or bitters on the thumb (5)[C].

**MEDICATION**

Most pediatric behavioral issues respond well to nonpharmacologic therapy:

- **Sleep disorders**
  - Insufficient efficacy data exists to recommend routine psychopharmacology. As in adults, cognitive-behavioral therapy and/or sleep hygiene should be first-line treatment.
  - For certain delayed sleep-onset disorders, after behavioral methods are exhausted, melatonin 0.5 to 10.0 mg PO can be tried while behavior modification is continued. Sleep latency is likely to be reduced. However, this is not approved by the FDA for children. Expect rebound insomnia.
Daytime exposure to bright or sunlight should be assured before treatment.

- **Nocturnal enuresis**
  - Desmopressin can decrease urine output to reduce enuresis episodes. Expect fewer episodes, not full cessation. Not before age 6 years; begin with 0.2 mg tablet nightly 1 hour before bedtime; titrate to 0.6 mg. However, use is questionable because its effects do not persist posttreatment. Intranasal formulations can cause severe hyponatremia, resulting in seizures and death in children (3).
  - Tricyclic antidepressants (e.g., imipramine) have been compared solely or in combination with desmopressin interventions, with similar outcomes to desmopressin (e.g., one fewer wet night in 7-night period). Effects are inferior to alarms, are short term and do not sustain post treatment (8)[A].
  - Behavioral interventions are more likely to sustain and should be first-line treatment.

**ISSUES FOR REFERRAL**

- A patient who exhibits self-injurious behaviors, slow recovery time from tantrums, more tantrums in the home than outside the home, or more aggressive behaviors toward others may require referral to a psychologist or psychiatrist.
- Children with chronic insomnia or anxiety that interferes with sleep should be referred to a psychologist or psychiatrist.
- A child with loud nightly snoring, with observed apnea spells, daytime excessive sleeping, and neurobehavioral signs such as mood changes, ADHD-like symptoms, or academic problems should be referred for sleep studies (2).
- With enuresis and obstructive sleep apnea symptoms, refer for sleep studies because surgical correction of airway obstruction often improves or cures enuresis and daytime wetting.
- Must distinguish sexual behavior problems: Developmentally inappropriate behaviors—greater frequency or earlier age than expected—becomes a preoccupation, recurs after adult intervention/corrective efforts. If abuse is not suspected, consider referral to a child psychologist. If abuse is suspected, must report to child protective services.
- If disimpaction by either manual or medical methods is unsuccessful, consult gastroenterology or general surgery. Patients who show no improvement after 6 months of maintenance medical therapy should be referred to gastroenterology (4).
- Thumb-sucking resistant to behavioral intervention and threatening oral development may be evaluated by a pediatric dentist for use of habit-breaking
ONGOING CARE

DIET
Nutrition is very important in behavioral issues. Avoiding high-sugar foods and caffeine and providing balanced meals have been shown to decrease aggressive and noncompliant behaviors in children.

PATIENT EDUCATION

REFERENCES

**CODES**

***ICD10***
- F91.9 Conduct disorder, unspecified
- F91.1 Conduct disorder, childhood-onset type
- F91.2 Conduct disorder, adolescent-onset type

**CLINICAL PEARLS**
- Well-child visits provide opportunities for systematic screening for these common conditions.
- Noncompliance: In extreme child disobedience, child may need to be screened for ADHD, OCD, ODD, or CD.
- Self-injurious behaviors, slow recovery time from tantrums, more tantrums in the home than outside the home, or more aggressive behaviors toward others may require referral to a psychologist or psychiatrist.
- Parental education, including a review of age-appropriate discipline, is a key component of treatment.
BELL PALSY
Assim AlAbdulKader, MD • Jason Chao, MD, MS

BASICS

DESCRIPTION
An acute, usually unilateral, peripheral facial nerve palsy of unknown etiology. Herpes-mediated viral inflammatory/immune mechanism is the likely cause of most cases, causing subsequent swelling and compression of cranial nerve VII (facial) and the associated vasa nervorum.

EPIDEMIOLOGY
- Affects 0.02% of the population annually
- No race, geographic, or gender predominance
- Median age of onset is 40 years but affects all ages.
- Accounts for about half of all cases of unilateral facial paralysis
- Occurs with equal frequency on the left and right sides of the face
- Most patients recover, but as many as 30% are left with facial disfigurement and pain.

Incidence
- 25 to 30 cases per 100,000 people in the United States per year
- Lowest in children ≤10 years of age; highest in adults ≥70 years of age
- Higher among pregnant women (3 times the risk)

Prevalence
Affects 40,000 Americans every year

ETIOLOGY AND PATHOPHYSIOLOGY
- Results from damage to the facial cranial nerve (VII)
- Exact pathogenesis is still controversial; infective, immune, and ischemic mechanisms are potential contributors.
- The most likely cause is activation of latent herpes virus (herpes simplex virus [HSV] type 1 and herpes zoster virus) in cranial nerve ganglia.
- Inflammation of cranial nerve VII causes swelling and subsequent compression and possibly demyelination of both the nerve and the associated
vasa nervorum.

- Ischemia from arteriosclerosis associated with diabetes mellitus

**Genetics**

May be associated with a genetic predisposition, but it remains unclear which factors are inherited

**RISK FACTORS**

- Pregnancy, especially in the 3rd trimester or in the 1st postpartum week
- Immunocompromised status
- Diabetes mellitus
- Age >30 years
- Exposure to cold temperatures
- Upper respiratory infection (e.g., coryza, influenza)
- Chronic HTN
- Obesity
- Migraine headache

**COMMONLY ASSOCIATED CONDITIONS**

- HSV
- Herpes zoster virus
- Lyme disease
- Diabetes mellitus
- Hypertension, Ramsay-Hunt syndrome
- Sjögren syndrome
- Sarcoidosis
- Eclampsia
- Amyloidosis

**DIAGNOSIS**

**HISTORY**

- Time course of the illness: rapid onset of sudden unilateral lower motor neuron-type facial weakness
- Peak of symptoms occur within 72 hours.
- Predisposing factors: recent viral infection, tick bite, trauma, new medications, hypertension, diabetes mellitus
- Associated symptoms (in 50–60% of cases):
  - Mastoid or postauricular pain
  - Hyperacusis: increased sensitivity to sounds (nerve to the stapedius muscle)
  - Dysgeusia: alteration of taste on the ipsilateral anterior 2/3 of the tongue (chorda tympani branch of the facial nerve)
  - Numbness on the ipsilateral side of the face
  - Skin rash (suggestive of herpes zoster, Lyme disease, or sarcoid)
  - Decreased lacrimation or salivation (parasympathetic effects)
  - Presence of hyperacusis or history of recurrent Bell palsy (both associated with poor prognosis)

**PHYSICAL EXAM**

- Neurologic
  - Determine if the weakness is caused by a problem in either the central or peripheral nervous systems.
  - Flaccid paralysis of muscles on the affected side, including the forehead
    - Impaired ability to raise the ipsilateral eyebrow
    - Impaired closure of the ipsilateral eye
    - Impaired ability to smile, grin, or purse the lips
    - Bell phenomenon: upward diversion of the eye with attempted closure of the lid
  - Patients may complain of numbness, but no deficit is present on sensory testing.
  - Examine for involvement of other cranial nerves.

- Head, ears, eyes, nose, and throat
  - Carefully examine to exclude a space-occupying lesion.
  - Perform pneumatic otoscopic exam.

- Skin: Examine for erythema migrans (Lyme disease) and vesicular rash (herpes zoster virus).

**DIFFERENTIAL DIAGNOSIS**

- Misdiagnosis is not uncommon (10.8%).
- Facial cranial nerve palsy etiologies include:
  - Congenital causes: genetic syndromes, birth-related trauma, developmental hypoplasia of facial muscles
  - Acquired causes: infective (HZV, Lyme, TB, HIV), inflammatory (vasculitis, sarcoidosis, autoimmune), neoplastic (benign, malignant), cerebrovascular (stroke, aneurysm), and traumatic

- Clinical approach based on facial palsy pattern (1)[B]:

mebooksfree.com
– Recurrent, ipsilateral palsy: neoplasm of the nerve (schwannoma), or adjacent structures (parotid, temporal bone, or cerebellopontine angle [CPA])
– Bilateral palsy: neurologic (Guillain-Barré syndrome), or associated with neoplasm (lymphoma, disseminated carcinomatosis, malignant pachymeningitis); rare: cryptococcal meningitis associated with HIV, autoimmune (MS, myasthenia gravis), sarcoid, Wegener
– Palsy at birth: segmental developmental palsy (associated with synkinesis, recovers spontaneously)
– Facial palsy syndromes: Ramsay-Hunt (rash in the ear [zoster oticus] and/or mouth caused by VZV); Melkersson-Rosenthal (orofacial edema, recurrent facial palsy, and fissured tongue); Heerfordt- Waldenström (parotid enlargement, anterior uveitis, facial palsy, and fever)

**DIAGNOSTIC TESTS & INTERPRETATION**

Bell palsy is a clinical diagnosis. However, further testing may be considered in:
- Atypical presentation of facial palsy
- Recurrent facial palsy
- Slowly progressive disease >3 weeks
- Lack of improvement after 4 months

**Initial Tests (lab, imaging)**
- Blood glucose level (if diabetes a consideration)
- Consider CBC, CRP/ESR
- Lyme serology: ELISA or IFA, followed by Western blot for IgM, IgG for *Borrelia burgdorferi*
- Consider rapid plasma reagin (RPR) test.
- Consider HIV test.
- Consider titers for VZV, rubella, cytomegalovirus, hepatitis A, hepatitis B, and hepatitis C.
- Salivary polymerase chain reaction (PCR) for HSV-1 or herpes zoster virus (mostly for research purposes)
- Procalcitonin level may predict severity and prognosis of Bell palsy (2)[C].

**Follow-Up Tests & Special Considerations**
- Trauma: facial radiographs to evaluate for fractures
- Contrast–enhanced CT: to evaluate for stroke and/or temporal bone fracture
- Contrast–enhanced MRI: to evaluate for brain and/or parotid neoplasms
Invasive diagnostic procedures are not indicated because biopsy could further damage the nerve.

**Diagnostic Procedures/Other**
- Electromyography (EMG)
- Nerve Conduction Study (NCS)
- Parotid gland biopsy: considered if no recovery with negative imaging at 7 months

**Test Interpretation**
Test results mainly help determine prognosis and surgical planning, if indicated.

**TREATMENT**

**GENERAL MEASURES**
- Artificial tears should be used to lubricate the cornea.
- The ipsilateral eye should be patched and taped shut at night to avoid drying and infection.

**MEDICATION**
- Corticosteroids decrease inflammation and limit nerve damage, thereby increase the number of patients who make full recovery and reduce disabling sequelae.
- Antiviral agents are less likely to produce full recovery than corticosteroids.

- The combination of corticosteroids and antivirals is more effective than corticosteroids alone for complete recovery (NNT=15) and for resolution of excessive tear production and motor dyskinesia (NNT=12) (3)[B].
- The use of antivirals alone is not recommended (3)[A].
- Corticosteroids:
  - Recommended in all Bell palsy cases (4,5)[A]
  - Should be started within 72 hours of symptoms onset
  - Prednisone 50 mg PO daily for 10 days, or prednisone 60 mg PO daily for the first 5 days, and then tapering dose (by 10 mg/day) the next 5 days. Both regimens are equally effective (5)[A].
  - Contraindications: documented hypersensitivity, preexisting infections (TB,
systemic mycosis)

- **Antivirals:**
  - Agents that target HSV-1 and VZV
  - Should not be used alone (3)[A], rather in combination with steroids (3)[B]
  - Valacyclovir has a higher bioavailability than acyclovir.
  - Valacyclovir 1,000 mg PO TID for 7 days
  - Precautions: Use with discretion in patients with chronic kidney disease.
  - Contraindications: documented hypersensitivity

**Pregnancy Considerations**
Steroids should be used cautiously during pregnancy; consult with an obstetrician. Acyclovir and valacyclovir are considered category B drugs in pregnancy by the U.S. FDA.

**ISSUES FOR REFERRAL**
Patients may need to be referred to an ear, nose, and throat specialist or a neurologist.

**ADDITIONAL THERAPIES**
- Physical therapy: insufficient evidence that physical therapy combined with drug treatment has positive effect on grade and time of recovery compared with drug treatment only (6)[A]
- Electrostimulation and mirror biofeedback rehabilitation have limited evidence of effect.
- Acupuncture with strong stimulation has shown some therapeutic promise but no clear recommendations.
- Routine use of eye-protective measures for patients with incomplete eye closure is recommended (4)[A].

**SURGERY/OTHER PROCEDURES**
- Surgical treatment of Bell palsy remains controversial and is reserved for intractable cases.
- There is insufficient evidence to decide whether surgical intervention is beneficial or harmful in the management of Bell palsy.
- In those cases where surgical intervention is performed, cranial nerve XII is surgically decompressed at the entrance to the meatal foramen where the labyrinthine segment and geniculate ganglion reside.
- Decompression surgery should not be performed >14 days after the onset of
paralysis because severe degeneration of the facial nerve is likely irreversible after 2 to 3 weeks.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Patients should start steroid treatment immediately and be followed for 12 months.
- Patients who do not recover complete facial nerve function should be referred to an ophthalmologist for tarsorrhaphy.

PATIENT EDUCATION
American Academy of Family Physicians:

PROGNOSIS
- Most patients achieve complete spontaneous recovery within 2 weeks. >80% recover within 3 months.
- 85% of untreated patients will experience the first signs of recovery within 3 weeks of onset.
- 16% are left with a partial palsy, motor synkinesis, and autonomic synkinesis.
- 5% experience severe sequelae, and a small number of patients experience permanent facial weakness and dysfunction.
- Poor prognostic factors include the following:
  - Age >60 years
  - Complete facial weakness
  - Hypertension
  - Ramsay-Hunt syndrome
- The Sunnybrook and House-Brackmann facial grading systems are clinical prognostic models that identify Bell palsy patients at risk for nonrecovery at 12 months.
- Treatment with corticosteroids and the Sunnybrook score are significant factors for predicting nonrecovery at 1 month.
- Patients with no improvement or progression of symptoms should be referred to ENT (4)[A] and may require neuroimaging to rule out neoplasms (4)[A].
COMPLICATIONS

- Corneal abrasion or ulceration
- Steroid-induced hyperglycemia, psychological disturbances; avascular necrosis of the hips, knees, and/or shoulders
- Steroid use can unmask subclinical infection (e.g., TB).

CODES

ICD10
G51.0 Bell’s palsy
CLINICAL PEARLS

- Initiate steroids immediately following the onset of symptoms.
- Look closely at the voluntary movement on the upper part of the face on the affected side; in Bell palsy, all of the muscles are involved (weak or paralyzed), whereas in a stroke, the upper muscles are spared (because of bilateral innervation).
- Protect the affected eye with lubrication and taping.
- In areas with endemic Lyme disease, Bell palsy should be considered due to Lyme disease until proven otherwise.
BIPOLAR I DISORDER
Wendy K. Marsh, MD, MSc

BASICS

DESCRIPTION
- Bipolar I (BP-I) is an episodic mood disorder of at least one manic or mixed (mania and depression) episode that causes marked impairment, psychosis, and/or hospitalization; major depressive episodes are not required but usually occur.
- Symptoms are not caused by a substance or general medical condition.

Geriatric Considerations
New onset in older patients (>50 years of age) requires a workup for organic or chemically induced pathology.

Pediatric Considerations
Diagnosis less well defined. For example, mood elevation symptoms overlap with those of ADHD.

Pregnancy Considerations
- Pregnancy does not reduce risk of mood episodes.
- Need to weigh risk of exposure to mood episode to that of medication
- Avoid divalproex due to high teratogenicity risk.
- Postpartum carries risk of severe acute episode with psychosis and/or infanticidal ideation.

EPIDEMIOLOGY
Onset usually between 15 and 30 years of age

Prevalence
- 1.0–1.6% lifetime prevalence
- Equal among men and women (manic episodes more common in men; depressive episodes more common in women)
- Equal among races; however, clinicians tend to diagnose schizoaffective in African Americans with BP-I.
ETIOLOGY AND PATHOPHYSIOLOGY
Genetic predisposition and major life stressors can trigger initial and subsequent episodes:
- Dysregulation of biogenic amines or neurotransmitters (particularly serotonin, norepinephrine, and dopamine)
- MRI findings suggest abnormalities in prefrontal cortical areas, striatum, and amygdala that predate illness onset (1)[C].

**Genetics**
- Monozygotic twin concordance 40–70%
- Dizygotic twin concordance 5–25%
- 50% have at least one parent with a mood disorder.
- First-degree relatives are 7 times more likely to develop BP-I than the general population.

**RISK FACTORS**
Genetics, major life stressors, or substance abuse

**GENERAL PREVENTION**
No known way to prevent onset, but treatment adherence and education can help to prevent relapses.

**COMMONLY ASSOCIATED CONDITIONS**
Substance abuse (60%), ADHD, anxiety disorders, and eating disorders

**DIAGNOSIS**
- The diagnosis of BP-I requires at least one manic or mixed episode (simultaneous mania and depression). Although a depressive episode is not necessary for the diagnosis, 80–90% of people with BP-I also experience depression.
- Manic episode, *DSM-5* criteria (2)
  - Distinct period of abnormally and persistently elevated, expansive, or irritable mood plus increased activity or energy for at least 1 week (or any duration if hospitalization is necessary)
  - During the period of mood disturbance, three or more of the “DIG FAST” symptoms must persist (four if the mood is only irritable) and must be
present to a significant degree.
  o Distractibility
  o Insomnia, decreased need for sleep
  o Grandiosity or inflated self-esteem
  o Flight of ideas or racing thoughts
  o Agitation or increase in goal-directed activity
  o Speech-pressed/more talkative than usual
  o Taking risks: excessive involvement in pleasurable activities that have a high potential for painful consequences (e.g., financial or sexual)
  – Mixed specifier: when three or more symptoms of opposite mood pole are present during primary mood episode, for example, mania with mixed features (of depression)

HISTORY
• Collateral information makes diagnostics more complete and is often necessary for a clear history.
• History: safety concerns (e.g., Suicidal/homicidal ideation? Safety plan? Psychosis present?), physical well-being (e.g., Number of hours of sleep? Weight change? Substance abuse?), personal history (e.g., Talkative? Risky driving? Excessive spending? Credit card debt? Promiscuity? Other risk-taking behavior? Legal trouble?)

PHYSICAL EXAM
• Mental status exam in acute mania
  – General appearance: bright clothing, excessive makeup, disorganized or discombobulated, psychomotor agitation
  – Speech: pressured, difficult to interrupt
  – Mood/affect: euphoria, irritability, expansive, labile
  – Thought process: flight of ideas (streams of thought occur to patient at rapid rate), easily distracted
  – Thought content: grandiosity, paranoia, hyperreligious
  – Perceptual abnormalities: 3/4 of manic patients experience delusions, grandiose, or paranoia.
  – Suicidal/homicidal ideation: aggression toward self or others; suicidal ideation is common with mixed episode.
  – Insight/judgment: poor/impaired
• See “Bipolar II Disorder” for an example of a mental status exam in depression.
• With mixed episodes, patients may exhibit a combination of manic and
depressive mental states.

**DIFFERENTIAL DIAGNOSIS**
- Other psychiatric considerations: unipolar depression ± psychotic features, schizophrenia, schizoaffective disorder, personality disorders (particularly antisocial, borderline, histrionic, and narcissistic), ADD ± hyperactivity, substance-induced mood disorder
- Medical considerations: epilepsy (e.g., temporal lobe), brain tumor, infection (e.g., AIDS, syphilis), stroke, endocrine (e.g., thyroid) disease, multiple sclerosis
- In children, consider ADHD and ODD.

**DIAGNOSTIC TESTS & INTERPRETATION**
- BP-I is a clinical diagnosis.
- The Mood Disorder Questionnaire is a self-assessment screen for bipolar disorders (sensitivity 73%, specificity 90%) (3).
- Patient Health Questionnaire-9 helps to determine the presence and severity of a depressive episode.

**Initial Tests (lab, imaging)**
- TSH, CBC, BMP, LFTs, ANA, RPR, HIV, ESR
- Drug/alcohol screen with each presentation
- Dementia workup if new onset in elderly
- Consider brain imaging (CT, MRI) with initial onset of mania to rule out organic cause (e.g., tumor, infection, or stroke), especially with onset in elderly and if psychosis is present.

**Diagnostic Procedures/Other**
Consider EEG if presentation suggests temporal lobe epilepsy (hyperreligiosity, hypergraphia).

**TREATMENT**
- Ensure safety.
- Psychotherapy (e.g., cognitive-behavioral therapy, social rhythm therapy, educational)
- Stress reduction
- Patient and family education
GENERAL MEASURES
- Psychotherapy for depression (e.g., cognitive-behavioral therapy, social rhythm, interpersonal) in conjunction with medications
- Regular daily schedule, exercise, a healthy diet, and sobriety

MEDICATION
- Acute mania
  - First line
    - Lithium monotherapy (see lithium)
    - Aripiprazole, asenapine, quetiapine, risperidone, or ziprasidone monotherapy (see atypicals)
    - Divalproex (see antiseizure)
    - Olanzapine or haloperidol*
    - Lithium or divalproex plus haloperidol or olanzapine*
  - Second line
    - Lithium plus divalproex
    - Lithium or divalproex plus atypical (nonclozapine)
    - Paliperidone
    - Carbamazepine
- Acute bipolar depression
  - First line
    - Quetiapine monotherapy (see atypicals)
    - Lurasidone monotherapy (see atypicals)
    - Lurasidone or quetiapine adjunctive to lithium or divalproex
    - Olanzapine* (see atypicals) + fluoxetine
  - Second line
    - Lithium
    - Lamotrigine (see antiseizure)
    - Lamotrigine adjunctive to Lithium
    - Two drug combination of above of different classes (i.e., not two atypicals)
- *Side effects concerns: Weight gain, metabolic syndrome and extrapyramidal symptoms (EPS) warrant vigilance and monitoring by the clinician.
- Treatment mood stabilizer(s) or other psychotropic medications. When combining, use different classes (e.g., an atypical antipsychotic and/or an antiseizure medication and/or lithium).
  - Lithium (Lithobid, Eskalith, generic): dosing: 600 to 1,200 mg/day divided BID–QID; start 600 to 900 mg/day divided BID–TID, titrate based on
blood levels. *Warning:* caution in kidney and heart disease; use can lead to diabetes insipidus or thyroid disease. Caution with diuretics or ACE inhibitors; dehydration can lead to toxicity (seizures, encephalopathy, arrhythmias). Pregnancy Category D (Ebstein anomaly). *Monitor:* Check ECG >40 years, TSH, BUN, creatinine, electrolytes at baseline and every 6 months; check level 5 to 7 days after initiation or dose change, then every 2 weeks × 3, and then every 3 months (goal: 0.8 to 1.2 mmol/L).

- **Antiseizure medications**
  - Divalproex sodium, valproic acid (Depakote, Depakene, generic): dosing: start 250 to 500 mg BID–TID; maximum 60 mg/kg/day. Black box warnings: hepatotoxicity, pancreatitis, thrombocytopenia, pregnancy Category D. Monitor CBC and LFTs at baseline and every 6 months; check level 5 days after initiation and dose changes (goal: 50 to 125 μg/mL).
  - Carbamazepine (Equetro, Tegretol, generic): dosing: 800 to 1,200 mg/day PO divided BID–QID; start 100 to 200 mg PO BID and titrate to lowest effective dose. *Warning:* Do not use with TCA or within 14 days of an MAOI. Caution in kidney/heart disease; risk of aplastic anemia/agranulocytosis, enzyme inducer; pregnancy Category D. Monitor CBC and LFTs at baseline and every 3 to 6 months; check level 4 to 5 days after initiation and dose changes (goal: 4 to 12 μg/mL).
  - Lamotrigine (Lamictal, generic): dosing: 200 to 400 mg/day; start 25 mg/day for 2 weeks, then 50 mg/day for 2 weeks, then 100 mg/day for 1 week, and then 150 mg/day. (Note: Use different dosing if adjunct to valproate.) *Warning:* Titrate slowly (risk of Stevens-Johnson syndrome); caution with kidney/liver/heart disease; pregnancy Category C
  - Oxcarbazepine (Trileptal) dosing: 300 mg PO QD. Titrate to 1,800 to 2,400/day max.

- **Atypical antipsychotics**
  - Side effects: orthostatic hypotension, metabolic side effects (glucose and lipid dysregulation, weight gain), tardive dyskinesia, neuroleptic malignant syndrome (NMS), prolactinemia (except Abilify), increased risk of death in elderly with dementia-related psychosis, pregnancy Category C
  - Monitor LFTs, lipids, glucose at baseline, 3 months, and annually; check for EPS with Abnormal Involuntary Movement Scale (AIMS) and assess weight (with abdominal circumference) at baseline; at 4, 8, and 12 weeks; and then every 3 to 6 months; monitor for orthostatic hypotension 3 to 5 days after starting or changing dose.
  - Aripiprazole (Abilify): dosing: 15 to 30 mg/day; less likely to cause metabolic side effects
- Asenapine: dosing: 5 to 10 mg sublingual BID
- Cariprazine: dosing: 1.5 mg/day only for depression; 3 to 6 mg/day mood elevation
- Lurasidone: dosing: 20 to 60 mg/day; FDA-approved for bipolar depression
- Olanzapine (Zyprexa, Zydis, generic): dosing: 5 to 20 mg/day; most likely to cause metabolic side effects (weight gain, diabetes)
- Paliperidone dosing: 6 mg/AM; may cause agranulocytosis, cardiac arrhythmias
- Quetiapine (Seroquel, Seroquel XR, generic): dosing: in mania, 200 to 400 mg BID; in bipolar depression, 50 to 300 mg QHS; XR dosing 50 to 400 mg QHS
- Risperidone (Risperdal, Risperdal Consta, generic): dosing: 1 to 6 mg/day divided QD–QID; IM preparation available (q2wk)
- Ziprasidone (Geodon): dosing: 40 to 80 mg BID; less likely to cause metabolic side effects. Caution: QTc prolongation (>500 ms) has been associated with use (0.06%). Consider ECG at baseline.

- Unipolar antidepressants
  - There is inadequate information to recommend in bipolar disorder. If used (for example for anxiety), antimanic agent is essential.

- Avoid
  - Tricyclic antidepressants (TCAs) and serotonin norepinephrine reuptake inhibitor (SNRI); increases mood cycling risk.

**ISSUES FOR REFERRAL**
- Refer to psychiatry, depends on knowledge level of the doctor, stability of patient.
- Patients benefit from a multidisciplinary team, including a primary care physician, psychiatrist, and therapist.

**ADDITIONAL THERAPIES**
- Electroconvulsive therapy can be helpful in acute or treatment-resistant mania and depression.
- Modest evidence supports transcranial magnetic stimulation, vagus nerve stimulation, ketamine infusion, sleep deprivation, and hormone therapy (e.g., thyroid) in bipolar depression.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
• Admit if dangerous to self or others.
• To admit involuntarily, the patient must have a psychiatric diagnosis (e.g., BP-I) and present a danger to self or others, or the mental disease must be inhibiting the person from obtaining basic needs (e.g., food, clothing).
• Nursing: Alert staff to potentially dangerous or agitated patients. Acute suicidal threats need continuous observation.
• Discharge criteria determined by safety

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
• Regularly scheduled visits support adherence with treatment.
• Frequent communication among primary care doctor, psychiatrist, and therapist

Patient Monitoring
Mood charts are helpful to monitor symptoms.

PATIENT EDUCATION
• National Alliance on Mental Illness (NAMI): http://www.nami.org/
• National Institutes of Mental Health (NIMH):
• Depression and Bipolar Support Alliance (DBSA): http://www.dbsalliance.org

PROGNOSIS
• Frequency and severity of episodes are related to medication adherence, consistency with therapy, quality of sleep, and support systems.
• 40–50% of patients experience another manic episode within 2 years of first episode.
• 25–50% attempt suicide, and 15% die by suicide.
• Substance abuse, unemployment, psychosis, depression, and male gender are associated with a worse prognosis.

**CLINICAL PEARLS**

- BP-I is characterized by at least one manic or mixed episode that causes marked impairment, major depressive episodes usually occur but are not necessary.
- 25–50% of BP-I patients attempt suicide, and 15% die by suicide.
- There is no known way to prevent BP-I, but treatment adherence and education helps reduce further episodes.
- Goal of treatment is to decrease the intensity, length, and frequency of
episodes as well as greater mood stability between episodes.
BASICS

DESCRIPTION
Bipolar II (BP-II) is a mood disorder characterized by at least one episode of major depression (with or without psychosis) and at least one episode of hypomania, a nonsevere mood elevation.

Geriatric Considerations
New onset in older patients (>50 years) requires a workup for organic or chemically induced pathology.

Pediatric Considerations
Diagnosis less well defined

Pregnancy Considerations
- Pregnancy does not reduce risk of mood episodes.
- Need to weigh risk of exposure to mood episode to that of medication
- Avoid divalproex due to high teratogenicity risk.
- Postpartum caries risk of severe acute episode with psychosis and/or infanticidal ideation.

EPIDEMIOLOGY
Onset usually between 15 and 30 years of age

Prevalence
- 0.5–1.1% lifetime prevalence
- More common in women

ETIOLOGY AND PATHOPHYSIOLOGY
Dysregulation of biogenic amines or neurotransmitters (particularly serotonin, norepinephrine, and dopamine)

Genetics
Heritability estimate: >77%

RISK FACTORS
Genetics, major life stressors, or substance abuse

GENERAL PREVENTION
No known way to prevent onset, but treatment adherence and education can help to prevent further episodes.

COMMONLY ASSOCIATED CONDITIONS
Substance abuse or dependence, ADHD, anxiety disorders, and eating disorders

DIAGNOSIS

- **DSM-5 criteria:** one hypomanic episode and at least one major depressive episode. The symptoms cause unequivocal change in functioning noticed by others but not severe enough to cause marked impairment (1)[C].
- Hypomania is a distinct period of persistently elevated, expansive, or irritable mood, different from usual euthymic mood, including increase in activity or energy lasting at least 4 days:
  - The episode must include at least three of the “DIG FAST” symptoms plus *increased energy* below (four if the mood is only irritable):
    - Distractibility
    - Insomnia, decreased need for sleep
    - Grandiosity or inflated self-esteem
    - Flight of ideas or racing thoughts
    - Agitation or increase in goal-directed activity (socially, at work or school, or sexually)
    - Speech-pressured/more talkative than usual
    - Taking risks: excessive involvement in pleasurable activities that have high potential for painful consequences (e.g., sexual or financial)
- Major depression
  - Depressed mood or diminished interest and four or more of the “SIG E CAPS” symptoms are present during the same 2-week period:
    - Sleep disturbance (e.g., trouble falling asleep, early-morning awakening)
    - Interest: loss or anhedonia
    - Guilt (or feelings of worthlessness)
    - Energy, loss of
o Concentration, loss of
o Appetite changes, increase or decrease
o Psychomotor changes (retardation or agitation)
  o Suicidal/homicidal thoughts
    – Rapid cycling is ≥4 mood episodes in 12 months (major depression or hypomania).
    – Mixed specifier: when three or more symptoms of opposite mood pole are present during primary mood episode, for example, hypomania with mixed features (of depression)
  • Note: If symptoms have ever met criteria for a full manic episode or hospitalization was necessary secondary to manic/mixed symptoms or psychosis was present, then the diagnosis is BP-I.

HISTORY
• Collateral information makes diagnostics more complete and is often necessary for a clear history.
• History: safety concerns (e.g., Suicidal/homicidal ideation? Safety plan? Psychosis present?), physical well-being (e.g., Number of hours of sleep? Substance abuse?), personal history (e.g., Risky driving? Excessive spending? Credit card debt? Promiscuity? Other risk-taking behavior? Legal trouble?)

PHYSICAL EXAM
• Mental status exam in hypomania
  – General appearance: usually appropriately dressed, with psychomotor agitation
  – Speech: may be pressured, talkative, difficult to interrupt
  – Mood/affect: euphoria, irritability/congruent, or expansive
  – Thought process: may be easily distracted, difficulty concentrating on one task
  – Thought content: usually positive, with “big” plans
  – Perceptual abnormalities: none
  – Suicidal/homicidal ideation: low incidence of homicidal or suicidal ideation
  – Insight/judgment: usually stable/may be impaired by their distractibility
• Mental status exam in acute depression
  – General appearance: unkempt, psychomotor retardation, poor eye contact
  – Speech: low, soft, monotone
  – Mood/affect: sad, depressed/congruent, flat
  – Thought process: ruminating thoughts, generalized slowing
  – Thought content: preoccupied with negative or nihilistic ideas
– Perceptual abnormalities: 15% of depressed patients experience hallucinations or delusions.
– Suicidal/homicidal ideation: Suicidal ideation is very common.
– Insight/judgment: often impaired

DIFFERENTIAL DIAGNOSIS

- Other psychiatric considerations
  – BP-I disorder, unipolar depression, personality disorders (particularly borderline, antisocial, and narcissistic), ADD with hyperactivity, substance-induced mood disorder
- Medical considerations
  – Epilepsy (e.g., temporal lobe), brain tumor, infection (e.g., AIDS, syphilis), stroke, endocrine (e.g., thyroid disease), multiple sclerosis

DIAGNOSTIC TESTS & INTERPRETATION

- BP-II is a clinical diagnosis.
- Mood Disorder Questionnaire, self-assessment screen for BP, sensitivity 73%, specificity 90% (2)[B]
- Hypomania Checklist-32 distinguishes between BP-II and unipolar depression (sensitivity 80%, specificity 51%) (3)[B].
- Patient Health Questionnaire-9 helps to determine the presence and severity of depression.

Initial Tests (lab, imaging)

- Rule out organic causes of mood disorder during initial episode.
- Drug/alcohol screen is prudent with each presentation.
- Dementia workup if new onset in elderly
- With initial presentation: Consider CBC, chem 7, TSH, LFTs, ANA, RPR, HIV, and ESR.
- Consider brain imaging (CT, MRI) with initial onset of hypomania to rule out organic cause, especially with onset in the elderly.

TREATMENT

- Ensure safety.
- Medication management
- Psychotherapy (e.g., cognitive-behavioral therapy [CBT], social rhythm therapy, educational therapy)
• Stress reduction
• Patient and family education
• Refer to psychiatrist.

**GENERAL MEASURES**
• Psychotherapy (e.g., CBT, social rhythm, interpersonal, family focused) in conjunction with medications
• Regular daily schedule, exercise, a healthy diet, and sobriety have been shown to help.

**MEDICATION**
• Acute mood elevation
  – First line
    o Atypical: aripiprazole, asenapine, quetiapine, risperidone, or ziprasidone monotherapy (see atypicals)
    o Lithium monotherapy (see lithium)
    o Divalproex (see antiseizure)
    o Olanzapine or haloperidol
    o Lithium or divalproex plus haloperidol or olanzapine
  – Second line
    o Lithium plus divalproex
    o Lithium or divalproex plus atypical (nonclozapine)
    o Paliperidone
    o Carbamazepine
• Acute bipolar depression
  – First line
    o Quetiapine monotherapy (see atypicals)
    o Lurasidone monotherapy (see atypicals)
    o Lurasidone or quetiapine adjunctive to lithium or divalproex
    o Olanzapine (see atypicals) + fluoxetine
  – Second line
    o Lithium
    o Lamotrigine (see antiseizure)
    o Lamotrigine adjunctive to lithium
    o Two drug combination of above of different classes (i.e., not two atypicals)
• Side effects concerns: Weight gain, metabolic syndrome, and extrapyramidal symptoms (EPS) warrant vigilance and monitoring by the clinician.
• Treatment mood stabilizer(s) or other psychotropics medications. When
combining, use different classes (e.g., an atypical antipsychotic and/or an antiseizure medication and/or lithium).

- **Lithium** (*Lithobid, Eskalith, generic*): dosing: 600 to 1,200 mg/day divided BID–QID; start 600 to 900 mg/day divided BID–TID, titrate based on blood levels. *Warning*: caution in kidney and heart disease; use can lead to diabetes insipidus or thyroid disease. Caution with diuretics or ACE inhibitors; dehydration can lead to toxicity (seizures, encephalopathy, arrhythmias). Pregnancy Category D (Ebstein anomaly). *Monitor*: Check ECG >40 years, TSH, BUN, creatine, electrolytes at baseline and every 6 months; check level 5 to 7 days after initiation or dose change, then every 2 weeks × 3, and then every 3 months (goal: 0.8 to 1.2 mmol/L).

- **Antiseizure medications**
  - Divalproex sodium, valproic acid (*Depakote, Depakene, generic*): dosing: Start 250 to 500 mg BID–TID; maximum 60 mg/kg/day. Black box warnings: hepatotoxicity, pancreatitis, thrombocytopenia, pregnancy Category D. Monitor CBC and LFTs at baseline and every 6 months; check level 5 days after initiation and dose changes (goal: 50 to 125 μg/mL).
  - Carbamazepine (*Equetro, Tegretol, generic*): dosing: 800 to 1,200 mg/day PO divided BID–QID; start 100 to 200 mg PO BID and titrate to lowest effective dose. *Warning*: Do not use with tricyclic antidepressants (TCAs) or within 14 days of monoamine oxidase inhibitor (MAOI). Caution in kidney/heart disease; risk of aplastic anemia/agranulocytosis, enzyme inducer; pregnancy Category D. Monitor CBC and LFTs at baseline and every 3 to 6 months; check level 4 to 5 days after initiation and dose changes (goal: 4 to 12 μg/mL).
  - Lamotrigine (*Lamictal, generic*): dosing: 200 to 400 mg/day; start 25 mg/day for 2 weeks, then 50 mg/day for 2 weeks, then 100 mg/day for 1 week, then 150 mg/day. (Note: Use different dosing if adjunct to valproate.) *Warning*: Titrate slowly (risk of Stevens-Johnson syndrome); caution with kidney/liver/heart disease; pregnancy Category C.
  - Oxcarbazepine (*Trileptal*): dosing: 300 mg PO QD. Titrate to 1,800 to 2,400/day max.

- **Atypical antipsychotics**
  - Side effects: orthostatic hypotension, metabolic side effects (glucose and lipid dysregulation, weight gain), tardive dyskinesia, neuroleptic malignant syndrome (NMS), prolactinemia (except Abilify), increased risk of death in elderly with dementia-related psychosis, pregnancy Category C
  - Monitor LFTs, lipids, glucose at baseline, 3 months and annually; check for EPS with Abnormal Involuntary Movement Scale (AIMS) and assess
weight (with abdominal circumference) at baseline, at 4, 8, and 12 weeks and then every 3 to 6 months; monitor for orthostatic hypotension 3 to 5 days after starting or changing dose.

- Aripiprazole (Abilify): dosing: 15 to 30 mg/day; less likely to cause metabolic side effects
- Asenapine: dosing: 5 to 10 mg sublingual BID
- Cariprazine: dosing: 1.5 mg/day only for depression; 3 to 6 mg/day mood elevation
- Lurasidone: dosing: 20 to 60 mg/day; FDA-approved for bipolar depression
- Olanzapine (Zyprexa, Zydis, generic): dosing: 5 to 20 mg/day; most likely to cause metabolic side effects (weight gain, diabetes)
- Paliperidone: dosing 6 mg/AM; may cause agranulocytosis, cardiac arrhythmias
- Quetiapine (Seroquel, Seroquel XR, generic): dosing: in mania, 200 to 400 mg BID; in bipolar depression, 50 to 300 mg QHS; XR dosing 50 to 400 mg QHS
- Risperidone (Risperdal, Risperdal Consta, generic): dosing: 1 to 6 mg/day divided QD–QID; IM preparation available (q2wk)
- Ziprasidone (Geodon): dosing: 40 to 80 mg BID; less likely to cause metabolic side effects. Caution: QTc prolongation (>500 ms) has been associated with use (0.06%). Consider ECG at baseline.

- **Unipolar antidepressants**
  - There is inadequate information to recommend in bipolar disorder. If used (e.g., for anxiety), antimanic agent is essential.
- **Avoid**
  - TCAs and serotonin norepinephrine reuptake inhibitor (SNRI); increases mood cycling risk

### ISSUES FOR REFERRAL
- Refer to psychiatry, depends on knowledge level of the doctor, stability of patient.
- Patients benefit from a multidisciplinary team, including a primary care physician, psychiatrist, and therapist.

### ADDITIONAL THERAPIES
- Electroconvulsive therapy can be helpful in acute or treatment-resistant mania and depression.
- Modest evidence supports transcranial magnetic stimulation, vagus nerve stimulation, ketamine infusion, sleep deprivation, and hormone therapy (e.g.,
thyroid) in bipolar depression.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admit if dangerous to self or others.
- To admit involuntarily, the patient must have a psychiatric diagnosis (e.g., BP-I) and present a danger to self or others or the mental disease must be inhibiting the person from obtaining basic needs (e.g., food, clothing).
- Nursing: Alert staff to potentially dangerous or agitated patients. Acute suicidal threats need continuous observation.
- Discharge criteria determined by safety

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Regularly scheduled visits support adherence with treatment.
- Frequent communication among primary care doctor, psychiatrist, and therapist

Patient Monitoring
Mood charts are helpful to monitor symptoms.

PATIENT EDUCATION

- National Alliance on Mental Illness (NAMI): http://www.nami.org/
- National Institute of Mental Health (NIMH):
- Depression and Bipolar Support Alliance (DBSA): http://www.dbsalliance.org

PROGNOSIS

- Frequency and severity of episodes are related to medication adherence, consistency with therapy, quality of sleep, and support systems.
- 40–50% of patients experience another manic episode within 2 years of first episode.
- 25–50% attempt suicide, and 15% die by suicide.
- Substance abuse, unemployment, psychosis, depression, and male gender are associated with a worse prognosis.
REFERENCES

ADDITIONAL READING

SEE ALSO

Algorithm: Depressive Episode, Major

CODES

**ICD10**

F31.81 Bipolar II disorder

CLINICAL PEARLS

- BP-II is characterized by at least one episode of major depression and one episode of hypomania.
• Patients may not recognize symptoms and or decline treatment during a hypomanic episode; they may enjoy the elevated mood and productivity.
• Patients with BP-II are at great risk of both attempting and completing suicide.
BASICS

DESCRIPTION
- Bite rates vary by species: dogs (60–90%), cats (5–20%), rodents (2–3%), humans (2–3%), and rarely other animals, including snakes
- System(s) affected: potentially any

Pediatric Considerations
Young children are more likely to sustain bites and have bites that include the face, upper extremity, or trunk.

EPIDEMIOLOGY
- Predominant age: all ages but children > adults
- Predominant gender: dog bites, male > female; cat bites, female > male

Incidence
- 3 to 6 million animal bites per year in the United States (1)
- Account for 1% of all injury-related ED visits
- 1–2% will require hospital admission, and 20 to 35 victims die from dog bite complications annually.

ETIOLOGY AND PATHOPHYSIOLOGY
- Most dog bites are a domestic pet known to the victim.
- Most (~90%) cat bites are provoked.
- Dog bites most commonly reported from pit bull terriers, and German shepherds.
- Human bite wounds are typically incurred by striking another in the mouth with a clenched fist.
- Bites also occur incidentally (e.g., paronychia due to nail biting, thumb sucking, or nonmalicious gentle bites to the face, breasts, or genital areas).
- Animal bites can cause tears, punctures, scratches, avulsions, or crush injuries.
- Contamination by oral flora leads to infection.
RISK FACTORS
- Older, male dogs more likely to bite.
- Clenched-fist human bites are frequently associated with the use of alcohol or drugs.
- Patients presenting >8 hours following the bite are at greater risk of infection.

GENERAL PREVENTION
- Instruct children and adults about animal hazards.
- Enforce animal control laws.
- Educate dog owners.

DIAGNOSIS

HISTORY
- Detailed history of the incident (provoked or unprovoked); type/breed of animal; vaccine status
- Site of the bite
- Geographic setting
- Underlying medical history

PHYSICAL EXAM
- Dog bites (60–90% of bites)
  - Hands and face most common site of injury in adults and children, respectively
  - More likely to have associated crush injury
- Cat bites (5–20% of bites)
  - Predominantly involve the hands, followed by lower extremities, face, and trunk
- Human bites (2–3% of bites)
  - Intentional bite: semicircular or oval area of erythema and bruising, with or without break in skin
  - Clenched-fist injury: small wounds over the metacarpophalangeal joints from striking the fist against another’s teeth
- Signs of wound infection include fever, erythema, swelling, tenderness, purulent drainage, and lymphangitis.

ALERT
Cat bites (often puncture wounds) are twice as likely to cause infection as dog bites, with higher risks of osteomyelitis, tenosynovitis, and septic arthritis.

**Pediatric Considerations**

Human bite marks on a child with an intercanine distance >3 cm, probably came from an adult and should raise concerns about child abuse.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Gram stain and culture from wound drainage (2)[A]
  - If wound fails to heal, culture for atypical pathogens (fungi, *Nocardia*, and mycobacteria); keep bacterial cultures for 7 to 10 days (some pathogens are slow-growing).
  - 85% of bite wounds will yield a positive culture; most are polymicrobial with an average of five pathogens
  - Obtain aerobic and anaerobic blood cultures before starting antibiotics if bacteremia suspected.
  - Recent antibiotic therapy may alter culture results.

**ALERT**

If bite wound is near a bone or joint, a plain radiograph is needed to check for bone injury; can also be helpful for comparison later if osteomyelitis is suspected (2)

- Radiographs to check for fractures in clenched-fist injuries

**Follow-Up Tests & Special Considerations**

Suspicion for osteomyelitis warrants comparison of plain radiograph or MRI. CT scan for severe skull bites. Ultrasound can detect abscess formation.

**Diagnostic Procedures/Other**

Surgical exploration may be needed to determine the extent of injuries or to drain deep (e.g., tendon sheath) infections, especially in serious hand wounds.

**Test Interpretation**

- Dog bites (3,4)
  - *Pasteurella* species is present in 50% of bites.
  - Viridans streptococci, *Staphylococcus aureus*, *Staphylococcus intermedius*,

mebooksfree.com
Bacteroides, Capnocytophaga canimorsus, Fusobacterium

- Cat bites (4)
  - Pasteurella species in 75% of bites
  - Streptococcus spp. (including Streptococcus pyogenes), Staphylococcus spp. (including methicillin-resistant S. aureus [MRSA]), Fusobacterium spp., Bacteroides spp., Porphyromonas spp., Moraxella spp.

- Human bites
  - Streptococcus spp., S. aureus, Eikenella corrodens (29%), and various anaerobic bacteria (e.g., Fusobacterium, Peptostreptococcus, Prevotella, and Porphyromonas spp.)
  - Although rare, case reports suggest transmission of viruses (hepatitis, HIV, and herpes simplex).

- Reptile bites
  - If from a venomous snake, use antivenom; Pseudomonas aeruginosa, Proteus spp., Salmonella, Bacteroides fragilis, and Clostridium species also found

- Rodent bites
  - Streptobacillus moniliformis or Spirillum minus, which causes rat-bite fever

- Monkey bites
  - All monkey bites can transmit rabies, and bites of a macaque monkey may transmit herpes B virus, which is potentially fatal.

- Ungulate (hooved animals) bites
  - Pigs are the most likely to bite; commonly polymicrobial infections (Staphylococcus and Streptococcus spp, Haemophilus influenzae, Pasteurella, Actinobacillus and Flavobacterium species)
  - Other ungulates are more likely to cause injury by kicking or crushing.

**ALERT**
Asplenic patients and those with underlying hepatic disease are at risk for bacteremia and fatal sepsis after dog bites infected with C. canimorsus (gram-negative rod).

**TREATMENT**

**GENERAL MEASURES**
- Complete bite report according to local policy
- Elevate the injured extremity to prevent swelling.
Contact local health department to determine the prevalence of rabies in the involved species (highest in bats).

Snake bite: If venomous, transport to facility that can provide appropriate evaluation and antivenom. Be sure patient is stable for transport; assess coagulation and renal status.

Monkey bite: Contact CD; consider an antiviral, such as valacyclovir, active against herpes B virus.

MEDICATION

Determine need for anti-rabies therapy: rabies immunoglobulin and human diploid cell rabies vaccine for those bitten by wild animals (in the United States, primary vector is bat or raccoon bite), rabid pets, unvaccinated pets, or if animal cannot be quarantined for 10 days.

ALERT

Refer to State and Local Rabies Consultation (https://www.cdc.gov/rabies/resources/contacts.html)

- Tetanus toxoid (Td) for previously immunized with >10 years since their last dose (2)[C]; tetanus, diphtheria, and pertussis (Tdap) preferred to Td (2)
- Anti-HBs negative patients bitten by HBsAg-positive individuals should receive both hepatitis B immunoglobulin (HBIG) and hepatitis B vaccine.
- HIV postexposure prophylaxis is generally not recommended for human bites, unless there is significant blood exposure to broken skin.
- Preemptive antibiotics recommended only for human bites and high-risk wounds (deep puncture, crush injury, venous or lymphatic compromise, hands or near joint, face or genital area, immunocompromised hosts, requiring surgical repair, asplenic, advanced liver, edema).
- For preemptive and for empiric treatment of established infection, amoxicillin/clavulanate is first line (2)[B].
  - Adults: amoxicillin 875 mg/clavulanate 125 mg PO BID
  - Children: <3 months: 30 mg/kg/day PO q12h; ≥3 months and <40 kg: 25 to 45 mg/kg/day q12h; >40 kg, use adult dosing
    - Precautions: dose antibiotics by body weight and renal function
  - Duration of therapy: preemptive, 3 to 5 days; treatment of cellulitis/skin abscess, 5 to 10 days
    - Adults: clindamycin (300 mg PO TID) plus either
      ■ Trimethoprim-sulfamethoxazole (TMP-SMX; 1 DS tablet PO BID) or
      ■ Ciprofloxacin (500 to 750 mg PO BID) Children: clindamycin 25 to
30 mg/kg/day PO in 3 divided doses to a maximum of 300 mg per dose) plus

- TMP-SMX (8 to 10 mg/kg/day of trimethoprim) PO in 2 divided doses

- Avoid 1st-generation cephalosporins (e.g., cephalexin), penicillinase-resistant penicillins (e.g., dicloxacillin), macrolides (e.g., erythromycin), and clindamycin (when not administered with another agent) as they lack activity against Pasteurella multocida (dog/cat bites) and E. corrodens (human bites).

**Pregnancy Considerations**

- Pregnant women who cannot take penicillins or cephalosporin due to severe allergy
  - Azithromycin 250 to 500 mg PO every day
- Observe closely and note potential increased risk of failure.

**ALERT**

Consider community-acquired MRSA as possible pathogen (from human skin or colonized pet). If high suspicion, doxycycline or TMP-SMX provide good coverage.

**ISSUES FOR REFERRAL**

- Deep wounds to the hand and face should be referred to a hand surgeon or plastic surgeon.
- Bites from primates or unusual species of animals should be referred to infectious disease specialist.

**SURGERY/OTHER PROCEDURES**

- Copious irrigation of the wound with normal saline via a catheter tip to reduce risk of infection.
- Devitalized tissue needs débridement.
- Débridement of puncture wounds is not advised.
- Consider primary closure if the wound is clean after irrigation, the bite is <12 hours old, and in bites to the face (cosmesis).
- Infected wounds and those at high risk for infection (cat bites, human bites, bites to the hand, crush injuries, presentation >12 hours from injury) should be left open.
- Delayed primary closure in 3 to 5 days is an option for infected wounds.
- Splint hand if it is injured.
- Large, gaping wounds should be reapproximated with widely spaced sutures or Steri-Strips.
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Patients with deep or severe wound infections, systemic infections requiring IV therapy, and the immunocompromised:

- **Adults:** ampicillin and sulbactam 1.5 to 3.0 g IV q6h or piperacillin and tazobactam 3.375 g IV q6h (2). Alternative: ciprofloxacin 400 mg IV q12h or levofloxacin 750 mg IV every day with metronidazole 500 mg IV q8h (2).
- **Children:** ampicillin and sulbactam 200 mg/kg/day IV given in 4 divided doses to maximum of 3 g per dose.
- Discharge pending clinical improvement.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

**Patient Monitoring**

- Recheck for infection in 24 to 48 hours.
- Daily follow-up for infections to ensure resolution.
- Base revisions of antibiotic therapy on culture results and clinical response.

PATIENT EDUCATION

Educate parents at well-child checks about how to avoid animal bites.

PROGNOSIS

Wounds should steadily improve and close over by 7 to 10 days.

COMPLICATIONS

- Septic arthritis
- Osteomyelitis
- Extensive soft tissue injuries with scarring
- Hemorrhage
- Gas gangrene
- Sepsis
- Meningitis
- Endocarditis
- Posttraumatic stress disorder

CODES

**ICD10**

- S61.459A Open bite of unspecified hand, initial encounter
- S01.85XA Open bite of other part of head, initial encounter
- S20.97XA Other superficial bite of unspecified parts of thorax, initial encounter

CLINICAL PEARLS
- Wound cleansing, débridement, and culture are essential. Most wounds should be left open.
- Antibiotic prophylaxis is recommended for human bites and high-risk wounds.
- Consider rabies and tetanus vaccination.
- Adjust antibiotic choice and duration of therapy based on culture results and clinical improvement.
- Patients bitten by animals or humans require close follow-up to monitor for infection.
BLADDER CANCER
Margaret E. Thompson, MD

BASICS

DESCRIPTION
- Primary malignant neoplasms arising in the urinary bladder
- Most common type is transitional cell carcinoma (90%).
- Other types include adenocarcinoma, small cell carcinoma, and squamous cell carcinoma.
- Rhabdomyosarcoma of the bladder may occur in children.

EPIDEMIOLOGY

Incidence
- Increases with age (median age at diagnosis is 73 years) (1)
- More common in Caucasians than in Asians or African Americans
- Male > female (4:1); but in smokers, risk is 1:1.
- 34.9/100,000 men per year (1)
- 8.4/100,000 women per year (1)
- 19.8/100,000 men and women per year (1)

Prevalence
In 2014, 696,440 cases in the United States (1)

ETIOLOGY AND PATHOPHYSIOLOGY
Unknown, other than related to risk factors:
- 70–80% is nonmuscle invasive (in lamina propria or mucosa):
  - Usually highly differentiated with long survival
  - Initial event seems to be the activation of an oncogene on chromosome 9 in superficial cancers.
- 20% of tumors are muscle invasive (deeper than lamina propria) at presentation:
  - Tend to be high grade with worse prognosis
  - Associated with other chromosome deletions
Genetics
Hereditary transmission is unlikely, although transitional cell carcinoma pathophysiology is related to oncogenes.

RISK FACTORS
- Smoking is the single greatest risk factor (increases risk 4-fold) and increases risk equally for men and women (2).
- Use of pioglitazone for >1 year may be associated with an increased risk of bladder cancer. The risk seems to increase with duration of therapy and may also be present with other thiazolidinediones.
- Other risk factors:
  - Occupational carcinogens in dye, rubber, paint, plastics, metal, carbon black dust, and automotive exhaust
  - Schistosomiasis in Mediterranean (squamous cell) cancer
  - Arsenic in well water
  - History of pelvic irradiation
  - Chronic lower UTI
  - Chronic indwelling urinary catheter
  - Cyclophosphamide exposure
  - High-fat diet
  - Coffee consumption associated with reduced risk (RR 0.83; 95% CI 0.73–0.94)

Alert
Any patient who smokes and presents with microscopic or gross hematuria or irritative voiding symptoms such as urgency and frequency not clearly due to UTI should be evaluated by cystoscopy for the presence of a bladder neoplasm.

General Prevention
- Avoid smoking and other risk factors.
- Counseling of individuals with occupational exposure
- The U.S. Preventive Services Task Force has concluded that there is insufficient evidence to determine the balance between risk and harm of screening for bladder cancer (3).
HISTORY
- Painless hematuria is the most common symptom.
- Urinary symptoms (frequency, urgency)
- Abdominal or pelvic pain in advanced disease
- Exposures (see “Risk Factors”)

PHYSICAL EXAM
Normal in early cases, pelvic or abdominal mass in advanced disease, wasting in systemic disease

DIFFERENTIAL DIAGNOSIS
- Other urinary tract neoplasms
- UTI
- Prostatism
- Bladder instability
- Interstitial cystitis
- Urolithiasis
- Interstitial nephritis
- Papillary urothelial hyperplasia

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Urinalysis is the initial test in patients presenting with gross hematuria or urinary symptoms such as frequency, urgency, and dysuria.
- Urine cytology (Consult your local lab for volume needed and proper fixative/handling.)
- Cystoscopy with biopsy is the gold standard for at-risk patients with painless hematuria.
- CT or MRI prior to resection of suspected muscle-invasive cancer may be helpful in staging.
- Macroscopic hematuria (55% sensitivity, positive predictive value [PPV] 0.22 for urologic cancer)

Follow-Up Tests & Special Considerations
- Urine cytology: 54% sensitivity overall (lower in less advanced tumors), 94% specific
- Other urine markers (of little clinical benefit):
- Nuclear matrix protein-22 (NMP22): 67% sensitive, 78% specific
- Bladder tumor–associated antigen stat: 70% sensitive, 75% specific, may be falsely positive in inflammatory conditions
- Fluorescence in situ hybridization (FISH) assay: 69% sensitive, 78% specific (PPV 27.1, negative predictive value 95.3) for all tumors, more sensitive and specific for higher grade
- FGFR3 mutation has high specificity (99.9%) but low sensitivity (34.5%); PPV 95.2%

- Bottom line: None of the urine markers is sensitive enough to rule out bladder cancer on its own.
- Liver function tests, alkaline phosphatase if metastasis suspected
- Done for staging and to evaluate extent of disease but not for diagnosis itself:
  - CT urogram replacing IVP to image upper tracts if there is a suspicion of disease there
  - Diffusion-weighted MRI and multidimensional CT scan are undergoing study for use in diagnosis and staging of bladder tumors.
  - For invasive disease, metastatic workup should include chest x-ray.
  - Bone scan should be performed if the patient has bone pain or if alkaline phosphatase is elevated.
- Urologic CT scan (abdomen, pelvis, with and without contrast) or MRI (40–98% accurate), with MRI slightly more accurate, is recommended if metastasis is suspected.
- Regular cystoscopy (initiated at 3 months postprocedure) is indicated after transurethral resection of bladder tumor (TURBT) and intravesical chemotherapy for superficial bladder cancers. Urinary biomarkers should not be routinely used for follow-up.

**Diagnostic Procedures/Other**

- Cystoscopy with biopsy is the gold standard for diagnosis, but one study showed that 33% of patients had residual tumor after TURBT.
- Using photodynamic diagnosis (PDD; employing a photosensitizing agent in the bladder that is taken up by tumor cells and visualized using a particular wavelength of light, which is changed to a different wavelength by the photosensitizing agent) has been shown to increase detection and identification of cancerous superficial tumors when compared with plain white light cystoscopy. A recent meta-analysis shows that this increases the likelihood of total resection.

**Test Interpretation**
Characterized as superficial (nonmuscle invasive) or invasive (muscle invasive)
70–80% present as superficial lesion.
Superficial lesions
- Carcinoma in situ: flat lesion, high grade
- Ta: noninvasive papillary carcinoma
- T1: extends into submucosa, lamina propria
Invasive cancer
- T2: invasion into muscle
  o pT2a: invasion into superficial muscle
  o pT2b: invasion into deep muscle
- T3: invasion into perivesical fat
  o pT3a: microscopic
  o pT3b: macroscopic
- T4: invasion into adjacent organs
  o aT4a: invades prostate, uterus, or vagina
  o aT4b: invades abdominal or pelvic wall
N1–N3: invades lymph nodes
M: metastasis to bone or soft tissue

**TREATMENT**

For nonmuscle-invasive bladder cancer, the treatment is generally removal via cystoscopic surgery (see earlier discussion on PDD). For muscle-invasive cancer, a radical cystectomy with pelvic lymphadenectomy is preferred.

**MEDICATION**

**First Line**
- A recent meta-analysis demonstrated neoadjuvant chemotherapy using platinum-based combination chemotherapy (with ≥1 of doxorubicin/epirubicin, methotrexate, or vinblastine), but not platinum alone, confers a significant survival advantage in patients with invasive bladder cancer, with an increase in survival at 5 years from 45% (without neoadjuvant treatment) to 50% (with treatment) (combined hazard ratio 0.86; 95% CI, 0.77–0.95).
- Intravesical bacillus Calmette-Guérin (BCG) after TURBT in high-grade lesions has been shown to decrease recurrence in Ta and T1 tumors (4)[A].
**Second Line**

- Chemotherapy is the first-line treatment for metastatic bladder cancer:
  - Methotrexate-vinblastine-doxorubicin-cisplatin (MVAC) is the preferred regimen.
- A recent review showed that gemcitabine plus cisplatin may be better tolerated and result in equivalent survival to MVAC, making it a possible first choice in metastatic bladder cancer.

**ISSUES FOR REFERRAL**

Patients with microscopic or gross hematuria not otherwise explained or resolving should be referred to a urologist for cystoscopy.

**ADDITIONAL THERAPIES**

Radiotherapy:

- In the United States, used for patients with muscle-invasive cancer who are not surgical candidates
- Preoperative (radical cystectomy) radiotherapy also an option
- Treatment of choice for muscle-invasive cancer in some European and Canadian centers:
  - 65 to 70 Gy over 6 to 7 weeks is standard.

**SURGERY/OTHER PROCEDURES**

- Surgery is definitive therapy for superficial and invasive cancer:
  - Superficial cancer: TURBT sometimes followed by intravesical therapy
- Invasive cancer
  - Radical cystectomy for invasive disease that is confined to the bladder is more effective than radical radiotherapy. There is insufficient evidence to recommend one form of urinary diversion over another (5).
  - Currently under trial is a trimodal therapy implementing transurethral resection, radiotherapy, and radiosensitizing chemotherapy (6).

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Need for surgery or intensive therapy
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Superficial cancers
  - Urine cytology alone has not been shown to be sufficient for follow-up.
  - Cystoscopy every 3 months for 18 to 24 months, every 6 months for the next 2 years and then annually
- Follow-up for invasive cancers depends on the approach to treatment.
- Patients treated with BCG require lifelong follow-up.

DIET
Continue adequate fluid intake.

PATIENT EDUCATION
Smoking cessation

PROGNOSIS
- 5-year relative survival rates (1)
  - Overall survival: 77.3%
    - In situ: 95.7%
    - Localized: 70.1%
    - Regional metastasis: 35.2%
    - Distant metastasis: 5.0%
- Superficial bladder cancer
  - BCG treatment prevents recurrence versus TURBT alone; difference 30%, NNT 3.3
  - BCG prevents progression versus TURBT alone; difference 8%
- Invasive cancer
  - T2 disease: Radical cystectomy results in 60–75% 5-year survival.
  - T3 or T4 disease: Radical cystectomy results in 20–40% 5-year survival.
  - Neoadjuvant chemotherapy with cystectomy has led to varying degrees of increased survival.
  - Radiation with chemotherapy has led to varying degrees of increased survival.
- Metastatic cancer:
  - MVAC resulted in mean survival of 12.5 months.
COMPLICATIONS

- Superficial bladder cancer
  - Local symptoms
    - Dysuria, frequency, nocturia, pain, passing debris in urine
    - Bacterial cystitis
    - Perforation
  - General symptoms
    - Flulike symptoms
    - Systemic infection
- Invasive cancer
  - Symptoms related to definitive treatment, including incontinence, bleeding
  - Patients with neobladder at risk for azotemia and metabolic acidosis

REFERENCES

ADDITIONAL READING

**SEE ALSO**

- Hematuria
- Algorithm: Hematuria

**CODES**

**ICD10**

- C67.9 Malignant neoplasm of bladder, unspecified
- C67.4 Malignant neoplasm of posterior wall of bladder
- C67.3 Malignant neoplasm of anterior wall of bladder

**CLINICAL PEARLS**

- Painless hematuria in smokers should be evaluated with cystoscopy.
- Be aware of potential link between pioglitazone treatment and risk for bladder cancer.
- The U.S. Preventive Services Task Force recommends against routine screening for bladder cancer.
BORDERLINE PERSONALITY DISORDER
William G. Elder, PhD

BASICS
DESCRIPTION
A psychiatric disorder that begins no later than adolescence or early adulthood, borderline personality disorder (BPD) is a consistent and pervasive pattern of unstable and reactive moods and sense of self, impulsivity, and volatile interpersonal relationships (1):

- Common behaviors and variations:
  - Self-mutilation: pinching, scratching, cutting
  - Suicide: ideation, history of attempts, plans
  - Splitting: idealizing then devaluing others
  - Presentation of helplessness or victimization
  - High utilization of emergency department and resultant inpatient hospitalizations for psychiatric treatment
- High rate of associated mental disorders
- Typically display little insight into behavior

Geriatric Considerations
Illness (both acute and chronic) may exacerbate BPD and may lead to intense feelings of fear and helplessness.

Pediatric Considerations
Diagnosis is rarely made in children. Axis I disorders and general medical conditions (GMCs) are more probable.

Pregnancy Considerations
Physical, emotional, and social concerns may transiently mimic symptoms of BPD: Consider delay in diagnosis until pregnancy completed. Pregnancy may also induce stress or increased fears, resulting in escalation of borderline behaviors.

EPIDEMIOLOGY
Predominant age: onset no later than adolescence or early adulthood (may go
Prevalence

- General population: 0.5–5.9% of U.S. population
- May be over represented in primary care
- 10% of all psychiatric outpatients and between 15% and 25% of patients in psychiatry inpatient settings have BPD (2).

ETIOLOGY AND PATHOPHYSIOLOGY

Undetermined but generally accepted that BPD is due to a combination of the following:

- Hereditary temperamental traits
- Environment (i.e., history of childhood sexual and/or physical abuse, history of childhood neglect, ongoing conflict in home)
- Neurobiologic research suggests that stress exerts damaging effects on the brain, specifically the hippocampus (2). Other findings demonstrate heightened activity in brain circuits involved in the experience of negative emotions and reduced activation that normally suppresses negative emotion once it is generated.

Genetics

First-degree relatives are at greater risk for this disorder (undetermined if due to genetic or psychosocial factors).

RISK FACTORS

- Genetic factors contribute; however, no specific genes have yet been identified.
- Childhood sexual and/or physical abuse and neglect
- Disrupted family life
- Physical illness and external social factors may exacerbate BPD.

GENERAL PREVENTION

- Tends to be a multigenerational problem
- Children, caregivers, and significant others should have some time and activities away from the borderline individual, which may protect them.

COMMONLY ASSOCIATED CONDITIONS

Other psychiatric disorders, including:
- Co-occurring personality disorders, frequent
- Mood disorders, common
- Anxiety disorders, common
- Substance-related disorders, common
- Eating disorders, common
- Posttraumatic stress disorder, common
- BPD does not appear to be independently associated with increased risk of violence.

## DIAGNOSIS

- The comprehensive evaluation should identify
  - Comorbid conditions
  - Functional impairments
  - Adaptive/maladaptive coping styles
  - Psychosocial stressors
  - Patient strengths; needs/goals
- Initial assessment should focus on risk factors:
  - Establish treatment agreement with patient and outline treatment goals.
  - Assess suicide ideation and self-harm behavior.
  - Assess for psychosis.
  - Hospitalization is necessary if patient presents a threat of harm to self or others.

## HISTORY

- Clinic visits for problems that do not have biologic findings
- Conflicts with medical staff members
- Idealizing or unexplained anger at physician
- History of unrealistic expectations of physician (e.g., “I know you can take care of me.” “You’re the best, unlike my last provider.”)
- Obtain collateral information (i.e., from family, partner) about patient behaviors.
- History of interpersonal difficulties, affective instability, and impulsivity
- History of self-injurious behavior, possibly with suicidal threats or attempts

## PHYSICAL EXAM

- BPD patients should have a thorough physical examination to help lower suspicion of organic disease (especially thyroid disease) (1,2).
Often physical examination reveals no gross abnormalities other than related to scarring from self-mutilation.

DIFFERENTIAL DIAGNOSIS

- Mood disorders:
  - Look at baseline behaviors when considering BPD versus mood disorder.
  - BPD symptoms increase the likelihood of misdiagnosing bipolar disorder.
  - In particular, disruptive mood dysregulation disorder, a new diagnosis appearing in DSM-5 and characterized by severe recurrent temper outbursts manifesting verbally or behaviorally and grossly out of proportion to the situation, may appear quite similar to the acting out and intense emotions seen in BPD. Look for other symptoms characteristic of BPD to differentiate (1).
- Psychotic disorder:
  - With BPD, typically only occurs under intense stress and is characterized as “micropsychotic”
- Other PD:
  - Thoughts, feelings, and behavior will differentiate BPD from other PDs.
- GMC:
  - Traits may emerge due to the effect of a GMC on the CNS.
- Substance use

DIAGNOSTIC TESTS & INTERPRETATION

- Consider age of onset. To meet criteria for BPD, borderline pattern will be present from adolescence or early adulthood.
- Formal psychological testing
- Rule out personality change due to a GMC (1)[C]:
  - Traits may emerge due to the effect of a GMC on the CNS.
- Rule out symptoms related to substance use.
- If symptoms begin later than early adulthood or are related to trauma (e.g., after a head injury), a GMC, or substance use, then consider other diagnoses.

Diagnostic Procedures/Other

According to DSM-5 criteria, patient must meet at least five of the following criteria (1)[C]:

- Attempt to avoid abandonment
- Volatile interpersonal relationships
- Identity disturbance
Impulsive behavior:
- In ≥2 areas
- Impulsive behavior is self-damaging.

Suicidal or self-mutilating behavior

Mood instability

Feeling empty

Is unable to control anger or finds it difficult

Paranoid or dissociative when under stress

With advent of DSM-5, an alternative model is being promulgated that may come to define the diagnosis as impairments in personality functioning AND the presence of pathologic traits. Attention to these features may ultimately enhance provider understanding, diagnosis, and treatment of patients with personality dysfunction.

- Criteria regarding personality functioning refer to impairments of self-functioning (i.e., identity or self-direction) AND interpersonal functioning (i.e., empathy or intimacy).
- Pathologic personality traits refer to characteristics in the domains of negative affectivity (i.e., emotional liability, anxiousness, separation insecurity, depressivity), disinhibition (i.e., impulsivity, risk taking), OR antagonism (1).

TREATMENT

Outpatient psychotherapy for BPD is the preferred treatment (2)[B]:

- Dialectical behavior therapy (DBT) combines cognitive-behavioral techniques for emotional regulation and reality-testing with concepts of distress tolerance, acceptance, and self-awareness.
  o Following a dialectical process, therapists are tough-minded allies, who validate feelings and are unconditionally accepting, while also reminding patients to accept their dire level of emotional dysfunction and to apply better alternative behaviors.
  o DBT may be done individually and in groups.

Also consider CBT or transference-focused (psychodynamic) psychotherapy.

Patient may need to be placed on suicide watch.

Brief inpatient hospitalizations are ineffective in changing Axis II disorder behaviors:
- Hospitalizations should be limited, and of short duration to adjust medications, implement psychotherapy for crisis intervention, and to
stabilize patients from psychosocial stressors.

- Extended inpatient hospitalization should be considered for the following reasons:
  - Persistent/severe suicidal ideation or risk to others
  - Comorbid substance use and/or nonadherence to outpatient or partial hospitalization treatments
  - Comorbid Axis I disorders that may increase threat to life for the patient (i.e., eating disorders, mood disorders).

**GENERAL MEASURES**

- Patients with BPD require more medical care and increased “intentionality” by the provider. Therefore, it is important to be aware of which patients in your practice have BPD and to limit this number if demands exceed practice resources.
- Focus on patient management rather than on “fixing” behaviors:
  - Schedule consistent appointment follow-ups to relieve patient anxiety.
  - Meet with and rely on treatment team to avoid splitting of team by patient and to provide opportunity to discuss patient issues.
  - Treatment is usually most effective when both medications and psychotherapy are used simultaneously.

**MEDICATION**

- Although no specific medications are approved by the FDA to treat BPD, American Psychiatric Association (APA) guidelines recommend pharmacotherapy to manage symptoms (2)[A],(3)[B].
- Treat Axis I disorders (3)[B].
- Consider high rate of self-harm and suicidal behavior when prescribing (2)[A].
- APA guideline recommendations (3)[B]:
  - Affective dysregulation: mood stabilizers, SSRIs, and monoamine oxidase inhibitors (MAOIs)
  - Impulsive-behavioral control: SSRIs and mood stabilizers
  - Cognitive-perceptual symptoms: antipsychotics on a short-term basis
- With more neurobiologic causes considered in relation to BPD, SSRIs are having a less prominent roles with more emphasis on mood stabilizers and atypical antipsychotics, but research is uncertain and inconclusive (3)[B].

**ISSUES FOR REFERRAL**
If hospitalized, consider for suicide risk, mood or anxiety disorders, or substance-related disorders.

Urgency for scheduled follow-up depends on community resources (e.g., outpatient day programs for suicidal patients; substance abuse programs):
- With increased risk for self-harm or self-defeating behaviors and low community resources, the patient can/will have increased need for frequent visits.

ADDITIONAL THERAPIES
Consider referring patient for specialized mental health behavioral services, including partial hospital therapy.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Omega-3 fatty acid dietary supplementation has shown beneficial effects (2)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Admit for inpatient services immediately in presence of psychosis or threat of injury to self or others; include police, as necessary, for safety measures.
- Assess suicidal ideation.
- Consider trial of antipsychotic medications for psychosis.
- Nurses can be instrumental in managing and calling patients, potentially relieving patient stress.
- Patient should not present risk of harm to self or others and have a safety plan.
- Follow-up should be scheduled with a mental health specialist and primary care provider.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Schedule visits that are short, more frequent, and focused to relieve patients’ anxiety about relationships with their physician/provider and to help reduce risk of provider burnout.
- Maintain open lines of communication with mental health professionals providing psychological support.
Emphasize importance of healthy lifestyle modifications (i.e., exercise, rest, diet).

**Patient Monitoring**
Monitor for suicidal or other self-harm behaviors.

**PATIENT EDUCATION**
Include patients in the diagnosis so they can make sense of their disease process and participate in the treatment strategy.

**PROGNOSIS**
- Borderline behaviors may decrease with age and over time.
- Patients in treatment improve at a rate of 7 times compared with following natural course.
- Treatment is complex and takes time.
- Medical focus includes patient management and caring for medical and Axis I disorders.

**REFERENCES**

**ADDITIONAL READING**

**CODES**
ICD10
F60.3 Borderline personality disorder

CLINICAL PEARLS

- BPD may be discerned by the impropriety of reactions to situations others find or minor.
- View BPD as a chronic condition with waxing and waning features. It is important to adjust medications/treatments as clinically appropriate when symptoms change.
- If there are problems with the patient disrespecting the physician or support staff, clear guidelines should be established with the treatment team and then with the patient.
- When considering terminating care, the patient may improve if empathetically confronted about certain behaviors and is given clear guidelines on how to behave in the clinic. It is the patient’s job to follow the guidelines, and it is you and your team’s job to enforce the guidelines. Designate a case management nurse or well-trained support staff person who can be the primary contact person for the patient.
- Have an agenda when you visit with BPD patients. Be cordial—they deserve the same professionalism any patient gets. Have and identify one to two issues to be discussed per clinic visit. Frequently scheduled visits can help with this.
- Regularly scheduled psychotherapy improves medical care by becoming the “home” for mental health treatment, leaving the physician to focus on the patient’s immediate medical issues.
BRAIN INJURY, TRAUMATIC
Caleb J. Mentzer, DO ● James R. Yon, MD

BASICS
DESCRIPTION
- Traumatic brain injury (TBI) is defined as an alteration in brain function or other evidence of brain pathology, caused by an external force.
- System(s) affected: neurologic; psychiatric; cardiovascular; endocrine/metabolic; gastrointestinal
- Synonym(s): head injury, concussion

EPIDEMIOLOGY

Incidence
- 2.2 million ED visits and 280,000 hospitalizations/year
- 50,000 deaths/year; ~30% of all injury-related deaths
- Incidence in males twice that of females with 4-fold risk of fatal trauma

Prevalence
- Predominant age: 0 to 4 years, 15 to 19 years, and >65 years
- Predominant gender: male > female (2:1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Falls (40%)
- Motor vehicle accidents (14%)
- Assault (10%)
- Child abuse (24% of TBI age ≤2 years)
- Recreational activities (21% of pediatric TBI, peak seasons spring/summer; peak ages 10 to 14 years)
- Primary insult: direct mechanical damage
- Secondary insult: actuation of complex cellular and molecular cascades that promote cerebral edema, ischemia, and apoptotic cell death

RISK FACTORS
Alcohol and drug use, prior/recurrent head injury, contact sports, seizure disorder, ADHD, male sex, luteal phase of female menstrual cycle
Geriatric Considerations
Subdural hematomas are common after a fall or blow in elderly; symptoms may be subtle and not present until days after trauma. Many elderly patients are on antiplatelet or anticoagulation therapy.

General Prevention
- Safety education
- Seat belts; bicycle and motorcycle helmets
- Protective headgear for contact sports

Pediatric Considerations
Child abuse: Consider if dropped or fell <4 feet (e.g., off bed, couch), suspicious history, significant injury present, or any retinal hemorrhages.

Diagnosis

History
- Loss of consciousness (LOC), headache, vomiting, amnesia
- Epidural hemorrhage from blunt trauma: 30% with a “lucid interval” (initial LOC followed by recovery of consciousness and then LOC recurs and persists)

Physical Exam
- Neurologic and cognitive testing is important.
- Repeat neurologic exams every 30 minutes until 2 hours after Glasgow Coma Scale (GCS) reaches 15, then hourly for 4 hours and then every 2 hours.
- Evidence of increased intracranial pressure (ICP) (elevated BP, decreased pulse rate, or slow/irregular breathing [Cushing triad]—only 30% have all three)
- Decorticate or decerebrate posturing
- Signs of basilar skull fracture: raccoon eyes, Battle sign, hemotympanum, CSF rhinorrhea or otorrhea

Differential Diagnosis
Other causes of altered mental status (e.g., toxicologic, infectious, metabolic, vascular)
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Mild TBI and concussions cognitive screening tests
  - Sports Concussion Assessment Tool V3 (SCAT3)
  - Child SCAT3
  - Concussion Recognition Tool (CRT)
  - Standardized Assessment of Concussion (SAC)
  - King-Devick Test
  - Balance Error Scoring System (BESS)
- Evaluate for coagulopathy.
- Type and screen for possible surgical intervention.
- Perform drug and alcohol screening.
- CT, noncontrast, is the study of choice to review bone windows, tissue windows, and subdural space.
- NEXUS II study demonstrated that if all eight clinical criteria are absent, there is a low likelihood of significant TBI:
  - Evidence of significant skull fracture (depressed, basilar, or diastatic)
  - Altered level of alertness
  - Neurologic deficit
  - Persistent vomiting
  - Presence of scalp hematoma
  - Abnormal behavior
  - Coagulopathy
  - Age >65 years

Follow-Up Tests & Special Considerations
Blast-related TBI: much higher rates of postconcussive syndrome, PTSD, depression, and chronic pain. Chronic impairment is strongly correlated with psychological factors; return to battlefield guidelines similar to return to play (RTP) in sports (see “General Measures”) (1)[A]

Pediatric Considerations
Skull radiographs are not indicated unless abuse is suspected in which case they can detect fractures not seen under CT; no return to activity until they are asymptomatic, and return to school should precede return to sport/physical activity (2)[A]
Diagnostic Procedures/Other

- CSF rhinorrhea
  - Contains glucose; nasal mucus does not
  - Check for the double-halo sign: If nasal discharge contains CSF and blood, two rings appear when placed on filter paper—a central ring followed by a paler ring.

TREATMENT

GENERAL MEASURES

- Acute management depends on injury severity. Most patients need no interventions.
- Immediate goal: Determine who needs further therapy, imaging studies (CT), and hospitalization to prevent further injury.
- For the mildly injured patient
  - Early education is beneficial for recovery (3)[A].
  - RTP
    - Never RTP on same day.
    - Strict guidelines for graduated return to cognitive and physical activity when there are no evident signs or symptoms (physical, cognitive, emotional, or behavioral) on neuropsychological and clinical evaluation (2)[A]
- For the moderate to severely injured patient
  - Avoid hypotension or hypoxia. Head injury causes increased ICP secondary to edema, and cerebral perfusion pressure (CPP) should be maintained between 60 and 70 mm Hg (4)[A].
  - 30-degree head elevation decreases ICP and improves CPP.
  - Hyperventilation (hypocapnia)
    - Use should be limited to patients with impending herniation while preparing for definitive treatment or intraoperatively; risk of worsening cerebral ischemia and organ damage (4,5)[A]
    - Addition of tromethamine can offset deleterious effects and lead to better outcomes (5)[A].
  - Mild systematic hypothermia lowers ICP but leads to increased rates of pneumonia. Selective brain cooling may also decrease ICP with improved outcomes at 2 years postinjury (5)[A].
- Seizure prophylaxis
Does not change morbidity or mortality. Consider phenytoin or levetiracetam for 1 week postinjury or longer for patients with early seizures, dural-penetrating injuries, multiple contusions, and/or subdural hematomas requiring evacuation (6)[A].

MEDICATION

First Line

- Pain
  - Morphine: 1 to 2 mg IV PRN, with caution, because it can depress mental status, further altering serial neurologic evaluations

ALERT

Bolus doses increase ICP and decrease CPP (7)[A].

- Increased ICP
  - Hypertonic saline: 2 mL/kg IV decreases ICP without adverse hemodynamic status; preferred agent (4,7)[A]
  - Mannitol: 0.25 to 2.00 g/kg (0.25 to 1.00 g/kg in children) given over 30 to 60 minutes in patients with adequate renal function. Prophylactic use is associated with worse outcomes (7)[A].

- Sedation
  - Propofol: preferred due to short duration of action. Avoid high doses to prevent propofol infusion syndrome. When combined with morphine, it can also effectively decrease ICP and decrease use of other meds (7)[A].
  - Midazolam: similar sedating effect to propofol but may cause hypotension (7)[A]

- Seizures
  - Phenytoin (Dilantin): 15 mg/kg IV (1 mg/kg/min IV, not to exceed 50 mg/min). Stop infusion if QT interval increases by >50%.

ALERT

Avoid corticosteroid use, because it increases mortality rates and risk of developing late seizures (7)[A]. Avoid barbiturates due to risk of hypotension (7)[A].

ISSUES FOR REFERRAL

Consult neurosurgery for:

- All penetrating head trauma
• All abnormal head CTs

**ADDITIONAL THERAPIES**
• Emerging therapies with limited but promising evidence: coma arousal therapy: amantadine, zolpidem, and levodopa/carbidopa; postcoma therapy: bromocriptine
• Mixed results for therapeutic hypothermia with defined physiologic parameters (8)[A]

**SURGERY/OTHER PROCEDURES**
• Early evacuation of trauma-related intracranial hematoma decreases mortality especially with GCS <6 and CT evidence of hematoma, cerebral swelling, or herniation.
• Decompressive craniectomy reduces ICP especially when a large bone flap is removed; ONLY for adults and ONLY with GCS >6 (5)[A]
• Hyperbaric oxygen temporarily lowers ICP and improves mortality, but evidence is conflicting about outcomes at 6 to 12 months postinjury (5)[A].
• CSF drainage reduces ICP but has not been demonstrated to have long-term benefit (5)[A].
• CSF leakage often resolves in 24 hours with bed rest, but if not, may require surgical repair (4)[A].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Music therapy in conjunction with multimodal stimulation improves awareness in comatose TBI patients (8)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
• Abnormal GCS or CT
• Clinical evidence of basilar skull fracture
• Persistent neurologic deficits (e.g., confusion, somnolence)
• Patient with no competent adult at home for observation
• Possibly admit: LOC, amnesia, patients on anticoagulants with negative CT
• ABCs take priority over head injury.
• C-spine immobilization should be considered in all head trauma.
• Use normal saline for resuscitation fluid.
Discharge criteria: normal CT with return to normal mental status and responsible adult to observe patient at home (see “Patient Monitoring”)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Schedule regular follow-up within a week to determine return to activities.
- Rehabilitation indicated following a significant acute injury. Set realistic goals.
- For patients on anticoagulants, net benefit to restarting therapy after discharge despite increased bleeding risk

Patient Monitoring
Patient should be discharged to the care of a competent adult with clear instructions on signs and symptoms that warrant immediate evaluation (e.g., changing mental status, worsening headache, focal findings, or any signs of distress). Patients should be monitored but not awakened from sleep.

DIET
As tolerated, monitor for signs of nausea.

PATIENT EDUCATION
Proper counseling, symptomatic management, and gradual return to normal activities are essential.

PROGNOSIS
- Gradual improvement may continue for years.
- 30–50% of severe head injuries may be fatal.
- Predicting outcome is difficult; many with even minor to moderate injuries have moderate to severe disability at 1 year, whereas prolonged coma may be followed by satisfactory outcome.
- Patients may have new-onset seizures over 2 years following trauma.
- Poor prognostic factors: low GCS on admission, nonreactive pupils, old age, comorbidity, midline shift

COMPLICATIONS
- Chronic subdural hematoma, which may follow even “mild” head injury,
especially in the elderly; often presents with headache and decreased mentation
- Delayed hematomas and hydrocephalus
- Emotional disturbances and psychiatric disorders resulting from head injury may be refractory to treatment.
- Seizures: seen in 50% of penetrating head injuries, 20% of severe closed head injuries, and <5% of head injuries overall. Hematomas increase risk of epilepsy.
- Postconcussion syndrome can follow mild head injury without LOC and includes headaches, dizziness, fatigue, and subtle cognitive or affective changes.
- Second-impact syndrome occurs when the CNS loses autoregulation. An individual with a minor head injury is returned to a contact sport, and, following even minor trauma (e.g., whiplash), the patient loses consciousness and may quickly herniate, with a 50% mortality. A similar syndrome of malignant edema can occur in children with even a single injury.
- Increased risk for Alzheimer disease, Parkinson disease, and other brain disorders whose prevalence increases with age

REFERENCES

**CODES**

**ICD10**

- S06.9X0A Unsp intracranial injury w/o loss of consciousness, init
- S06.5X0A Traum subdr hem w/o loss of consciousness, init
- S06.6X0A Traum subrac hem w/o loss of consciousness, init

**CLINICAL PEARLS**

- TBI involves two distinct phases: the primary mechanical insult and secondary dysregulation of the cerebrovascular system with cerebral edema, ischemia, and cell-mediated death.
- Indications for imaging include evidence of skull fracture, altered consciousness, neurologic deficit, persistent vomiting, scalp hematoma, abnormal behavior, coagulopathy, age >65 years.
- Strict criteria exist for patients to return to normal sport activity following head injury to avoid the second-impact syndrome, which has 50% mortality.
BREAST ABSCESS
Shannon A. Sanchez Oviedo, MD, MS • Kelley V. Lawrence, MD, IBCLC • Lloyd A. Runser, MD, MPH

BASICS
DESCRIPTION
- Localized accumulation of infected fluid within the breast parenchyma
- Can be associated with lactation or fistulous tracts secondary to squamous epithelial neoplasm or duct occlusion
- System(s) affected: skin/exocrine, immune
- Synonym(s): mammary abscess; peripheral breast abscess; subareolar abscess; puerperal abscess

Pregnancy Considerations
Most commonly associated with postpartum lactation

EPIDEMIOLOGY
- Predominantly reproductive age and perimenopausal
  - Puerperal abscess: lactational
  - Subareolar abscess: perimenopause to postmenopause (1)
- Predominant sex: female
- Higher incidence in African American women, diabetics, smokers

Incidence
- Ranges from 0.4–11% of breastfeeding women; the Academy of Breastfeeding Medicine cites 3% (1,2).
- Puerperal abscess has highest incidence within 6 weeks postpartum and while weaning from breastfeeding (2).

ETIOLOGY AND PATHOPHYSIOLOGY
- Puerperal abscesses:
  - Insufficient treatment of mastitis
  - Unattended postpartum engorgement
  - Plugged lactiferous duct causing stasis, leading to microbial growth and secondary abscess formation
Subareolar abscess: associated with squamous metaplasia of the lactiferous duct epithelium, keratin plugs, ductal ectasia, fistula formation (1)

Microbiology
- *Staphylococcus aureus* is most common cause.
- Less common causes
  - *Streptococcus pyogenes, Escherichia coli, Bacteroides*
  - *Corynebacterium*
  - *Pseudomonas*
  - *Proteus*
- Methicillin-resistant *S. aureus* (MRSA) is a significant cause.

**RISK FACTORS**
- Maternal age >30 (3)
- Primiparous (3)
- Gestational age ≥41 weeks (3)
- Puerperal mastitis
  - Up to 11% progression to abscess (4)
  - Most often due to inadequate therapy
  - Risk factors (stasis):
    - Infrequent or missed feeds
    - Poor latch (1)
    - Damage or irritation of the nipple
    - Suboptimal use of breast pump
    - Illness in mother or baby
    - Rapid weaning; plugged duct
    - Mother employed outside the home (4)
    - Breastfeeding difficulties identified by in-hospital lactation consultant (4)
- General risk factors
  - Smoking
  - Diabetes
  - Obesity
  - Rheumatoid arthritis
- Medically related risk factors
  - Steroids
  - Silicone/paraffin implant
  - Lumpectomy with radiation
  - Inadequate antibiotics to treat mastitis
  - Topical antifungal medication used for mastitis
• Nipple retraction
• Nipple piercing (mastitis, subareolar abscess)
• Higher recurrence rate if polymicrobial abscess

GENERAL PREVENTION
• Frequent breast emptying with on-demand feeding and/or pumping to prevent mastitis
• Early treatment of mastitis with milk expression, antibiotics, and compresses
• Smoking cessation to minimize occurrence/recurrence

COMMONLY ASSOCIATED CONDITIONS
Lactation, weaning

DIAGNOSIS

HISTORY
• Tender breast lump, usually unilateral
• Breastfeeding, weaning, returning to work
• Perimenopausal/postmenopausal
• Systemic malaise (usually less than with mastitis)
• Localized erythema, edema, and pain
• Fever, nausea, vomiting
• Spontaneous nipple drainage
• Prior breast infection
• Diabetes

PHYSICAL EXAM
• Fever, tachycardia, (not always present)
• Erythema of overlying skin
• Tenderness, fluctuance on palpation
• Induration (4)
• Local edema
• Draining pus or skin ulceration
• Nipple and/or skin retraction
• Regional lymphadenopathy
• Puerperal abscesses are generally peripheral; nonlactational abscesses are more commonly found in periareolar/subareolar region (4).
DIFFERENTIAL DIAGNOSIS
- Engorgement
- Plugged milk duct
- Galactocele (sometimes referred to as a milk lake)
- Fibrocystic breasts
- Fat necrosis
- Tuberculosis (may be associated with HIV infection)
- Sarcoid; granulomatous mastitis
- Syphilis
- Foreign body reactions (e.g., to silicone and paraffin)
- Mammary duct ectasia
- Carcinoma (inflammatory or primary squamous cell)

DIAGNOSTIC TESTS & INTERPRETATION
- Ultrasound (US) helps identify fluid collection (5).
- CBC (leukocytosis), elevated ESR
- Culture and sensitivity of expressed breast milk or infected aspirate to identify pathogen (usually Staphylococcus or Streptococcus)
- MRSA is an increasingly important pathogen in both lactational and nonlactational abscesses.
- Other bacteria:
  - Nonlactational abscess and recurrent abscesses associated with anaerobic bacteria
    - E. coli, Proteus; mixed bacteria less common
- Mammogram to rule out carcinoma (generally not during acute phase)

Diagnostic Procedures/Other
Aspiration for culture (does not exclude carcinoma); cytology (particularly in nonlactating patient)

🌱 TREATMENT

GENERAL MEASURES
- Cold and/or warm compresses for pain control
- Continue to breastfeed or express milk to drain the affected breast.
- Antibiotic treatment without puerperal abscess drainage is ineffective (3)[A].
MEDICATION
Combination of antibiotics and drainage for cure

First Line
- NSAIDs for analgesia and/or antipyresis
- Optimal antibiotic first-line treatment for mastitis includes dicloxacillin 500 mg q6h or 1st-generation cephalosporin; clindamycin if penicillin-allergic
- Breast abscess first-line treatment includes empiric antibiotics to cover community-acquired MRSA.
- Nonsevere infection:
  - TMP-SMZ DS 1 to 2 PO BID for 10 to 14 days
  - Clindamycin 300 to 450 mg PO QID as alternative for penicillin-allergic and if concern for anaerobes (1)[C]
  - *Contraindications:* antibiotic allergy
- In severe infections, vancomycin as an inpatient may be necessary (6)[C].
  - Dose (30 mg/kg) IV in 2 divided doses every 24 hours until culture results are available
- Daptomycin can be used as an alternative to vancomycin due to once daily infusion (outpatient), allowing breastfeeding mothers to feed and pump frequently at home (6)[C].
  - Dose (4 mg/kg) IV every 24 hours may be necessary until culture results are available.
  - Modify antibiotics based on culture and sensitivity (1)[A].

SURGERY/OTHER PROCEDURES
Drain all abscesses and treat with antibiotics (1)[A].
- Aspiration with or without US guidance for abscesses <3 cm (1)[B] (Serial aspirations may be necessary.)
- Consider US-guided percutaneous catheter placement if abscess >3 cm (1)[B].
- Consider incision and drainage (I&D) if abscess is >5 cm, recurrent, or chronic (1)[B].
- Biopsy all nonpuerperal abscesses to rule out carcinoma; remove all fistulous tracts in nonlactating patients as well (1)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Lecithin supplementation
- Acupuncture may help with breast engorgement and prevention of breast abscess.
- Breast lymphatic massage may ease engorgement.
- Judicious use of cabbage leaves applied over affected area (to decrease inflammation and milk production)

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Outpatient, unless systemically immunocompromised, septic, or requiring inpatient antibiotic treatment
- Hospital-grade breast pump should be made available to patient from time of admission.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*
Ensure complete resolution to exclude carcinoma.

**PATIENT EDUCATION**
- Wound care, rest, breast milk emptying
- Continue with breastfeeding or pumping (if breastfeeding is not possible due to location of abscess) to prevent engorgement.

**PROGNOSIS**
- Drained abscess heals from inside out (in 8 to 10 days).
- Subareolar abscesses frequently recur, even after I&D and antibiotics; may require surgical removal of ducts

**COMPLICATIONS**
- Fistula: mammary duct or milk fistula
- Poor cosmetic outcome
- Early cessation of breastfeeding (2)

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- N61 Inflammatory disorders of breast
- O91.13 Abscess of breast associated with lactation
- O91.12 Abscess of breast associated with the puerperium

**CLINICAL PEARLS**
- 0.4–11% of cases of puerperal mastitis go on to abscess (most often due to inadequate therapy for mastitis).
- Risk factors for mastitis result from milk stasis (poor milk transfer, infrequent feeds, missing feeds, weaning) (1,2).
Treat abscesses not associated with lactation with antibiotics that cover anaerobic bacteria and work up for malignancy.

The treatment of choice for most breast abscesses is the combination of antibiotics and aspiration.

US-guided aspiration of breast abscess is preferred to I&D in most cases due to better cosmesis and faster recovery.

Continue to empty the breast (feeding, pumping, or expression of breast milk) with lactation-associated breast infections.
**BREAST CANCER**

*Renata Gazzi, MD*

---

**BASICS**

**DESCRIPTION**
- Malignant neoplasm of cells native to the breast—epithelial, glandular, or stroma
- Types: DCIS, infiltrating ductal carcinoma, infiltrating lobular carcinoma, Paget disease, phyllodes tumor, inflammatory breast cancer, angiosarcoma
- Molecular subtypes: luminal A (HR+/HER2−), triple negative (HR−/HER2−), luminal B (HR+/HER2+), HER2-enriched (HR−/HER2+)

**EPIDEMIOLOGY**

**Incidence**
- Estimated new female breast cancer (BC) cases for in situ 63,410; invasive 252,710 in 2017
- Estimated new male BC cases 2,470
- Estimated deaths 2017 females 40,610; males 440
- Most commonly diagnosed cancer and the second most common cause of cancer death for U.S. women

**Prevalence**
Estimated >3.1 million of 164 million U.S. women (1.9%) as of March 1, 2017

---

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Genes such as *BRCA1* and *BRCA2* function as tumor suppressor genes, and mutation leads to cell cycle progression and limitations in DNA repair (2).
- Mutations in estrogen/progesterone induce cyclin D1 and c-Myc expression, leading to cell cycle progression.
- Additional tumors (33%) may cross-talk with estrogen receptors and epidermal growth factors receptors (EGFR), leading to similar abnormal cellular replication.

**Genetics**
Criteria for additional risk evaluation/gene testing in affected individual (2)

[A]

- BC at age ≤50 years
- BC at any age and ≥1 family member with BC ≤50 years of age or ovarian/fallopian tube/primary peritoneal CA any age or ≥2 family members with BC or pancreatic CA any age or population at increased risk (e.g., Ashkenazi Jew with BC or ovarian CA at any age)
- Triple-negative BC (ER−, PR−, HER2−)
- Two BC primaries in single patient
- Ovarian/fallopian tube/primary peritoneal CA
- 1+ family member with BC and CA of thyroid, adrenal cortex, endometrium, pancreas, CNS, diffuse gastric, aggressive prostate (Gleason >7), leukemia, lymphoma, sarcoma, dermatologic manifestations, and/or macrocephaly, GI hamartomas
- Male BC
- Known BC susceptibility gene mutation in family

Criteria for additional risk evaluation/gene testing in unaffected BC individual

- First- or second-degree relative with BC ≤45 years of age
- ≥2 breast primaries in one individual or ≥1 ovarian/fallopian tube/primary peritoneal CA from same side of family or ≥2 w/ breast primaries on same side of family
- 1+ family member with BC and CA of thyroid, adrenal cortex, endometrium, pancreas, CNS, diffuse gastric, aggressive prostate (Gleason >7), leukemia, lymphoma, sarcoma, dermatologic manifestations, and/or macrocephaly, GI hamartomas
- Ashkenazi Jewish with breast/ovary cancer at any age
- Male BC
- Known BC susceptibility gene mutation in family

- BRCA1 and BRCA2 are inherited in an autosomal fashion and account for 5–10% of female and 5–20% male cancers; 15–20% familial BCs
  - Mutations higher in Ashkenazi Jewish descent (2%)
  - Mutation in BRCA raises risk to 45–65% from 7% at age 70 years.
- Other genes: ATM, BARD1, BRIP, CDH1, PTEN, STK11, CHEK2, p53, ERBB2, DIRAS3, NBN, RAD50, RAD51
- Cowden syndrome (PTEN): autosomal dominant, BC, hamartomas of skin, intestine, oral mucosa (trichilemmoma), microencephaly, endometrial CA, nonmedullary thyroid CA, benign thyroid lesions
- Li-Fraumeni syndrome (TP53): autosomal dominant, BC and CA in CNS, leukemia, sarcoma, osteosarcoma, adrenal cortex
Ataxia-telangiectasia (ATM): autosomal recessive, ataxia, telangiectasia, lymphoma, leukemia, CA of breast, stomach, ovary

Peutz-Jeghers (STK11): autosomal dominance; hamartomatous polyps of GI tract, mucocutaneous melanin in lips, buccal mucosa, fingers, toes; CA in GI, lung, breast, uterus, ovary

RISK FACTORS

- Relative risk increase:
  - >4.0: age >65 years, atypical hyperplasia, BRCA mutation, DCIS, LCIS, personal history <40 years, two or more first-degree relatives at early age
  - 2.1 to 4.0 RR: postmenopausal, radiation history, dense breasts (>50%), single first-degree relative
  - 1.1 to 2.0 RR: EtOH, Ashkenazi Jewish, DES exposure, early menarche, high socioeconomic status, first pregnancy >30 years, fibroadenoma, never breastfed, no full-term pregnancies, obesity, personal history >40 years, personal history of endometrial, ovarian, colon cancer, HRT long term, recent OCP use
  - 20–25% lifetime risk: BRCA mutation, first-degree relative with BRCA mutation, history of radiation age 10 to 30 years, Li-Fraumeni or Cowden syndrome or first-degree relative with the same
  - 15–20% lifetime risk: personal history of BC, DCIS, LCIS, atypical ductal hyperplasia, atypical lobular hyperplasia, dense or unevenly dense breasts

GENERAL PREVENTION

- Maintain healthy weight—obesity increases BC risk; limit high carbohydrates.
- Be physically active—150 minutes of moderate-intensity or 75 minutes vigorous activity weekly.
- Eat healthy diet—limit processed/red meat, 7 to 10 servings of vegetables and fruits daily; limit refined-grain.
- Limit EtOH—moderate alcohol use increases risk of BC.
- Clinical breast exam (CBE):
  - USPFTF: insufficient evidence to assess clinical benefits and harms (3)[A]
  - ACS: does not recommend in average risk
- Mammography:
  - USPSTF: women biennial at age 50 to 74 years (3)[B]
  - ACS: women yearly mammograms at age 45 years and can change to every other year beginning at age 55 years
DIAGNOSIS

HISTORY
- Painless lump in breast or axilla
- Breast pain, heaviness
- Swelling, thickening, redness, or dimpling of the skin
- Nipple discharge (bloody), erosion, or retraction

PHYSICAL EXAM
- Visualize breasts with patient sitting for skin dimpling, peau d’orange, asymmetry.
- Palpation of breast and regional lymph node exam: supraclavicular, infraclavicular, axillary

DIFFERENTIAL DIAGNOSIS
- Benign breast disease: fibrocystic disease, fibroadenoma, intraductal papilloma (bloody nipple discharge), duct ectasia, cyst, sclerosing adenosis, fat necrosis (serial/parallel [s/p] breast trauma)
- Infection: abscess, cellulitis, mastitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Mammography BI-RADS: Breast Imaging–Reporting and Data System is a quality assurance (QA) method published by the American Radiology Society.
- BI-RADS interpretation: 0: incomplete (need additional imaging); 1: negative; 2: benign; 3: probably benign; 4: suspicious; 5: highly suggestive of malignancy; 6: known biopsy—proven malignancy
- All newly diagnosed BC: history and physical, CBC, LFTs, ALP, pathology review, ER/PR and HER2 status determination, genetic counseling if high risk, fertility counseling if indicated
- Palpable mass ≥30 years: Obtain mammogram.
  - If BI-RADS 1 to 3, then get ultrasound ± biopsy.
  - If BI-RADS 4 to 6, then get core needle biopsy ± surgical excision.
- Palpable mass <30 years: Obtain ultrasound ± mammogram ± biopsy; if low clinical suspicion, observe for 1 to 2 menstrual cycles for resolution.
- Spontaneous, reproducible nipple discharge: Obtain mammogram ± ultrasound.
– If BI-RADS 1 to 3, then get ductogram or MRI.
– If BI-RADS 4 to 5, then surgical excision
  • Asymmetric thickening/nodularity ≥30 years: Obtain mammogram + ultrasound ± biopsy.
  • Asymmetric thickening/nodularity <30 years: Obtain ultrasound ± mammogram ± biopsy.
  • Skin changes, peau d’orange: Obtain mammogram ± ultrasound ± biopsy.

**Follow-Up Tests & Special Considerations**
  • Early disease (clinical stage I and IIB)
  • Consider additional studies only if signs and symptoms warrant.
  • Advanced disease (stage IIIA or higher)
  • Chest diagnostic CT, abdominal ± pelvis CT, FDG positron emission tomography (PET)/CT scan, bone scan or sodium fluoride PET/CT if FDG-PET/CT indeterminate
  • Most common metastasis: lungs, liver, bone, brain
  • Bone scan: localized pain, elevated alkaline phosphate
  • Abdominal ± pelvis CT: abdominal symptoms, elevated alkaline phosphate, abnormal LFTs
  • Chest imaging: pulmonary symptoms
  • MRI: CNS/spinal cord symptoms

**Diagnostic Procedures/Other**
  • Primary tumor: FNA, ultrasound-guided core needle biopsy, stereotactic-guided core needle biopsy ± wire localization, sentinel lymph node, surgical excision, sentinel lymph node biopsy (SLNB); postbiopsy may get inflammatory changes/hematoma.
  • Genomic assay on formalin-fixed tissue for select +ER, −HER2, node negative tumor to assess chemotherapy responsiveness
  • Consider 21-gene PT-PCR assay to potentially assess risk of recurrence; not validated to predict chemotherapy response

**Test Interpretation**
  • Ductal/lobular/other: tumor size, inflammatory component, invasive/noninvasive, margins, nodal involvement
  • Nodal micrometastases: increased risk of disease recurrence
  • ER, PR, HER2 assay
TREATMENT

MEDICATION

- **Secondary prevention**
  - ASA use at least once per week may be associated with as much as a 50% reduction in death from BC; chemoprevention/hormone therapy for patients age ≥35 years
  - Risk reduction for ER-positive tumors

- **Hormone therapy for ER-positive tumors**
  - SERM (tamoxifen, raloxifene, and toremifene): premenopausal at diagnosis: 5-year treatment and consider for additional 5 years; avoid during lactation, pregnancy, or with history of deep venous thrombosis/pulmonary embolism; routine CYP2D6 testing not recommended; use strong CYP2D6-inhibiting medications with caution in conjunction.
  - Aromatase inhibitors (anastrozole, letrozole, and exemestane): postmenopausal women, 5-year treatment following endocrine therapy for 4.5 to 6 years, or endocrine therapy for up to 10 years
  - Ovarian ablation or suppression with luteinizing hormone–releasing hormone agonists: premenopausal women

- **Target drugs for HER2 positive tumors**
  - Anti-HER2/neu antibody (e.g., trastuzumab with or without pertuzumab) in select HER2/neu-positive patients

- **Neoadjuvant chemotherapy**: Premenopausal women should be counseled on potential effect of chemotherapy on fertility; refer to fertility expert.
  - Locally advanced, inoperable advanced BC (stage III)
  - Early operable BC for breast conservation surgery
  - Triple negative BC and tumor size >0.5 cm

- **Cytotoxic therapy**: anthracyclines, taxanes, alkylating agents, antimetabolites
  - Higher risk patients with nonmetastatic operable tumors
  - Patients with high risk of recurrence after local treatment (s/p surgery ± radiation)

- **Online tool to estimate recurrence risk and benefits of adjuvant chemotherapy** ([https://adjuvantonline.com/](https://adjuvantonline.com/))
  - Monitor cardiac toxicity via ECG, especially with anthracycline.

- **Dose-dense chemotherapy demonstrates overall survival advantage in early BC (4)[A].**

- **Advanced disease**
- Hormone therapy
- Cytotoxic therapy
- Bisphosphonates to decrease skeletal complications
- Antivascular endothelial growth factor antibody
- Anti-HER2/neu antibody in select HER2/neu-positive patients

Metastatic disease
- Monitoring metastatic disease: system assessment, physical examination, performance status, weight, LFT/CBC, CT scan/chest/abdomen/pelvis, bone scan, PET/CT, tumor markers

SURGERY/OTHER PROCEDURES
Secondary prevention
- Risk-reducing mastectomy and bilateral salpingo-oophorectomy for breast and ovary CA syndromes
- Breast-conserving therapy (lumpectomy plus radiation therapy) or modified radical mastectomy. The surgical approach depends on the size of tumor, whether or not multifocal disease is present, and the size of the breast.
- RT should be initiated without delay.
- Evaluation of axillary node: preop ultrasound and biopsy for all patients with clinically suspicious axillary nodes. If biopsy is positive, an axillary node dissection should be performed. If negative, an SLNB at the time of surgery should be performed. Patients with clinically negative axillary nodes should undergo an SLNB at the time of surgery.
- Postmastectomy in select high-risk patients; palliation of metastatic disease; cord compression

Pregnancy Considerations
- Treatment varies on trimester.
- Surgical: mastectomy or breast conservation: mastectomy preferred due to limitations of radiation during pregnancy
- SLNB: safe to use with lymphoscintigraphy
- Chemotherapy: appropriate in 2nd and 3rd trimesters; trastuzumab contraindicated
- RT: Avoid until after delivery.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Postmastectomy
Complications: seroma, phantom breast syndrome, cellulitis, chest wall/axilla/arm pain, long thoracic nerve damage leading to winged scapula sign
Lymphedema; avoid having BP taken on side of surgery.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Every 4 to 6 months for 5 years, then annually
- No evidence to support the use of routine CBC, LFTs, “tumor markers,” bone scan, CXR, liver ultrasound, CT scans, MRI, PET
- Mammogram/imaging 1 year after initial mammogram but 6 to 12 months postradiation and then annually
- Annual gynecologic exam for women on endocrine therapy; bone mineral density at baseline and follow-up for women on aromatase inhibitors or with ovarian failure secondary to treatment

PROGNOSIS (5)

COMPLICATIONS

- Hypercalcemia, metastatic disease, lymphedema
- Emotional issues (depression, body-image alteration)

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- C50.919 Malignant neoplasm of unsp site of unspecified female breast
- D05.90 Unspecified type of carcinoma in situ of unspecified breast
- Z12.31 Encntr screen mammogram for malignant neoplasm of breast

CLINICAL PEARLS

- BC is most common CA death in U.S. women; lifetime risk of 1 in 8
- High alcohol use, high body mass index (BMI), and physical inactivity are modifiable risk factors.
- Pursue/refer all abnormal breast physical examination/imaging findings.
- If patient ≥30 years of age with palpable mass, obtain mammogram; if <30 years of age, obtain ultrasound.
- Normal mammography does not exclude possibility of CA with a palpable mass.
- No alternative medicine treatment has been found to cure BC, but complementary and alternative medicine therapies may help your patient to cope with side effects of treatment.
BREASTFEEDING

Angelia Leipelt, BA, IBCLC, ICCE, CLE • Ronald G. Chambers Jr., MD, FAAFP

BASICS

- Breastfeeding is the natural process of feeding human milk directly from the breast.
- Breast milk is the preferred nutritional source and the normal and physiologic way to feed all newborns and infants.
- Breast milk contains over 200 active components which provide nutrition, fight pathogens, promote healthy gut microbiome, and aid in maturity of immune system.

The American Academy of Pediatrics (AAP), the American Academy of Family Physicians (AAFP), American Congress of Obstetricians and Gynecologists (ACOG), WHO, and other medical organizations recommend exclusive breastfeeding for 6 months, with continuation of breastfeeding for ≥1 year as desired by mother and infant (1)[A].

DESCRIPTION

- Maternal benefits (as compared with mothers who do not breastfeed) include the following:
  - Rapid involution/decreased postpartum bleeding (due to oxytocin release)
  - Association of decreased risk of postpartum depression and increased bonding
  - Associated postpartum weight loss
  - Decreased risk of breast cancer and association of decreased risk of pre- and postmenopausal ovarian cancer, decreased risk of type 2 diabetes, hypertension, hyperlipidemia, rheumatoid arthritis, and cardiovascular disease
  - Decreased risk of prematurity due to child spacing
  - Increased bone density
  - Convenience and economic savings
  - Association of longer continuation in work/school activities

- Infant benefits (as compared with children who are formula-fed) include the following (1):
– Ideal food: easily digestible, nutrients well absorbed, less constipation
– Lower rates of virtually all infections via maternal antibody protection
  o Fewer respiratory and GI infections
  o Decreased incidence of otitis media
  o Decreased risk of bacterial meningitis, pneumonia, and sepsis
  o Decreased incidence of necrotizing enterocolitis
  o Decreased risk of ear infections
– Decreased incidence of obesity and type 1 and 2 diabetes
– Decreased incidence of allergies, clinical asthma, and atopic dermatitis in childhood
– Decreased risk of developing celiac disease and inflammatory bowel disease
– Decreased risk of childhood leukemia
– Decreased risk of sudden infant death syndrome (SIDS) and decreased mortality
– Enhanced neurodevelopmental performance
– Increased attachment between mother and baby
– Decreased child abuse
– Decreases the risk of urinary tract infection

EPIDEMIOLOGY

Incidence
• According to CDC’s Breastfeeding Scorecard, U.S. breastfeeding rates are on the rise in 2016: any breastfeeding: 81.1% (however, differs among different sociodemographic and culture) (2)
• Breastfeeding at 6 months: 51.8%
• Breastfeeding at 12 months: 30.7%
• Exclusive breastfeeding at 3 months: 44.4%
• Exclusive breastfeeding at 6 months: 22.3%

ETIOLOGY AND PATHOPHYSIOLOGY
• The mechanism of milk production is based on several hormones: Prolactin triggers milk production and oxytocin releases milk based on supply and demand (3). Endocrine control system triggers making of colostrum at 5 months’ gestation.
• Alveoli make milk in response to hormone prolactin. Sucking stimulates secretion of prolactin, which triggers milk production.
• Stimulation of areola causes secretion of oxytocin. Oxytocin is responsible for
let-down reflex when myoepithelial cells contract and milk is ejected into milk ducts (3).

- Endocrine/metabolic: Cystic fibrosis, diabetes, galactosemia, phenylketonuria, and thyroid dysfunction may cause delayed lactation or decreased milk.

**GENERAL PREVENTION**

- Most vaccinations can be given to breastfeeding mothers. The CDC recommends that the diphtheria-tetanus-acellular pertussis, hepatitis B, inactivated influenza virus (as opposed to live attenuated), measles-mumps-rubella (MMR), and inactivated polio and varicella vaccines can be given. The CDC recommends avoiding the yellow fever or smallpox vaccine in breastfeeding mothers (4).
- The inactivated influenza virus is preferred to the live attenuated virus in women with infants’ age 6 to 23 months, regardless of whether these infants are being breastfed (4).
- Protective measures include breastfed infants who are more easily aroused than formula-fed infants, triggering a mechanism for the protective effect of breastfeeding against SIDS (5).

**DIAGNOSIS**

**PHYSICAL EXAM**

Examine breasts, ideally during pregnancy, looking for scars, lumps, or flat/inverted nipples. Confirm history of infertility, endocrine disorders, breast and hormonal pathology, overall health and psychosocial concerns, perinatal complications, and previous breastfeeding problem.

**ALERT**

A breast lump should be followed to complete resolution or worked up if present and not just attributed to changes from lactation.

**TREATMENT**

**GENERAL MEASURES**

Breastfeeding initiation

- Initiate breastfeeding immediately after birth, ideally placing the infant on
mother’s chest skin-to-skin in first hour (1,5)[A].

- Mother placed in a comfortable position, usually sitting or leaning back, with baby naked on mom’s naked chest allowing baby to move toward breast
- As baby opens wide, bring baby close, tucking baby in “belly to belly.” Line baby’s nose to nipple, baby tilts its head back with wide open mouth, bring baby close as baby latches to ensure baby’s gum takes in more of the areola.
- Baby’s lips are flanged, rounded cheeks, no clicking or popping sounds, and absence of nipple pain when latched.
- Feed baby on demand, practice rooming in, watch for hunger cues and cluster feeding.
- Feed baby 2 to 8 times for first 24 hours and 8 to 15 times per 24 hours, feeding 10 or more minutes, emptying and alternating breasts.
- Observation of a nursing session by an experienced physician, nurse, or IBCLC
- Avoid supplementation with formula or water and/or artificial nipples unless medically indicated.
- Contraindications to breastfeeding are few (WHO) (1).
  - Maternal HIV (in industrialized world) or human T-cell leukemia virus (HTLV) infection
  - Active untreated tuberculosis
  - Active herpes simplex virus (HSV) lesions on the breast *
  - Substances of abuse without evaluation
  - Review medications that will pass into human milk.
  - Infants with galactosemia or maple syrup urine disease should not be fed with breast milk. Infants with phenylketonuria may be fed breast milk under close observation.
  - Mothers who develop varicella 5 days before through 2 days after delivery *
  - Mothers acutely infected with influenza H1N1 until afebrile *
  - Maternal hepatitis is not a contraindication.
  - *Expressed milk be used

ISSUES FOR REFERRAL

- Refer to trained physician, nurse, or IBCLC for inpatient and/or outpatient teaching.
- Frequent follow-up if having problems with latching, sore nipples, breast pain, over active let down, over supply inadequate milk production

COMPLEMENTARY & ALTERNATIVE
MEDICINE
Galactagogues
- Metoclopramide, domperidone, oxytocin, fenugreek, goat’s rue, and milk thistle have mixed results in improving milk production, but efficacy and safety data are lacking in literature.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
See mother and baby within a few days of hospital discharge, especially if first time breastfeeding.
- Risk factors for suboptimal initiation
  - Breast surgery, especially reduction surgery, prior to pregnancy may disrupt breast milk production.
  - Severe postpartum hemorrhage may lead to Sheehan syndrome, associated with difficulty breastfeeding due to poor milk production.
  - Other factors: delivery mode, duration of labor, gestational age, maternal infection, parity, culture, mother–baby separation, maternal anxiety, use of artificial nipple, and non–breast milk fluids

Patient Monitoring
- Monitor maternal breast milk supply concerns.
- Supplementation with infant formula should be considered if infant has lost ≥10% of birth weight and is recommended if signs of dehydration such as decreased urine output are present.
- Supplementation without persistent breast stimulation with frequent feedings or breast pump use will decrease milk production and decrease breastfeeding success.

DIET
- For mothers:
  - Drink plenty of fluids to satisfy thirst and optimal hydration.
  - Breastfeeding mothers may require ~500 more calories per day.
  - Gassy foods can cause baby to be fussy.
Limit caffeine to <300 mg/day.

Alcohol should be avoided. Possible long-term effects of alcohol in maternal milk remain unknown. If alcohol is used, limit intake to no more than 0.5 (In United States, one drink contains ~14 g of pure alcohol, which is found in: 12 oz of beer [~5% alcohol], 5 oz of wine [~12% alcohol], or 1.5 oz of distilled spirits [~40% alcohol]). Intake over this level may impair the milk ejection reflex.

- Continue prenatal vitamin supplements.

- For infants:
  - In 2008, the AAP increased its recommended daily intake of vitamin D for infants from 200 to 400 IU. For exclusively breastfed babies, this will require taking a vitamin supplement, such as Poly-Vi-Sol or Vi-Daylin vitamin drops, 0.5 mL/day, beginning in the first few days of life (1).
  - In 2010, the AAP recommended adding supplementation for breastfed infants with oral iron 1 mg/kg/day beginning at age 4 months.
    - Preterm infants fed by human milk should receive an iron supplement of 2 mg/kg/day by 1 month of age, and this should be continued until the infant is weaned to iron-fortified formula or begins eating complementary foods that supply the 2 mg/kg of iron.
    - Fluoride supplement is unnecessary until 6 months of age (1).

PATIENT EDUCATION

- Primary care–initiated interventions and support measures to normalize breastfeeding have been shown to be successful with respect to child and maternal health outcomes.
  - U.S. Preventive Services Task Force (USPSTF) recommends structured breastfeeding education and behavioral counseling programs to promote breastfeeding.
    - Regular promotion of the advantages of breastfeeding/risks of not breastfeeding (5)[A]
    - Emphasize importance of exclusive breastfeeding for first 4 weeks of life to allow adequate buildup of sufficient milk supply.

- Milk usually transitions to mature milk about postpartum day 3 to 5.
- Frequent nursing (8 to 12 feedings per 24 hours by day 2)
- Baby should have 6 to 8 wet diapers per day and 3 to 4 bowel movements per day by day 6 to 8.
- Signs of adequate nursing
  - Baby feeding on demand
  - Proper latching and positioning, nipples intact
– Hard breasts become soft after feeding.
– Baby satisfied; appropriate weight gain (average 1 oz/day in first few months)

**Weaning**
– Solid food may be introduced at 4 months with continuation of breastfeeding.
– Mothers returning to work/school should be introduced to alternative feeding methods 1 to 2 weeks prior. Initiate pumping to supply expressed breast milk.

**Family planning**
– Lactational amenorrhea method (LAM): Breastfeeding may be used as effective birth control option if (i) infant is <6 months old, (ii) infant is exclusively breastfeeding, and (iii) mother is amenorrheic.
– Other options include barrier methods, implants, Depo-Provera, PO contraception, and intrauterine devices (IUDs). ACOG recommends that progesterone-only pills be used 2 to 3 weeks postpartum, and that Depo-Provera, IUDs, combined OCPs, and Implanon can be used 6 weeks postpartum. However, ACOG recommends delaying use of combined OCPs until after 6 weeks postpartum when lactation is well established.
– Monitor for changes in milk supply after starting a contraceptive.

**COMPLICATIONS**
– Breast milk jaundice should be considered if jaundice persists for >1 week in an otherwise healthy, well-hydrated newborn. It peaks at 10 to 14 days.

**Plugged duct**
– Mother is well except for sore lump in one or both breasts and is without fever.
– Use moist, hot packs on lump prior to, and during, nursing; more frequent nursing on affected side

**Mastitis (see “Mastitis”)**
– Sore lump in one or both breasts plus maternal fever and/or redness on skin overlying lump
– Use moist, hot packs on lump prior to, and during, nursing.
– Antibiotics covering for *Staphylococcus aureus* (most common organism)
– Other possible sources of fever should be ruled out, that is, endometritis and pyelonephritis.
– Mother should get increased rest; use acetaminophen (Tylenol) PRN.
– Fever should resolve within 48 hours or consider changing antibiotics.
– Lump should resolve. If it continues, an abscess may be present, requiring
surgical drainage.

• Milk supply inadequate
  – Check infant weight gain.
  – Review signs of adequate supply; technique, frequency, and duration of nursing
  – Check to see if mother has been supplementing with formula, thereby decreasing her own milk production.
  – Review health concerns for causes of low milk supply.

• Sore nipples
  – Check technique and improve latch-on.
  – Baby should be taken off the breast by breaking the suction with a finger in the mouth.
  – Air-dry nipples after each nursing and/or coat with expressed breast milk.
  – Use lanolin cream to help in healing.
  – Do not wash nipples with soap and water.
  – Check for signs of thrush in baby and on mother’s nipple. If affected, treat both.
  – Check for evidence of ankyloglossia (tongue tie) in the infant. Correction of ankyloglossia may lead to decreased nipple soreness and improved breastfeeding.
  – Nipple Bleb (a blister on the nipple that can be filled with serous fluid or another fluid) due to improper positioning. Moist heat and improve latching techniques.

• Flat or inverted nipples
  – When stimulated, inverted nipples will retract inward, flat nipples remain flat; check for this on initial prenatal physical.
  – Nipple shells, a doughnut-shaped insert, can be worn inside the bra during the last month of pregnancy to force the nipple gently through the center opening of the shell.

• Engorgement
  – Develops after milk first comes in (day 3 or 4 postpartum), resolves within a day or 2
  – Signs are warm, hard, sore breasts.
    o To resolve, offer baby more frequent nursing; breastfeed long enough to empty breasts.
    o Pump to relieve discomfort.
    o Explore reasons for ongoing problems.

  - La Leche League at [www.llli.org](http://www.llli.org)
CODES

ICD10

Z39.1 Encounter for care and examination of lactating mother

CLINICAL PEARLS

- Women who do not receive support are at risk for shorter durations of breastfeeding.
- Virtually all mothers can breastfeed, provided they have accurate information, and the support of their family, the health care system, and society at large.
- Breast milk is the optimal food for infants, with myriad health benefits for mothers and children.
- USPSTF recommends regular, structured education during pregnancy to promote breastfeeding.
BRONCHIECTASIS
Sumera R. Ahmad, MD • Scott E. Kopec, MD

BASICS
DESCRIPTION
- Bronchiectasis is an irreversible dilatation of ≥1 airways accompanied by recurrent transmural bronchial infection/inflammation and chronic mucopurulent sputum production.
- Generally classified into cystic fibrosis (CF) and noncystic fibrosis (non-CF) bronchiectasis

EPIDEMIOLOGY
- Predominant age: most commonly presents in 6th decade of life
- Predominant sex: female > male (1)

Incidence
Incidence has decreased in the United States for two reasons:
- Widespread childhood vaccination against pertussis
- Effective treatment of childhood respiratory infections with antibiotics

Prevalence
- In the United States, prevalence estimated to be 52.3/100,000.
- Prevalence increased substantially with age from 4.2/100,000 persons aged 18 to 34 years to 271.8/100,000 among those aged 75 years and older (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- CF bronchiectasis: bronchiectasis due to CF
- Non-CF bronchiectasis
  - Most cases are idiopathic.
  - Most commonly associated with non-CF bronchiectasis is childhood infection.
- Vicious circle hypothesis: Transmural infection, generally by bacterial organisms, causes inflammation and obstruction of airways. Damaged airways and dysfunctional cilia foster bacterial colonization, which leads to further inflammation and obstruction.
RISK FACTORS
- Nontuberculous mycobacterial infection is both a cause and a complication of non-CF bronchiectasis.
- Severe respiratory infection in childhood (measles, adenovirus, influenza, pertussis, or bronchiolitis)
- Systemic diseases (e.g., rheumatoid arthritis and inflammatory bowel disease)
- Chronic rhinosinusitis
- Recurrent pneumonia
- Aspirated foreign body
- Immunodeficiency
- Congenital abnormalities

GENERAL PREVENTION
- Routine immunizations against pertussis, measles, Haemophilus influenzae type B, influenza, and pneumococcal pneumonia
- Genetic counseling if congenital condition is etiology
- Smoking cessation

COMMONLY ASSOCIATED CONDITIONS
- Mucociliary clearance defects
  - Primary ciliary dyskinesia
  - Young syndrome (secondary ciliary dyskinesia)
  - Kartagener syndrome
- Other congenital conditions
  - $\alpha_1$-Antitrypsin deficiency
  - Marfan syndrome
  - Cartilage deficiency (Williams-Campbell syndrome)
- Chronic obstructive pulmonary disease
- Pulmonary fibrosis, causing traction bronchiectasis
- Postinfectious conditions
  - Bacteria (H. influenzae and Pseudomonas aeruginosa)
  - Mycobacterial infections (tuberculosis [TB] and Mycobacterium avium complex [MAC])
  - Whooping cough
  - Aspergillus species
  - Viral (HIV, adenovirus, measles, influenza virus)
- Immunodeficient conditions
  - Primary: hypogammaglobulinemia
– Secondary: allergic bronchopulmonary aspergillosis (ABPA), posttransplantation
– Sequelae of toxic inhalation or aspiration (e.g., chlorine, luminal foreign body)

- Rheumatic/chronic inflammatory conditions
  - Rheumatoid arthritis
  - Sjögren syndrome
  - Systemic lupus erythematosus
  - Inflammatory bowel disease
- Miscellaneous
  - Yellow nail syndrome

**DIAGNOSIS**
- Typical symptoms include chronic productive cough, wheezing, and dyspnea.
- Symptoms are often accompanied by repeated respiratory infections.
- Once diagnosed, investigate etiology.

**HISTORY**
- Any predisposing factors (congenital, infectious, and/or exposure-related)
- Immunization history

**PHYSICAL EXAM**
Symptoms are commonly present for many years and include the following:
- Chronic cough (90%)
- Sputum: may be copious and purulent (90%)
- Rhinosinusitis (60–70%)
- Fatigue: may be a dominant symptom (70%)
- Dyspnea (75%)
- Chest pain: may be pleuritic (20–30%)
- Hemoptysis (20–30%)
- Wheezing (20%)
- Bibasilar crackles (60%)
- Rhonchi (44%)
- Digital clubbing (3%)

**DIFFERENTIAL DIAGNOSIS**
DIAGNOSTIC TESTS & INTERPRETATION

- Spirometry
  - Moderate airflow obstruction and hyperresponsive airways
  - Forced expiratory volume in the 1st second of expiration (FEV$_1$): <80% predicted and FEV$_1$/FVC <0.7
  - Special tests
    - Ciliary biopsy by electron microscopy
- Sputum culture
  - *H. influenzae*, nontypeable form (42%)
  - *P. aeruginosa* (18%)
  - Cultures may also be positive for *Streptococcus pneumoniae, Moraxella catarrhalis*, MAC, and *Aspergillus*.
  - Screen for TB and non-TB in selected individuals.
  - Of all isolates, 30–40% will show no growth.
- Special tests
  - Sweat test for CF
  - Purified protein derivative (PPD) test for TB
  - Skin test for *Aspergillus*
  - HIV
  - Serum immunoglobulins to test for humoral immunodeficiency
  - Protein electrophoresis to test for α$_1$-antitrypsin deficiency
  - Barium swallow to look for abnormalities of deglutition, achalasia, esophageal hypomotility
  - pH probe to characterize reflux
  - Screening tests for rheumatologic diseases
- Chest radiograph
  - Nonspecific; increased lung markings or may appear normal
- Chest computed tomography (CT)
  - Noncontrast high-resolution chest CT is the most important diagnostic tool.
  - Bronchi are dilated and do not taper, resulting in “tram track sign”; parallel opacities seen on scan
– Varicose constrictions and balloon cysts may be seen.
– For focal bronchiectasis, rule out endobronchial obstruction.
– For exclusively upper lobe bronchiectasis, consider CF and ABPA.

**Diagnostic Procedures/Other**
- Bronchoscopy may be used to obtain cultures and evacuate sputum.
- Bronchoscopy for hemoptysis
- Bronchoscopy may be useful to rule out airway-obstructing lesions with focal bronchiectasis.

**Test Interpretation**
Bronchoscopic findings include the following:
- Dilatation of airways and purulent secretions
- Thickened bronchial walls with necrosis of bronchial mucosa
- Peribronchial scarring

**TREATMENT**
- Treat underlying conditions.
- Recognize an acute exacerbation with four out of nine criteria.
  - Change in sputum production
  - Increased dyspnea
  - Increased cough
  - Fever
  - Increased wheezing
  - Malaise, fatigue, lethargy
  - Reduced pulmonary function
  - Radiographic changes
  - Changes in chest sounds
- Non-CF bronchiectasis: Determine cause of exacerbations; promote good bronchopulmonary hygiene via daily airway clearance.
- Consider surgical resection of damaged lung for focal disease that is refractory to medical management.
- Medical management: Reduce morbidity by controlling symptoms and preventing disease progression.
- Patients with non-CF bronchiectasis may not respond to CF treatment regimens in the same way as patients with CF do.
MEDICATION

- Insufficient evidence exists to support efficacy of short-course antibiotics in adults and children with bronchiectasis (2).
- Frequent exacerbations may be treated with prolonged and aerosolized antibiotics (3,4).
- Role of mucolytics, anti-inflammatory agents, and bronchodilators is still unclear.

**First Line**

**Antibiotics**
- Potentially useful in acute exacerbations
- Chronic therapy decreases sputum production, number of exacerbations, and hospitalizations, but there is a risk of emergence of resistance to antibiotics (5,6).
- Use of inhaled antibiotics can be considered for selected individuals with gram-negative organisms. Caution needs to be taken with airway and systemic adverse effects noted with inhaled tobramycin and aztreonam (4).
- Patients may require twice the usual dose and longer treatment for 14 days (10 to 21 days) for an acute exacerbation.
- Sputum culture and sensitivity should direct therapy; antibiotic selection is complicated by a wide range of pathogens and resistant organisms.
- Should be administered IV in cases of severe infection (4)
  - Augmentin: 500 mg PO q8–12h. Pediatric: base dosing on amoxicillin content
  - Trimethoprim (TMP)/sulfamethoxazole (SMX): 160 mg TMP/800 mg SMX PO q12h. Pediatric: ≥2 months, 8 mg/kg TMP and 40 mg/kg SMX PO/24 hours, administered in two divided doses q12h
  - Doxycycline and cefaclor given PO are also effective.
  - Nebulized aminoglycosides (tobramycin): 300 mg by aerosol BID
  - Ciprofloxacin: 750 mg PO q12h for adults for susceptible strain of *Pseudomonas*
  - Macrolides: appear to have immunomodulatory benefits

- Chronic use of azithromycin as an oral macrolide for 6 to 12 months in non-CF bronchiectasis has been shown to reduce exacerbations; needs caution with respect to cardiovascular deaths, where it is a QTc-prolonging medication
- All patients considered for chronic therapy with azithromycin should be screened for non-TB mycobacterium infection prior (4).
Bronchodilators
- Chronic use of β₂-agonists (e.g., albuterol) reverses airflow obstruction (2).

Inhaled corticosteroids
- Inhaled corticosteroids may improve lung function, but the effect is small (6).
  - Fluticasone propionate: 110 to 220 μg inhaled BID
  - Use of combination of long-acting bronchodilator with inhaled corticosteroid may reduce dyspnea, wheeze, and cough (6).
    - Budesonide 160 μg/formoterol 4.5 μg 2 puffs inhaled BID

**Second Line**
Other broad-spectrum antimicrobials, including those with antipseudomonal coverage

**ADDITIONAL THERAPIES**
Sputum clearance techniques, including chest physiotherapy (percussion and postural drainage) and pulmonary rehabilitation (improves exercise tolerance)

**SURGERY/OTHER PROCEDURES**
- Surgery if area of bronchiectasis is localized and symptoms remain intolerable despite medical therapy or if disease is life-threatening (3)
- Surgery effectively improves symptoms in 80% of these cases.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Bronchiectasis can present as life-threatening massive hemoptysis. In this situation, in addition to airway protection and resuscitation, bronchial artery embolization or surgical intervention is necessary to control bleeding (2).

**ONGOING CARE**
Long-term outpatient treatment recommendations for bronchiectasis in children and adults (3):
- Children and adults with CF and non–CF-related bronchiectasis should be treated by comprehensive interdisciplinary chronic disease management programs.
- In children, aim to achieve normal growth and development.
Patients with primary and secondary immune deficiencies should be under joint care with a clinical immunologist.

Patient with CF should be referred to a CF center.

Patient should be informed of the various techniques for airway clearance.

Nebulized saline or hypertonic saline (7% saline) use prior to airway clearance techniques can help augment sputum production (3)[B].

Whereas nebulized dornase and high dose anti-inflammatory agents such as ibuprofen have some benefit in CF-related bronchiectasis, there is no role of such agents in non–CF-related bronchiectasis. In fact, nebulized dornase in adults can be harmful with more frequent exacerbations and decline in lung function.

Pulmonary rehabilitation should be offered to patients with symptoms of breathlessness affecting activities of daily living (3)[B].

In situation of an acute exacerbation, use and modify antibiotics as per sputum microbiology.

Consider suitability of long-term antibiotics for patients with recurrent exacerbations.

Noninvasive ventilation can improve quality of life in patients with chronic respiratory failure and can reduce hospitalizations.

Consider lung transplant evaluation in patients with declining respiratory status and FEV₁ <30%. However, because non-CF bronchiectasis has significantly lower mortality hazard compared to CF-related bronchiectasis, separate referral and listing criteria should be considered (7).

FOLLOW-UP RECOMMENDATIONS
Regular exercise is recommended.

**Patient Monitoring**

- Serial spirometry at least annually (3)
- Chest CTs to monitor progression of disease may be indicated with some conditions such as bronchiectasis with MAC infections.
- Routine microbiologic sputum analysis

**PATIENT EDUCATION**
http://www.lungusa.org/

**PROGNOSIS**

- Mortality rate (death due directly to bronchiectasis) is 10.6–29.7% (7).
- *Pseudomonas* infection, low body mass index, and advanced age are associated with poorer prognosis (5).

**COMPLICATIONS**
- Hemoptysis
- Recurrent pulmonary infections
- Pulmonary hypertension
- Cor pulmonale
- Lung abscess

**REFERENCES**

**CODES**

**ICD10**
- J47.9 Bronchiectasis, uncomplicated
- J47.1 Bronchiectasis with (acute) exacerbation
- J47.0 Bronchiectasis with acute lower respiratory infection
CLINICAL PEARLS

- Symptoms of bronchiectasis include chronic productive cough, wheezing, and dyspnea often accompanied by repeated respiratory infections.
- A chest x-ray has poor sensitivity and specificity for the diagnosis; a noncontrast high-resolution chest CT is the most important diagnostic tool.
- Current practice guidelines recommend treating acute exacerbations with a 14-day course of antibiotics. Frequent exacerbations may be treated with prolonged and aerosolized antibiotics.
BRONCHIOLITIS

Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION

- Inflammation and obstruction of small airways and reactive airways generally affecting infants and young children—upper respiratory infection (URI) prodrome followed by increased respiratory effort and wheezing
- Usual course: insidious, acute, progressive
- Leading cause of hospitalizations in infants and children in most Western countries
- Predominant age: newborn–2 years (peak age <6 months). Neonates are not protected despite transfer of maternal antibody.
- Predominant sex: male > female

EPIDEMIOLOGY

Incidence

- There is a 21% incidence of bronchiolitis in the United States and it accounts for ~$1.7B in health care cost in United States.
- May be seasonal (October to May in the Northern Hemisphere) and often occurs in epidemics
- Responsible for 18.8% (90,000 annually) of all pediatric hospitalizations (excluding live births) in children <2 years.
- Incidence increasing since 1980 (with concomitant increase in relative rate of hospitalization from 2002 to 2007); of those <12 months with condition, the hospitalization rate ~2–3%

ETIOLOGY AND PATHOPHYSIOLOGY

RSV accounts for 70–85% of all cases (children <12 months of age), but rhinovirus, parainfluenza virus, adenovirus, influenza virus, *Mycoplasma pneumoniae*, and *Chlamydia pneumoniae* have all been implicated:

- Infection results in necrosis and lysis of epithelial cells and subsequent release of inflammatory mediators.
- Edema and mucus secretion, which combined with accumulating necrotic
debris and loss of cilia clearance, result in airflow obstruction.
- Ventilation–perfusion mismatching resulting in hypoxia
- Air trapping is caused by dynamic airways narrowing during expiration, which increases work of breathing.
- Bronchospasm appears to play little or no role.

**RISK FACTORS**
- Secondhand cigarette smoke
- Low birth weight, premature birth
- Immunodeficiency
- Formula feeding (little or no breastfeeding)
- Contact with infected person (primary mode of spread)
- Children in daycare environment
- Congenital cardiopulmonary disease
- <12 weeks of age

**GENERAL PREVENTION**
- Hand washing or use of alcohol-based hand rubs (preferred)
- Contact isolation of infected babies
- Persons with colds should keep contact with infants to a minimum.
- Breastfeeding of infants has been associated with reduced morbidity of disease.
- Palivizumab (Synagis), a monoclonal product, administered monthly, October to May, 15 mg/kg IM; used for RSV prevention ONLY in high-risk patients (see American Academy of Pediatrics [AAP] recommendations)

**Pediatric Considerations**
Prior infection does not seem to confer subsequent immunity.

**COMMONLY ASSOCIATED CONDITIONS**
- Upper respiratory congestion
- Conjunctivitis
- Pharyngitis
- Otitis media
- Diarrhea

![DIAGNOSIS](mebooksfree.com)
History and physical examination should be the basis for the diagnosis of bronchiolitis; ancillary testing only indicated if clinical picture is unclear (no single of group of tests confirmatory for bronchiolitis)

**HISTORY**
- Irritability
- Anorexia
- Fever
- Noisy breathing (due to rhinorrhea)
- Cough
- Grunting
- Cyanosis
- Apnea
- Vomiting

**PHYSICAL EXAM**
- Tachypnea
- Retractions (increased work of breathing)
- Rhinorrhea
- Wheezing
- Upper respiratory findings: pharyngitis, conjunctivitis, otitis

**DIFFERENTIAL DIAGNOSIS**
- Other pulmonary infections such as pertussis, croup, or bacterial pneumonia
- Aspiration
- Vascular ring
- Foreign body
- Asthma
- Heart failure
- Gastroesophageal reflux
- Cystic fibrosis

**DIAGNOSTIC TESTS & INTERPRETATION**
Laboratory and other ancillary testing (including chest x-ray) are not required if clinical diagnosis is bronchiolitis.

*Initial Tests (lab, imaging)*
- Arterial oxygen saturation by pulse oximetry. Results need to be interpreted in
clinical context. Transient hypoxemia is a common phenomenon in healthy infants (1).

- Rapid respiratory viral antigen testing is not necessary during RSV season because the disease is managed symptomatically but may be useful for epidemiologic, hospital cohorting, or in the very young to reduce unnecessary other workup; also indicated in infants admitted while receiving palivizumab prophylaxis (if positive, prophylaxis may be discontinued)
- The AAP does not recommend routine RSV testing in infants and children with bronchiolitis.
- Chest x-ray findings are variable and may include atelectasis, peribronchial cuffing, hyperinflation, and perihilar infiltrates.

**TREATMENT**
The cornerstone of therapy is supportive to include upper airway suctioning, prevention of significant and prolonged hypoxia, and dehydration. The other interventions noted have historically varying effect on the course of the illness despite numerous studies. Recent clinical practice guidelines do not support the routine use of corticosteroids, bronchodilators, or epinephrine. Parental education and support is vital (1)[A].

**MEDICATION**

**First Line**

- Humidified oxygen for hypoxia of <90% (many feel that transient pulse oximetry in 85–90% range during sleeping in clinically well-appearing infant may be observed) (1)[C]
- Nebulized hypertonic saline (3%) can be effective in reducing LOS in hospitalized patients but not recommended use in the ED (more recent literature review shows some signal of benefit) (1,2)[B].
- Antibiotics only if secondary bacterial infection present (rare); not indicated for routine use (1)[B]
- Positive-pressure ventilation (PPV) in the form of continuous positive airway pressure (CPAP) can be used in cases of respiratory failure. There is limited clinical evidence other than observational studies (3)[C].
- High-flow nasal cannula oxygen widely used in various settings to improve oxygen saturation with resultant reduction in end-tidal CO₂ (ETCO₂) and respiratory rate, but overall effectiveness remains unproven to date (3)[C]. (A
prospective, randomized, multicenter trial is ongoing in AUS, NZ.)

ADDITIONAL THERAPIES

- Ribavirin (palivizumab) for patients at high risk (for prophylaxis per CDC/AAP guidelines) (4)[A]
- Heliox therapy (70% helium and 30% oxygen) may be of benefit early in moderate to severe bronchiolitis to reduce degree of respiratory distress due to airflow restriction, but Cochrane Review found little evidence of sustained benefit at 24 hours (5)[A].
- Although not routinely recommended, inhaled β-agonists (albuterol) can be effective in selected cases (particularly in patients with a history of bronchospasm). Many clinicians will attempt an empiric trial of bronchodilators in a primary presentation to judge the clinical response (some argue that this condition maybe asthma equivalent).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Bronchiolitis can be associated with apnea in children <6 weeks of age.
- Respiratory rate >45 breaths/min with respiratory distress or apnea
- Hypoxia is common, so clinical criteria are more helpful (pulse oximetry <94% used by many as cutoff).
- Ill or toxic appearance
- Underlying heart condition, respiratory condition, or immune suppression
- High risk for apnea (age <30 days, preterm birth [<37 weeks])
- Dehydrated or unable to feed
- Uncertain home care
- Use of Respiratory distress assessment instrument may aid in determining admission. The five best predictors of admission, age, respiratory rate, heart rate, oxygen saturation, and duration of symptoms, were recently incorporated into a scoring instrument.
- Supplemental oxygen for pulse oximetry <94% on room air if clinically indicated (i.e., retractions, increased WOB, etc.). AAP recommends O2 saturation >90% if infant otherwise well.
- IV fluids indicated only if tachypnea precludes oral feeding; weight-based maintenance rate plus insensible losses
- Discharge criteria
  - Normal respiratory rate and no oxygen requirement: Recent small studies suggest that after a period of observation, children can be safely discharged
on home oxygen with home health follow-up.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Hospitalization is usually required only if oxygen is a requirement or unable to feed/drink.
- For a hospitalized patient, monitor as needed depending on the severity of the infection.
- If the patient is receiving home care, follow daily by telephone call for 2 to 4 days; the patient may need frequent office visits.

PATIENT EDUCATION
- American Academy of Family Physicians: http://www.familydoctor.org

PROGNOSIS
- Recovery time is variable. 40% can have symptoms at 14 days and 10% at 4 weeks.
- Mortality statistics differ but probably <1%.
- High-risk infants (bronchopulmonary dysplasia, congenital heart disease) may have a prolonged course.

COMPLICATIONS
- Bacterial superinfection
- Bronchiolitis obliterans
- Apnea
- Respiratory failure
- Death
- Increased incidence of development of reactive airway disease (asthma)

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- J21.9 Acute bronchiolitis, unspecified
- J21.0 Acute bronchiolitis due to respiratory syncytial virus
- J21.8 Acute bronchiolitis due to other specified organisms

**CLINICAL PEARLS**

- Bronchiolitis is the leading cause of hospitalizations in infants and children—especially <3 months of age.
- Diagnosis is a clinical one of children in the first 2 years of life, associated with rhinorrhea, cough, labored breathing, and irritability.
- RSV causes the majority of bronchiolitis.
- Parental education and support is essential.
- Nasal and upper airway suctioning mainstay of treatment
BRONCHITIS, ACUTE

Ashlee N. Russo, MD • Alan Cropp, MD, FCCP • Ghazaleh Bigdeli, MD, FCCP

BASICS
DESCRIPTION
- Inflammation of trachea, bronchi, and bronchioles resulting from a respiratory tract infection or chemical irritant (1)
- Cough, the predominant symptom, may last as long as 3 weeks (2,3).
- Generally self-limited, with complete healing and full return of function (2).
- Most infections are viral if no underlying cardiopulmonary disease is present (2).
- Synonym(s): tracheobronchitis

Geriatric Considerations
Can be serious, particularly if part of influenza, with underlying COPD or CHF (3)

Pediatric Considerations
- Usually occurs in association with other conditions of upper and lower respiratory tract (trachea usually involved)
- If repeated attacks occur, child should be evaluated for anomalies of the respiratory tract, immune deficiencies, or for asthma.
- Acute bronchitis caused by RSV may be fatal.
- Antitussive medication not indicated in patients age <6 years (2)

EPIDEMIOLOGY
- Predominant age: all ages
- Predominant gender: male = female

Incidence
- ~5% of adults per year
- Common cause of infection in children

Prevalence
Results in 10 to 12 million office visits per year

ETIOLOGY AND PATHOPHYSIOLOGY

- Viral infections such as adenovirus, influenza A and B, parainfluenza virus, coxsackievirus, RSV, rhinovirus, coronavirus (types 1 to 3), herpes simplex virus, metapneumovirus (2)
- Bacterial infections, such as *Chlamydia pneumoniae*, *Mycoplasma*, *Bordetella pertussis*, *Haemophilus influenzae*, *Streptococcus pneumoniae*, *Moraxella catarrhalis*, and *Mycobacterium tuberculosis* (2)
- Secondary bacterial infection as part of an acute upper respiratory infection
- Possible fungal infections
- Chemical irritants
- Acute bronchitis causes an injury to the epithelial surfaces, resulting in an increase in mucus production and thickening of the bronchiole wall (1).

Genetics

No known genetic pattern

RISK FACTORS

- Infants
- Elderly
- Air pollutants
- Smoking
- Secondhand smoke
- Environmental changes
- Chronic bronchopulmonary diseases
- Chronic sinusitis
- Tracheostomy or endobronchial intubation
- Bronchopulmonary allergy
- Hypertrophied tonsils and adenoids in children
- Immunosuppression
  - Immunoglobulin deficiency
  - HIV infection
  - Alcoholism
- Gastroesophageal reflux disease (GERD)

GENERAL PREVENTION

- Avoid smoking and secondhand smoke.
Control underlying risk factors (i.e., asthma, sinusitis, and reflux).
Avoid exposure, especially daycare.
Pneumovax, influenza immunization

COMMONLY ASSOCIATED CONDITIONS
- Allergic rhinitis
- Sinusitis
- Pharyngitis
- Epiglottitis (rare but can be rapidly fatal)
- Coryza
- Croup
- Influenza
- Pneumonia
- Asthma
- COPD/emphysema
- GERD

DIAGNOSIS

HISTORY
- Onset of cough for >5 days and no evidence of pneumonia, asthma, exacerbation of COPD (3)
- Cough is initially dry and nonproductive, then productive; later, mucopurulent sputum, which may indicate secondary infection
- Cough lasts >5 days (1).
- Dyspnea, wheeze, and fatigue may occur.
- Possible contact with others who have respiratory infections (1)
- Fever may suggest pneumonia or influenza infection (1).

PHYSICAL EXAM
- Fever
- Tachypnea
- Pharynx injected
- Rhonchi, wheezing
- No evidence of pulmonary consolidation

DIFFERENTIAL DIAGNOSIS
- Common cold
- Acute sinusitis
- Bronchopneumonia
- Influenza
- Bacterial tracheitis
- Bronchiectasis
- Asthma
- Reactive airways dysfunction syndrome (RADS)
- Allergy
- Eosinophilic pneumonitis
- Aspiration
- Retained foreign body
- Inhalation injury
- Cystic fibrosis
- Bronchogenic carcinoma
- Heart failure
- GERD
- Chronic cough

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- None normally needed; diagnosis is based on history and physical exam showing no postnasal drip or rales (1,3).
- For a complicated picture, consider the following:
  - CBC with differential
  - Sputum culture/sensitivity if CXR is abnormal (3)
  - Influenza titers (if appropriate for time of year) (1)
  - Viral panel
- No testing needed unless concerned about pneumonia
- Pulse oximetry if underlying pulmonary disease is present
- CXR
  - Lungs normal, if uncomplicated
  - Helps to rule out other diseases (pneumonia) or complications

**Follow-Up Tests & Special Considerations**
- Arterial blood gases: hypoxemia (rarely)
- Pulmonary function tests (seldom needed during acute stages): increased residual volume, decreased maximal expiratory rate (2)
Sputum culture in those patients intubated or with tracheostomy

**TREATMENT**

**GENERAL MEASURES**
- Outpatient treatment unless elderly or complicated by severe underlying disease
- Rest
- Stop smoking and avoid secondhand smoke.
- Steam inhalations
- Vaporizers
- Adequate hydration
- Antitussives
- Antibiotics are usually not recommended (1,3,4)[A].
- Treat associated illnesses (e.g., GERD).

**MEDICATION**

**ALERT**
Antibiotics are not recommended (1,3)[A] unless a treatable pathogen has been identified or significant comorbidities are present. This should be explained to patients who likely expect an antibiotic to be prescribed (3)[B].

**First Line**
- Supportive; increased fluids (cough results in increased fluid loss)
- Antipyretic analgesic such as aspirin, acetaminophen, or ibuprofen
- Decongestants if accompanied by sinus condition
- Cough suppressant for troublesome cough (not with COPD); honey, benzonatate (Tessalon), guaifenesin with codeine or dextromethorphan. Not indicated in children age <6 years (2)[C].
- Mucolytic agents are not recommended (3)[B].
- Inhaled β-agonist (e.g., albuterol) or in combination with high-dose inhaled corticosteroids for cough with bronchospasm in those with known airflow obstruction (2,5)[B]
- If influenza is highly suspected and symptom onset is <48 hours: oseltamivir (Tamiifu) or zanamivir (Relenza) (2)[B]
- Antibiotics ONLY if a treatable cause (i.e., pertussis) is identified (2)[A].
– Clarithromycin (Biaxin): 500 mg q12h or azithromycin (Zithromax) Z-Pak for atypical or pertussis infection (1)[A]
– In patients with acute bronchitis of a suspected bacterial cause, azithromycin tends to be more effective in terms of lower incidence of treatment failure and adverse events than amoxicillin or amoxicillin-clavulanic acid (6)[B].
  o Doxycycline: 100 mg/day × 10 days if Moraxella, Chlamydia, or Mycoplasma suspected
  o Quinolone for more serious infections or other antibiotic failure or in elderly or patients with multiple comorbidities

Contraindication(s): Doxycycline and quinolones should not be used during pregnancy or in children.

Precautions:
– Multiple antibiotics have the potential to interfere with the effectiveness of oral contraceptives.
– Antibiotic use can be associated with *Clostridium difficile* infections.
– Cough and cold preparations should not be used in children <6 years (2)[B].

**Second Line**
Other antibiotics if indicated by sputum culture

**ISSUES FOR REFERRAL**
– Complications such as pneumonia or respiratory failure
– Comorbidities such as COPD
– Cough lasting >3 months

**ADDITIONAL THERAPIES**
– Antipyretic for fever (e.g., acetaminophen, or ibuprofen)
– Inhaled β-agonist (e.g., albuterol) or in combination with high-dose inhaled corticosteroids for cough with bronchospasm (2)[B]
– Oral corticosteroids probably not indicated (2)[C]

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Throat lozenges for pharyngitis

**ADMISSION, INPATIENT, AND NURSING**
CONSIDERATIONS

- Hypoxia—may require supplemental oxygen.
- Respiratory failure that may require CPAP/bilevel ventilation
- Severe bronchospasm
- Exacerbation of underlying disease
- Bronchodilators if patient is bronchospastic
- IV fluids may be helpful if patient is dehydrated.
- Ensure patient comfort and monitor for signs of deterioration, especially if underlying lung disease exists.
- May need to follow oxygen saturation in patients with underlying lung disease
- Discharge criteria: improvement in symptoms and comorbidities

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Usually a self-limited disease not requiring follow-up
- Cough may linger for several weeks.
- In children, if recurrent, need to consider other diagnoses, such as asthma (4)

Patient Monitoring

- Oximetry until no longer hypoxemic
- Recheck for chronicity.

DIET

Increased fluids (3 to 4 L/day) while febrile

PATIENT EDUCATION

- For patient education materials favorably reviewed on this topic, contact the American Lung Association: 1740 Broadway, New York, NY 10019 (212) 315-8700; www.lungusa.org
- American Academy of Family Physicians: www.familydoctor.org

PROGNOSIS

- Usual: complete resolution
- Can be serious in the elderly or debilitated
- Cough may persist for several weeks after an initial improvement.
- Postbronchitic reactive airways disease (rare)
Bronchiolitis obliterans and organizing pneumonia (rare)

COMPLICATIONS
- Superinfection such as bronchopneumonia
- Bronchiectasis
- Hemoptysis
- Acute respiratory failure
- Chronic cough

REFERENCES

SEE ALSO
- Asthma; Chronic Obstructive Pulmonary Disease and Emphysema
- Algorithm: Cough, Chronic

CODES

**ICD10**
- J20.9 Acute bronchitis, unspecified
- J68.0 Bronchitis and pneumonitis due to chemicals, gases, fumes and vapors
B97.0 Adenovirus as the cause of diseases classified elsewhere

CLINICAL PEARLS

- Acute bronchitis is a common and generally self-limited disease.
- It usually does not require treatment with antibiotics. This needs to be explained to patients who expect antibiotics to be prescribed.
- Cough may linger for several weeks.
- Recurrent or seasonal episodes may suggest another disease process, such as asthma.
- Fever is uncommon and should prompt investigation for pneumonia or influenza.
BULIMIA NERVOSA
Umer Farooq, MD • Saeed Ahmed, MD

BASICS
DESCRIPTION
• A pattern of discrete periods of binge eating (within 2-hour period) along with lack of control over eating, followed by compensatory behaviors such as self-induced vomiting, misuse of laxatives, and so forth
• Both binge eating and compensatory behaviors happening at least once per week for 3 months
• DSM-5 classifies bulimia nervosa as
  – Mild: 1 to 3 episodes of compensatory behaviors
  – Moderate: 4 to 7 episodes of compensatory behaviors
  – Severe: 8 to 13 episodes of compensatory behaviors
  – Extreme: 14 or more episodes of compensatory behaviors
• System(s) affected: oropharyngeal, endocrine/metabolic, gastrointestinal, dermatologic, cardiovascular, nervous

EPIDEMIOLOGY
• Predominant age: adolescents and young adults
• Mean age of onset: 18 to 21 years
• Predominant sex: female > male (10:1)

Incidence
28.8 women, 0.8 men per 100,000 per year

Prevalence
• More prevalent than anorexia nervosa
• 1–3% in women age 16 to 35 years
• 0.5% in young men (higher among gay and bisexual men)

ETIOLOGY AND PATHOPHYSIOLOGY
• Combination of biologic, psychological, environmental, and social factors. Unique contribution of any specific factor remains unclear.
• Strong evidence of serotonergic dysregulation in bulimia nervosa
Substantial literature shows genetic evidence for bulimia nervosa.

**RISK FACTORS**
- Female gender
- History of obesity and dieting
- Body dissatisfaction
- Critical comments about weight, body shape, or eating
- Severe life stressor
- Low self-esteem
- Perceived pressure to be thin
- Perfectionist or obsessive thinking
- Poor impulse control, substance abuse
- Environment stressing high achievement, physical fitness (e.g., armed forces, ballet, cheerleading, gymnastics, or modeling)
- Family history of substance abuse, affective disorders, eating disorder, or obesity
- Type 1 diabetes
- Sexual abuse is not causally related to bulimia.

**GENERAL PREVENTION**
- Prevention programs can reduce risk factors and future onset of eating disorders.
- Target adolescents and young women ≥15 years.
- Realistic and healthy weight management strategies and attitudes
- Decrease body dissatisfaction and promote self-esteem.
- Reduce focus on thin as ideal.
- Decrease anxiety/depressive symptoms and improve stress management.

**COMMONLY ASSOCIATED CONDITIONS**
- Major depression and dysthymia
- Anxiety disorders
- Substance use disorder
- Bipolar disorder
- Obsessive-compulsive disorder
- Borderline personality disorder

**DIAGNOSIS**

mebooksfree.com
**HISTORY**
- Patients unlikely to self-identify binge eating or purging behaviors; corroborate with parent/relative.
- Unhappiness and/or preoccupation with weight and diet attempts
- Pattern of binge eating and compensatory behaviors
  - Binge is context-specific (usually within 2-hour period, they will eat what would be an unusually large amount for most people)
  - Vomiting (often with little effort)
  - Vigorous aerobic exercise
  - Distress/shame related to loss of control
- Depressed mood and self-depreciation following the binges
- Other possible signs and symptoms
  - Requesting weight loss help and mildly underweight to overweight
  - Diet pill, diuretic, laxative, ipecac, and thyroid medication use/abuse
  - Menstrual disturbance
  - Fatigue and lethargy
  - Abdominal pain, bloating, constipation, diarrhea, rectal prolapse
  - Sore throat
  - Thermal tooth sensitivity
  - Frequent fluctuations in weight
  - Omission/underdosing insulin in diabetes patients
- Screening
  - Clinician administered eating-disorder screen for primary care to identify patients with eating disorders.
    - Are you satisfied with your eating patterns? (No is abnormal.)
    - Do you ever eat in secret? (Yes is abnormal.)
    - Does your weight affect the way you feel about yourself? (Yes is abnormal.)
    - Have any members of your family suffered with an eating disorder? (Yes is abnormal.)
    - Do you currently suffer with or have you ever suffered in the past with an eating disorder? (Yes is abnormal.)

**PHYSICAL EXAM**
- Often normal
- Bradycardia
- Eroded tooth enamel
- Perimyololysis
- Cheilosis
- Gingivitis
- Sialadenosis
- Asymptomatic, noninflammatory parotid gland enlargement
- Epigastric tenderness to palpation
- Calluses, abrasions, bruising on hand, thumb (Russell sign)
- Peripheral edema

**Differential Diagnosis**
- Anorexia, binge eating/purging type
- Major depressive disorder
- Addison disease
- Celiac disease
- Diabetes mellitus
- Hyperthyroidism, hypothyroidism
- Hyperpituitarism
- Hypothalamic brain tumor
- Kleine-Levin syndrome
- Body dysmorphic disorder
- Borderline personality disorder

**Diagnostic Tests & Interpretation**
All lab results may be within normal limits and are not necessary for diagnosis.
- Psychological self-report screening tests may be helpful, but diagnosis is based on meeting the DSM-5 criteria:
  - SCOFF Questionnaire (1)[B]
  - Eating Disorder Screen for Primary Care

**Initial Tests (lab, imaging)**
- Blood work, CBC, and CMP
  - Hypokalemia, hypochloremia
  - Hypomagnesemia, hyponatremia, hypocalcemia, hypophosphatemia
  - Serum amylase levels
  - Alkalosis
  - Elevated BUN
  - Hypoglycemia
- Urinalysis
  - Increased urine specific gravity
Diagnostic Procedures/Other

- Electrocardiogram
- Bradycardia or arrhythmias
- Conduction defects
- Depressed ST segment due to hypokalemia

Test Interpretation

- Esophagitis
- Acute pancreatitis
- Cardiomyopathy and muscle weakness due to ipecac abuse
- Melanosis coli
- Cathartic colon syndrome
- Delayed or arrested skeletal growth
- Stress fracture
- Irreversible dental erosions
- Osteopenia/osteoporosis

TREATMENT

- Cognitive-behavioral therapy (CBT) should be considered as first-line treatment (2,3)[A].
  - Interpersonal therapies and group therapies have been found to be helpful.

GENERAL MEASURES

- Multidisciplinary team
  - Primary care physician, behavioral health provider, nutritionist
- Build trust; increase motivation for change.
- Assess psychological and nutritional status.
- Consider evidence-based self-help program.

  CBT for bulimia nervosa (2,3)[A]
  - Sixteen to twenty 50-minute appointments
  - Involve patient in establishing goals.
  - Self-monitoring of food intake, frequency of binges/purges, related antecedents, consequences, thoughts, and emotions
  - Self-monitoring of weight once per week
  - Educate about ineffectiveness of purging for weight control and adverse outcomes.
– Establish prescribed eating plan to develop regular eating habits and realistic weight goal.
– Gradually introduce feared foods into diet.
– Problem-solve how to cope with triggers.
– Decrease ruminations about calories, weight, and purging.
– Challenge fear of loss of control.
– Establish relapse prevention plan.
– Gradual laxative withdrawal

- Interpersonal therapy
  – May act more slowly than CBT
- Transdiagnostic CBT
- Dialectical behavior therapy
- Family therapy for adolescents
- Nutritional education, relaxation techniques
- Educate patient to brush teeth and use baking soda to rinse mouth after vomiting.

**ALERT**
Contraindications to treating bulimia nervosa with CBT (4)[B] are

- Medical instability
- Severe major depression
- Substance use disorder
- Suicidal ideation or behavior
- Psychosis

**MEDICATION**

**First Line**

- Selective serotonin reuptake inhibitors (SSRIs) (5)[A], (6)[B], particularly fluoxetine (Prozac) titrated to 60 mg/day, are effective in reducing symptoms with relatively few side effects. Higher doses than standard doses for depression are often needed.
  – Combination of medication and CBT has been shown to have added benefit over medication or therapy alone.
- To prevent relapse, maintain antidepressant at full therapeutic dose for at least 1 year.
- Avoid bupropion: contraindicated due to its association with seizures in patients who purge
- Precautions
– Serious toxicity following overdose is common.
– Patients may vomit medications.

**Second Line**
- Select different SSRI (citalopram, fluvoxamine, and sertraline).
- Ondansetron (Zofran) 4 to 8 mg TID between meals can help prevent vomiting.
- The anticonvulsant topiramate may have some usefulness in helping to diminish binge-purge episodes in bulimic patients. Additionally, bright light therapy in certain controlled trials has reduced binge-purge frequency in bulimia nervosa patients.
- Psyllium (Metamucil) preparations, 1 tbsp QHS with glass of water, can prevent constipation during laxative withdrawal.

**ISSUES FOR REFERRAL**
Patients with bulimia require a multidisciplinary team, including a primary care physician, behavioral health provider, and a nutritionist. Important part of treatment is to arrange mental health therapist for psychotherapy.

**ADDITIONAL THERAPIES**
Most patients can be treated as outpatients.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Bright light therapy may help.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
If possible, admit to a specialized eating disorders unit.
- Supervised meals and bathroom privileges
- Monitor weight and physical activity.
- Monitor electrolytes.
- Gradually shift control to patients as they demonstrate improvement.
- Hospitalize if severe malnutrition.
- Admission to inpatient general guidelines:
  – Syncope
  – Potassium <3.0
– Esophageal tears
– Cardiac arrhythmias
– Hypothermia
– Suicide risk
– Intractable vomiting
– Hematemesis
– Failure to response outpatient treatment

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Binge–purge activity, including antecedents and consequences
- Level of exercise activity
- Self-esteem, comfort with body and self
- Ruminations and depressive symptoms
- Repeat any abnormal lab values weekly or monthly until stable.

**DIET**
- Balanced diet, normal eating pattern
- Reintroduce feared foods.

**PATIENT EDUCATION**
- [http://www.nami.org/helpline/bulimia.html](http://www.nami.org/helpline/bulimia.html)

**PROGNOSIS**
- After effective CBT
  - In the short term, 50% of treated individuals do not meet criteria for diagnosis.
  - In the long term (2 to 10 years), 70% may be asymptomatic.
  - Symptomatic individuals may demonstrate remissions, relapses, subclinical, or other eating disorder–related behaviors.
- Untreated
– Likely to remain chronic/relapsing problem
  - Greater weight fluctuations, other impulsive behaviors, childhood obesity, low self-esteem, family history of alcohol abuse, psychiatric comorbidity, and personality disorder diagnoses (e.g., avoidant personality disorder) may predict poor prognosis.
  - Mortality rate: 0.4%. The death rate for bulimia nervosa is much lower than that for anorexia nervosa. Patients who remain in remission for >1 year have a better long-term outcome.

**COMPLICATIONS**

- Substance use disorder
- Osteopenia/osteoporosis
- Stress fracture
- Gastric dilatation
- Boerhaave syndrome
- Mallory-Weiss tears
- Pseudo-Bartter syndrome
- Spontaneous pneumomediastinum
- Potassium depletion, cardiac arrhythmia, cardiac arrest
- Suicide

**Pregnancy Considerations**

Maternal and fetal problems if pregnant
- Binging/purging behaviors may persist, increase, or decrease with pregnancy.
- Increased risk for preterm delivery, operative delivery, and infants with low birth weight should be managed as high risk.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

F50.2 Bulimia nervosa

**CLINICAL PEARLS**

- Asking “Are you satisfied with your eating patterns?” and/or “Do you worry that you have lost control over how much you eat?” may help to screen for an eating problem.

- Weight is not severely lowered as in anorexia nervosa.

- Consider using a stepped care approach. Start with a guided self-help program using instructional aids; next, begin CBT (e.g., 16 to 20 sessions over 4 to 5 months).

- SSRIs, particularly fluoxetine (60 mg daily), may be helpful as a first step or as an adjunctive treatment with CBT.
BUNION (HALLUX VALGUS)

Jennifer G. Chang, MD

BASICS

DESCRIPTION

- Lateral deviation of the great toe (Hallux abducto valgus derives from the Latin for “big toe askew.”)
- Associated with medial deviation of the 1st metatarsal, leading to a medial prominence of the 1st metatarsophalangeal (MTP) joint (also known as “Bunion”); progressive subluxation of the 1st MTP joint is common.
- System(s) affected: musculoskeletal/skin

EPIDEMIOLOGY

- Predominant age: more common in adults
  - Estimated 23% in adults aged 18 to 65 years
  - Estimated 35.7% in elderly >65 years
- Predominant sex: female > male by ~2:1

Prevalence

- Prevalence increases with age particularly in females.
- Juvenile hallux valgus
  - More common in girls (>80% of cases)
- Commonly bilateral
- Pain is not usually the presenting symptom.

ETIOLOGY AND PATHOPHYSIOLOGY

Multifactorial. Contributing factors include the following:

- Valgus deviation of the hallux promotes varus position of the 1st metatarsal.
- Medial MTP joint capsule stretches and attenuates, whereas the lateral capsule contracts.
- Metatarsal head moves medially, shifting the sesamoid bones to a more lateral position.
- Extensor hallucis longus deviates laterally.
- Lateral and plantar migration of abductor hallucis moves the great toe into plantar flexion and lateral pronation.
- Medial collateral ligament stretches and eventually ruptures due to this deviation, decreasing stability and causing progressive subluxation of the 1st MTP joint.

**RISK FACTORS**
- Familial predisposition
- Abnormal biomechanics (i.e., flexible flat feet)
- Joint laxity; pronation of hindfoot; Achilles tendon contracture; pes planus (fallen arches)
- Metatarsus primus varus
- Amputation of second toe
- Inflammatory joint disease
- Neuromuscular disorders
- Improper footwear, narrow toe box

**GENERAL PREVENTION**
Proper footwear may decrease the progression of the disease.

**COMMONLY ASSOCIATED CONDITIONS**
- Medial bursitis of the 1st MTP joint (most common)
- Hammertoe deformity of the 2nd phalanx
- Plantar callus
- Metatarsalgia
- Degeneration of 1st metatarsal head cartilage
- Pronated feet; ankle equinus
- Onychocryptosis (ingrown toenail)
- Entrapment of the medial dorsal cutaneous nerve
- Synovitis of the MTP joint

**DIAGNOSIS**
- Based on clinical exam
- Radiographs are used for staging.

**HISTORY**
- Painful MTP joint (most common symptom in adults)
- Abnormal position of great toe
- Enlargement of the MTP joint medially (patients complain of a “bump”)

mebooksfree.com
Shoes don’t fit properly
Pain on ambulation
Skin irritation, blistering, callus formation at 1st MTP

PHYSICAL EXAM
- Observe gait; may be antalgic due to pain
- Increased distal metatarsal articular angle (DMAA)
- Medial prominence at the MTP joint
- Skin changes: inflammation, blistering, callus or ulceration at the MTP joint
- Great toe over- or underriding the second toe
- Examine the entire first ray for:
  - 1st MTP range of motion
  - 1st tarsometatarsal mobility
  - Neurovascular integrity
  - Degenerative osteoarthritis

DIFFERENTIAL DIAGNOSIS
- Trauma
  - Turf toe; sesamoiditis; stress fracture
- Infection
  - Osteomyelitis; septic arthritis
- Joint disorder
  - Osteoarthritis; rheumatoid arthritis; pseudogout; gout
- Tendon disorder
  - Tendinosis; tenosynovitis; tendon rupture
- Other
  - Bursitis; ganglia; foreign body granuloma

DIAGNOSTIC TESTS & INTERPRETATION
- Weight-bearing AP and lateral radiographs (sesamoid view optional) to assess:
  - Joint congruency and degenerative changes
  - Lateral sesamoid bone displacement
  - Rounded 1st MT head
  - Longer 1st metatarsal
- Radiographic parameters:
  - Hallux valgus angle (HA): Long axis of the 1st MT and proximal phalanx is normally <15 degrees.
  - Intermetatarsal angle (IM): Between long axis of 1st and 2nd MT is
normally <9 degrees.
- DMAA: Between 1st MT long axis and line through base of distal articular cap is normally <15 degrees.
- Hallux valgus interphalangeus: Between long axis of distal phalanx and proximal phalanx is normally <10 degrees.

**TREATMENT**

- Primary indication for treatment is pain.
- There are conservative and surgical approaches.
- Surgical treatment is generally more effective in improving pain but has attendant risks.

**GENERAL MEASURES**

Nonoperative treatment options may improve symptoms and delay the progression of hallux valgus deformity, although high-quality evidence is limited:

- Proper fitting footwear: low-heeled, wide-toe shoes to decrease stress on MTP joint (i.e., wide toe box)
- Orthoses to correct foot alignment (pes planus and overpronation). Improving gait may prevent bunion formation and reduce pressure on the MTP.
- Night splinting: In theory, splinting stabilizes and balances soft tissue structures around the MTP. Limited evidence shows improvement in degree of angulation in mild hallux valgus.
- Manual and manipulative therapy (MMT): stretches contracted soft tissue
- Foot exercises and stretching to improve intrinsic foot muscle strength and increase range of motion
- Pads/spacers: Pads decrease friction on the MTP joint. A toe spacer in the 1st interdigital space may reduce pain (1)[C].

**MEDICATION**

- Topical and PO medications (NSAIDs) can be used to relieve pain and swelling. Other topical options include capsaicin cream.
- Corticosteroid injections improve pain.

**ADDITIONAL THERAPIES**

Custom orthoses are a safe intervention that may decrease pain at 6 and 12
months compared with no treatment; however, this improvement is less than that seen with surgical intervention (2)[B].

SURGERY/OTHER PROCEDURES
- Surgery is indicated for patients with severe pain, dysfunction, or persistent symptoms that do not abate with conservative therapy.
- >150 different surgical techniques to treat hallux valgus:
  - No technique is proven superior; no universally accepted standard exists for procedure selection.
  - Choice of technique depends on disease severity, radiographic findings, and patient/surgeon-specific factors.
    - There are arthrodesis: fusion of the 1st MTP joint; reserved for severe and/or recurrent hallux valgus (rarely performed)
    - Arthroplasty: removing the joint or replacing it with a prosthesis
    - Exostectomy/bunionectomy: removing the medial bony prominence of the MTP joint
    - Soft tissue realignment: alters the function of surrounding ligaments and tendons; used for minor, flexible deformities
    - Osteotomy and realignment: can correct large deformities, but evidence of long-term outcome is lacking (3)[C]
    - Mini-tight rope procedure: use of a FiberWire to correct the misalignment of the deformity
- Surgery may decrease pain and improve foot alignment.
- Some patients may have little to no improvement in symptoms despite interventions. Providers should establish realistic expectations prior to surgery.
- In pediatric patients, surgery should generally be delayed until skeletal maturity (4)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE
Marigold ointment may reduce pain and soft tissue swelling related to bunion.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Postoperative treatment includes physical therapy, physiotherapy, supportive
footwear, continuous passive motion, or manual manipulation.
- Time until full weight bearing depends on the surgical procedure.

PROGNOSIS
Patient outcome varies depending on biomechanical factors, severity of the deformity, and treatment modality used. The radiologic HA angle predicts surgical outcomes. Patients with an HA angle <37 degrees have a higher chance of having the deformity successfully corrected with surgery compared with patients with an HA angle >37 degrees (5)[B].

COMPLICATIONS
- Risks associated with surgery include infection, persistent pain, and poor cosmetic result.
- Additional risks vary with the surgical procedure.
- Other complications may include:
  - Early swelling
  - Hallux varus
  - Recurrence of bunion
  - Metatarsal fracture
  - Decreased sensation over the 1st metatarsal or phalanx

REFERENCES
ADDITIONAL READING

CODES

**ICD10**

- M20.10 Hallux valgus (acquired), unspecified foot
- M20.11 Hallux valgus (acquired), right foot
- M20.12 Hallux valgus (acquired), left foot
CLINICAL PEARLS

- Avoid footwear with high heels, pointed toe boxes, or inadequate toe space to reduce development or progression of bunions.
- Surgery generally results in superior outcomes for pain relief in appropriately selected patients.
- No single surgical method has shown to be superior for long-term pain relief.
- Establish realistic expectations prior to surgery to improve patient satisfaction with surgical outcomes.
BASICS

DESCRIPTION

- Tissue injuries caused by application of heat, chemicals, electricity, or irradiation.
- Extent of injury (depth of burn) is a result of intensity and duration of exposure.
  - 1st degree involves superficial layers of epidermis.
  - 2nd degree involves varying amounts of epidermis (with blister formation) and part of the dermis.
  - 3rd degree involves destruction of all skin elements (full thickness) with coagulation of subdermal plexus.
- System(s) affected: endocrine/metabolic, pulmonary, skin/exocrine

Geriatric Considerations

- Prognosis is worse for severe burns.
- Patients >60 years of age account for 11% all of burns

Pediatric Considerations

Consider child abuse or neglect when dealing with hot water burns in children; abuse accounts for 15% of pediatric burns. Special concerns are sharply demarcated wounds, immersion injuries, and suspect stories. Involve child welfare services early.

EPIDEMIOLOGY

- Predominant age: 30 years; 13% infants; 11% >60 years of age
- Predominant gender: males account for 70%.

Incidence

Per year in the United States

- 1.2 to 2 million burns; 700,000 emergency room visits; 45,000 to 50,000 hospitalizations; 3,900 deaths owing to burn-related complications
- In children: 250,000 burns; 15,000 hospitalizations; 1,100 deaths
- Estimated total cost of $2 billion annually for burn care
- House fires cause 75% of deaths.
- Burn deaths decreasing nationally due to improved prevention and treatment
- Increase in burns from the illegal production of methamphetamines. Patients can present with a combination of chemical burn, thermal burn, and explosion injury.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Open flame and hot liquid are the most common causes of burns (heat usually ≥45°C): flame burns more common in adults; scald burns are more common in children.
- Caustic chemicals or acids (may show little signs or symptoms for the first few days)
- Electricity (may have significant injury with very little damage to overlying skin)
- Excess sun exposure

**RISK FACTORS**
- Water heaters set too high
- Workplace exposure to chemicals, electricity, or irradiation
- Young children and older adults with thin skin are more susceptible to injury.
- Carelessness with burning cigarettes: related to 18% of fatal fires in 2006
- Inadequate or faulty electrical wiring
- Lack of smoke detectors: Lacking or nonfunctioning smoke alarms are implicated in 63% of residential fires.
- Arson: cause of 12.4% of fires that resulted in fatalities in 2012

**GENERAL PREVENTION**
Home safety education should be a key mechanism for injury prevention.
- Families educated on home safety were more likely to have safe hot water temperatures.
- Safety education results in more families having functioning smoke alarms and increased use of fireguards.

**COMMONLY ASSOCIATED CONDITIONS**
Smoke inhalation syndrome
- May involve thermal burn to respiratory mucosa (e.g., trachea, bronchi) as well as carbon monoxide inhalation
• Occurs within 72 hours of burn
• Should be suspected in all burns occurring in an enclosed space or exposure to explosions

**DIAGNOSIS**

**HISTORY**
• History of source of burn
• In children or elderly: Check for consistency between the history and the burn’s physical characteristics.

**PHYSICAL EXAM**
• 1st degree: Erythema of involved tissue, skin blanches with pressure, skin may be tender.
• 2nd degree: Skin is red and blistered, skin is very tender.
• 3rd degree: Burned skin is tough and leathery; skin is nontender.
• Rule of 9s
  – Each upper extremity: adult and child 9%
  – Each lower extremity: adult 18%; child 14%
  – Anterior trunk: adult and child 18%
  – Posterior trunk: adult and child 18%
  – Head and neck: adult 10%; child 18%
• Quick estimate: The surface area of the patient’s hand (palmar surface plus fingers) is 1% of the body surface area (BSA).
• Careful documentation of extent of burn and the estimated depth of burn
• Check for any signs suggestive of potential airway involvement: singed nasal hair, facial burns, carbonaceous sputum, progressive hoarseness, inflamed oropharynx, circumferential burns around the neck, tachypnea

**DIAGNOSTIC TESTS & INTERPRETATION**
• Children: glucose (hypoglycemia may occur in children because of limited glycogen storage)
• Smoke inhalation: arterial blood gas, carboxyhemoglobin
• Electrical burns: ECG, urine myoglobin, creatine kinase isoenzymes

*Initial Tests (lab, imaging)*
• Labs: hematocrit; type and crossmatching; electrolytes, including BUN and
creatinine; urinalysis

- Imaging: Chest radiograph; Xenon scan is useful in suspected smoke inhalation.

**Diagnostic Procedures/Other**

Bronchoscopy may be necessary in smoke inhalation to evaluate lower respiratory tract (1)[A].

---

**TREATMENT**

- **Prehospital care**
  - Remove the patient from the source of burn.
  - Extinguish and remove all burning clothing.
  - Room-temperature water may be poured onto burn but only in the first 15 minutes following burn exposure.
  - Wrap patient to prevent hypothermia.
  - All patients to receive 100% oxygen via face mask.

- **Hospitalization for all serious burns**
  - 2nd-degree burns >10% of BSA
  - Any 3rd-degree burn
  - Burns of hands, feet, face, or perineum
  - Electrical or lightning burns
  - Inhalation injury
  - Chemical burns
  - Circumferential burn

- **Transfer to burn center for (2)[C]**
  - 2nd- and 3rd-degree burns >10% of BSA in patients <10 years and >50 years of age
  - 2nd-degree burns >20% of BSA and full-thickness burns >5% BSA in any age range
  - 3rd-degree burns in any age group
  - Burns of hands, feet, face, or perineum
  - Electrical or lightning burns
  - Inhalation injury
  - Chemical burns
  - Circumferential burn
  - Burns in patients with additional trauma (fractures, etc.) in which the burn is the more severe injury; otherwise, send to trauma center for stabilization.
Burn injuries in patients with preexisting medical conditions that could affect management, mortality, or recovery

GENERAL MEASURES

- Based on depth of burns and accurate estimate of total BSA involved (rule of 9s)
- Tetanus prophylaxis (if not current)
- Remove all rings, watches, and other items from injured extremities to avoid tourniquet effect.
- Remove clothing and cover all burned areas with dry sheets.
- Flush area of chemical burn (for ~2 hours).
- For all major burns, use 100% oxygen administration; consider early intubation.
- Do not apply ice to burn site.
- Nasogastric tube (high risk of paralytic ileus)
- Foley catheter
- Analgesia
- ECG monitoring in first 24 hours following electrical burn
- Whirlpool hydrotherapy followed by silver sulfadiazine (Silvadene) occlusive dressings in severe burns
- Daily or BID cleansing with dressing changes
- Burn fluid resuscitation
  - Calculate fluid resuscitation from time of burn, not from time treatment begins.
  - 2 to 4 mL lactated Ringer × body weight (kg) × % BSA burn (1/2 given in first 8 hours, in second 8 hours, and in third 8 hours); in children, this is given in addition to maintenance fluids and is adjusted according to urine output and vital signs. Protocol-based resuscitation leads to superior outcomes.
  - Colloid solutions are not recommended during the first 12 to 24 hours of resuscitation (3)[A].
  - Other: Use of biologic membranes or skin substitutes may be indicated for burn coverage.
- Inhalation injury
  - Intubation, ventilation with positive end-expiratory pressure assistance
  - Hyperbaric oxygen treatment may be useful in patients with carbon monoxide levels >25%, patients with coma, focal neurologic deficit, ischemic ECG changes, and pregnant patients.
MEDICATION

First Line
- IV morphine or hydromorphone (Dilaudid) for severe pain
- Oral analgesics, such as acetaminophen (Tylenol) with codeine, acetaminophen with oxycodone (Percocet), or acetaminophen with hydrocodone (Lortab) for moderate pain
- Silver sulfadiazine (Silvadene): Apply topically to burn site (can cause leukopenia). Do not use in sulfa-allergic patients, women who are pregnant/breastfeeding, or infants (<2 months).
- Neosporin or bacitracin ointment: Apply to facial burns.
- Mupirocin: has potent inhibitory activity against methicillin-resistant *Staphylococcus aureus* (MRSA)
- Acticoat A.B. (a dressing consisting of two sheets of high-density polyethylene mesh coated with nanocrystalline silver) has a more controlled, prolonged release of silver, allowing less frequent dressing changes.
- Electrical burn with myoglobinuria will require alkalinization of urine and mannitol.
- Consider H₂ blockers (e.g., famotidine) or proton pump inhibitors (e.g., lansoprazole, pantoprazole) for stress ulcer prophylaxis in severely burned patients.
- Tetanus toxoid/tetanus immunoglobulin
- There is no clear indication for prophylactic systemic antibiotics.
- Use of negative pressure wound therapy may result in a low-protease environment with higher levels of angiogenic factor (vascular endothelial growth factor [VEGF]) during wound healing, leading to more chaotic, hyperkeratinized, thickened epidermis when compared with a standard hydrocolloid dressing.

Second Line
- Mafenide (Sulfamylon) for full-thickness burn, best against *Pseudomonas* (Caution: metabolic acidosis, painful)
- Silver nitrate 0.5% (messy, leeches electrolytes from burn, causes water toxicity)
- Povidone–iodine (Betadine) may result in iodine absorption from burn and “tan eschar,” makes débridement more difficult.
- Travase (enzymatic débridement)
SURGERY/OTHER PROCEDURES

- Escharotomy may be necessary in constricting circumferential burns of extremities or chest due to compartment syndrome.
- Tangential excision with split-thickness skin grafts: Early excision of burns results in a significant reduction in mortality (excluding patients with inhalational injury) and a significant decrease in hospital length of stay (4)[B].
- Various dressings (e.g., biosynthetic, biologic) are available to help reduce the number of dressing changes and promote healing.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Early mobilization is the goal.

DIET

- High-protein, high-calorie diet when bowel function resumes
- Nasogastric tube feedings may be required in early postburn period.
- Total parenteral nutrition if NPO is expected for >5 days
- Early initiation of enteral nutrition in the first 24 hours of admission results in shorter intensive care unit (ICU) stay and lower wound infection rates

PATIENT EDUCATION

- Use of sunscreen: Skin grafts or newly epithelialized skin is highly sensitive to sun exposure and thermal extremes.
- Prevent access to electrical cords/outlets.
- Isolate household chemicals.
- Use low-temperature setting for water heater (<54°C).
- Household smoke detectors with special emphasis on maintenance
- Family/household evacuation plan
- Proper storage and use of flammable substances

PROGNOSIS

- 1st-degree burn: complete resolution
- 2nd-degree burn: epithelialization in 10 to 14 days (deep 2nd-degree burns probably will require skin graft)
- 3rd-degree burn: no potential for reepithelialization; skin graft is required.
- Baux score (sum of age and TBSA burned) and Denver 2 score (pulmonary score ranging 0 to 3, using \( \text{PaO}_2 / \text{FiO}_2 \) cutoffs of 100, 175, and 250), renal score (0 to 3, using creatinine cutoffs of 1.8, 2.5, and 5.0 mg/dL), hepatic score (0 to 3, using bilirubin cutoffs of 2, 4, and 8 mg/dL), and cardiac score (0 to 3, based on number and dosage of inotropes) can be used to estimate mortality (5)[B].
- Length of hospital stay and need for ICU care depend on extent of burn, smoke inhalation, comorbidities, and age.
- Burn size is correlated to complications; >60% TBSA burned in children and >40% in adults are at increased risk for mortality and morbidity (5)[B].
- A 50% survival rate can be expected with a 62% burn in patients aged 0 to 14 years, 63% burn in patients aged 15 to 40 years, 38% burn in patients aged 40 to 65 years, and 25% burn in patients >65 years of age.
- 90% of survivors can be expected to return to an occupation comparable to their preburn employment.

COMPLICATIONS
- Gastroduodenal ulceration (Curling ulcer)
- Marjolin ulcer: malignant squamous cell carcinoma developing in old burn site
- Signs of infection: discoloration, green fat, edema, eschar separation, and conversion of 2nd-degree to 3rd-degree wound
- Biopsy is the best way to diagnose wound infection.
- Burn wound sepsis: most commonly \( S. \text{ aureus} \) (including MRSA), vancomycin-resistant enterococci, and gram-negative organisms
- Pneumonia
- Decreased mobility with possibility of future flexion contractures
- Hypertrophic scarring common with burns

REFERENCES

**CODES**

**ICD10**
- T30.0 Burn of unspecified body region, unspecified degree
- T30.4 Corrosion of unspecified body region, unspecified degree

**CLINICAL PEARLS**
- 1st degree: erythema of involved tissue; skin blanches with pressure. Skin may be tender.
- 2nd degree: Skin is red and blistered. Skin is very tender.
- 3rd degree: Burned skin is tough and leathery. Skin is not tender.
BURSITIS, PES ANSERINE (PES ANSERINE SYNDROME)

Jennifer B. Schwartz, MD

BASICS

DESCRIPTION

- The pes anserinus ("goosefoot") is the combined insertion of the sartorius, gracilis, and semitendinosus (SGT) tendons on the anteromedial tibia.
- The pes anserine muscles help flex the knee and resist valgus stress.
- The pes anserine bursa lies deep to the SGT tendons and superficial to the tibial attachment of the medial collateral ligament.
- *Pes anserine syndrome* is due to irritation of the bursa and/or tendons in this area.

EPIDEMIOLOGY

Incidence

Inflammation of the pes anserine bursa is detected in up to 2.5% of MRI studies of patients with knee pain. The overall incidence is likely higher.

ETIOLOGY AND PATHOPHYSIOLOGY

Pes anserine bursitis occurs due to:

- Overuse injury
- Excessive valgus and rotary stresses
- Mechanical forces and degenerative changes
- Direct trauma

RISK FACTORS

- Obesity
- Age, female gender
- Pes planus; genu valgum
- Knee joint laxity/ligamentous injury
- Long distance running, hill running; change in mileage
- Swimming ("breaststroker’s knee"); cycling
- Sports with side-to-side (cutting) activity (soccer, basketball, racquet sports)
COMMONLY ASSOCIATED CONDITIONS

- Osteoarthritis (OA)
- Knee pain due to OA is often associated with pes anserine bursitis, both of which may need specific treatment.
- Higher grades of OA associated with a thicker pes anserine bursa and larger area of bursitis (1)
- Valgus knee deformity
- Obesity
- Diabetes mellitus (questionable association)

DIAGNOSIS

HISTORY

- Medial knee pain is the most common complaint.
- Pain is located 4 to 6 cm distal to the medial joint line on the anteromedial aspect of the tibia.
- Pain exacerbated by knee flexion:
  - Going up or down stairs
  - Getting out of a chair

PHYSICAL EXAM

- Common findings include:
  - Tenderness to palpation at the pes anserine insertion
    - 30% of asymptomatic patients will have tenderness to deep palpation in this area.
  - Pain worsens with flexion of the knee against resistance.
  - Localized swelling of the pes anserine insertion
- Findings that suggest an alternative diagnosis: joint effusion, tenderness directly over the joint line, erythema or warmth, locking of the knee, systemic signs such as fever or pain with passive knee movement

DIFFERENTIAL DIAGNOSIS

- Medial collateral ligament injury
- Medial meniscal injury
- Medial plica syndrome
- Medial compartment OA
- Semimembranosus bursitis
• Popliteal/meniscal cyst
• Tibial stress fracture
• Septic arthritis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Primarily a clinical diagnosis
- Lab work not indicated
- Imaging is not indicated unless there is concern for bony injury/fracture, ligamentous injury, or meniscal tear.

**Follow-Up Tests & Special Considerations**
- Ultrasound (US)
  - Can demonstrate focal edema within the pes anserine bursa but has poor correlation with clinical findings
  - Many patients with the clinical diagnosis of pes anserine bursitis have no morphologic changes of the pes anserine complex on US.
- MRI: can demonstrate inflammation of the bursa and delineate the pes anserine bursa from other structures. T2-weighted axial images are best on MRI.
  - No large studies have evaluated the correlation between the clinical diagnosis of pes anserine bursitis and radiographic evidence of pes anserine pathology on MRI.
  - May see fluid in the pes bursa on MRI in 5% of asymptomatic patients

**TREATMENT**

Pes anserine bursitis is often self-limited. Conservative therapy is most common:
- Relative rest and activity modification to avoid offending movements (especially knee flexion)
- Ice to the affected area
- Physical therapy for knee strengthening and range of motion activities (2)[C]
- NSAIDs for pain control
- Corticosteroid injection
- Weight loss to improve biomechanical forces at the knee
- Extracorporeal shock wave therapy (3)[C]
MEDICATION

First Line
NSAIDs, such as ibuprofen (800 mg PO TID) or naproxen (500 mg PO BID), are common first-line therapy.

Second Line
- Corticosteroid injection combined with local anesthetic provides relief in many patients.
  - Inject at the point of maximal tenderness using standard aseptic technique.
  - ~2 mL of anesthetic (i.e., 1% lidocaine) and 1 mL of steroid (i.e., 40 mg of methylprednisolone) is injected into the bursa using a small (e.g., 25-gauge, 1-inch) needle.
  - Insert needle perpendicular to the skin until bone is felt and then withdraw slightly before injecting.
  - Avoid injecting directly into the tendon (4)[C].
- US-guided injection is superior to blind injection (5)[C].
- Platelet-rich plasma injections also provide pain relief (6)[C].

ADDITIONAL THERAPIES
- Hamstring and Achilles stretching
- Quadriceps strengthening—particularly of the vastus medialis (terminal 30 degrees of knee extension)
- Adductor strengthening

SURGERY/OTHER PROCEDURES
- No role for surgery in routine isolated cases
- Drainage or removal of bursa may be used in severe/refractory cases.

ONGOING CARE
Home exercise program focusing on flexibility and strengthening

DIET
Consider dietary changes as part of a comprehensive weight-loss program if obesity is a contributing factor.
PROGNOSIS
Most cases of pes anserine syndrome respond to conservative therapy. Recurrence is common, and multiple treatments may be required.

REFERENCES

ADDITIONAL READING

CODES
ICD10
- M70.50 Other bursitis of knee, unspecified knee
- M70.51 Other bursitis of knee, right knee
- M70.52 Other bursitis of knee, left knee

**CLINICAL PEARLS**

- Consider pes anserine syndrome in patients presenting with medial knee pain.
- Pes anserine syndrome is relatively common in athletes and in older, obese patients with OA.
- Tenderness over the insertion of the pes anserine tendon on the medial aspect of the tibia 4 to 6 cm distal to the joint line is common in asymptomatic patients as well—correlation of the entire clinical picture is necessary for accurate diagnosis.
- Consider pes anserine syndrome in patients who have persistent symptoms associated with medial-sided OA.
- Treatment is typically conservative. A local steroid/anesthetic injection may provide pain relief and enhance rehabilitation.
CANDIDIASIS, MUCOCUTANEOUS
Sheila O. Stille, DMD • Hugh Silk, MD, MPH, FAAFP

BASICS
DESCRIPTION
- Heterogeneous mucocutaneous disorder caused by infection with common commensal Candida species
- Characterized by superficial infection of the skin, mucous membranes, and nails
- >20 Candida species cause infection in humans. Candida albicans is most common, at 80% of isolates.
- Candidiasis affects:
  - Aerodigestive system
    - Oropharyngeal candidiasis (thrush): mouth, pharynx
    - Angular cheilitis: corner of the mouth
    - Esophageal candidiasis
    - Gastritis and/or ulcers, associated with thrush; alimental or perianal
  - Other systems
    - Candida vulvovaginitis: vaginal mucosa and/or vulvar skin
    - Candidal balanitis: glans of the penis
    - Candidal paronychia: nail bed or nail folds
    - Folliculitis
    - Interdigital candidiasis: webs of the digits
    - Candidal diaper dermatitis and intertrigo (within skin folds)
- Synonym(s): monilia; thrush; yeast; intertrigo

ALERT
Vaginal antifungal creams and suppositories can weaken condoms and diaphragms.

Pregnancy Considerations
- Vaginal candidiasis is common during pregnancy.
- Topical treatment during pregnancy should be extended by several days (typically a full 7-day course).
- Vaginal yeast infection at birth increases the risk of newborn thrush but is of
no overall harm to baby.

EPIDEMIOLOGY

- Common in the United States; particularly with immunodeficiency and/or uncontrolled diabetes
- Age considerations
  - Infants and seniors: thrush and cutaneous infections (infant diaper rash)
  - Women of childbearing age: vaginitis
  - Prepubertal or postmenopausal: yeast vaginitis
  - Predominant sex: female > male

Incidence

Unknown—mucocutaneous candidiasis is common in immunocompetent patients. Complication rates are low.

Prevalence

*Candida* species are normal flora of oral cavity, pharynx, esophagus, and GI tract that are present in >70% of the U.S. population.

ETIOLOGY AND PATHOPHYSIOLOGY

*C. albicans* (responsible for 80–92% vulvovaginal and 70–80% oral isolates). Altered cell–mediated immunity against *Candida* species (either transient or chronic) increases susceptibility to infection (2)[A].

Genetics

Chronic mucocutaneous candidiasis is a heterogeneous, genetic syndrome with infection of skin, nails, hair, and mucous membranes; typically presents in infancy.

RISK FACTORS

- Immune suppression (antineoplastic treatments, transplant patients, cellular immune defects) (2)[A]
- Malignant diseases
- AIDS or hematologic/immune disorders (neutropenia)
- Corticosteroid use
- Smoking and alcoholism
- Hyposalivation (Sjögren disease, drug-induced xerostomia, radiotherapy) (2)[A]
• Broad-spectrum antibiotic therapy
• Douches, chemical irritants, and concurrent vaginitides alter vaginal pH and predispose patients to candidal vaginitis.
• Denture wear, poor oral hygiene
• Birth control pills, intrauterine devices
• Endocrine alterations (DM, pregnancy, renal failure, hypothyroidism)
• Uncircumcised men at higher risk for balanitis

GENERAL PREVENTION

• Use antibiotics and steroids judiciously; rinse mouth after inhaled steroid use (1)[A].
• Avoid douching.
• Treat other vaginal infections.
• Minimize perineal moisture (wear cotton underwear; frequent diaper changes).
• Clean dentures often; use well-fitting dentures and remove during sleep.
• Optimize glycemic control in diabetics.
• Preventive regimens during cancer treatments (2)[A]
• Treat with HAART in HIV-infected patients.
• Antifungal prophylaxis against oral candidiasis is not recommended in HIV-infected adults unless patients have frequent or severe recurrences (2)[A].

COMMONLY ASSOCIATED CONDITIONS

• HIV
• Leukopenia
• Diabetes mellitus
• Cancer and other immunosuppressive conditions

DIAGNOSIS

HISTORY

• Infants/children
  – Oral: adherent white patches on oral mucosae or on the tongue that do not wipe away easily
  – Perineal: erythematous rash with characteristic satellite lesions; painful if skin layer eroded. 40–75% of diaper rashes lasting >3 days are C. albicans (2)[A].
Angular cheilitis: painful fissures at corners of mouth

- Adults
  - Vulvovaginal lesions; whitish “curd-like” discharge; pruritus; burning
  - Balanitis: erythema, erosions, scaling; dysuria
- Immunocompromised hosts
  - Oral: white, raised, painless, distinct patches; red, slightly raised patches
  - Esophagitis: dysphagia, odynophagia, retrosternal pain; usually concomitant thrush
  - GI symptoms: abdominal pain
  - Folliculitis: follicular pustules

PHYSICAL EXAM

- Infants/children
  - Oral: white, raised, distinct patches within the mouth; when wiped off, reveals red base
  - Perineal: erythematous maculopapular rash with satellite pustules or papules
  - Angular cheilitis: tender fissures in mouth corners, often cracked and bleeding
- Adults
  - Vulvovaginal: thick, whitish, cottage cheese-like discharge; vagina or perineum erythema
  - Balanitis: erythema, linear erosions, scaling
  - Interdigital: redness, excoriation at base and webspaces of fingers and/or toes, possible maceration
- Immunocompromised hosts
  - Oral: white, raised, nontender, distinct patches; red, slightly raised patches; thick, dark-brownish coating; deep fissures
  - Esophagitis: Often, oral thrush is visible.
  - Folliculitis: follicular pustules
  - Interdigital: redness, excoriations at base of fingers and/or toes, often maceration

DIFFERENTIAL DIAGNOSIS

- For oral candidiasis
  - Leukoplakia; lichen planus; geographic tongue
  - Herpes simplex; erythema multiforme
  - Pemphigus
- Baby formula or breast milk can mimic thrush—easier to remove than thrush
(no red base when wiped away)
- Hairy leukoplakia: does not rub off; dorsum and lateral margins of tongue
- Angular cheilitis from vitamin B or iron deficiency, staphylococcal infection, or edentulous overclosure
- *Bacterial vaginosis* and *Trichomonas vaginalis* tend to have more odor, itch, and a different discharge.

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- 10% KOH slide preparation: mycelia (hyphae) or pseudomycelia (pseudohyphae) yeast forms; few WBC or 15–30% NaOH (3,4)[A]
- Associated with normal vaginal pH (<4.5)
- Barium swallow: cobblestone appearance, fistulas, or dilatation (denervation)

*Diagnostic Procedures/Other*

- If first-line treatment fails, obtain samples for culture.
- Sabouraud dextrose agar plates for fungal growth (3)[A]
- Biopsy of hyperplastic candidiasis (3)[A]
- Esophagitis may require endoscopy with biopsy (if suspicious for cancer).
- HIV-seropositive patients with thrush and dysphagia relieved by antifungal have *Candida* esophagitis.

*Test Interpretation*

Biopsy: epithelial parakeratosis with polymorphonuclear leukocytes in superficial layers; periodic acid–Schiff staining reveals candidal hyphae (3,4) [A].

**TREATMENT**

*GENERAL MEASURES*

Screen for immunodeficiency (diabetes, HIV).

*MEDICATION*

*First Line*

- Vaginal (choose 1)
  - Miconazole (Monistat) 2% cream: one applicator or 200 mg (one
suppository), intravaginally QHS for 7 days
  - Clotrimazole (Gyne-Lotrimin, Mycelex): intravaginal suppository (100 mg QHS for 7 days; 200 mg QHS for 3 days; 500 mg daily for 1 day) or 2% cream (one applicator QHS for 3 days)
  - Fluconazole 150 mg PO single dose

- **Oropharyngeal**
  - **Mild disease**
    o Clotrimazole (Mycelex): oral 10-mg troche; 20 minutes 5 times daily for 7 to 14 days
    o Nystatin suspension: 100,000 U/mL swish and swallow 400,000 to 600,000 U 4 times per day
    o Nystatin pastilles: 200,000 U each, QID daily for 7 to 14 days (4)[A]
  - **Denture wearers**
    - Nystatin ointment: 100,000 U/g under denture and corners of mouth for 3 weeks
    - Remove dentures at night; clean 2× weekly with diluted (1:20) bleach.
  - **Moderate to severe disease**
    o Fluconazole: 200 mg load and then 100 to 200 mg (>14 days of age: 6 mg/kg × 1 dose and then 3 mg/kg q24h × 7 to 14 days [max 100 mg/day])

- **Esophagitis**
  - Fluconazole: PO 400 mg load and then 200 to 400 mg/day for 14 to 21 days or IV 400 mg (6 mg/kg) daily if oral therapy not tolerated

**Pregnancy Considerations**
2% miconazole cream, intravaginally, for 7 days in uncomplicated candidiasis; systemic amphotericin B for invasive candidiasis in pregnancy

**Second Line**

- **Vaginal**
  - Terconazole (Terazol): 0.4% cream (one applicator QHS for 7 days of induction therapy); 0.8% cream/80-mg suppositories (one applicator or one suppository QHS for 3 days)
  - For recurrent cases (≥4 symptomatic episodes in 1 year): induction therapy with 10 to 14 days of topical or oralazole and then fluconazole 150 mg once per week for 6 months (4)[A]
    o In HIV patients: Concerns with this regimen include emergence of drug resistance (5)[A].
– Miconazole oral gel (20 mg/mL): QID, swish and swallow.
– Itraconazole (Sporanox) suspension: 200 mg (20 mL) daily; swish-swallow for 7 to 14 days.
– Posaconazole (Noxafil) oral suspension: 400 mg BID for 3 days and then 400 mg daily for up to 28 days
– Amphotericin B (Fungizone) oral suspension (100 mg/mL): 1 mL QID daily, swish and swallow; use between meals.

- Esophagitis
  – Amphotericin B (variable dosing) IV dose of 0.3 to 0.7 mg/kg daily or an echinocandin should be used for patients who cannot tolerate oral therapy.
  – For refractory disease:
    o Itraconazole (Sporanox) oral solution: 200 mg daily
    o Posaconazole (Noxafil) oral suspension: 400 mg BID
    o Voriconazole (Vfend) 100 to 200 mg q12h PO or IV for 14 to 21 days (4) [A]

- Continue treatments for 2 days after infection gone:
  – Contraindications
    o Ketoconazole, itraconazole, or nystatin (if swallowed): severe hepatotoxicity
    o Amphotericin B: can cause nephrotoxicity
  – Precautions
    o Miconazole: can potentiate the effect of warfarin but drug of choice in pregnancy
    o Fluconazole: renal excretion: rare; hepatotoxicity: resistance frequent
    o Itraconazole: Doubling the dosage results in ~3-fold increase in itraconazole plasma concentrations.

- Possible interactions (rarely seen with creams, lotions, or suppositories)
  – Fluconazole
    o Rifampin: decreased fluconazole concentrations
    o Tolbutamide: decreased concentrations
    o Warfarin, phenytoin, cyclosporine: altered metabolism; check levels.
  – Itraconazole: potent CYP 3A4 inhibitor. Carefully assess all coadministered medications.

- Work in progress for a vaccine in patients with chronic mucocutaneous candidiasis (3)[A]

**ISSUES FOR REFERRAL**
- Evaluate patients without obvious reasons for recurrent superficial candidal
infections for immunodeficiency (5)[A].

- GI candidiasis

**ADDITIONAL THERAPIES**

- For infants with thrush: Boil pacifiers and bottle nipples; assess mother’s breasts/nipples for *Candida* infection.
- For denture-related candidiasis: Disinfect dentures (using soak solution of benzoic acid, 0.12% chlorhexidine gluconate, 1:20 NaOCl or alkalize proteases) and treat orally.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Probiotics: *Lactobacillus* and *Bifidobacterium* may inhibit *Candida* spp.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Proper oral hygiene. Protocols for brushing, denture care, and oral cavity moistening reduce oral candidiasis.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*

Immunocompromised persons benefit from regular evaluation and screening.

**DIET**

Active-culture yogurt or other live lactobacillus may decrease colonization; indeterminate evidence

**PATIENT EDUCATION**

- Advise patients at risk for recurrence about potential for overgrowth with antibacterial therapy.
- “Azole” medications are pregnancy Category C.
- Polyene medications are pregnancy Category B; however, only give orally when benefits outweigh risks.
PROGNOSIS
- Benign prognosis in immunocompetent patients
- For immunosuppressed persons, *Candida* may become an AIDS-defining illness with significant morbidity.

COMPLICATIONS
In HIV patients, moderate immunosuppression (e.g., CD4 200 to 500 cells/mm³) may be associated with chronic candidiasis (5)[A]. With more severe immunosuppression (e.g., CD4 <100 cells/mm³), esophagitis or systemic infection are possible.

REFERENCES

ADDITIONAL READING
- Panel on Opportunistic Infections in HIV-Infected Adults and Adolescents. Guidelines for the prevention and treatment of opportunistic infections in HIV-infected adults and adolescents: recommendations from the Centers for...

SEE ALSO
Candidiasis, Invasive; HIV/AIDS

CODES

ICD10
- B37.9 Candidiasis, unspecified
- B37.0 Candidal stomatitis
- B37.49 Other urogenital candidiasis

CLINICAL PEARLS
- Candidiasis is generally a clinical diagnosis. KOH preparations are a simple confirmatory office test. Culture and biopsy are rarely needed.
- Person-to-person transmission is rare.
- If tongue pain continues after treatment, consider burning mouth syndrome. Obtain a biopsy if there is concern for oral cancer.
- Oral antifungal medications are hepatically metabolized and may have serious side effects.
CARBON MONOXIDE POISONING

Viren Kaul, MD • Ahmed Agameya, MBBCh • Anthony W. Gray Jr., MD, FCCP, FCCM

BASICS

DESCRIPTION

- Carbon monoxide (CO) is an odorless, tasteless, colorless gas that has the potential to cause sudden illness and death if inhaled.
- CO is produced by combustion of carbon-containing compounds (wood, charcoal, oil, gas):
  - CO inhalation leads to displacement of oxygen from binding sites on hemoglobin.
  - Detrimental effects are related to tissue hypoxia from decreased oxygen content and a (left) shift of the oxyhemoglobin dissociation curve that impairs oxygen unloading from hemoglobin.
- CO binds to mitochondrial cytochrome oxidase, impairing adenosine triphosphate (ATP) production. It also binds to myoglobin, affecting muscle function.
- System(s) affected: cardiovascular, pulmonary, musculoskeletal, nervous

Pregnancy Considerations

Tissue hypoxia due to CO poisoning may cause significant fetal abnormalities. CO has a greater affinity for (and longer half-life bound to) fetal hemoglobin. A pregnant mother may be unaffected, whereas the fetus is adversely impacted.

EPIDEMIOLOGY

Incidence

Third leading cause of unintentional poisoning deaths in the United States with an average 438 deaths annually

- ~50,000 emergency department visits annually
- Unintentional poisoning is most common during winter months in cold climates.
- Intentional CO poisoning ~10 times higher than unintentional poisonings
- Likely underdiagnosed because some patients may not seek medical attention
due to vague symptoms

ETIOLOGY AND PATHOPHYSIOLOGY
- CO is rapidly absorbed in lungs.
- CO has ~240 times the affinity for hemoglobin compared to oxygen.
- CO binds to hemoglobin to form carboxyhemoglobin (COHb), resulting in impaired oxygen-carrying capacity, utilization, and delivery:
  - CO interferes with peripheral oxygen utilization by inactivating cytochrome oxidase.
- Delayed neurologic sequelae, related to lipid peroxidation by toxic oxygen species generated by xanthine oxidase
- The half-life of CO on room air is ~320 minutes, whereas breathing 100% oxygen via a tight-fitting, nonrebreathing face mask decreases to ~74 minutes. With 100% hyperbaric oxygen, T1/2 is ~30 minutes (1).
- CO can promote nitric oxide release causing profound hypotension.
- CO affects L-type myocardial calcium channels causing myocardial depression.
- Inhaled or ingested methylene chloride (from paint remover [dichloromethane]) is metabolized to CO by the liver, potentially resulting in acute CO toxicity.

RISK FACTORS
- Alcohol use; smoking
- Elderly and infants at higher risk if exposed
- Closed or improperly ventilated space with faulty furnace, stove, engine, or other fuel-burning device
- Cigarette smoking
- Use of generators during power outages and storms
- Underlying cardiovascular disease, anemia, chronic respiratory conditions
- Exposure to exhaust (e.g., riding in the back of enclosed pickup trucks or swimming near a motor boat) in precatalytic converter era automobiles
- Employment in a coal mine, as an auto mechanic, paint stripper, or in the solvent industry
- Increased endogenous production in patients with hemolytic anemia

GENERAL PREVENTION
- Appropriate ventilation, especially around fuel-burning devices
- Use of CO monitors
Determining the mechanism of exposure is critical in cases of accidental poisoning helps limit future risk.

- Victims must not return to contaminated environment.
- Regular building maintenance to ensure safe environment and adequate ventilation
- Public policy to ensure building code safety

COMMONLY ASSOCIATED CONDITIONS

- CO and cyanide poisoning can occur simultaneously following smoke inhalation (synergistic effect).
- Consider CO poisoning in a burn victim who has been in an enclosed space.

DIAGNOSIS

- Acute CO poisoning: inhalation of air with high concentrations of CO, usually after a single occasion, leading to a spectrum of nonspecific symptoms ranging from headaches, nausea, malaise, and dizziness to seizures, syncope, coma, arrhythmias, myocardial ischemia, and profound lactic acidosis
- Chronic CO poisoning: repeated exposure to low concentrations of CO
- Older pulse oximeters do not differentiate COHb from oxyhemoglobin, causing normal pulse oximeter readings in hypoxic patients. Eight-wavelength CO-oximeters that can detect CO exposure are not yet routinely available for diagnostic purposes.
- Level >3% in a nonsmoker and >10% in a smoker confirms exposure. The level does not correlate with the severity of the illness or long-term prognosis (1).

HISTORY

- Duration and mechanism of exposure
- Exclude pregnancy
- Minor nonspecific symptoms
  - Headaches: occurs in 84% patients
  - Dizziness
  - Nausea, vomiting, diarrhea
  - Weakness or fatigue
- Major symptoms
  - Confusion or impaired judgment
  - Seizures
– Chest pain
– Shortness of breath
– Loss of consciousness
– Visual disturbances

**PHYSICAL EXAM**
- Patients usually present with confusion or altered mental status.
- Examine for signs of burns (enclosed space fires) or other secondary injuries.
- “Cherry red” appearance of the lips and skin (<1% cases)
- Respiratory depression or tachypnea
- Cyanosis
- Visual-field defects, papilledema, or nystagmus
- CNS depression or coma, ataxia, seizure
- Tachycardia, hypotension, cardiac dysrhythmias, or even (cardiac) arrest
- Mental status examination

**DIFFERENTIAL DIAGNOSIS**
- Cyanide toxicity
- Methylene chloride (dichloromethane) inhalation or ingestion
- Viral syndromes
- Psychological disorders including major depressive disorder
- Other causes of mental status changes:
  - Infections such as meningitis or encephalitis
  - Metabolic causes such as hypoglycemia
  - Drugs: alcohol (EtOH) intoxication, opiates, acetylsalicylic acid (ASA) overdose
  - Trauma
  - CNS lesions

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Measurement of COHb (may be low despite significant poisoning if patient had been treated with O₂ or if significant time elapses before the level is drawn)
- ABG (metabolic acidosis)
  - Blood PO₂ (PaO₂) tends to be normal as O₂ dissolved in blood is not affected by CO.
• Anion gap = ([Na\(^+\)] + [K\(^+\)]) – ([Cl\(^-\)] + [HCO\(_3^-\)]); >16
• Pregnancy test in all women of childbearing age
• Toxicology screen
• Serum chemistries
• ECG in all patients
• Hemoglobin/hematocrit
• CK to evaluate rhabdomyolysis
• Consider cardiac enzymes if:
  – ≥65 years
  – Patient with cardiac risk factors or anemia
  – Symptoms suggestive of cardiac ischemia
• Head CT/MRI scan can help rule out other causes of neurologic
decompensation; may also show infarction due to hypoxia/ischemia

**Follow-Up Tests & Special Considerations**
• Consider CO poisoning in younger patients with chest pain or symptoms
  suggestive of ischemia.
• Consider the diagnosis and explore potential exposure in afebrile patients with
  “flulike” symptoms, (especially in the winter when influenza and CO
  poisoning are both more common).
• Look for clusters of patients (coworkers, family members, school children)
  with similar symptoms.
• Patients with intentional poisoning require behavioral evaluation when
  medically stable.
• Implement acute suicide precautions if appropriate.

**TREATMENT**

**GENERAL MEASURES**
• Prompt removal from the CO source
• Supportive care as necessary
• Intubation and mechanical ventilation may be necessary for severe
  intoxication, if patient is not able to protect airway, or if patient has significant
  respiratory depression.
• Poison Control: 800-222-1222 (United States only)

**MEDICATION**
Rapid reduction in tissue hypoxia with 100% oxygen via nonrebreathing reservoir facemask (2) [A] until COHb is normal (<3%) and patient is asymptomatic, regardless of oxygen saturation or PO2

ADDITIONAL THERAPIES

- Hyperbaric oxygen is controversial (2,3) [A]. Existing trials do not establish whether hyperbaric reduces the incidence of adverse neurologic outcomes (3) [A].

- Hyperbaric oxygen currently recommended for:
  - Age > 36 years
  - Levels >25–30%
  - Exposure >24 hours
  - Loss of consciousness (4) [C]
  - Abnormal neuropsychiatric testing
  - Evidence of cardiac involvement
  - Severe acidosis (4)

- Hyperbaric oxygen is safe in pregnant woman, but there have been no prospective studies of efficacy (2) [A]. International consensus favors it for treating pregnant women (4) [C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Patients whose symptoms do not improve after 4 to 5 hours of 100% O2 should be transported to the nearest hyperbaric oxygen facility. Hospitalize patients with ECG or laboratory evidence of severe poisoning, evidence of end-organ damage, or other concerning medical or social factors.
- Admit comatose patients and patients with CO poisoning after smoke inhalation to the ICU.
- Patients with mild symptoms from accidental poisoning can be managed in the ED and safely discharged.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- All patients treated for acute CO poisoning should be seen in follow-up in 1 to 2 months after discharge (2). Patients should undergo neuropsychological
testing if there are behavioral or cognitive concerns.
- Behavioral assessment is crucial following intentional CO poisoning.

**Patient Monitoring**
- Measurement of COHb levels
- Arterial blood gases

**PATIENT EDUCATION**
- Professional installation and maintenance of combustion devices: 1-800-638-2772; Consumer Products Safety Commission hotline
- CO detector installation in homes, especially near bedrooms and potential CO sources
- Annual furnace inspections (5)[B]

**PROGNOSIS**
Most survivors recover completely, with only a minority developing chronic neuropsychiatric impairment.

**COMPLICATIONS**
- Cardiac:
  - Myocardial infarction
  - Dysrhythmia
- Pulmonary:
  - Pulmonary edema
  - Pneumonia (aspiration)
- Neurologic:
  - Anoxic encephalopathy
  - Intellectual deterioration
  - Memory impairment
  - Parkinsonism
- Behavioral:
  - Irritability
  - Aggressiveness
  - Violence
  - Moodiness

**Geriatric Considerations**
Higher incidence of cardiovascular and neurologic disease, increasing
complications

ADDITIONAL READING

- Centers for Disease Control and Prevention: [http://www.cdc.gov/co](http://www.cdc.gov/co)
- United States Environmental Protection Agency: [http://www.epa.gov/iaq/co.html](http://www.epa.gov/iaq/co.html)

CODES

ICD10
- T58.91XA Toxic effect of carb monx from unsp source, acc, init
- T58.8X1A Toxic effect of carb monx from oth source, accidental, init
- T58.01XA Toxic effect of carb monx from mtr veh exhaust, acc, init
CLINICAL PEARLS

- If there is a concern for CO poisoning, remove individuals from the source and deliver 100% oxygen by high-flow face mask or endotracheal tube.
- During pregnancy, there is disproportionate impact on the fetus due to CO binding by fetal hemoglobin.
- Consider CO poisoning in younger patients with chest pain or ischemia or if patients who present in case clusters with similar symptoms and a potential CO source exposure.
- COHb levels do not correlate well with symptoms or severity of illness.
CARDIOMYOPATHY

Timothy P. Fitzgibbons, MD, PhD • Theo E. Meyer, MD, DPhil

BASICS

DESCRIPTION

● Cardiomyopathy encompasses a large group of diseases of the myocardium that commonly result in mechanical pump dysfunction. The current classification scheme attempts to differentiate between myocardial diseases confined to the myocardium (primary) and those due to systemic disorders (secondary). Specific causes of myocardial dysfunction due to other cardiovascular disorders are considered a third, separate category (1).

● Classification of cardiomyopathy
  – Primary
    o Genetic
      ■ Hypertrophic cardiomyopathy (HCM)
      ■ Arrhythmogenic right ventricular cardiomyopathy/dysplasia (ARVC/D)
      ■ Left ventricular (LV) noncompaction (LVNC)
      ■ Glycogen storage (Danon type, PRKAG2)
      ■ Conduction defects
      ■ Mitochondrial myopathies
      ■ Ion channel disorders: long QT syndrome (LQTS), Brugada syndrome, short QT syndrome, catecholaminergic polymorphic ventricular tachycardia (CPVT), Asian SUNDS
    o Mixed
      ■ Dilated cardiomyopathy (DCM) (genetic or nongenetic)
      ■ Restrictive
    o Acquired
      ■ Myocarditis, stress cardiomyopathy, peripartum, tachycardia-induced, infants of type 1 diabetic mothers
  – Secondary (see list below)
    o Specific
      ■ Ischemic
      ■ Valvular
- Hypertensive
- Congenital heart disease

- Patients with end-stage cardiomyopathy have stage D heart failure or severe symptoms at rest refractory to standard medical therapy.
- System(s) affected: cardiovascular; renal

**Pediatric Considerations**
Etiology: idiopathic, viral, congenital heart disease, and familial

**Pregnancy Considerations**
May occur in women postpartum

**EPIDEMIOLOGY**
Predominant age: Ischemic cardiomyopathy is the most common etiology; predominantly in patients aged >50 years. Consider uncommon causes in young.

**Incidence**
- 60,000 patients <65 years old die each year from end-stage heart disease.
- 35,000 to 70,000 people might benefit from cardiac transplant or chronic support.

**Prevalence**
Most rapidly growing form of heart disease

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Ischemic heart disease: most common etiology; up to 66% of patients
- Hypertension
- Valvular heart disease
- Primary genetic causes
- Congenital heart disease
- Peripartum/postpartum
- Endocrine
  - Diabetes mellitus
  - Hyperthyroidism
  - Hypothyroidism
  - Hyperparathyroidism
  - Pheochromocytoma
  - Acromegaly
- **Nutritional deficiencies**
  - Beriberi, pellagra, scurvy, selenium, carnitine, kwashiorkor
- **Autoimmune/collagen**
  - Systemic lupus erythematosus
  - Dermatomyositis
  - Rheumatoid arthritis
  - Scleroderma
  - Polyarteritis nodosa
- **Infectious causes**
  - Viral (e.g., HIV, coxsackievirus, adenovirus)
  - Bacterial and mycobacterial (e.g., diphtheria, rheumatic fever)
  - Parasitic (e.g., toxoplasmosis, *Trypanosoma cruzi*)
- **Infiltrative**
  - Amyloidosis
  - Gaucher disease
  - Hurler disease
  - Hunter disease
  - Fabry disease
- **Storage**
  - Hemochromatosis
  - Fabry disease
  - Glycogen storage disease (type II, Pompe)
  - Niemann-Pick disease
- **Neuromuscular/neurologic**
  - Duchenne and Emery-Dreifuss muscular dystrophies
  - Friedreich ataxia
  - Myotonic dystrophy
  - Neurofibromatosis
  - Tuberous sclerosis
- **Toxic**
  - Alcohol
  - Drugs and chemotherapy: anthracyclines, cyclophosphamide, Herceptin
  - Radiation
  - Heavy metal, chemical agents
- **Inflammatory (granulomatous):**
  - Sarcoidosis
- **Idiopathic**
- **Endomyocardial**
  - Endomyocardial fibrosis
– Hypereosinophilic syndrome (Loeffler endocarditis)

**Genetics**

Autosomal dominant HCM is the most common form of primary genetic cardiomyopathy (1/500 in the general population). Genetic causes of DCM are less common, accounting for 1/3 cases, with mostly autosomal dominant inheritance. LVNC and ARVC are also inherited in an autosomal dominant fashion in addition to LQTS and other ion-channel disorders.

**RISK FACTORS**

- Hypertension
- Hyperlipidemia
- Obesity
- Coronary artery disease
- Diabetes mellitus
- Smoking
- Physical inactivity
- Excessive alcohol intake
- Dietary sodium
- Obstructive sleep apnea
- Chemotherapy

**GENERAL PREVENTION**

Reduce salt and water intake; home BP and daily weight measurement

**DIAGNOSIS**

**HISTORY**

- Dyspnea at rest or with exertion
- Paroxysmal nocturnal dyspnea
- Orthopnea
- Postprandial dyspnea
- Right upper quadrant pain or bloating
- Fatigue
- Syncope
- Edema
PHYSICAL EXAM
- Tachypnea
- Cheyne-Stokes breathing
- Low pulse pressure
- Cool extremities
- Jugular venous distention
- Bibasilar rales
- Tachycardia
- Displaced point of maximal impulse (PMI)
- $S_3$ gallop
- Blowing systolic murmur
- Hepatosplenomegaly
- Ascites
- Edema

DIFFERENTIAL DIAGNOSIS
- Severe pulmonary disease
- Primary pulmonary hypertension
- Recurrent pulmonary embolism
- Constrictive pericarditis
- Some advanced forms of malignancy
- Anemia

DIAGNOSTIC TESTS & INTERPRETATION
- ECG: LV hypertrophy, interventricular conduction delay, atrial fibrillation, evidence of prior Q-wave infarction
- Hyponatremia
- Prerenal azotemia
- Anemia
- Mild elevation in troponin
- Elevated B-type natriuretic peptide (BNP) or pro-BNP
- Mild hyperbilirubinemia
- Elevated liver function tests
- Elevated uric acid

Initial Tests (lab, imaging)
- ECG
- Chest radiograph
– Cardiomegaly
– Increased vascular markings to the upper lobes
– Pleural effusions may or may not be present.

**Echocardiography**
– In DCM, four-chamber enlargement and global hypokinesis are present.
– In HCM, severe LV hypertrophy is present.
– Segmental contraction abnormalities of the LV are indicative of previous localized myocardial infarction.

**Cardiac MRI**
– May be useful to characterize certain nonischemic cardiomyopathies

**Stress myocardial perfusion imaging (MPI)**
– Recommended in those with new-onset LV dysfunction or when ischemia is suspected

### Diagnostic Procedures/Other

Cardiac catheterization

- Helpful to rule out ischemic heart disease
- Characterize hemodynamic severity
- Pulmonary artery catheters may be reasonable in patients with refractory heart failure to help guide management.

### TREATMENT

See “Heart Failure, Chronic” for detailed treatment protocols.

### GENERAL MEASURES

- Reduction of filling pressures
- Treatment of electrolyte disturbances

### MEDICATION

**First Line**

- Systolic failure syndromes
  – Either an ACE inhibitor or an ARB are equally effective and should be considered in all patients; initiate at low doses and titrate as tolerated to target doses (33)[A].
  – Entresto, a combination drug containing a neprilysin inhibitor and valsartan (ARNI), was recently approved for the treatment of systolic heart failure
(ejection fraction [EF] <40%) as an alternative to an ACE/ARB (4)[A].

- In patients who have been stable on an ACE or ARB, morbidity and mortality may be further reduced (all-cause mortality reduction approximately NNT 33 over 2 years treatment) by replacement with an ARNI (4)[A], with careful monitoring needed for hypotension and angioedema.

- Loop diuretics
  - May need to be given IV initially and then orally as patient stabilizes
- Furosemide, 40 to 120 mg/day or TID (3)[A]

- β-Blockers
  - Use with caution in acutely decompensated or low-cardiac output states.
  - Initiate with low doses and titrate as tolerated.
- Metoprolol succinate, 12.5 to 200 mg/day; carvedilol, 3.125 to 25 mg BID; or bisoprolol, 1.25 to 10 mg/day (3)[A]
- Patients with New York Heart Association (NYHA) II to IV heart failure, EF <35%, on standard therapy: aldosterone antagonists: spironolactone or eplerenone (3)[A]
- Digoxin, 0.125 to 0.250 mg/day for symptomatic patients on standard therapy (3)[B]
- Combination hydralazine/isosorbide dinitrate is first-line treatment in African American patients with class III to IV symptoms already on standard therapy and for all patients with reduced EF and symptoms incompletely responsive to ACE inhibitor and β-blocker (3)[A].

- Contraindications
  - β-Blockers: low cardiac output, 2nd- or 3rd-degree heart block
  - Avoid use of diltiazem and verapamil in patients with systolic dysfunction.
  - Aldosterone antagonists: oliguria, anuria, renal dysfunction
  - Loop diuretics: hypokalemia, hypomagnesemia
  - ACE inhibitors: pregnancy, angioedema
  - ARNIs: patients currently on an ACE inhibitor or who have taken one in the past 36 hours, patients with a history of angioedema

- Precautions
  - In patients with chronic kidney disease, digoxin dosage should be ≤0.125 mg/day and drug levels followed carefully to avoid toxicity.
  - Closely monitor electrolytes.
  - ACE inhibitors and ARNIs: Initiate with care if BP is low.
  - β-Blockers: Avoid in patients with evidence of poor tissue perfusion; they may further depress systolic function.
  - Milrinone, dobutamine: long-term use associated with increased mortality
Medications to avoid
- NSAIDs
- Glitazones
- Cilostazol

Second Line
- Inotropic therapy (e.g., dobutamine or milrinone) for cardiogenic shock and support prior to surgery or cardiac transplantation (3)[B]
- Continuous inotrope infusion may be considered in stage D outpatients for symptom control in those who are not eligible for transplantation or mechanical circulatory support (3)[B].

ISSUES FOR REFERRAL
Management by a heart failure team improves outcomes and facilitates early transplant referral.

ADDITIONAL THERAPIES
- Prophylactic implantable cardioverter-defibrillator (ICD) should be considered for patients with a left ventricular ejection fraction (LVEF) <35% and mild to moderate symptoms (3)[A].
- Cardiac resynchronization therapy (CRT) is recommended and should be considered for patients in sinus rhythm with a QRS >150 ms, LVEF <35%, in functional class (FC) I to III, and ambulatory FC IV patients (3)[A].
- Patients with severe, refractory heart failure with no reasonable expectation of improvement should not be considered for an ICD. Palliative care is a reasonable option in such patients.
- Consideration of an LV assist device as “permanent” or destination therapy or cardiac transplantation is reasonable in selected stage D patients.

ONGOING CARE

DIET
Low fat, low salt, fluid restriction

PROGNOSIS
~20–40% of patients in NYHA FC IV die within 1 year. With a transplant, 1-year survival is as high as 94%.
COMPLICATIONS
Worsening congestive heart failure syncope, renal failure, arrhythmias, or sudden death

REFERENCES

CODES

ICD10
- 142.9 Cardiomyopathy, unspecified
• I42.0 Dilated cardiomyopathy
• I42.5 Other restrictive cardiomyopathy

CLINICAL PEARLS

• Cardiomyopathy represents the end-stage of a large number of disease processes involving the heart muscle.
• Ischemic, hypertensive, postviral, familial, alcoholic, and incessant tachycardia-induced are the most common cardiomyopathy varieties seen in the United States.
• Core therapy for heart failure applies salt restriction, diuretics, ACE inhibitors, β-blockers, digoxin, and electrical treatments, such as cardiac resynchronization and implantable defibrillators, as appropriate.
BASICS

DESCRIPTION

- The carotid sinus, located at the bifurcation of the internal and external carotid arteries, contains baroreceptors that are responsive to increases or decreases in arterial pressure. It plays a central role in blood pressure (BP) homeostasis.
- An endogenous increase in BP or external pressure applied to a carotid sinus causes an increase in the baroreceptor firing rate and activates vagal efferents and/or inhibits the sympathetic discharge to the heart and blood vessels, resulting in a slowing of the heart rate and/or drop in BP.
- In carotid sinus hypersensitivity (CSH), stimulation of one or both carotid sinuses causes an exaggerated baroreceptor response that can result in dizziness or syncope.
- CSH is defined as asystole for at least 3 seconds and/or a drop in systolic BP of at least 50 mm Hg during carotid sinus massage (CSM).
- CSH is generally divided into three subtypes, based on response to CSM:
  - Cardioinhibitory (70–75%): asystole for at least 3 seconds
  - Vasodepressor (5–10%): fall in systolic BP of at least 50 mm Hg
  - Mixed (20–25%): combination of the first 2 subtypes
- Carotid sinus syndrome (CSS) typically (but not consistently) refers to CSH with syncope and may be classified as:
  - Spontaneous CSS: syncope after accidental mechanical manipulation (trigger) of the carotid sinuses (e.g., shaving, tight collars, or tumors)
  - Induced CSS: syncope diagnosed by CSM although no mechanical trigger is found

EPIDEMIOLOGY

- Disease of elderly; virtually unknown in people aged <50 years
- More prevalent in males by ratio of 4:1
- Typical patient is an older man, usually with a history of coronary artery disease (CAD) and hypertension (HTN), with right CSH > left CSH.
- CSH may be a cause of the symptoms in 30% of elderly patients with
unexplained syncope (1).

- CSH was also present in 35% of community-dwelling older individuals without any symptoms of syncope, falls or drop attacks (2).

ETIOLOGY AND PATHOPHYSIOLOGY

- The exact mechanism of CSH remains unknown. Changes in any part of the reflex arc or the target organs may give rise to this condition, or it may be a part of a generalized autonomic disorder associated with autonomic dysregulation.
- Associated with resting sympathetic overactivity and increased baroreflex sensitivity (2)
- Bradycardia and asystole seen in cardioinhibitory and mixed CSH subtypes appear to be mediated by vagal efferents, whereas vasodilatation and arterial hypotension in the vasodepressor and mixed subtypes are attributed to decrease sympathetic tone.
- Symptomatic CSH has been shown to be associated with impaired cerebral autoregulation, and in asymptomatic CSH, it was found to be normal (2).
- Atherosclerosis may diminish carotid sinus compliance, resulting in a reduction in afferent impulse traffic in the baroreflex pathway (3).
- CSH is often idiopathic but can be caused by:
  - Carotid body tumors
  - Inflammatory and malignant lymph nodes in the neck
  - Extensive scarring from prior neck surgery in the area of the carotid sinus
  - Metastatic cancer

RISK FACTORS

- Male gender
- Advanced age
- CAD
- HTN
- DM

COMMONLY ASSOCIATED CONDITIONS

- Sick sinus syndrome
- Atrioventricular block
- CAD
- HTN
- Orthostatic hypotension
• Vasovagal syncope
• Alzheimer disease
• Parkinson disease

**DIAGNOSIS**

**HISTORY**

• Recurrent syncope: usually sudden, unexplained, of short duration, seemingly spontaneous, and with complete recovery, although fractures and other injuries may occur
• Unexplained falls: Evidence of a causal relationship is suggested between falls and the cardioinhibitory subgroup.
• Dizziness: Manifests as transient light-headedness or presyncope but not usually as true vertigo; associated more with vasodepressor and mixed subtypes
• Syncope may be associated with prodrome or retrograde amnesia.
• Causative or exacerbating factors
  – Any CSM-like maneuver such as shaving, wearing tight collars, or turning one’s head sharply
  – Neck tumors, extensive neck scarring secondary to radical dissection or radiation fibrosis, and neck trauma
  – Certain medications can potentiate symptoms associated with CSH:
    o Digoxin or β-blockers (especially with cardioinhibitory subtype)
    o Physostigmine, morphine, methacholine: increase vagal sensitivity and may predispose to cardioinhibitory subtype of CSH

**PHYSICAL EXAM**

Normal unless carotid baroreceptor is stimulated, then

• Bradycardia
• Hypotension
• Pallor
• Diaphoresis

**DIFFERENTIAL DIAGNOSIS**

• Neurocardiogenic syncope
• Postural hypotension
• Situational syncope
Postural tachycardia syndrome (POTS)
Primary autonomic insufficiency
Hypovolemia
Dysrhythmias
Sick sinus syndrome
Cerebrovascular insufficiency
Other causes of syncope (e.g., metabolic, psychogenic)
ECG may demonstrate sinus pause(s) or atrial-ventricular block.
Carotid duplex scan to rule out carotid stenosis in presence of a bruit (see the following section)

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

CSM is indicated in patients >40 years of age with syncope of unknown etiology after a negative initial evaluation (4)[B]. Commonly accepted technique for accurate diagnosis involves the following steps:

- Patient in supine for 5 minutes with continuous BP monitoring and ECG (on footplate-type tilt table for increased diagnostic accuracy); baseline BP and ECG are recorded.
- For 5 to 10 seconds, apply firm longitudinal massage over the right carotid sinus (between the superior border of the thyroid and the angle of the mandible) at the site of maximal pulsation:
  - Note that light pressure over the carotid sinus will not reliably produce a hypersensitivity response.
  - Record symptoms, BP, and note ECG changes.
  - Discontinue if asystole ≥3 seconds.

- Positive response defined per criteria is listed above (asystole ≥3 seconds and/or drop in BP ≥50 mm Hg), although specificity of the CSM technique increases if reproduction of a patient’s syncope is demonstrated during a test (4)[B]. If nondiagnostic, apply pressure to the left carotid sinus while the patient remains supine; if still nondiagnostic, repeat in 70-degree head-up tilt (first on the right then, if necessary, the left), allowing time for hemodynamic adjustment to the head-up position.

- Evidence behind the testing strategy
  - Right side first: Up to 66% with CSH have positive response on the right; if a positive right response, no need to repeat test on the left side
  - 30% of CSM exams are found to be nondiagnostic in the supine position but diagnostic in the 70-degree position (1).
– Positive predictive value increases from 77% to 96% with a specificity of 93% by also performing CSM in 60- to 70-degree tilt position (5).

- **Absolute contraindications for CSM testing**
  - Carotid bruit present: must examine via carotid ultrasound with Doppler first:
    - No testing if >70% stenosis
    - Supine only testing if 50–70% stenosis
  - Myocardial infarction, transient ischemic attack, or stroke within the past 3 months

- **Relative contraindications to CSM testing**
  - History of ventricular tachycardia or ventricular fibrillation
  - False-positive results with CSM are relatively common in the elderly. Care should be taken to exclude other causes of syncope.

- **Neurologic and cardiovascular complications** have been reported during CSM. Cardiovascular complications (primarily arrhythmia) are extremely rare. Transient neurologic symptoms and signs occur in up to 0.9% of patients. Persistent neurologic deficits are extremely rare following CSM. Correctly performed CSM should be considered a safe, low-risk procedure (3)[C].

### TREATMENT

#### GENERAL MEASURES

- No treatment is required for asymptomatic individuals.
- High-dietary salt intake and increased fluid intake may be helpful to maintain intravascular volume in patients with vasodepressor subtype and absence of other cardiovascular disease.

#### MEDICATION

**First Line**

No single agent has demonstrated long-term effectiveness for treatment of recurrent and symptomatic CSH.

**Second Line**

- Fludrocortisone or midodrine may be used to improve orthostatic symptoms in patients with vasodepressor subtype (not approved by FDA for this indication). However, fludrocortisone causes sodium and water retention and should be used with caution in elderly patients with heart disease. An adverse
effect with midodrine is that it increases mean ambulatory BP (3)[C].
• Atropine may be used in the acute setting in patients with cardioinhibitory subtype with bradycardia.
• Some evidence of benefit from sertraline and fluoxetine in patients unresponsive to pacemakers (3)[C]

SURGERY/OTHER PROCEDURES
• Permanent pacing: treatment of choice for patients with cardioinhibitory and mixed type CSH with recurrent syncope; based on 2012 ACCF/AHA/HRS Focused Update Incorporated into the ACCF/AHA/HRS 2008 Guidelines for Device-Based Therapy in CSH (6)[C]:
  – Class I indication: Permanent pacing is indicated for recurrent syncope caused by spontaneously occurring carotid sinus stimulation and carotid sinus pressure that induces ventricular asystole of >3 seconds.
  – Class IIa indication: Permanent pacing is reasonable for syncope without clear, provocative events and with a hypersensitive cardioinhibitory response of 3 seconds or longer.
  – Class IIb indication: Permanent pacing may be considered for significantly symptomatic neurocardiogenic syncope associated with bradycardia documented spontaneously or at the time of tilt-table testing.
  – Class III indication: Permanent pacing is not indicated for a hypersensitive cardioinhibitory response to carotid sinus stimulation without symptoms or with vague symptoms.
• Permanent pacing may reduce the frequency of symptoms but may not completely eliminate them.
• Surgery for patients with CSH secondary to mass effect from tumor burden
• Carotid sinus denervation by surgery or radiation therapy is no longer recommended because of the high rate of complications.

ONGOING CARE
PATIENT EDUCATION
• Avoid precipitating maneuvers (as described above) that place pressure on the neck, such as tight collars and neckties.
• With syncope, restrict driving or other potentially hazardous activities until the patient is cleared by the physician (4).
• Avoid precipitating medications like vasodilators and those temporally related
to symptoms.

- Teach patient to assume supine position if prodromal symptoms or presyncope occurs.
- Explain diagnosis, provide reassurance, and explain risk of recurrence.

**PROGNOSIS**

- The presence of CSH has not been demonstrated to confer an independent mortality risk.
- Untreated CSS patients have a syncope recurrence rate as high as 62% within 4 years.
- Patients with cardioinhibitory CSH who received a pacemaker had a significant reduction in their mean number of falls, from 9.3 to 4.1 falls in a 1-year follow-up period (3).

**REFERENCES**

**ADDITIONAL READING**

SEE ALSO

Syncope

CODES

**ICD10**

G90.01 Carotid sinus syncope

**CLINICAL PEARLS**

- Consider CSH as a potential cause for syncope, dizziness, or unexplained falls, especially in the elderly.
- Diagnose CSH via CSM (using firm pressure for 5 to 10 seconds), producing asystole of at least 3 seconds and/or a drop in systolic BP of at least 50 mm Hg. (See contraindications discussed earlier before undertaking CSM as a diagnostic maneuver.)
- Remember to auscultate for carotid artery bruit prior to considering CSM.
- Consider dual-chamber pacemaker in patients with recurrent syncope and cardioinhibitory or mixed CSH subtypes.
- The finding of CSH does not exclude other causes of syncope.
CAROTID STENOSIS

Naureen Rafiq, MBBS • Austin C. Saavedra, MD

BASICS

Carotid stenosis may be caused by atherosclerosis, intimal fibroplasia, vasculitis, adventitial cysts, or vascular tumors; atherosclerosis is the most common etiology.

DESCRIPTION

- Narrowing of the carotid artery lumen is typically due to atherosclerotic changes in the vessel wall. Atherosclerotic plaques are responsible for 90% of extracranial carotid lesions and up to 30% of all ischemic strokes.
- A “hemodynamically significant” carotid stenosis produces a drop in pressure or a reduction in flow. It corresponds approximately to a 60–99% diameter-reducing stenosis.
- Carotid lesions are classified by the following:
  - Symptom status
    - Asymptomatic: tend to be homogenous and stable
    - Symptomatic: tend to be heterogeneous and unstable; present with stroke or transient cerebral ischemic attack
  - Degree of stenosis
    - High grade: 80–99% stenosis
    - Moderate grade: 50–79% stenosis
    - Low grade: <50% stenosis

EPIDEMIOLOGY

More common in men and with increasing age (see “Risk Factors”)

Incidence

Unclear (asymptomatic patients often go undiagnosed)

Prevalence

- Moderate stenosis
  - Age <50 years: men 0.2%, women 0%
  - Age >80 years: men 7.5%, women 5%
- Severe stenosis
- Age <50 years: men 0.1%, women 0%
- Age >80 years: men 3.1%, women 0.9%

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Atherosclerosis begins during adolescence, consistently at the carotid bifurcation. The carotid bulb has unique blood flow dynamics. Hemodynamic disturbances cause endothelial injury and dysfunction. Plaque formation in vessel wall results and stenosis then ensues.
- Initial cause is not well understood, but certain risk factors are frequently present (see “Risk Factors”). Tensile stress on the vessel wall, turbulence, and arterial wall shear stress seem to be involved.

**Genetics**
- Increased incidence among family members
- Genetically linked factors
  - Diabetes mellitus (DM), race, hypertension (HTN), family history, obesity
  - In a recent single nucleotide polymorphism study, the following genes were strongly associated with worse carotid plaque: *TNFSF4, PPARA, TLR4, ITGA2, HABP2.*

**RISK FACTORS**
- Nonmodifiable factors: advanced age (>65 years old), male sex, family history, cardiac disease, congenital arteriopathies
- Modifiable factors: smoking, diet, dyslipidemia, physical inactivity, obesity, HTN, DM

**GENERAL PREVENTION**
- Antihypertensive treatment to maintain BP <140/90 mm Hg (systolic BP of 150 mm Hg is target in elderly)
- Smoking cessation to reduce the risk of atherosclerosis progression and stroke
- Lipid control: regression of carotid atherosclerotic lesions seen with statin therapy

**COMMONLY ASSOCIATED CONDITIONS**
- Transient ischemic attack (TIA)/stroke
- Coronary artery disease (CAD)/myocardial infarction (MI)
- Peripheral vascular disease (PVD)
- HTN
DM
Hyperlipidemia

**DIAGNOSIS**

Screening for carotid stenosis is not recommended. However, in the setting of symptoms suggestive of stroke or TIA, workup for this condition may be indicated.

**HISTORY**

- Identification of modifiable and nonmodifiable comorbidities (see “Risk Factors”)
- History of cerebral ischemic event
- Stroke, TIA, amaurosis fugax (monocular blindness), aphasia
- CAD/MI
- Peripheral arterial disease
- Review of systems, with focus on risk factors for
  - Cardiovascular disease
  - Stroke (HTN and arrhythmias)

**PHYSICAL EXAM**

- Lateralizing neurologic deficits: contralateral motor and/or sensory deficit
- Amaurosis fugax: ipsilateral transient visual obscuration from retinal ischemia
- Visual field defect
- Dysarthria, aphasia (in the case of dominant hemisphere involvement, usually left)
- Carotid bruit (low sensitivity and specificity)

**DIFFERENTIAL DIAGNOSIS**

- Aortic valve stenosis
- Aortic arch atherosclerosis
- Arrhythmia with cardiogenic embolization
- Migraine
- Brain tumor
- Metabolic disturbances
- Functional/psychological deficit
- Seizure
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Workup for suspected TIA/stroke may include the following:

- CBC with differential
- Basic metabolic panel
- ESR (if temporal arteritis a consideration)
- Glucose/hemoglobin A1c
- Fasting lipid profile
- Duplex ultrasonography is the recommended initial diagnostic test in asymptomatic patients with known or suspected carotid stenosis.
- Duplex ultrasound (US) identifies ≥50% stenosis, with 98% sensitivity and 88% specificity.

Follow-Up Tests & Special Considerations

- Proceed to imaging if there is suggestion of stenosis from history or physical exam.
- Other noninvasive imaging techniques can add detail to duplex results:
  - CT angiography
    - 88% sensitivity and 100% specificity
    - Requires IV contrast with risk for subsequent renal morbidity
  - MR angiography
    - 95% sensitivity and 90% specificity
    - Evaluates cerebral circulation (extracranial and intracranial) as well as aortic arch and common carotid artery
    - The presence of unstable plaque can be determined if the following characteristics are seen:
      ■ Presence of thin/ruptured fibrous cap
      ■ Presence of lipid-rich necrotic core
      ■ Tends to overestimate degree of stenosis

Diagnostic Procedures/Other

Cerebral angiography is the traditional gold standard for diagnosis:

- Delineates the anatomy pertaining to aortic arch and proximal vessels
- The procedure is invasive and has multiple risks:
  - Contrast-induced renal dysfunction (1–5% complication rate)
  - Thromboembolic-related complications (1–2.6% complication rate) and neurologic complications
– Should be used only when other tests are not conclusive

**Test Interpretation**

- Stenosis consistently occurs at the carotid bifurcation, with plaque formation most often at the level of the proximal internal carotid artery:
  - Plaque is thickest at the carotid bifurcation.
  - Plaque occupies the intima and inner media and avoids outer media and adventitia.
- Plaque histology
  - Homogenous (stable) plaques seldom hemorrhage or ulcerate:
    - Fatty streak and fibrous tissue deposition
    - Diffuse intimal thickening
  - Heterogenous (unstable) plaques may hemorrhage or ulcerate:
    - Presence of lipid-laden macrophages, necrotic debris, cholesterol crystals
    - Ulcerated plaques
  - Soft and gelatinous clots with platelets, fibrin, and red and white blood cells

**TREATMENT**

Smoking cessation, BP control, blood glucose control, antiplatelet medication, and statin medication are the primary treatments for both asymptomatic and symptomatic carotid stenosis.

**GENERAL MEASURES**

- Lifestyle modifications: dietary control and weight loss, exercise of 30 min/day at least 5 days/week
- Patients should be advised to quit smoking and offered smoking cessation intervention to reduce the risk of atherosclerotic progression and stroke.
- Control of HTN with antihypertensive agents to maintain BP <140/90 mm Hg; <150/90 mm Hg in the elderly. In carefully selected individuals, tighter blood pressure control might reduce cerebrovascular events, but this remains uncertain.

**MEDICATION**

- Antihypertensive treatment (<140/90 mm Hg), <150/90 mm Hg in the elderly
- Diet, smoking cessation, and exercise are useful adjuncts to therapy.
- Statin initiation is recommended; choose moderate- to high-intensity statin therapy for anti-inflammatory benefit.
A comprehensive program that includes tight control of HTN with ACEI or ARB treatment reduces the risk in individuals with diabetes.

Aspirin: 75 to 325 mg/day

If patient has sustained TIA or ischemic stroke, antiplatelet therapy with
- Aspirin alone (75 to 325 mg/day) or
- Clopidogrel alone (75 mg/day), or
- Aspirin plus extended-release dipyridamole (25 and 200 mg BID, respectively)
- A combination of clopidogrel plus aspirin is NOT recommended within 3 months post-TIA or CVA.

ISSUES FOR REFERRAL
- For acute symptomatic stroke, order imaging and contact neurology.
- For known carotid stenosis, some suggest duplex imaging every 6 months if stenosis is >50% and patient is a surgical candidate.

SURGERY/OTHER PROCEDURES
- Symptomatic carotid stenosis (history of ischemia ipsilateral to stenosis)
  - Carotid endarterectomy (CEA) is of some benefit in 50–69% symptomatic stenosis, highly beneficial for those with 70–99% stenosis without near occlusion and has no benefit in people with carotid near-occlusion (1)[A].
  - CEA is recommended for patients with a life expectancy of at least 5 years. The anticipated rate of perioperative stroke or mortality must be <6% (2) [B].
  - Treatment with aspirin (81 to 325 mg/day) is recommended for all patients who are having CEA. Aspirin should be started prior to surgery and continued for at least 3 months postsurgery but may be continued indefinitely (2)[B].
  - Carotid artery stenting (CAS) provides similar long-term outcomes as CEA (3)[A]. Age should be considered when planning a carotid intervention.
    - CAS has an increased risk of adverse cerebrovascular events in the elderly compared to the young but similar mortality risk. CEA is associated with similar neurologic outcomes in the elderly and young, at the expense of increased mortality (4)[A].
    - CAS is suggested in selected patients with neck anatomy unfavorable for arterial surgery and those with comorbid conditions that greatly increase the risk of anesthesia and surgery.
    - Dual antiplatelet therapy with aspirin (81 to 325 mg/day) plus clopidogrel
(75 mg/day) is recommended for 30 days post-CAS.

- Asymptomatic patients
  - As compared with CAS, CEA is the preferred option for the management of asymptomatic carotid stenosis if a surgical option is chosen. CAS has the potential for increased risks of periprocedural stroke and periprocedural death (5)[A].
  - The advantage of surgical compared with medical therapy has decreased with contemporary medical management. It is not possible to make an evidence-based recommendation for or against surgical therapy with current literature (6)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Any patient with presentation of acute symptomatic carotid stenosis should be hospitalized for further diagnostic workup and appropriate therapy.
- Rapid evaluation for symptoms compatible with TIA should be obtained in the emergency department (ED) or inpatient setting.
- Discharge criteria: 24 to 48 hours post-CEA, if ambulating, taking adequate PO intake, and neurologically intact

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Duplex at 2 to 6 weeks postoperatively
- Duplex every 6 to 12 months
- Reoperative CEA or CAS is reasonable, if there is rapidly progressive restenosis.
- Patients with any of the following: renal failure, heart failure, diabetes, and age >80 years have a high readmission rate following CEA; thus, intensive medical therapy and rigorous follow-up is recommended.

DIET

Low-fat, low-cholesterol, low-salt diet at discharge

PATIENT EDUCATION
For patient education materials on this topic, consult the following:

- American Heart Association: [http://www.heart.org](http://www.heart.org)

**COMPLICATIONS**

- Untreated: TIA/stroke (risk of ipsilateral stroke approximately 1.68% per year)
- Postoperative (s/p CEA)
  - Perioperative (within 30 days)
    - Stroke/death, cranial nerve injury, hemorrhage, hemodynamic instability, MI
  - Late (>30 days postop)
    - Recurrent stenosis, false aneurysm at surgical site

**REFERENCES**

ADDITIONAL READING

SEE ALSO

Algorithms: Stroke; *Transient Ischemic Attack and Transient Neurologic Defects*

CODES

**ICD10**

- I65.29 Occlusion and stenosis of unspecified carotid artery
- I65.21 Occlusion and stenosis of right carotid artery
- I65.22 Occlusion and stenosis of left carotid artery

CLINICAL PEARLS

- Atherosclerosis is responsible for 90% of all cases of carotid artery stenosis.
- Duplex US is the best initial imaging modality.
- Antiplatelet therapy and aggressive treatment of vascular risk factors are the mainstays of medical therapy.
- Compared with CEA, CAS increases the risk of any stroke and decreases the risk of MI. For every 1,000 patients opting for stenting rather than endarterectomy, 19 more patients would have strokes and 10 fewer would have MIs.
CARPAL TUNNEL SYNDROME
Philip H. Aurigemma, MD • Marci D. Jones, MD

BASICS
DESCRIPTION
- Symptomatic compression neuropathy of the median nerve
- Increased pressure within the carpal tunnel leads to compression of the median nerve and characteristic motor-sensory findings.
- The dorsal aspect of the carpal tunnel is composed of the carpal bones. The transverse carpal ligament defines the palmar boundary:
  - The carpal tunnel contains nine flexor tendons and the median nerve.
- Symptoms most commonly affect the dominant hand; >50% of patients will experience bilateral symptoms.
- System(s) affected: musculoskeletal, nervous

ALERT
Increased incidence during pregnancy (up to 20–45%)

EPIDEMIOLOGY
- Predominant age: 40 to 60 years
- Predominant sex: female > male (3:1 to 10:1)

Incidence
- Two peaks: late 50s (women), late 70s (both genders)
- Incidence up to 276/100,000 has been reported.
- Incidence increases with age.

Prevalence
- 9% in women and 6% in men; 50 cases per 1,000 individuals per year in United States
- 14% in diabetics without neuropathy and 30% in patients with diabetic neuropathy
- Rising prevalence may be the result of increasing lifespan and increasing prevalence of diabetes.
ETIOLOGY AND PATHOPHYSIOLOGY
- Combination of mechanical trauma, inflammation, increased pressure, and ischemic injury to the median nerve within the carpal tunnel.
- Acute CTS caused by rapid and sustained pressure in carpal tunnel, usually secondary to trauma, may require urgent surgical decompression.
- Chronic CTS divided into four categories:
  - Idiopathic: combination of edema and fibrous hypertrophy without inflammation
  - Anatomic: persistent median artery, ganglion cyst, infection, space-occupying lesion in carpal tunnel
  - Systemic: associated with conditions such as obesity, diabetes, hypothyroidism, rheumatoid arthritis, amyloidosis, scleroderma, renal failure, and drug toxicity
  - Exertional: repetitive use of hands and wrists, repeated palmar impact, use of vibratory tools. Repetitive use is an objective cause of CTS.

Genetics
Unknown; however, a familial type has been reported.

RISK FACTORS
- Prolonged postures in extremes of wrist flexion and extension; repetitive exposure to vibration
- Alterations of fluid balance: pregnancy, arthritis, menopause, obesity, renal failure, hypothyroidism, congestive heart failure and oral contraceptive use
- Neuropathic factors (diabetes, alcoholism, vitamin deficiency, or exposure to toxins) can elicit symptoms.

GENERAL PREVENTION
There is no known prevention for CTS. It is recommended to take occasional (e.g., hourly) breaks when doing repetitive work involving hands or if prolonged occupational exposure to vibratory tools.

COMMONLY ASSOCIATED CONDITIONS
- Diabetes, obesity; pregnancy; hypothyroidism
- Osteoarthritis of small joints of hand and wrist
- Hyperparathyroidism, hypocalcemia
- Miscellaneous associations include the following:
  - Acromegaly; lupus erythematosus; leukemia
Pyogenic infections; sarcoidosis
Primary amyloidosis; Paget disease
Hormone replacement therapy

**DIAGNOSIS**

**HISTORY**
- Nocturnal pain, numbness, and tingling of the thumb, index, long, and radial portion of the ring fingers; patients may not localize and alternatively describe the entire hand as being affected.
- Hand weakness during tasks as opening jars is often noted early in the disorder.
- Atypical presentation involves paresthesias in radial digits, with pain radiating proximally along median nerve to elbow and sometimes the shoulder.
- Symptoms characteristically are relieved by shaking or rubbing the hands.
- During waking hours, symptoms occur when driving, talking on the phone, and occasionally when using the hands for repetitive maneuvers.
- Presence of predisposing factors, such as diabetes, obesity, acromegaly, pregnancy, or occupational exposure

**PHYSICAL EXAM**
- Positive Tinel sign: Tapping over the palmar surface of the wrist proximal to the carpal tunnel may produce an electric sensation along the distribution of the median nerve (50% sensitivity; 77% specificity).
- Positive Phalen sign: Holding the wrist in fully flexed position for 60 seconds precipitates paresthesias (68% sensitivity; 73% specificity).
- Durkan compression test: Direct compression of median nerve at carpal tunnel for 30 seconds elicits symptoms (87% sensitivity; 90% specificity).
- Wasting of thenar musculature is a late sign.
- Loss of 2-point discrimination
- Ulceration of fingertips is associated with loss of protective sensation.

**DIFFERENTIAL DIAGNOSIS**
- Cervical spondylosis (carpal tunnel may also occur with cervical spine disease; “double crush”)
- Generalized peripheral neuropathy
- Brachial plexopathy, in particular upper trunk
● CNS disorders (multiple sclerosis, cerebral infarction)
● Thoracic outlet syndrome
● Pronator syndrome
● Anterior interosseous syndrome
● Musculoskeletal disorders of the wrist:
  – Trauma or distal radius fracture
  – Degenerative joint disease
  – Rheumatoid arthritis
  – Ganglion cyst
● Scleroderma

**DIAGNOSTIC TESTS & INTERPRETATION**

No laboratory test is diagnostic.

- Normal serum thyrotropin (thyroid-stimulating hormone [TSH]) and normal serum chemistries help exclude secondary conditions associated with CTS.

**Initial Tests (lab, imaging)**

- Special tests
  - Electrodiagnostic studies
    - Sensitivity 85%; specificity 95%
    - Nerve conduction studies compare latency and amplitude of median nerve signals across the carpal tunnel.
    - Prolonged distal latency of the median motor and/or sensory fibers may be seen. Decreased amplitudes suggest axon loss.
    - The most sensitive indicator is median sensory distal latency, which is prolonged in CTS. Sensory nerve action potentials may be reduced or unobtainable.
    - Electromyographic changes are indicative of long-standing or severe nerve dysfunction.
- Perform ulnar nerve stimulation to exclude generalized polyneuropathy.
- Standard radiographs of the wrist evaluate bony anatomy and degenerative joint disease.
- Special radiographic views of the carpal tunnel are of limited use.
- Magnetic resonance imaging and ultrasound are of limited benefit in diagnosis of CTS.
TREATMENT

GENERAL MEASURES

- Splinting the wrist in a neutral position while sleeping may provide significant symptom relief:
  - Limited evidence indicates that night splints are more effective than no treatment in the short term; insufficient evidence to recommend a specific splint design or wearing schedule (1)[A]
  - American Academy of Orthopaedic Surgeons (AAOS) guidelines indicate immobilization improves outcomes.
- Splinting (sometimes prolonged) typically promotes symptom resolution.
- Corticosteroid injections are effective for up to 3 months compared with placebo (2)[A]. Outcomes at 1 year show no benefit for local steroid injections compared to placebo (3)[A].

MEDICATION

First Line

NSAIDs, such as ibuprofen or naproxen sodium, are commonly used. There is insufficient evidence to determine their routine efficacy:

- Contraindications: GI intolerance
- Precautions: GI side effects of NSAIDs may preclude their use in selected patients.

Second Line

- Local steroid injection: Methylprednisolone injections are more effective than systemic steroids or placebo at 1 and 3 months and more effective than splinting at 6 months.
- Response to injections helps confirm diagnosis of CTS and predicts a better response to surgery.
- Side effects include reduction of collagen and proteoglycan synthesis, limiting tenocytes, and reducing mechanical strength of tendon, leading to further degeneration and risk for rupture.
- Oral steroids may provide a short-term improvement (2 to 8 weeks) in symptoms.
- The long-term risks of even a short course of steroids should be balanced with the limited potential benefit of symptom improvement.
ISSUES FOR REFERRAL
Preoperative electrodiagnostic studies are generally obtained prior to any surgical intervention.

SURGERY/OTHER PROCEDURES
- Completely dividing the transverse carpal ligament provides symptom relief in >95% of patients.
- Surgical decompression is an outpatient procedure performed under local or regional anesthesia.
- Incisional healing generally takes 2 weeks; an additional 2 weeks may be required before using the affected hand for tasks requiring strength.
- Long-term results of open carpal tunnel release are excellent. Patients experience consistent pain relief for 10 to 15 years (3)[B].
- Recent randomized, controlled studies indicate that surgery leads to better functional improvements at 1 year compared with nonoperative management.
- Open versus endoscopic surgical procedures produce similar outcomes at 6 months. The approach should be based on surgeon and patient preference.
- Risk of transient nerve injuries is higher with endoscopic release (4)[A].
- Therapeutic ultrasound, exercise, and mobilization techniques have limited benefit compared with other nonsurgical interventions. Poor quality evidence shows ultrasound may be more effective than placebo (5,6)[A].

COMPLEMENTARY & ALTERNATIVE MEDICINE
No trial data support the use of vitamin B₆ in the prevention or treatment of CTS.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Outpatient

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Patients treated nonoperatively (splinting, injections) require follow-up over 4 to 12 weeks to ensure adequate progress.

- There is only limited, low-quality evidence to suggest that rehabilitation exercises such as wrist immobilization, ice therapy, and multimodal hand rehabilitation are beneficial.
- 7–20% of patients treated surgically may experience recurrence.

**PATIENT EDUCATION**

American Society for Surgery of the Hand:
http://www.assh.org/Public/HandConditions/Pages/CarpalTunnelSyndrome.aspx

**PROGNOSIS**

- Patients with severe CTS may not recover completely after surgical release. Paresthesias and weakness may persist, but night symptoms generally resolve.
- If untreated, more severe cases of CTS can lead to numbness and weakness in the hand, atrophy of the thenar muscles, and permanent loss of median nerve function.

**COMPLICATIONS**

- Postoperative infection (rare)
- Injury to the median nerve or its recurrent (motor) branch

**REFERENCES**

### ADDITIONAL READING

### SEE ALSO

- Arthritis, Rheumatoid (RA); Hypoparathyroidism; Lupus Erythematosus, Systemic (SLE); Scleroderma
- Algorithms: Carpal Tunnel Syndrome; Pain in Upper Extremity

### CODES

**ICD10**

- G56.00 Carpal tunnel syndrome, unspecified upper limb
- G56.01 Carpal tunnel syndrome, right upper limb
- G56.02 Carpal tunnel syndrome, left upper limb

### CLINICAL PEARLS

- Paresthesias associated with CTS are characteristically confined to the thumb, index, long, and radial 1/2 of the ring fingers of the affected hand.
- Thenar atrophy is a late finding, indicating severe nerve damage.
The Durkan (carpal compression) test is superior to Tinel sign (tapping on median nerve over carpal tunnel) and Phalen maneuver (holding wrists in flexion) for the clinical diagnosis of CTS.

Steroid injections offer short-term relief, but clinical outcomes at 1 year are no different than placebo.
CATARACT

Yasir Ahmed, MD • Ingrid U. Scott, MD, MPH

BASICS

DESCRIPTION

- A cataract is any opacity or discoloration of the lens, localized or generalized; the term is usually reserved for changes that affect visual acuity (1,2).
- Etymology: from Latin catarractes, for “waterfall”; named after foamy appearance of opacity
- Leading cause of blindness worldwide, estimated 20 million people (1,2)
- Types include the following:
  - Age related: 90% of total
  - Metabolic (diabetes via accelerated sorbitol pathway, hypocalcemia, Wilson disease)
  - Congenital (1/250 newborns; 10–38% of childhood blindness)
  - Systemic disease associated (myotonic dystrophy, atopic dermatitis [AD])
  - Secondary to associated eye disease, so-called complicated (e.g., uveitis associated with juvenile rheumatoid arthritis or sarcoid, tumor such as melanoma or retinoblastoma)
  - Traumatic (e.g., heat, electric shock, radiation, concussion, perforating eye injuries, intraocular foreign body)
  - Toxic/nutritional (e.g., corticosteroids)
- Morphologic classification:
  - Nuclear: exaggeration of normal aging changes of central lens nucleus, often associated with myopia due to increased refractive index of lens (Some elderly patients consequently may be able to read again without spectacles, so-called second sight of the aged.)
  - Cortical: outer portion of lens; may involve anterior, posterior, or equatorial cortex; radial, spoke-like opacities
  - Subcapsular: Posterior subcapsular cataract has more profound effect on vision than nuclear or cortical cataract; patients particularly troubled under conditions of miosis; near vision frequently impaired more than distance vision
- System(s) affected: nervous
**Geriatric Considerations**
Some degree of cataract formation is expected in all people >70 years of age.

**Pediatric Considerations**
See Congenital cataract; may present as leukocoria

**Pregnancy Considerations**
See Congenital cataract (i.e., medications, metabolic dysfunction, intrauterine infection, and malnutrition).

**EPIDEMIOLOGY**

**Incidence**
- ~48% of the 37 million cases of blindness worldwide result from cataracts (1,2).
- Leading cause of treatable blindness and vision loss in developing countries (1,2)
- Predominant age: depends on type of cataract
- Predominant sex: male > female

**Prevalence**
- Cataract type and prevalence are highly variable based on population demographic.
- An estimated 50% of people 65 to 74 years of age and 70% of people >75 years of age have age-related cataract.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Age-related cataract:
  - Continual addition of layers of lens fibers throughout life creates hard, dehydrated lens nucleus that impairs vision (nuclear cataract).
  - Aging alters biochemical and osmotic balance required for lens clarity; outer lens layers hydrate and become opaque, adversely affecting vision.
- Congenital:
  - Usually unknown etiology
  - Drugs (corticosteroids in 1st trimester, sulfonamides)
  - Metabolic (diabetes in mother, galactosemia in fetus)
  - Intrauterine infection during 1st trimester (e.g., rubella, herpes, mumps)
  - Maternal malnutrition
• Other cataract types:
  – Common feature is a biochemical/osmotic imbalance that disrupts lens clarity.
  – Local changes in lens protein distribution lead to light scattering (lens opacity).

**Genetics**
• Congenital (e.g., chromosomal disorders [Down syndrome])
• Genetics of age-related cataract are not yet established but likely multifactorial contribution.

**RISK FACTORS**
• Aging
• Cigarette smoking
• Ultraviolet (UV) sunlight exposure
• Diabetes
• Prolonged high-dose steroids
• Positive family history
• Alcohol

**GENERAL PREVENTION**
• Use of UV protective glasses
• Avoidance of tobacco products
• Effective control of diabetes
• Care with high-dose, long-term steroid use (systemic therapy > inhaled treatment)
• Protective methods using pharmaceutical intervention (e.g., antioxidants, acetylsalicylic acid [ASA], hormone replacement therapy [HRT]) show no proven benefit to date.

**COMMONLY ASSOCIATED CONDITIONS**
• Diabetes (especially with poor glucose control)
• Myotonic dystrophy (90% of patients develop visually innocuous change in 3rd decade; becomes disabling in 5th decade)
• AD (10% of patients with severe AD develop cataracts in 2nd to 4th decades; often bilateral)
• Neurofibromatosis type 2
• Associated ocular disease or “secondary cataract” (e.g., chronic anterior
uveitis, acute [or repetitive] angle-closure glaucoma or high myopia)
• Drug induced (e.g., steroids, chlorpromazine)
• Trauma

DIAGNOSIS

HISTORY
• Age-related cataract:
  – Decreased visual acuity, blurred vision, distortion, or “ghosting” of images (1,2)
  – Problems with visual acuity in any lighting condition
  – Falls or accidents; injuries (e.g., hip fracture)
• Congenital: often asymptomatic; leukocoria; parents notice child’s visual inattention or strabismus.
• Other types of cataract:
  – May also present with decreased visual acuity
  – Appropriate clinical history or signs to help with diagnosis

PHYSICAL EXAM
• Visual acuity assessment for all cataracts
• Age-related cataract: lens opacity on eye examination
• Congenital:
  – Lens opacity present at birth or within 3 months of birth
  – Leukocoria (white pupil), strabismus, nystagmus, signs of associated syndrome (as with Down or rubella syndrome)
  – Note: must always rule out ocular tumor; early diagnosis and treatment of retinoblastoma may be lifesaving.
• Other types of cataract: may present with decreased visual acuity associated with characteristic physical findings (e.g., metabolic, trauma)

DIFFERENTIAL DIAGNOSIS
• An opaque-appearing eye may be due to opacities of the cornea (e.g., scarring, edema, calcification), lens opacities, tumor, or retinal detachment. Biomicroscopic examination (slit lamp) or careful ophthalmoscopic exam should provide diagnosis.
• In the elderly, visual impairment is often due to multiple factors such as cataract and macular degeneration, both contributing to visual loss.
- Age-related cataract is significant if symptoms and ophthalmic exam support cataract as a major cause of vision impairment.
- Congenital lens opacity in the absence of other ocular pathology may cause severe amblyopia.
- Note: Cataract does not produce a relative afferent pupillary reaction defect. Abnormal pupillary reactions mandate further evaluation for other pathology.

**DIAGNOSTIC TESTS & INTERPRETATION**
- Visual quality assessment: Glare testing, contrast sensitivity is sometimes indicated.
- Retinal/macular function assessment: potential acuity meter testing
- Workup of underlying process

**Test Interpretation**
Consistent with lens changes found in the type of cataract; however, diagnosis is made by clinical examination.

**TREATMENT**
- Outpatient (usually)
- ~1.64 million cataract extractions in the United States yearly (3,4)

**GENERAL MEASURES**
Eye protection from UV light

**MEDICATION**
There are currently no medications to prevent or slow the progression of cataracts.

**ISSUES FOR REFERRAL**
If patient has cataract and symptoms do not seem to support recommended surgery, a second opinion by another ophthalmologist may be indicated.

**SURGERY/OTHER PROCEDURES**
- Age-related cataract:
  - Surgical removal is indicated if visual impairment–producing symptoms are distressing to the patient, interfering with lifestyle or occupation, or posing
a risk for fall or injury (3,4)[A].

- Because significant cataract may develop gradually, the patient may not be aware of how it has changed his or her lifestyle. Physician may note a significant cataract, and patient reports “no problems.” Thus, evaluation requires effective physician–patient exchange of information.
- Preoperative evaluation: by the primary care physician:
  o Patients on anticoagulants may need to be temporarily discontinued 1 to 2 weeks before surgery if possible (but not always necessary, thus need to discuss with ophthalmologist).
  o Patients who have ever taken an α-blocker such as tamsulosin (Flomax) should alert their ophthalmologist (increased risk of intraoperative floppy iris syndrome [IFIS] even in patients who no longer use these drugs).
- Anesthesia: usually regional injection or topical with sedation and monitoring of vital signs
- Surgical technique: cataract extraction via phacoemulsification through small incisions created by blade or laser, followed by implantation of a prosthetic intraocular lens; lenses have power calculated based on size of the eye and curvature of cornea usually to correct for distance vision; surgery performed on one (usually worse) eye, with contralateral surgery after recovery and if deemed necessary; generally takes <1 hour depending on surgical technique
- Postoperative care: usually protective eye shield as directed, topical antibiotic, NSAIDs, and steroid ophthalmic medications; keeping eye protected, avoid lifting or bending over for a few weeks.

* Congenital cataract:
  - Treatment is surgical removal of cataract. Newborns may require surgery within days to reduce risk of severe amblyopia. Use of lens implants is controversial because the eyes are growing.
  - Postoperative care: long-term patching program for good eye to combat amblyopia; refractive correction of operative eye, with multiple repeat examinations; challenging for physician and parents

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

* As cataract progresses, an ophthalmologist may change spectacle correction to
maintain vision. When this is no longer successful and interferes with patient’s activities of daily living, surgery is indicated.

- Following surgery, spectacle correction may be required to maximize near and/or far visual acuity. Refraction is usually prescribed several weeks after surgery.

**PATIENT EDUCATION**

**PROGNOSIS**

- Ocular prognosis is good after cataract removal if no prior or coexisting ocular disease: 94.3% of otherwise healthy eyes achieve best corrected visual acuity of 20/40 or better. Success rates are lower with comorbidities such as diabetes and glaucoma (5).
- In congenital cataracts, prognosis often is poorer because of the high risk of amblyopia.

**COMPLICATIONS**

- Vary widely from delay in visual recovery or protracted visual discomfort to blindness and loss of eye

  Nearly all reported complications occur rarely (<2% of eyes) except for posterior capsule opacification (14.7–42.7% of eyes, usually treated with Nd-YAG laser capsulotomy in office with a rate of 4–25.3%) (6)[B].
- Poor preoperative visual acuity is related to surgical complications.

**REFERENCES**

SEE ALSO
- Floppy Iris Syndrome
- Algorithm: Cataracts

CODES

**ICD10**
- H26.9 Unspecified cataract
- H25.9 Unspecified age-related cataract
- Q12.0 Congenital cataract

**CLINICAL PEARLS**
- Cataracts are the leading cause of blindness worldwide; 90% are age-related.
- Primary indication for cataract surgery is visual impairment leading to significant lifestyle changes for the patient.
- For congenital cataracts, must always rule out ocular tumor because early diagnosis and treatment of retinoblastoma may be lifesaving.
- Before prescribing an α-blocker for an older adult with hypertension or a prostate or urinary retention problem, consider whether the patient has cataracts (due to increased risk of IFIS).
CELIAC DISEASE
Zachariah John Kamla, DO • Lloyd A. Runser, MD, MPH

BASICS
DESCRIPTION
- An immune-mediated reaction to dietary gluten (found in wheat, barley, rye) primarily affecting the small intestine in genetically predisposed individuals
- Presentations
  - Typical
    o Diarrheal illness characterized by villous atrophy with symptoms of malabsorption (steatorrhea, weight loss, vitamin deficiencies, anemia); resolves with a gluten-free diet
    o <50% of adults present with GI symptoms.
  - Atypical
    o Minor GI symptoms, with a myriad of extraintestinal manifestations (e.g., anemia, LFTs, dental enamel defects, neurologic symptoms, infertility)
  - Asymptomatic (silent) disease
    o Found when screening first-degree relatives
    o Positive laboratory tests and genetics, without signs/symptoms and with normal histology on biopsy
- System(s) affected: gastrointestinal
- Synonym(s): celiac sprue; gluten enteropathy

EPIDEMIOLOGY

Incidence
- 1 to 13 per 100,000 worldwide (1)
- 6.5 per 100,000 in United States (2)
- Primarily affects those of Northern European ancestry
- Predominant sex: female > male (3:2)

Prevalence
- 0.7% in the United States; an estimated 3 million Americans have celiac disease (3).
- 8 to 204 per 100,000 worldwide and (1)
ETIOLOGY AND PATHOPHYSIOLOGY
Sensitivity to gluten, specifically gliadin protein fraction. Tissue transglutaminase (tTG) modification of the gliadin protein leads to immunologic cross-reactivity, inflammation, and tissue damage (villous atrophy) with subsequent GI symptoms and malabsorption.

Genetics
Homogenicity for HLA-DQ2/DQ8 increases risk of celiac disease and enteropathy-associated T-cell lymphoma.

RISK FACTORS
- First-degree relatives: 5–20% incidence (1)
- Second-degree relatives

Pediatric Considerations
No other risk factors explain why some susceptible individuals develop celiac, whereas others do not. Topics for investigation include grain processing, genetically modified organisms, hygiene and illness during childhood, breastfeeding, time of introduction of solid foods, pollution, tobacco use, and medication (4).

COMMONLY ASSOCIATED CONDITIONS
- Dermatitis herpetiformis: 85% of patients have celiac disease. All patients should follow gluten-free diet (1).
- Secondary lactase deficiency
- Osteopenia and osteoporosis
- Thyroid disease: Hashimoto thyroiditis
- Type 1 diabetes: 3–10% of patients with type 1 diabetes also have celiac disease (1).
- Symptomatic iron deficiency: 10–15% have celiac disease.
- Elevated AST and ALT (with no direct cause)
- Hyposplenism
- Irritable bowel syndrome (IBS)
- Restless leg syndrome
- Celiac disease is associated with increased risk for adenocarcinoma and lymphoma of the small bowel.
  - The risk of lymphoproliferative malignancies depends on small intestinal histopathology.
Little to no increased risk in latent celiac disease (seropositive but normal biopsy)

- Associated autoimmune conditions (type 1 diabetes, autoimmune thyroiditis, primary biliary cirrhosis, autoimmune hepatitis, psoriasis, Sjögren disease)
- Associated genetic conditions (Down syndrome, IgA deficiency, Turner syndrome, Williams syndrome)

**Pregnancy Considerations**

- Prevalence of celiac disease: 2.5 to 3.5 times higher in women with unexplained infertility
- Up to 19% of men with celiac disease have androgen resistance. Semen quality and likelihood of pregnancy increase with gluten-free diet.
- Higher rates of low birth weight, prematurity, spontaneous abortions, intrauterine growth restriction, and stillbirths

**Pediatric Considerations**

Children with CD at higher risk for type 1 diabetes, Down syndrome, Turner syndrome, Williams syndrome, IgA deficiency, and autoimmune thyroid disease (5)[C]

**DIAGNOSIS**

**HISTORY**

- Diarrhea, cramping are the most common GI symptoms.
- Steatorrhea (fatty stools)
- Abdominal pain or distension
- Nausea, vomiting, flatulence
- Weight loss, weakness, fatigue
- Delayed puberty
- Iron deficiency anemia
- Recurrent aphthous stomatitis
- Dental enamel hyperplasia
- Muscle cramps
- Bone or joint pain
- Anxiety, depression
- Tingling numbness in hands, feet
- Migraines
In children, malabsorption may manifest as failure to thrive, short stature, or chronic fatigue (5).

- Anorexia
- Constipation or encopresis

**PHYSICAL EXAM**
Often normal; look for specific findings with:

- Oropharynx: aphthous stomatitis
- Skin: dermatitis herpetiformis (symmetric erythematous papules and blisters on elbows, knees, buttocks, and back), signs of anemia
- Abdomen: distention

**DIFFERENTIAL DIAGNOSIS**

- Gluten allergy–type II allergic reaction with signs of anaphylaxis
- Nonceliac gluten sensitivity—GI symptoms and/or systemic symptoms improved by gluten-free diet but without biomarkers characteristic of celiac disease
- Short bowel syndrome, small intestinal bacterial overgrowth
- Lactose intolerance
- Dyspepsia
- Gastroesophageal reflux disease (GERD)
- Pancreatic exocrine insufficiency
- Crohn disease
- Whipple disease
- Tropical sprue
- Hypogammaglobulinemia
- Intestinal lymphoma
- Microscopic colitis
- Autoimmune enteropathy
- HIV enteropathy
- Acute enteritis; radiation enteritis
- Eosinophilic gastroenteritis
- Giardiasis
- IBS

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- Do not base diagnosis on serology alone. Patients with symptoms highly
suggestive of celiac disease or those with positive serologies should undergo endoscopy for small bowel biopsy while on a gluten-containing diet. Tissue biopsy is the gold standard for diagnosis.

- IgA anti-tTG is the preferred serologic test in patients >2 years (1)[C].
- Total serum IgA to screen for IgA deficiency

**ALERT**
Positive IgA tTG has high sensitivity and specificity (sensitivity, 95–98%; specificity, 95%) if on normal (non–gluten-free) diet for at least 4 weeks.

- IgA-deficient patients have false-negative IgA anti-tTG antibodies.
- IgA deficiency is 10 to 15 times more prevalent in patients with celiac disease.
- The tTG antibody test is the preferred test (over the deamidated gliadin peptide [DGP] antibody).

**Follow-Up Tests & Special Considerations**
- If patient is IgA deficient OR if IgA anti-tTG are negative, follow up with anti-DGP IgA and IgG.
  - Sensitivity, 94%; specificity, 99% (~anti-TTG)
- Do not use HLA DQ serotyping for initial diagnosis. Consider if discrepant serology–histology results in patients unable to test on gluten-free diet and children with Down syndrome (1)[C].
- Consider bone mineral density testing at diagnosis and after 1 year if osteopenia/osteoporosis on initial testing or 2 years if normal initially and patient still symptomatic or noncompliant.

**Pediatric Considerations**
- Screen symptomatic pediatric patients with serologic testing as above; may screen asymptomatic patients in at-risk category after 3 years of age, after a year of regular exposure to gluten
  - IgA antibody to endomysium (EMA) can be used but adds cost and risk of interpretation error.
  - Antigliadin antibody tests (AGA IgA and AGA IgG) are inferior and not recommended.
- In IgA-deficient individuals, compare TTG IgA with quantitative serum IgA and obtain TTG IgG.
- Confirm suspected diagnoses with intestinal biopsy.
- Biopsy seronegative patients with chronic diarrhea if at risk for false negative, including children <2 years, positive family history of CD, or IgA deficiency
Diagnostic Procedures/Other

- Endoscopy with a minimum of four biopsies of distal duodenum and two of duodenal bulb at time of initial evaluation correctly diagnosed 95% of children (1)[C].
- Video capsule endoscopy is a promising alternative with a sensitivity and specificity of 80% and 95%; particularly helpful if antibody screening and clinical picture are consistent with celiac disease despite nondiagnostic duodenal biopsies

Test Interpretation

Small-bowel biopsy

- Villous atrophy, hyperplasia and lengthening of crypts, infiltration of plasma cells, and intraepithelial lymphocytosis in lamina propria
- Villous atrophy also caused by Crohn disease, radiation enteritis, giardia, and other food intolerances

TREATMENT

GENERAL MEASURES

- Remove gluten from the diet.
  - Rice, corn, and nut flour are safe and palatable substitutes (1)[C].
  - Grains: uncontaminated oats, rice, corn, tapioca, quinoa, amaranth, sorghum
- Levels of IgA antigliadin normalize with gluten abstinence.
- Lifelong abstinence is required; immune response to gluten will recur with resumption of gluten intake.

MEDICATION

First Line

Usually no medications: Gluten-free diet is the treatment.

Second Line

- In refractory disease, consider
  - Steroids (prednisone (1)[C] or budesonide (1)[B])
– Azathioprine (used with caution; use may lead to lymphoma) (1)[C]
– Cyclosporine
– Infliximab
– Cladribine

● Depending on disease severity, patients may develop nutritional deficiencies that require appropriate supplementation.

ISSUES FOR REFERRAL
● Additional nutritional support with qualified dietitian
● Refractory celiac disease
● Child with positive celiac serology

COMPLEMENTARY & ALTERNATIVE MEDICINE
Many alternative therapies are in development, and future treatment may include predigestion of gluten with peptidase, tight junction blockade (zonulin), transglutaminase 2 or HLA DQ2/DQ8 blockers, and immune tolerance induction (NexVax) (4).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
● Consultation with registered dietitian
● Screen for osteoporosis and treat accordingly.
● Follow-up with GI at 3 to 6 months for serology and 12 months for repeat biopsy if indicated

Patient Monitoring
● Repeat EGD if no clinical response to gluten-free diet or relapse in symptoms (1)[C].
● Follow anti-tTG IgA or deaminated antigliadin antibodies as a measure of response/compliance with diet (vs. antigliadin IgA or IgG).

DIET
● Remove gluten: wheat, rye, barley, and products with gluten additives (processed food/meat, medications, hygiene products).
● Dietary change is challenging (especially learning sources of “hidden” gluten)
and should be coordinated with a skilled registered dietitian.

**PATIENT EDUCATION**

- Discuss how to recognize gluten in various products.
- Highlight potential complications and outcomes of failing to follow a gluten-free diet.
- Suggest support groups and self-education.

**PROGNOSIS**

- Good prognosis if adherent to gluten-free diet
- Patients should see improvement within 7 days of dietary modification.
- Symptoms usually resolve in 4 to 6 weeks.
- It is unknown whether strict dietary adherence decreases cancer risk.

**COMPLICATIONS**

- Malignancy: Untreated and refractory patients have increased cancer risk, but successful treatment decreases risk to population baseline (1)[C].
- Refractory disease (rare ~1–2% of all patients)
  - May respond to prednisone
  - May need total parenteral nutrition
- Osteoporosis
- Dehydration
- Electrolyte depletion

**ADDITIONAL READING**

**SEE ALSO**

Algorithms: [Diarrhea, Chronic](https://www.niddk.nih.gov/health-information/digestive-diseases/diarrhea); Malabsorption Syndrome

**CODES**

**ICD10**

K90.0 Celiac disease

**CLINICAL PEARLS**

- Screen for celiac disease in patients with non-specific GI symptoms, presumed IBS, dermatitis herpetiformis, unexplained transaminitis, or unexplained iron deficiency anemia.
- Test total IgA levels along with IgA anti-tTG antibodies in patients >2 years of age. Positive serology is not definitive.
- Diagnostic testing must be completed while on a gluten-containing diet.
- Endoscopic biopsy is the gold standard for diagnosis.
- Standard of treatment is a gluten-free diet. Patient symptoms should improve in 7 days if fully compliant.
CELLULITIS

Jowhara Al-Qahtani, MD • Amer Homsi, MD • Bakr Nour, MD, PhD, FACS

BASICS

A common global health burden with >650,000 admissions per year in the United States alone (1)[A]

DESCRIPTION

• An acute bacterial infection of the dermis and subcutaneous (SC) tissue
• Types and locations:
  – Periorbital cellulitis: bacterial infection of the eyelid and surrounding tissues (anterior compartment)
  – Orbital cellulitis: infection of the eye posterior to the septum; sinusitis is the most common risk factor.
  – Facial cellulitis: preceded by upper respiratory infection or otitis media
  – Buccal cellulitis: infection of cheek in children associated with bacteremia (common before Haemophilus influenzae type B vaccine)
  – Peritonsillar cellulitis: common in children; associated with fever, sore throat, and “hot potato” speech
  – Abdominal wall cellulitis: common in morbidly obese patients
  – Perianal cellulitis: sharply demarcated, bright, perianal erythema
  – Necrotizing cellulitis: gas-producing bacteria in the lower extremities; common in diabetics

EPIDEMIOLOGY

• Predominant sex: male = female
• All-cause mortality for patient admitted with cellulitis is 7%. Recurrence rate of cellulitis is 8–20% (2)[A].

Incidence

200/100,000 patient/years

Prevalence

• The exact prevalence is uncertain as cellulitis is common and not reportable. It
affects all age groups and all races; however, certain types of cellulitis/microorganisms occur in certain populations.

In the United States, ~14.5 million annual cases of cellulitis account for $3.7 billion in ambulatory costs (1)[A].

**ETIOLOGY AND PATHOPHYSIOLOGY**

Cellulitis is caused by bacterial penetration through a break in the skin. Hyaluronidase mediates SC spread.

- **Microbiology**
  - β-Hemolytic streptococci (groups A, B, C, G, and F), *Staphylococcus aureus*, including MRSA and gram-negative aerobic bacilli, are the most common.
  - *S. aureus* seen in periorbital and orbital cellulitis and IV drug users
  - *Pseudomonas aeruginosa* seen in diabetics and other immunocompromised patients
  - *H. influenza* causes buccal cellulitis.
  - Clostridia and non–spore-forming anaerobes: necrotizing cellulitis (crepitant/gangrenous)
  - *Streptococcus agalactiae*: cellulitis following lymph node dissection
  - *Pasteurella multocida* and *Capnocytophaga canimorsus*: cellulitis preceded by bites
  - *Streptococcus iniae*: immunocompromised hosts
  - Rare causes: *Mycobacterium*, fungal (mucormycosis, aspergillosis, syphilis)

**Genetics**

No genetic pattern

**RISK FACTORS**

- Disruption of skin barrier: trauma, infection, insect bites, injection drug use, body piercing
- Inflammation: eczema or radiation therapy
- Edema due to venous insufficiency; lymphatic obstruction due to surgery or congestive heart failure
- Elderly, diabetes, hypertension, obesity
- Recurrent cellulitis:
  - Cellulitis recurrence score (predicts recurrence of lower extremity cellulitis based on presence of lymphedema, chronic venous insufficiency, peripheral vascular disease, and deep venous thrombosis) (3)[A]
– Recurrent cellulitis is seen in immunocompromised patients (HIV/AIDS), steroids and TNF-α inhibitor therapy, diabetes, hypertension, cancer, peripheral arterial or venous diseases, chronic kidney disease, dialysis, IV or SC drug use (3)[A].

**GENERAL PREVENTION**

- Good skin hygiene
- Support stockings to decrease edema
- Maintain tight glycemic control and proper foot care in diabetic patients.

**DIAGNOSIS**

Primarily a clinical diagnosis

**HISTORY**

- Previous trauma, surgery, animal/human bites, dermatitis, fungal infection are portals of entry for bacterial pathogens.
- Pain, itching, and/or burning
- Fever, chills, and malaise

**PHYSICAL EXAM**

- Localized pain and tenderness with erythema, induration, swelling, and warmth
- Peau d’orange appearance
- Regional lymphadenopathy
- Purulent drainage (from abscesses)
- Orbital cellulitis: proptosis, globe displacement, limitation of ocular movements, vision loss, diplopia
- Facial cellulitis: malaise, anorexia, vomiting, pruritus, burning, anterior neck swelling

**DIFFERENTIAL DIAGNOSIS**

Toxic shock syndrome, venous stasis dermatitis (commonly mistaken as cellulitis), bursitis, acute dermatitis or intertrigo, herpes zoster or herpetic whitlow, deep vein thrombosis or thrombophlebitis, acute gout or pseudogout, necrotizing fasciitis or myositis, gas gangrene, osteomyelitis, erythema chronicum migrans or malignancy, drug reaction, sunburn, or insect stings. Spider bites and MRSA cellulitis can present similarly.
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- If there are signs of systemic disease (fever, heart rate >100 bpm, or systolic blood pressure <90 mm Hg): blood cultures, CPK, CRP. Consider serum lactate levels.
- WBC has 84% specificity and 43% sensitivity; CRP has a sensitivity of 67% and specificity of 95% (PPV 95% and NPV 68%).
- Aspirates from point of maximum inflammation are more sensitive (45% positive culture) than aspirates from leading edge (5% positive culture).
- Blood cultures: pathogens isolated in <5% of patients. Blood cultures in children are more likely to show a contaminant than true positive.
- Swab open cellulitis wounds for culture.
- Plain radiographs, CT, or MRI are useful if osteomyelitis, fracture, necrotizing fasciitis, retained foreign body, or underlying abscess is suspected.
- Gallium-67 scintigraphy helps detect cellulitis superimposed on chronic limb lymphedema.

Diagnostic Procedures/Other
Consider lumbar puncture in children with H. influenzae type B or if meningeal signs and facial cellulitis.

TREATMENT

GENERAL MEASURES
- Immobilize and elevate involved limb to reduce swelling.
- Sterile saline dressings or cool aluminum acetate compresses for pain relief
- Edema: compression stocking, pneumatic pumps; diuretic therapy for CHF patients
- Mark the area of cellulitis to monitor progression.
- Tetanus immunization if needed, particularly if there is an open (traumatic) wound

MEDICATION

First Line
- Target treatment if known pathogen and with certain exposures (animal bites).
- Empiric antibiotic selection:
- Nonpurulent cellulitis
  - With nonpurulent drainage, target treatment toward β-hemolytic streptococci and MSSA.
  - Outpatient: treatment duration of 5 to 10 days
    - Oral: for mild cellulitis
      - Cephalexin 500 mg PO q6h; children: 25 to 50 mg/kg/day in 3 to 4 doses
      - Dicloxacillin 500 mg PO q6h; children: 25 to 50 mg/kg/day in 4 doses
      - Clindamycin 300 to 450 mg PO q6–8h; children: 20 to 30 mg/kg/day in 4 doses
    - IV: for rapidly progressing cellulitis
      - Cefazolin 1 to 2 g IV q8h; children: 100 mg/kg/day IV in 2 to 4 divided doses
      - Oxacillin 2 g IV q4h; children: 150 to 200 mg/kg/day IV in 4 to 6 doses
      - Nafcillin 2 g IV q4h; children: 150 to 200 mg/kg/day IV in 4 to 6 doses
      - Clindamycin 600 to 900 mg IV q8h; children: 25 to 40 mg/kg/day IV in 3 to 4 doses
- Purulent cellulitis (probable CA-MRSA)
  - Culture all purulent wounds and follow up in 48 hours.
  - Incise and drain abscess and start empiric antibiotic therapy. Modify based on culture results; tailor duration based on clinical response (4)[B]:
    - Oral
      - Clindamycin 300 to 450 mg PO; children: 40 mg/kg/day in 3 to 4 doses
      - Trimethoprim-sulfamethoxazole (TMP-SMX) 1 DS tab PO BID; children: dose based on TMP at 8 to 12 mg/kg/day divided in 2 doses
      - Doxycycline 100 mg PO BID; children >8 years of age: ≤45 kg: 4 mg/kg/day divided in 2 doses; >45 kg: 100 mg PO BID
      - Minocycline 200 mg PO once and then 100 mg PO BID; children >8 years old: 4 mg/kg PO once and then 4 mg/kg PO BID
      - Linezolid 600 mg PO BID; children <12 years: 10 mg/kg/dose (max 600 mg/dose) PO TID; ≥12 years: 600 mg PO BID
      - Tedizolid 200 mg PO once daily; children: Dosing is not established.
    - IV
      - Vancomycin 15 to 20 mg/kg/dose IV every 8 to 12 hours
      - Daptomycin 4 mg/kg/dose IV once daily; if bacteremia is present or suspected: 6 mg/kg IV once daily
- Linezolid 600 mg IV BID
- Tedizolid 200 mg IV once daily
- Ceftaroline 600 mg IV q12h
- Tigecycline 100 mg IV once, thereafter 50 mg IV q12h

- Necrotizing cellulitis: requires broad-spectrum coverage to cover clostridial and anaerobic species: ampicillin-sulbactam 1.5 to 3.0 g q6–8h IV or piperacillin-tazobactam 3.37 g q6–8h IV plus ciprofloxacin 400 mg q12h IV plus clindamycin 600 to 900 mg q8h IV; have a low threshold for consultation and intensive care

- Freshwater exposure: penicillinase-resistant: penicillin plus gentamicin or fluoroquinolone; in salt water exposure: doxycycline 200 mg IV in 2 divided doses

- Bites: The combination of amoxicillin and clavulanic acid is recommended for human and dog bites. Ticarcillin and clavulanic acid or the combination of a 3rd-generation cephalosporin (i.e., ceftriaxone) plus metronidazole provides adequate parenteral therapy for animal or human bites. If allergic to penicillin, use fluoroquinolone plus metronidazole.

- Facial cellulitis in adults: ceftriaxone IV

- Diabetic foot infection: ampicillin/sulbactam or imipenem/cilastatin or meropenem; alternative: combinations of targeting anaerobes as well as gram-positive and gram-negative aerobes

- If severe infection, toxicity, immunocompromised patients, or worsening infection despite empirical therapy, admit for empiric antibiotic therapy covering MRSA.

- Recurrent streptococcal cellulitis: penicillin 250 mg BID, or if penicillin-allergic, use erythromycin 250 mg BID

**Pediatric Considerations**
Avoid doxycycline in children ≤8 years old and during pregnancy.

**Second Line**
Mild infection
- Penicillin allergy: erythromycin 500 mg PO q6h
- Cephalexin remains a cost-effective therapy for outpatient management of cellulitis at current estimated MRSA levels.

**SURGERY/OTHER PROCEDURES**
- Débridement for gas and purulent matter
• Intubation or tracheotomy may be needed for cellulitis of the head or neck.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Severe infection, suspicion of deeper or rapidly spreading infection, tissue necrosis, or severe pain
• Marked systemic toxicity or worsening symptoms that do not resolve after 24 to 48 hours of therapy
• Patients with underlying risk factors or severe comorbidities

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
• Repeat relevant labs (blood culture, CBC, potentially LP) if patient is toxic or not improving.
• Consider deep vein thrombosis prophylaxis.
• Cutaneous inflammation may worsen in the first 24 hours due to release of bacterial antigens. Symptomatic improvement usually occurs in 24 to 48 hours, but visible improvement may take 72 hours.

DIET
Glucose control in diabetics

PATIENT EDUCATION
Good skin hygiene

PROGNOSIS
With adequate antibiotic treatment, prognosis is good.

• Low-dose penicillin prophylaxis in patients with recurrent cellulitis decreases recurrence (5)[A].

COMPLICATIONS
• Local abscess or bacteremia, sepsis
• Superinfection with gram-negative organisms
• Lymphangitis, especially if recurrent
Thrombophlebitis or venous thrombosis
Bacterial meningitis
Gangrene

REFERENCES

ADDITIONAL READING

CODES

ICD10
- L03.90 Cellulitis, unspecified
- H05.019 Cellulitis of unspecified orbit
- L03.211 Cellulitis of face

CLINICAL PEARLS
- *S. aureus* and group A *Streptococcus* are the most common organisms causing cellulitis.
- Consider MRSA if cellulitis does not respond to antibiotics within 48 hours.
- Rapid expansion of infected area with red/purple discoloration and severe pain may suggest necrotizing fasciitis, requiring urgent surgical evaluation.
CELLULITIS, ORBITAL

Robert T. Carlisle, MD, MPH

BASICS

DESCRIPTION

- Acute, severe, vision-threatening infection of orbital contents posterior to orbital septum. Preseptal (previously referred to as periorbital) cellulitis is anterior to the septum. Distinguishing location determines the appropriate workup and treatment.
- Synonym(s): postseptal cellulitis

ALERT

- Differentiating orbital from preseptal cellulitis is the critical diagnostic step. Preseptal cellulitis can be identified by exam or, if needed, by CT scan.
- Both preseptal and orbital cellulitis present with a red, swollen painful eye or eyelid.
- Diplopia, proptosis, vision loss, and fever suggest orbital involvement.
- Contrast CT is the imaging method of choice and must be done for suspicion of orbital cellulitis.
- Treat with immediate IV antibiotics, hospital admission, and ophthalmology referral.
- Monitor frequently for vision loss, cavernous sinus thrombosis, abscess, and meningitis.

EPIDEMIOLOGY

- No difference in frequency between genders in adults
- More common in children; mean age of surgical cases: 10.1 years; medical pediatric cases: 6.1 years
- Much less common than preseptal cellulitis

Incidence

Orbital cellulitis has declined since Haemophilus influenzae type b (Hib) vaccine was introduced. Haemophilus is no longer the leading cause of orbital cellulitis (1,2)[B].
ETIOLOGY AND PATHOPHYSIOLOGY

- Sinusitis is classically associated with orbital cellulitis. Local skin conditions are typically associated with preseptal cellulitis.
- The ethmoid sinus is separated from the orbit by the lamina papyracea (“layer of paper”), a thin bony separation, and is often the source of contiguous spread of infection to the orbit.
- The orbital septum is a connective tissue barrier that extends from the skull into the lid and separates the preseptal from the orbital space.
- Cellulitis in the closed bony orbit causes proptosis, globe displacement, orbital apex syndrome (mass effect on the cranial nerves), optic nerve compression, and vision loss.
- Cultures of surgical specimens in adults often grow multiple organisms. In over 1/3 of cases, no pathogen is recovered (3)[B].
- Most common organisms (1,2)[C]:
  - *Staphylococcus aureus, Streptococcus pneumoniae, Streptococcus anginosus*
- Less common organisms:
- There are increasing cases of methicillin-resistant *S. aureus* (MRSA).

**Genetics**
No known genetic predisposition

RISK FACTORS

- Sinusitis present in 80–90% of cases (1)[C]
- Orbital trauma, retained orbital FB, ophthalmic surgery
- Dental, periorbital, skin, or intracranial infection; acute dacryocystitis (inflammation of the lacrimal sac) and acute dacryoadenitis (inflammation of the lacrimal gland)
- Atopy and HSV can lead to recurrent episodes (2).
- Immunosuppressed patients are at increased risk of adverse outcomes.

GENERAL PREVENTION

- Routine Hib vaccination
- Appropriate treatment of bacterial sinusitis
Proper wound care and perioperative monitoring of orbital surgery and trauma
Avoid trauma to the sinus and orbital regions.
High index of suspicion in febrile patients presenting with periorcular pain, swelling, and erythema

COMMONLY ASSOCIATED CONDITIONS
- Trauma and intraorbital FB
- Preseptal cellulitis
- Adverse outcomes of orbital apex syndrome, vision loss, ophthalmoplegia, abscess, meningitis, or cavernous sinus thrombosis

DIAGNOSIS

HISTORY
- Complaints of acute onset red, swollen, tender eye or eyelid, and pain with eye movements
- History of surgery, trauma, sinus or upper respiratory infection, dental infection
- Malaise, fever, stiff neck, mental status changes
- Specific signs of orbital cellulitis include:
  - Proptosis, double vision, ophthalmoplegia, vision loss (or decreased field of vision), pain with eye movement, decreased color vision

ALERT
- Septic appearance, mental status changes, contralateral cranial nerve palsy, or bilateral orbital cellulitis may indicate CNS involvement.
- MRSA orbital cellulitis may present without associated upper respiratory infection.

PHYSICAL EXAM
Vital signs
- Assess visual acuity (with glasses if required).
- Lid exam and palpation of the orbit
- Pupillary reflex for afferent pupillary defect
- Extraocular movements; assess for pain with eye movement—if present, concerning for orbital cellulitis.
- Red desaturation: Patient views red object with one eye and compares to the
other; reduced red color may indicate optic nerve involvement.

- Confrontation visual field testing

**DIFFERENTIAL DIAGNOSIS**

- Preseptal cellulitis
  - Eyelid erythema with or without conjunctival erythema, afebrile, no pain on eye movement, no diplopia, normal eye exam, vision intact
- Metastatic tumors and autoimmune inflammation may masquerade as orbital cellulitis in rare cases; usually present with painless slow onset of symptoms
- Idiopathic orbital inflammatory disease (orbital pseudotumor) (1)[C]
  - Afebrile, normal WBCs; usually subacute, may have pain, responds to steroids after ruling out orbital cellulitis
- Orbital foreign body
- Arteriovenous fistula (carotid-cavernous fistula)
  - Spontaneous or due to trauma; bruit may be present; insidious, subacute onset
- Cavernous sinus thrombosis
  - Signs of orbital cellulitis with cranial nerves III, IV, V, and VI findings; often bilateral and acute
  - Severely ill
- Acute thyroid orbitopathy
  - Afebrile; possible signs of thyroid disease
  - Bilateral orbital involvement
- Orbital tumor
  - Rhabdomyosarcoma, acute lymphoblastic leukemia, or metastatic tumors
  - Unilateral
  - Slow onset
- Trauma, insect bite, ruptured dermoid cyst
- Clinical signs help distinguish preseptal from orbital cellulitis. Preseptal infection causes erythema, induration, and tenderness of the eyelid and/or periorbital tissues, and patients rarely show signs of systemic illness. Local skin trauma, lacerations, or bug bites can be seen. Extraocular movements and visual acuity are intact.
- Orbital cellulitis also presents with complaints of a red, swollen, painful eye or eyelid. It also results in proptosis, conjunctival edema, ophthalmoplegia (diminished ocular movement), or decreased visual acuity.

**DIAGNOSTIC TESTS & INTERPRETATION**

- CBC with differential, C-reactive protein, ESR
Swab cultures of eye secretions or nasopharyngeal aspirates are often contaminated by normal flora but may identify causative organism(s).

Cultures from orbital and sinus abscesses at the time of surgery more often yield positive results but should be limited to cases where invasive procedures are indicated. Cultures from sinus aspirates and abscesses may grow multiple organisms.

Blood cultures (usually negative) should be obtained prior to initiation of antibiotic therapy in ill-appearing or febrile patients.

**Initial Tests (lab, imaging)**

- CT scan of orbits and sinuses with axial and coronal views, with and without contrast, is imaging modality of choice. US and MRI are alternatives.
  - Thin section (2 mm) CT, coronal and axial views with bone windows to differentiate preseptal from orbital cellulitis, confirm extension into orbit, detect coexisting sinus disease, identify orbital or subperiosteal abscesses requiring surgery.
  - Deviation of medial rectus indicates intraorbital involvement.
- MRI offers superior soft tissue resolution for identification of cavernous sinus thrombosis but is less effective for bone imaging.
- US is used to rule out orbital myositis, locate FBs or abscesses, and follow progression of drained abscess.

**Follow-Up Tests & Special Considerations**

- Frequent eye exam and vital signs (q4h)
- Identify associated conditions, such as meningitis or orbital abscess.

**Diagnostic Procedures/Other**

Consult ophthalmology for slit lamp and dilated funduscopic exam; proptosis, color vision, automated visual field; and need for surgery.

**TREATMENT**

Admit patients with orbital cellulitis for monitoring and treatment with broad-spectrum IV antibiotics.

**MEDICATION**

- Empiric antibiotic therapy to cover pathogens associated with acute sinusitis (S. pneumoniae, H. influenzae, M. catarrhalis, Streptococcus pyogenes) as
well as for *S. aureus*, *S. anginosus*, and anaerobes
- Modify IV antibiotic treatment when culture and sensitivity results are available. Duration of IV therapy is usually a week. Additional PO therapy depends on response.
- PO antibiotic therapy for 2 to 3 weeks or longer (3 to 6 weeks) is recommended for patients with severe sinusitis and bony destruction.

**First Line**
- Ampicillin/sulbactam (Unasyn) or ceftriaxone plus metronidazole or clindamycin if anaerobic infection is suspected (3)
  - Ampicillin/sulbactam: 3 g IV q6h for adult; 200 to 300 mg/kg/day divided q6h for children
  - Ceftriaxone: 1 to 2 g IV q12h for adults or 100 mg/kg/day divided BID in children with maximum 4 g/day
  - Clindamycin: 600 mg IV q8h for adults; 20 to 40 mg/kg/day IV q6–8h for children (5)
  - Metronidazole: 500 mg IV q8h for adult; 30 to 35 mg/kg/day divided q8h for children

**ALERT**
In severe orbital cellulitis and in suspected, or culture-proven MRSA infection, vancomycin remains the parenteral drug of choice. Use in conjunction with agents to cover gram-negative bacteria.

- Vancomycin: 1 g IV q12h for adults; 40 mg/kg/day IV divided q8–12h, max daily dose 2 g for children (3)

**ADDITIONAL THERAPIES**
- Steroid use is controversial (1)[C].
- PO steroids as an adjunct to IV antibiotics for orbital cellulitis may speed resolution of inflammation (6)[C].
- Topical erythromycin or nonmedicated ophthalmic ointment protects the cornea from exposure in cases with severe proptosis.
- PO antibiotics for ≥2 weeks are traditionally recommended following IV treatment.
- Children may be treated with amoxicillin/clavulanate 20 to 40 mg/kg/day divided TID or in adults 250 to 500 mg TID.

**ISSUES FOR REFERRAL**
Always admit to the hospital and consult with ophthalmology. Consider consultation with ID and ENT for orbital cellulitis; neurology/neurosurgery if intracranial spread is suspected

SURGERY/OTHER PROCEDURES
- IV antibiotic therapy is the initial therapy.
- Surgical intervention warranted for visual loss, complete ophthalmoplegia, well-defined large abscess (>10 mm) on presentation or no clinical improvement after 24 to 48 hours of antibiotic therapy
- Trauma cases may need débridement or FB removal.
- Orbital abscess may need surgical drainage.
- Surgical drainage with 4 to 8 weeks of antibiotics is the treatment of choice for brain abscess.
- Surgical interventions may include external ethmoidectomy, endoscopic ethmoidectomy, uncinectomy, antrostomy, and subperiosteal drainage.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Patients with orbital cellulitis should be admitted for IV antibiotics and serial eye exams to evaluate progression of infection or involvement of optic nerve.
- Follow temperature, WBC, visual acuity, pupillary reflex, ocular motility, and proptosis.
- Repeat CT scan, or surgical intervention, may be required for worsening orbital cellulitis cases.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Serial visual acuity testing and slit lamp exams

ALERT
Bedside exam q4h is indicated, as complications can develop rapidly.

PATIENT EDUCATION
- Maintain proper hand washing and good skin hygiene.
Avoid skin or lid trauma.

COMPPLICATIONS
- Vision loss, CNS involvement, and death
- Permanent vision loss
  - Corneal exposure
  - Optic neuritis
  - Endophthalmitis
  - Septic uveitis or retinitis
  - Exudative retinal detachment
  - Retinal artery or vein occlusions
  - Globe rupture
  - Orbital compartment syndrome
- CNS complications
  - Intracranial abscess, meningitis, cavernous sinus thrombosis

REFERENCES

CODES

ICD10
- H05.019 Cellulitis of unspecified orbit
- H05.011 Cellulitis of right orbit
- H05.012 Cellulitis of left orbit
CLINICAL PEARLS

- Most orbital cellulitis cases result from sinusitis.
- MRSA orbital cellulitis may present without an associated upper respiratory infection.
- CT of orbits and sinuses with axial and coronal views with and without contrast is diagnostic modality of choice for suspected cases of orbital cellulitis.
- Patients with orbital cellulitis must be admitted to the hospital for visual monitoring and IV antibiotic therapy.
- Older age (>10 years) and diplopia predict need for surgical intervention in children.
- Ophthalmoplegia, mental status changes, contralateral cranial nerve palsy, or bilateral orbital cellulitis raise suspicion for intracranial involvement.
CELLULITIS, PERIORBITAL
Fozia Akhtar Ali, MD

BASICS

DESCRIPTION
- An acute bacterial infection of the skin and subcutaneous tissue anterior to the orbital septum; does not involve the orbital structures (globe, fat, and ocular muscles)
- Synonym(s): preseptal cellulitis

ALERT
It is essential to distinguish periorbital cellulitis from orbital cellulitis. Orbital cellulitis is a potentially life-threatening condition. *Orbital cellulitis is posterior to the orbital septum; symptoms include restricted eye movement, pain with eye movement, proptosis, and vision changes.*

EPIDEMIOLOGY
- Occurs more commonly in children; mean age 21 months
- 3 times more common than orbital cellulitis (1)[C]

Incidence
Increased incidence in the winter months (due to increased cases of sinusitis) (1)[C]

ETIOLOGY AND PATHOPHYSIOLOGY
- The anatomy of the eyelid distinguishes periorbital (preseptal) from orbital cellulitis:
  - A connective tissue sheet (orbital septum) extends from the orbital bones to the margins of the upper and lower eyelids; it acts as a barrier to infection of deeper orbital structures.
  - Infection of tissues anterior to the orbital septum is periorbital (preseptal) cellulitis.
  - Infection deep to the orbital septum is orbital (postseptal) cellulitis.
- Periorbital cellulitis typically arises from a contiguous infection of soft tissues of the face.
– Sinusitis (via lamina papyracea) extension
– Local trauma; insect or animal bites
– Foreign bodies
– Dental abscess extension
– Hematogenous seeding
• Common organisms (1)[C]
  – *Staphylococcus aureus*, typically MSSA (MRSA is increasing)
  – *Staphylococcus epidermidis*
  – *Streptococcus pyogenes*
• Atypical organisms
  – *Acinetobacter* sp.; *Nocardia brasiliensis*
  – *Bacillus anthracis; Pseudomonas aeruginosa*
  – *Neisseria gonorrhoeae; Proteus* sp.
  – *Pasteurella multocida; Mycobacterium tuberculosis; Trichophyton* sp.
    (ringworm)
• Since vaccine introduction, the incidence of *Haemophilus influenzae* disease has decrease, (should still be suspected in unimmunized or partially immunized patients).

**Genetics**
No known genetic predisposition

**RISK FACTORS**
• Contiguous spread from upper respiratory infection
• Acute sinusitis
• Conjunctivitis
• Blepharitis
• Dental infection
• Local skin trauma/puncture wound
• Insect bite
• Bacteremia

**GENERAL PREVENTION**
• Avoid dermatologic trauma around the eyes.
• Avoid swimming in fresh or salt water with facial skin abrasions.
• Routine vaccination: particularly *H. influenzae* type B and *Streptococcus pneumoniae*
DIAGNOSIS

HISTORY

- Induration, erythema, warmth, and/or tenderness of periorbital soft tissue, usually with normal vision and normal eye movements
- Chemosis (conjunctival swelling), proptosis; pain with extraocular eye movements can occur in severe cases of periorbital cellulitis and are concerning for orbital cellulitis.
- Fever (not always present)

ALERT

Pain with eye movement, fever, and conjunctival swelling raise the suspicion for orbital cellulitis.

PHYSICAL EXAM

- Vital signs and general appearance (Patients with orbital cellulitis often appear systemically ill.)
- Thorough HEENT examination
- Inspect eyes and surrounding structures—lids, lashes, conjunctiva, and skin.
- Erythema, swelling, and tenderness of lids without orbital congestion
  - Violaceous discoloration of eyelid is more commonly associated with *H. influenzae*.
- Evaluate for any skin break down.
- Look for vesicles to rule out herpetic infection.
- Inspect nasal vaults and palpate sinuses for signs of acute sinusitis.
- Examine oral cavity for dental abscesses.
- Test ocular motility and visual acuity.

DIFFERENTIAL DIAGNOSIS

- Orbital cellulitis
  - Orbital cellulitis may have the same signs and symptoms as periorbital cellulitis, with fever, proptosis, chemosis, ophthalmoplegia, decreased visual acuity, pain with ocular movement.
- Abscess
- Dacryocystitis
- Hordeolum (stye)
- Allergic inflammation
- Orbital or periorbital trauma
Idiopathic inflammation from orbital pseudotumor
Orbital myositis
Rapidly progressive tumors
  – Rhabdomyosarcoma
  – Retinoblastoma
  – Lymphoma
Leukemia

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- CBC with differential
- Blood cultures (low yield) (2) [C]
- Wound culture of purulent drainage (if present)
- Imaging is indicated with suspicion for orbital cellulitis (marked eyelid swelling, fever, and leukocytosis or failure to improve on appropriate antibiotics within 24 to 48 hours).
- CT to evaluate the extent of infection and detect orbital inflammation or abscess:
  - The classic sign of orbital cellulitis on CT scan is bulging of the medial rectus.
  - CT with contrast, thin sections (2 mm); coronal and axial views with bone windows

**Follow-Up Tests & Special Considerations**
- Children with periorbital or orbital cellulitis often have underlying sinusitis.
- If a child is febrile, <15 months old, and appears toxic, admit for blood cultures, antibiotic therapy, and consider lumbar puncture.

**TREATMENT**

**MEDICATION**
- Treat periorbital cellulitis with oral antibiotics and ensure close follow-up.
  - Empiric antibiotic treatment should cover the most likely organisms (*Staphylococcus* and *Streptococcus*).
  - Observe local prevalence of MRSA to determine need for coverage.
  - No evidence that IV antibiotics are more effective than PO in reducing recovery time or preventing secondary complications in simple periorbital
cellulitis (1)[C]
- No evidence for steroid use

**First Line**
- Uncomplicated posttraumatic periorbital cellulitis
  - Usually due to skin flora, including *Staphylococcus* and *Streptococcus*
  - Cephalexin 500 mg PO q6h or dicloxacillin 500 mg PO q6h
  - Clindamycin 300 mg PO TID, doxycycline 100 mg PO BID, or trimethoprim-sulfamethoxazole (TMP-SMX) 1 to 2 DS tablets PO q12h if MRSA is suspected
- Extension from sinusitis
  - Amoxicillin-clavulanate 875 mg PO BID
  - 3rd-generation cephalosporin (e.g., cefdinir 300 mg PO BID)
- Dental abscess
  - Amoxicillin-clavulanate 875 mg PO BID or clindamycin 300 mg PO TID
- Bacteremic cellulitis
  - May be associated with meningitis
  - Ceftriaxone 1 g IV q24h plus vancomycin 15 mg/kg/dose IV q8–12h or clindamycin 600 to 900 mg IV q8h to cover MRSA
  - Duration of therapy: A 10- to 14-day course is usually sufficient. Follow patients treated with oral antibiotics for presumed periorbital cellulitis closely (daily follow-up until improvement occurs) for response to antibiotics and possible progression to orbital cellulitis. If symptoms do not improve within 24 hours, reevaluate for IV antibiotic therapy.

**ISSUES FOR REFERRAL**
Consult ENT and ophthalmology if there is concern for orbital cellulitis or if first-line treatment fails (3).

**SURGERY/OTHER PROCEDURES**
- Usually not indicated in uncomplicated cases
- If there is an abscess or potential compromise of critical structures, orbital surgery is indicated.
- Diplopia is the strongest clinical predictor for surgery.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- If the patient is stable and there are no systemic signs of toxicity, mild cases in
adults and children >1 year of age can be safely managed on an outpatient basis.

- Consider hospitalization and IV antibiotics:
  - If patient appears systemically ill
  - Children <1 year of age (3,4)[C]
  - Patients not immunized against S. pneumoniae or H. influenzae
  - If patients do not improve or deteriorate within 24 hours of oral antibiotics
  - High suspicion for orbital cellulitis (eyelid swelling with reduced vision, diplopia, abnormal light reflexes, or proptosis)

- No strict guidelines indicate when to switch from parenteral to PO therapy. In general, a switch from IV to oral antibiotics is reasonable once eyelid edema and erythema have significantly improved. A 10- to 14-day course of antibiotics is indicated.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Follow for signs of orbital involvement, including decreased visual acuity or painful/limited ocular motility.

**PATIENT EDUCATION**
- Maintain good skin hygiene.
- Avoid skin trauma.
- Report early skin changes (swelling, redness, and pain) if recurrent after a course of therapy.

**PROGNOSIS**
- With timely treatment, patients do well.
- Recurrent periorbital cellulitis occurs with ≥3 periorbital infections in 1 year with at least 1 month of in between episodes; must be differentiated from treatment failure due to antibiotic resistance (1)[C]

**COMPLICATIONS**
- Orbital cellulitis; orbital abscess formation
- Scarring
Vision loss
Cavernous sinus thrombosis
Osteomyelitis

REFERENCES

ADDITIONAL READING

CODES
ICD10
L03.211 Cellulitis of face

CLINICAL PEARLS
- Periorbital (preseptal) and orbital (postseptal) cellulitis occur most commonly in children.
- Orbital cellulitis typically has fever, pain with eye movement, diplopia, and/or proptosis. Prompt imaging is necessary if there is a concern for orbital cellulitis.
CT scan of sinuses and orbits can differentiate periorbital cellulitis from orbital cellulitis.
The two most important predisposing factors for periorbital cellulitis are upper respiratory infections and eyelid trauma; sinusitis is more typically associated with orbital cellulitis.
CEREBRAL PALSY

Christina Mezzone, DO, MS • Maria Lombardi, DO

BASICS

DESCRIPTION

Cerebral palsy (CP) is a group of clinical syndromes characterized by motor and postural dysfunction due to permanent and nonprogressive disruptions in the developing brain. Motor impairment resulting in activity limitation is necessary for this diagnosis. CP is classified by the nature of the movement disorder and its functional severity. Individuals with this disorder are affected with secondary musculoskeletal and neurologic problems (intellectual, sensory, speech and language impairment, and seizures).

EPIDEMIOLOGY

Incidence

- Overall, 1.5 to 2.5/1,000 live births
- Incidence increases as gestational age (GA) at birth decreases:
  - 146/1,000 for GA of 22 to 27 weeks
  - 62/1,000 for GA of 28 to 31 weeks
  - 7/1,000 for GA of 32 to 36 weeks
  - 1/1,000 for GA of 37+ weeks

Prevalence

3 to 4/1,000 of the population

ETIOLOGY AND PATHOPHYSIOLOGY

- Multifactorial; CP results from static injury or lesions in the developing brain, occurring prenatally, perinatally, or postnatally.
- Neuropathology linked to GA at time of brain insult
- Cytokines, free radicals, and inflammatory response are likely contributing factors.
- Etiology is most likely multifactorial and depends on timing of brain insult: prenatally, perinatally, or postnatally (see “Risk Factors”).
- Spastic CP is most common, usually related to premature birth, with either periventricular leukomalacia or germinal matrix hemorrhage.
Dystonic or athetotic CP, often resulting from kernicterus, is now rare due to improved management of hyperbilirubinemia.

**Genetics**
There are reports of associations between CP and polymorphisms of certain genes: thrombophilic, cytokines, and apolipoprotein E.

**RISK FACTORS**
- Prenatal: congenital anomalies, multiple gestation, in utero stroke, intrauterine infection (cytomegalovirus [CMV], varicella), intrauterine growth retardation (IUGR), clinical and histologic chorioamnionitis, antepartum bleeding, maternal factors (cognitive impairment, seizure disorders, hyperthyroidism), abnormal fetal position (e.g., breech)
- Perinatal: preterm birth, low-birth weight, periventricular leukomalacia, perinatal hypoxia/asphyxia, intracranial hemorrhage/intraventricular hemorrhage, neonatal seizure or stroke, hyperbilirubinemia
- Postnatal: traumatic brain injury or stroke, sepsis, meningitis, encephalitis, asphyxia, and progressive hydrocephalus

**GENERAL PREVENTION**
- Treating mothers with magnesium sulfate during preterm delivery is neuroprotective for fetus and may reduce the risk of CP. Effect on term fetus is unknown.
- Improved management of hyperbilirubinemia with decrease in kernicterus has greatly reduced dyskinetic CP.
- Prevention or reduction of chorioamnionitis and premature births

**COMMONLY ASSOCIATED CONDITIONS**
- Seizure disorder (22–40%)
- Intellectual impairment (23–44%)
- Behavioral problems
- Speech and language impairment (42–81%)
  - May have an impact on expressive and/or receptive language
  - May be nonverbal
- Sensory impairments
  - Hearing deficits
  - Visual (62–71%): poor visual acuity, strabismus (50%), or hemianopsia
- Feeding impairment, swallowing dysfunction, and aspiration: when severe,
may require gastrostomy feedings
- Poor dentition, excessive drooling
- GI conditions: constipation (59%), vomiting (22%), gastroesophageal reflux
- Decreased linear growth and weight abnormalities (under- and overweight)
- Osteopenia
- Bowel and bladder incontinence
- Orthopedic: contractures, hip subluxation/dislocation, scoliosis (60%)

**DIAGNOSIS**

- A clinical diagnosis including
  - Delayed motor milestones
  - Abnormal tone
  - Abnormal neurologic exam suggesting a cerebral etiology for motor dysfunction
  - Absence of regression (not losing function)
  - Absence of underlying syndromes or alternative explanation for etiology
- Although the pathologic lesion is static, clinical presentation may change as the infant grows and develops.
- Accurate early diagnosis remains difficult. Neurologic abnormalities observed in the first 1 to 2 years of life may resolve; be cautious of diagnosing CP before age 2 years.
- Serial exams are often required for a definitive diagnosis.

**HISTORY**

- Presentation: concerns over movements or delayed motor development
- Ask about
  - Prenatal, perinatal, and postnatal risk factors
  - Neurobehavioral signs
    - Poor feeding/frequent vomiting
    - Irritability
  - Timing of motor milestones: Delay in milestones is not sensitive or specific until after 6 months of age.
  - Abnormal spontaneous general movements
  - Asymmetry of movements such as early hand preference
- Regression of motor skills does not occur with CP.

**PHYSICAL EXAM**
Assess for more than one type of neurologic impairment:
- Spasticity: increased tone/reflexes/clonus
- Dyskinesia: abnormal movements
- Hypotonia: decreased tone
- Ataxia: abnormal balance/coordination

Areas of exam
- Tone: may be increased or decreased
- Trunk and head control: often poor but may be advanced due to high tone
- Reduced strength and motor control
- Persistence of primitive reflexes
- Asymmetry of movement or reflexes
- Decreased joint range of motion and contractures
- Brisk deep tendon reflexes
- Clonus
- Delayed motor milestones: serial exams most effective
- Gait abnormalities: scissoring, toe-walking

CP is classified by the following:
- Muscle tone or movement disorder
  o Spasticity
    ■ Unilateral: hemiplegic
    ■ Bilateral: diplegic (lower extremity [LE] > upper extremity [UE] involvement) or quadriplegic (UE ≥ LE involvement)
  o Dystonia: hypertonia and reduced movement
  o Choreaathetosis: irregular spasmodic involuntary movements of the limbs or facial muscles
  o Ataxia: loss of orderly muscular coordination
- Motor function severity
  o The Gross Motor Function Classification System (GMFCS) scores I to V are the following:
    ■ Score of I: ambulates without limitation
    ■ Score of II: ambulates without assistive devices but some limitation
    ■ Score of III: ambulates with assistive mobility devices
    ■ Score of IV: self-mobility limited, but technology can help
    ■ Score of V: self-mobility severely limited, even with technology
  o The Manual Ability Classification System (MACS) can be used to assess UE and fine motor function.

DIFFERENTIAL DIAGNOSIS
Benign congenital hypotonia, brachial plexus injury, familial spastic paraplegia,
dopa-responsive dystonia, transient toe-walking, muscular dystrophy, metabolic disorders (e.g., glutaric aciduria type 1), mitochondrial disorders, genetic disorders (e.g., Rett syndrome)

**DIAGNOSTIC TESTS & INTERPRETATION**

CP is a clinical diagnosis based on history, physical, and risk factors. Laboratory testing is not needed to make diagnosis but can help exclude other etiologies.

- Testing for metabolic and genetic syndromes (1)[C]
  - Not routinely obtained in the evaluation for CP
  - Considered if no specific etiology is identified by neuroimaging or there are atypical features in clinical presentation
  - Detection of certain brain malformations may warrant genetic or metabolic testing to identify syndromes.

- Screening for coagulopathies: Diagnostic testing for coagulopathies should be considered in children with hemiplegic CP with cerebral infarction identified on neuroimaging (1)[C].

**Initial Tests (lab, imaging)**

- Neuroimaging is not essential, but it is recommended in children with CP for whom the etiology has not been established (1)[C].
- MRI is preferred to CT if need to determine etiology and timing of a brain insult (1)[C].
- Abnormalities found in 80–90% of patients: brain malformation, cerebral infarction, intraventricular or other intracranial hemorrhage, periventricular leukomalacia, ventricular enlargement, or other CSF space abnormalities.

**Diagnostic Procedures/Other**

- The Communication Function Classification System has recently been developed as another means of assessing verbal performance.
- International Classification of Functioning, Disability and Health for CP have been newly developed to standardize functional assessments.
- Screening for comorbid conditions: developmental delay/intellectual impairment, vision/hearing impairments, speech and language disorders, feeding/swallowing dysfunction, or seizures.
- Electroencephalograms (EEGs) should only be obtained if there is a history of suspected seizures.

**Test Interpretation**
Perinatal brain injury may include the following:

- **White matter damage**
  - Most common in premature infants
  - Periventricular leukomalacia: gliosis with or without focal necrosis with resulting cysts and scarring; may be multiple lesions of various ages.
  - Necrosis can lead to cysts/scarring.
  - Germinal matrix hemorrhage: may lead to intraventricular hemorrhage

- **Gray matter damage**: more common in term infants; cortical infarcts, focal neuronal damage, myelination abnormalities

### TREATMENT

Focuses on control of symptoms; treatments reduce spasticity to prevent painful contractures, manage comorbid conditions, and optimize functionality and quality of life.

### GENERAL MEASURES

- Early intervention programs for preterm infants influences motor and cognitive outcomes (2)[A].
- Referral to early intervention for children ages 0 to 3 years is essential.
- Various therapy modalities enhance functioning:
  - Physical therapy to improve posture stability and gait, motor strength and control, and prevent contractures
  - Occupational therapy to increase functional activities of daily living and other fine motor skills
  - Speech therapy for verbal and nonverbal speech and to aid in feeding
- Equipment optimizes participation in activities:
  - Orthotic splinting (ankle–foot orthosis) maintains functional positioning and prevents contractures.
  - Spinal bracing (body jacket) may slow down scoliosis.
  - Augmentative communication with pictures, switches, or computer systems for nonverbal individuals
  - Therapeutic and functional electrical stimulation decreases activity limitation in gait.
  - Use of adaptive equipment such as crutches, walkers, gait trainers, and wheelchairs for mobility and standers for weight bearing
MEDICATION

First Line

- **Diazepam (3)[A]**
  - Short-term treatment for generalized spasticity; insufficient evidence on motor function
  - A γ-aminobutyric acid-A (GABA<sub>A</sub>) agonist that facilitates CNS inhibition at spinal and supraspinal levels to reduce spasticity
  - Adverse effects: ataxia and drowsiness
  - Adult dose: 2 to 12 mg/dose PO q6–12h
  - Pediatric dose (<12 years and <15 kg): <8.5 kg: 0.5 to 1.0 mg HS; 8.5 to 15.0 kg: 1 to 2 mg HS; children 5 to 16 years of age and ≥15 kg: 1.25 mg TID

- **Botulinum toxin type A (3)[A]**
  - Acts at neuromuscular junction to inhibit the release of acetylcholine to reduce tone
  - Injected directly into muscles of interest for localized spasticity; insufficient evidence on motor function
  - Higher functional benefit when combined with occupational therapy
  - Lasts for 12 to 16 weeks following injection

Second Line

- **Baclofen (3)[A]**
  - GABA<sub>B</sub> agonist, facilitates presynaptic inhibition of mono- and polysynaptic reflexes
  - Adverse effects: drowsiness and sedation
  - Abrupt withdrawal symptoms: spasticity, hallucinations, seizures, confusion, hyperthermia
  - Adults: Initial dose is 5 mg TID; increase dosage every 3 days to an average maintenance dose of 20 mg TID, 80 mg/day maximum.
  - Pediatric dose (>2 years): initial 10 to 15 mg/day. Titrate to effective dose (maximum 40 mg/day). <8 years old: 60 mg/day maximum; >8 years old: 60 mg/day maximum

- **Intrathecal baclofen (baclofen pump) (4)[A]**
  - Continuous intrathecal route allows greater maximal response with smaller dosage to reduce spasticity.
  - May help ambulatory individuals with gait but no improvement seen in nonambulatory patients
– Adverse effects: infection, catheter malfunction, CSF leakage

**ADDITIONAL THERAPIES**

- Multidisciplinary care including ophthalmology; neurology; orthopedics; physiatry along with physical, occupational, and speech therapists
- A primary care “medical home” that coordinates medical and community services, provides support for the patient and the patient’s family

**SURGERY/OTHER PROCEDURES**

- Dorsal root rhizotomy selectively cuts dorsal rootlets from L1–S2. Best for patients with normal intelligence with spastic diplegia. Decreases spasticity in lower limbs when done in conjunction with physiotherapy but associated with adverse effects. Evidence is lacking as to long-term outcomes.
- Surgical treatment of joint dislocations/subluxation, scoliosis management, tendon lengthening, gastrostomy

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Therapeutic horse riding or hippotherapy improves postural control and balance.
- Aquatherapy improves gross motor function in patients with various motor severities (5)[B].

**ONGOING CARE**

**PROGNOSIS**

Reduced lifespan strongly associated with level of functional impairment and intellectual disability

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- G80.9 Cerebral palsy, unspecified
- G80.1 Spastic diplegic cerebral palsy
- G80.2 Spastic hemiplegic cerebral palsy
CLINICAL PEARLS

- Management should focus on maximizing functioning and quality of life using multidisciplinary team approach.
- Regression of motor skills does not occur with CP.
CERVICAL HYPEREXTENSION INJURIES

Shane L. Larson, MD • Jason H. Hyde, DO

BASICS

DESCRIPTION

- Class of neck injuries typically seen in rapid, forceful extension of the cervical spine
- Usually from motor vehicle accidents (MVA—whiplash), falls, violence, or sports-related injuries (1)
- May involve:
  - Injury to vertebral and paravertebral structures: fractures, dislocations, ligamentous tears, and disc disruption/subluxation
  - Spinal cord injury (SCI): traumatic central cord syndrome (CCS) secondary to cord compression or vascular insult, SCI without radiologic abnormality (SCIWORA) (see “SCIWORA”)
  - Blunt cerebrovascular injury (BCVI): vertebral artery or carotid artery dissection
  - Soft tissue injury: cervical strain/sprain (i.e., whiplash), cervical stingers (see “Brachial Plexopathy”)

EPIDEMIOLOGY

- Predominant age: CCS mostly seen in older population (average age is 53 years). Trauma and sports injuries are more common in young adults (average age 29 years).
- Predominant sex: male > female (1)

Incidence

In the United States

- Cervical fractures: 2 to 5/100 blunt trauma patients
- CCS: 4/100,000 people/year
- BCVI: estimated 1/1,000 of hospitalized trauma patients; incidence increased with cervical spine or thoracic injury
- Cervical strain: 3 to 4/1,000 people/year
Whiplash is the most common injury in MVAs and accounts for 28% of all ED visits for MVAs.

Incidence of whiplash is 70 to 328/100,000 with rates highest in 20- to 24-year-old females.

5% of trauma patients have spinal fractures, and 20% of those have SCI.

The incidence of traumatic SCI ranges from 2.3 to 83 cases per million population per year.

**ETIOLOGY AND PATHOPHYSIOLOGY**

Blunt trauma due to MVAs, sports injuries, falls, and assaults

**RISK FACTORS**

- Whiplash, initial injury: no seat belt use, female gender
- Chronic pain and/or disability: litigation, previous neck pain or injury, female gender, report of headache/low back pain at inception, low education level
- Fractures: osteoporosis, conditions predisposing to spinal rigidity, such as ankylosing spondylitis or other spondyloarthropathies
- CCS: preexisting spinal stenosis present in >50%
  - Acquired: prior trauma, spondylosis
  - Congenital: Klippel-Feil syndrome (congenital fusion of any two cervical vertebrae)

**GENERAL PREVENTION**

Seat belts, use of proper safety equipment, rule changes for sports activities, and proper technique in sports activities can prevent or minimize injury.

**COMMONLY ASSOCIATED CONDITIONS**

Closed head injuries, whiplash-associated disorders (WAD), SCI, soft tissue trauma

**DIAGNOSIS**

**HISTORY**

Usually acute presentation with mechanism of cervical hyperextension and complaints of neck pain, stiffness, or headaches ± neurologic symptoms
PHYSICAL EXAM

- External signs of trauma on the head and neck such as abrasions, lacerations, or contusions provide clues to mechanism and associated injuries.
- Presence, severity, and location of neck tenderness help localize involved structure(s):
  - Posterior midline, bony tenderness raises concern for underlying fracture.
  - Paraspinal or lateral soft tissue tenderness suggests muscular/ligamentous injury.
  - Anterior tenderness concerning for vascular injury
- Carotid bruit suggests carotid dissection.
- Neurologic exam: Paresthesias, weakness suggests SCI or stroke secondary to BCVI:
  - CCS often presents as
    - Distal > proximal symptom distribution, upper extremity > lower extremity
    - Extremity weakness/paralysis predominates.
    - Variable sensory changes below level of lesion (including paresthesias and dysesthesia)
    - Bladder/bowel incontinence may occur.

DIFFERENTIAL DIAGNOSIS

- Acute or chronic disc pathology (including herniation or internal disruption)
- Osteoarthritis
- Cervical radiculopathy
- For CCS
  - Bell cruciate palsy
  - Bilateral brachial plexus injuries
  - Carotid or vertebral artery dissection

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Low-risk patients can be cleared clinically (without imaging) using either the Canadian C-spine Rule (CCR) or the National Emergency X-Ray Utilization Study (NEXUS) criteria (3)[B]:
  - CCR: A stable, adult patient with no history of cervical spine disease/surgery can be cleared if all of the following conditions are met:
    - Glasgow Coma Scale (GCS) ≥15
    - Nonintoxicated patients without a distracting mechanism of injury
- No dangerous mechanism or extremity paresthesias
- Age <65 years
- At least one “low-risk factor” (i.e., simple rear-end MVA, ambulation at the accident scene, no midline cervical tenderness, delayed onset of neck pain, or sitting at the time of exam)
  - NEXUS: clinically clear if all of the following:
    - No alteration of mental status or intoxication
    - No focal/neurologic deficits
    - No distracting injury
    - No posterior, midline C-spine tenderness
  - Reported sensitivity/specificity: CCR (99%/45%), NEXUS (91%/37%)
- In patients with high-risk mechanism or concerning historical/physical exam, recommend imaging based on the suspected injury and level of clinical suspicion:
  - Plain radiographs: in some patients who cannot be cleared clinically but still are in low-suspicion category: sensitivity for C-spine injury 39%:
    - Dynamic: flexion/extension; only if asymptomatic and no neurologic deficits or mental impairment, poor identification of ligamentous injury, limited diagnostic value
  - CT: axial CT from occiput to T1 with coronal and sagittal reconstructions; has replaced plain radiography as the test of choice for cases with moderate to high clinical suspicion of C-spine injury, given high sensitivity (90–100%)
  - MRI: test of choice in CCS with direct visualization of traumatic cord lesions (edema or hematomyelia), soft tissue compressing cord, and/or stenosis of canal; detects ligamentous injury and abnormalities of intervertebral discs and soft tissues; MRI poor for fractures due to false-positive results from nonspecific findings
  - CT angiography: visualization of cervical and cerebral vascular structures to detect BCVI, sensitivity approaches 100% when a ≥16-slice CT scanner is used. MR angiography is an alternative, although sensitivity of 47–50% limits utility.

**Test Interpretation**
- CCS: thought to be due to white matter axonal disruption of the lateral column, particularly the corticospinal tracts
- BCVI: intimal disruption, leading to thrombosis and embolization
- Acute cervical strain/sprain: Models suggest myofascial tearing, edema, and inflammation.
Geriatric Considerations
- Degenerative changes of the C-spine may be confused with acute traumatic change, and osteopenia may limit fracture visualization on x-ray—CT is more accurate.
- Degenerative disease and osteopenia increase risk of upper cervical spine injuries (even with low-velocity trauma).

Pediatric Considerations
SCIWORA: high incidence at <9 years accounting for up to 50% of pediatric cervical spine injuries. MRI helps detect injury.

TREATMENT

GENERAL MEASURES
- Whiplash, WAD
  - Limited or no benefit to cervical collar. If provided, use for <72 hours.
  - No advantage to engaging early multiprofessional intervention (e.g., pain management and psychology) (4)[C]
  - No outcome differences with PT versus passive (immobilization, rest) treatment; advance activity levels as tolerated
  - Lack of clear treatment approach in absence of fracture
- Fractures
  - Stability determined by imaging
  - Decompression, and stabilization are indicated for:
    - Incomplete SCIs with spinal canal compromise
    - Clinical deterioration or failure to improve despite conservative management
  - Hangman fracture: traumatic spondylolisthesis of C2 with bilateral fractures through C2 pedicles, often with anterior subluxation of C2 over C3; can be unstable:
    - Managed with halo vest immobilization for 12 weeks until flexion/extension films normal
  - Odontoid fractures: treated according to type:
    - I: through apex; usually stable; external immobilization with a cervical collar (less often halo vest) for up to 12 weeks
    - II: most common, at base of dens, usually unstable; nonunion rates of up to 67% with halo immobilization alone, especially with dens
displacement >6 mm or age >50 years
- III: through C2 body, usually stable; immobilization in halo or cervical collar for 12 to 20 weeks
  - Hyperextension teardrop fractures
    - If stable, rigid collar or cervicothoracic brace for 8 to 14 weeks
    - If unstable, halo brace for up to 3 months
- CCS: neck immobilization with cervical collar, physical therapy/occupational therapy (PT/OT)
- Cervical strain: no difference in outcomes with active (PT) versus passive (immobilization, rest) treatment; may use soft cervical collar for 10 days for symptomatic relief and then mobilize and increase activity as tolerated

MEDICATION
- Fractures: pain control with analgesics
- CCS: Within 8 hours of injury, consider methylprednisolone 30 mg/kg IV over 15 minutes and then continuous infusion 5.4 mg/kg/hr IV for 23 hours. Further improvement in motor function recovery may be seen if infusion is continued for 48 hours, especially if initial bolus administration is delayed by 3 to 8 hours after injury (5,6)[A].
- BCVI: Anticoagulation with IV heparin, followed by warfarin therapy for 3 to 6 months and then long-term antiplatelet therapy; antiplatelet agent as sole initial therapy in patients with contraindications to anticoagulation
- Cervical strain: Muscle relaxants, acetaminophen/NSAIDs ± opiate analgesics are commonly used.

ISSUES FOR REFERRAL
- If cervical spine injury is suspected, immobilize patient and send to ED for evaluation and clearance.
- Emergent consultation from a spine surgeon for any concern for unstable fracture or SCI

SURGERY/OTHER PROCEDURES
- Fractures
  - Hangman fracture: surgical fixation for excessive angulation or subluxation, disruption of intervertebral disc space, or failure to obtain alignment with external orthosis
  - Odontoid fractures
    - Type II: Early surgical stabilization is recommended in setting of age >50
years, dens displacement >5 mm, and specific fracture patterns.

- **Type III:** Surgical intervention is often reserved for cases of nonunion/malunion after trial of external immobilization.

- **CCS:** Surgical decompression/fixation is indicated in setting of unstable injury, herniated disc, or when neurologic function deteriorates.

- **BCVI:** Surgical and/or angiographic intervention may be required if there is evidence of pseudoaneurysm, total occlusion, or transection of the vessel.

### ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Varies by injury; clinical judgment, imaging findings, concomitant injuries, and need for operative intervention
- Advanced Trauma Life Support protocol with backboard and collar

### ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

**Patient Monitoring**

Follow patients with known injuries using serial imaging under the care of a specialist.

### PATIENT EDUCATION

ThinkFirst Foundation: [http://www.thinkfirst.org](http://www.thinkfirst.org)

### PROGNOSIS

- Presenting neurologic status is the most important factor in determining prognosis.

- **Fractures**
  - Hangman fracture: 93–100% fusion rate after 8 to 14 weeks external immobilization
  - Odontoid fracture, fusion rate by type: type I, ~100% with external immobilization alone; type II, nonunion rates of up to 67% with halo immobilization alone, especially with dens displacement >6 mm or age >50 years; type III, 85% with external immobilization, 100% with surgical fixation

- **BCVI:** Patients have fewer neurologic sequelae with early diagnosis and
antithrombotic therapy.

- CCS
  - Spontaneous recovery of motor function in >50% over several weeks.
  - Younger patients are more likely to regain function.
  - Leg, bowel, and bladder functions return first, followed by upper extremities.
- WAD: Prognostic factors for development of late whiplash syndrome (>6 months of symptoms affecting normal activity) include increased initial pain intensity, pain-related disability, and cold hyperalgesia.

**COMPLICATIONS**

- Fractures: instability or malunion/nonunion necessitating second operation, reactions, and infection related to orthosis
- BCVI: embolic ischemic events and pseudoaneurysm formation

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- S13.4XXA Sprain of ligaments of cervical spine, initial encounter
- S13.101A Dislocation of unspecified cervical vertebrae, init enctr
- S14.109A Unsp injury at unsp level of cervical spinal cord, init

**CLINICAL PEARLS**

- Follow NEXUS or Canadian Cervical Spine rules on every patient with potential neck injury to determine need for imaging.
- Always perform imaging if clinical judgment suggests the need to do so.
- Inquire about preexisting cervical spine conditions, especially in the elderly, as they may increase risk of injury or change radiographic interpretation.
- Suspect SCI until cleared through exam and imaging.
- Consider BCVI when neurologic deficits are inconsistent with level of known injury or in the setting of a significant mechanism of injury.
BASICS

DESCRIPTION

- Invasive cancer of the uterine cervix
- Most cervical cancers begin in the transformation zone. 60–75% of the cancers originate from squamous epithelium.
- 25–40% of the cancers are adenocarcinomas. These are more difficult to diagnose by cytology.
- Commonly involves the vagina, parametria, and pelvic side walls
- Invasion of bladder, rectum, and other pelvic structures can be seen in advanced stages.

EPIDEMIOLOGY

Incidence

- Cervical cancer is the second most common malignancy in women worldwide and the most common gynecologic cancer.
- The disease has a bimodal distribution, with the highest risk among women aged 40 to 59 years and >70 years.
- In recent years, there has been an increase in incidence in women aged 30 to 35 years.

Prevalence

- In 2017, the American Cancer Society (ACS) estimates 12,820 new cases of invasive cancer in the United States and 4,210 deaths.
- The death rate has decreased by 50% in the last 40 years due to increased screening using Pap testing, which allows for early detection of atypical changes in the cells and/or invasive cancer in its most curable stage.
- In the United States, Hispanic women are at highest risk of developing cervical cancer followed by African Americans, Asians, and whites. American Indians and Alaskan natives have the lowest. This may be due to low screening rates.
ETIOLOGY AND PATHOPHYSIOLOGY
- Human papillomavirus (HPV) infection is the most important etiologic factor. Infection with serotypes 16 and 18 account for about 70% of cervical cancer.
- Persistent HPV infection promotes coding errors in the cell cycle resulting in dysplastic changes to the endocervical cellular lining.
- In addition HPV activates E6 and E7 oncogenic proteins, which inactivate p53 and Rb tumor suppressor genes. Tumor growth is via lymphatic and hematogenous spread (Halstedian growth).
- Inheritance has not been established yet, except in very rare cases of Peutz-Jeghers syndrome.

RISK FACTORS
- Persistent HPV infection is the number one risk factor for developing cervical cancer. HPV infection is very common: At least 3 out of 4 persons become infected during their lifetime.
- Other risk factors include the following:
  - Lack of regular Pap smears
  - Early coitarche
  - Multiple sexual partners
  - Unprotected sex
  - A history of sexually transmitted diseases (STDs)
  - Low socioeconomic status
  - Obesity (increases the risk for adenocarcinoma type)
  - High parity (>3 full term deliveries)
  - Cigarette smoking (doubles the risk)
  - Immunosuppression (HIV/AIDs, chemotherapy)
  - Diethylstilbestrol (DES) exposure in utero

GENERAL PREVENTION
- Education on safe sex practices and smoking cessation
- HPV vaccines: There are currently two effective vaccines in clinical use for the prevention of HPV infections.
- The vaccines provide good protection against HPV types 16 and 18 and the cervical changes caused by them in young women with no previous HPV infection. The protective benefit from the vaccines appears to last for at least 6 years.
  - Gardasil vaccine: 9-valent; FDA-approved in females and in males (for prevention of genital warts and anal cancer)
– Cervarix vaccine: bivalent vaccine against oncogenic HPV strains 16 and 18
– Recommended age of vaccination is 11 to 12 years (prior to coitarche), but Gardasil is approved from 9 to 26 years and Cervarix from 10 to 25 years.

- Regular Pap smear (or likely high-risk HPV testing) is virtually the only way to identify premalignant lesions and possibly prevent progression to cancer. Screening has the potential to prevent up to 80% of cervical cancer worldwide.
- Although guideline changes are likely in 2018 to 2019, according to current guidelines from the American College of Obstetricians and Gynecologists (ACOG) and the American Society for Colposcopy and Cervical Pathology (ASCCP) screening should be performed as follows:
  - Cytology alone every 3 years between 21 and 29 years (1)[A]
  - Cytology plus HPV testing every 5 years after 30 years (1)[A]
- The International Federation of Gynecology and Obstetrics (FIGO) recommends visual inspection with acetic acid (VIA) or Lugol iodine (VILI) as alternatives to Pap smears in resource-poor settings (2)[C].
- Despite HPV vaccination, cervical cancer screening will remain the main preventive measure for both vaccinated and unvaccinated women.

COMMONLY ASSOCIATED CONDITIONS
- Condyloma acuminata
- Preinvasive/invasive lesions of the vulva and vagina

DIAGNOSIS

HISTORY
- Patient with HPV infection may be asymptomatic.
- The most common symptom is postcoital vaginal bleeding.
- Other symptoms include intermenstrual or postmenopausal bleeding and vaginal discharge.
- Less common symptoms include low back pain with radiation down posterior leg, lower extremity edema, vesicovaginal and rectovaginal fistula, and urinary symptoms.

PHYSICAL EXAM
- Thorough pelvic exam is essential:
Many patients have a normal exam, especially with microinvasive disease. Lesions may be exophytic, endophytic, polypoid, papillary, ulcerative, or necrotic. May have watery, purulent, or bloody discharge

Bimanual and rectovaginal examination should be performed to evaluate uterine size, vaginal wall, rectovaginal septum, parametrial, uterosacral, and pelvic sidewall involvement. Enlarged supraclavicular or inguinal lymphadenopathy, lower extremity edema, ascites, or decreased breath sounds with lung auscultation may indicate metastases or advanced stage disease.

DIFFERENTIAL DIAGNOSIS
- Marked cervicitis and erosion
- Glandular hyperplasia
- Sexually transmitted infection
- Cervical condyloma, leiomyoma, or polyp
- Metastasis from endometrial carcinoma or gestational trophoblastic neoplasia

DIAGNOSTIC TESTS & INTERPRETATION

**Initial Tests (lab, imaging)**
- Biopsy of gross lesions and colposcopically directed biopsies are the definitive means of diagnosis.
- CBC may show anemia.
- Urinalysis may show hematuria.
- In advanced disease, BUN, creatinine, and liver function tests (LFTs) may be helpful.
- CT scan of the chest, abdomen, and pelvis and/or a positron emission tomography (PET) scan for metastatic workup
- Apart from chest x-ray (CXR) and intravenous pyelogram (IVP), imaging does not alter tumor stage.
- MRI may be helpful in evaluating parametrial involvement in patients who are surgical candidates or for radiation treatment planning.

**Follow-Up Tests & Special Considerations**
Prompt multidisciplinary plan of care
- Exam under anesthesia may help in determining clinical stage and disease extent and determine if patient is a surgical candidate.
- Endocervical curettage and cervical conization as indicated to determine depth
of invasion and presence of lymphovascular involvement
- Cystoscopy to evaluate bladder invasion
- Proctoscopy for invasion into rectum

**Test Interpretation**
- Majority of cases are invasive squamous cell types usually arising from the ectocervix.
- Adenocarcinomas of cervical cancer arising from endocervical mucus-producing glandular cells. Often, a “bulky,” “barrel-shaped” cervix is present on exam.
- Other cell types that may be present include rare mixed cell types, neuroendocrine tumors, sarcomas, lymphomas, and melanomas.

**TREATMENT**

**GENERAL MEASURES**
Improve nutritional state, correct anemia (Hb <12 g/dL), and treat any vaginal and/or pelvic infections.

**MEDICATION**
- Chemoradiation with cisplatin-containing regimen has superior survival over pelvic and extended-field radiation alone.
- Neoadjuvant chemotherapy may improve survival for early and locally advanced tumors, but more data are needed (3)[A].
- Adjuvant chemotherapy after chemoradiation may improve progression-free survival in patients who receive primary chemoradiation for stages IIB to IVA tumors. The OUTBACK trial will further investigate these findings (http://www.clinicaltrials.gov).
- The addition of the antiangiogenesis drug bevacizumab to standard combination chemotherapy (cisplatin/topotecan or cisplatin/paclitaxel) for recurrent, persistent, or metastatic disease has been shown to improve overall survival (4)[A].

**ISSUES FOR REFERRAL**
Multidisciplinary management of patients as needed and in a timely fashion

**ADDITIONAL THERAPIES**
Chemoradiation (without surgery) is the first-line therapy for tumors stage IIB and higher (gross lesions with obvious parametrial involvement) and for most bulky stage IB2 tumors.

Combination of external beam pelvic radiation and brachytherapy is usually employed.

If para-aortic lymph node metastases are suspected, extended-field radiation or lymph node dissection prior to radiation therapy may be performed.

**Surgery/Other Procedures**

Surgical management is an option for patients with early-stage tumors. Robotic surgery is one option for surgical management of cervical cancer. It has several advantages over abdominal surgery with decreased estimated blood loss, postoperative hospital stay, and complications.

Removal of precursor lesions (cervical intraepithelial neoplasia [CIN]) by loop electrosurgical excision procedure (LEEP), cold knife conization, laser ablation, or cryotherapy

Stage IA1 (lesions with <3-mm invasion from basement membrane) without lymphovascular space invasion: option of conization or simple extrafascial hysterectomy

Stage IA2 (lesions with >3-mm but <5-mm invasion from basement membrane): option of radical hysterectomy with lymph node dissection or radiation, depending on clinical setting

Stages IA2 to IB1: Fertility-sparing radical trachelectomy may be considered in selected patients.

Stages IB1 to IIA (gross lesions without obvious parametrial involvement): option of radical hysterectomy with lymph node sampling or primary chemoradiation with brachytherapy and teletherapy, depending on clinical setting

Stage IVA (lesions limited to central metastasis to the bladder and/or rectum): Primary pelvic exenteration may be feasible.

Stage IVB disease is treated with goal of palliation. Early referral to palliative care should be made.

**Pregnancy Considerations**

Management is guided by consideration of stage of lesion, gestational age, and maternal assessment of risks and benefits from treatment.

Abnormal cytology is best followed up by colposcopy with directed biopsies.

In pregnant women diagnosed with cervical cancer before 16 weeks of gestation, treatment should be started immediately.
In pregnant women with early states (IA1, IA2, IB) diagnosed after 16 weeks of gestation, treatment may be delayed to allow for fetal maturity.
In pregnant women with advance disease 1B2 diagnosed after 16 weeks, treatment may be based on gestational age at the time of diagnosis. Microinvasive carcinoma: conization or trachelectomy. If depth of invasion ≤3 mm, follow-up at the 6-week postpartum visit.
Invasive carcinoma requires definitive therapy, with timing determined by maternal preference, stage of disease, and gestational age at the time of diagnosis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Signs of active bleeding
- Urinary symptoms
- Dehydration
- Complications from surgery, chemotherapy, or radiation
- Active vaginal bleeding can be controlled with timely vaginal packing and radiation therapy.
- Recognition of ureteral blockage, hydronephrosis, urosepsis, and timely intervention
- Discharge criteria based on multidisciplinary assessment

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- With completion of definitive therapy and based on individual risk factors, patients are evaluated with physical/pelvic examinations:
  - Every 3 to 6 months for 2 years
  - Every 6 to 12 months until the 5th year
  - Yearly thereafter
- Pap smears may be performed yearly but have a low sensitivity for detecting recurrence.
- CT and PET scan are useful in locating metastases when recurrence is suspected.
- Signs of recurrence include vaginal bleeding, unexplained weight loss, leg
edema, and pelvic or thigh pain.

PATIENT EDUCATION

PROGNOSIS

- If detected early, invasive cervical cancer can be treated successfully; 5-year survival for women with cancer in the earliest stage (stage 1A, in which the cancer has minimal spread to the inside of the cervix) is estimated at 92%.
- An elevated squamous cell carcinoma antigen (SCC-Ag) serum levels estimated by ELISA technique can be used to predict the clinical response to neoadjuvant chemotherapy and residual disease; persistently elevated SCC-Ag level at 2 to 3 months after RT had a significantly higher incidence of treatment failure.
- Serum SCC-Ag levels are useful for monitoring treatment efficacy, disease progression, and recurrence. In general, increased serum SCC-Ag levels reflect disease progression and poor prognosis in SCCs. Thus, the combination of clinical pelvic examination and SCC-Ag levels provides useful information for the further need of treatment.

COMPLICATIONS

- Loss of ovarian function from radiotherapy or indication for bilateral oophorectomy
- Hemorrhage
- Pelvic infection
- Genitourinary fistula
- Bladder dysfunction
- Sexual dysfunction
- Ureteral obstruction with renal failure
- Bowel obstruction
- Pulmonary embolism
- Lower extremity lymphedema

REFERENCES

**ADDITIONAL READING**

Abnormal Pap and Cervical Dysplasia

**CODES**

ICD10
C53.9 Malignant neoplasm of cervix uteri, unspecified
C53.0 Malignant neoplasm of endocervix
C53.1 Malignant neoplasm of exocervix

CLINICAL PEARLS

- Cervical cancer is the second most common malignancy in women worldwide. Improving access to screening is likely to have the greatest impact in reduction of the burden of disease.
- Women with cervical cancer may be asymptomatic and have a normal physical exam.
- Surgical management is an option for patients with early-stage tumors.
- Chemoradiation is the first-line therapy for higher stage tumors.
CHICKENPOX (VARICELLA ZOSTER)
Kay A. Bauman, MD, MPH

BASICS

DESCRIPTION
- Common, highly contagious generalized exanthem characterized by crops of pruritic vesicles on the skin and mucous membranes following exposure to varicella-zoster virus (VZV)
- VZV is spread by respiratory (airborne) droplets and direct contact with vesicles.
- VZV establishes latency in the dorsal root ganglia; reactivation results in zoster (shingles).
- Outbreaks tend to occur late winter through early spring in temperate climates.
- Usual incubation period is 14 to 16 days (range: 10 to 21). Patients are infectious from ~48 hours before appearance of vesicles until the final lesions have crusted. Historically, most people acquired chickenpox during childhood and develop lifelong immunity. Varicella is part of recommended primary vaccination schedule.
- System(s) affected: nervous, skin/exocrine
- Synonym(s): varicella

EPIDEMIOLOGY
- Predominant age: peak incidence 3 to 9 years but may occur at any age
- Predominant gender: male = female

Incidence
- Decreasing incidence since routine vaccination; estimated 3.5 million cases annually prior to vaccine, with an incidence of 8–9% in children age 1 to 9 years
- Reported U.S. varicella cases: 1991, 147,076; 2015, 9,789 cases (1,2)
- Prior to vaccine, ~100 deaths/year were reported in the United States; in 2015, there were six reported deaths (2).
- U.S. rates: 1994, prior to vaccine: 136/100,000 persons; 2013 to 2014: <0.001/100,000 persons
- Rates of varicella in the United States dropped after vaccine introduction until
mid-2000s when they plateaued; second dose of vaccine recommended in 2006, and rates have again declined

- In developing countries, varicella is still associated with a severe disease burden.
- Susceptible (immunologically naive) individuals exposed to varicella are at risk to develop disease and are also potentially infectious for 21 days.

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Skin lesions are histologically identical to herpes simplex virus.
- In fatal cases, intranuclear inclusions are found in vascular endothelium and most organs.
- VZV is a double-stranded DNA virus of the \( \alpha \)-Herpesviridae subfamily.
- Humans are primary disease reservoir.

**RISK FACTORS**

- No history of prior varicella infection or immunization
- Immunocompromised (especially children with leukemia/lymphoma in remission or receiving high-dose corticosteroids)
- Pregnancy

**Geriatric Considerations**

- Infection is more severe in adults.
- Reactivation of latent infection causes zoster (shingles).
- Herpes zoster vaccine, a live attenuated vaccine, is recommended as a single dose for all persons ≥60 years regardless of prior clinical history of shingles or chickenpox. The vaccine reduces shingles by 51% and the incidence of painful postherpetic neuralgia by 67%.
- The vaccine can be administered to persons ≥60 years who are receiving therapy to induce low-level immunosuppression but should not be given to highly immunocompromised patients. Giving the vaccine prior to starting chemotherapy significantly lowers risk of zoster (http://www.cdc.gov/vaccines/vpd-vac/shingles/hcp-vaccination.htm).
- Although approved by the FDA for patients 50 to 59 years of age, the vaccine is not routinely recommended in this age group.
- Primary viral pneumonia is the most common cause of death from varicella.

**Pediatric Considerations**

- Neonates born to mothers who develop chickenpox from 5 days before to 2
days after delivery are at risk for serious disease and should receive varicella-
zoster immune globulin (VZIG).
- Newborns are at highest risk for severe disease during the 1st month of life,
especially if mother is seronegative.
- Delivery prior to 28 weeks increases risk.
- Varicella bullosa is seen mainly in children <2 years. Lesions appear as bullae
  instead of vesicles. The clinical course is otherwise similar.
- Septic complications and encephalitis are the most common causes of death
  from zoster in children.
- Avoid aspirin/acetylsalicylic acid in children because of link to Reye
  syndrome.

**Pregnancy Considerations**
- 25% risk of transplacental infection after maternal infection
- Congenital malformations are seen in 2% of patients when the fetus is infected
during the 1st or 2nd trimesters, characterized by limb atrophy, cutaneous
  scarring, and occasional CNS and eye manifestations.
- Morbidity (e.g., pneumonia) is increased in women infected during pregnancy.

**GENERAL PREVENTION**
- Isolate hospitalized patients.
- When indicated, administer passive immunization using VZIG within 96
  hours (can be as long as up to 10 days) after exposure. VZIG recommended
  for:
  - Patients exposed to chickenpox or shingles who are immunocompromised,
    newborns of mothers with onset of chickenpox <5 days before delivery or
    <2 days after delivery, premature infants (<28 weeks) exposed in neonatal
    period either whose mothers are not immune, or babies who weigh <1,000 g
    regardless of maternal immunity
- Active immunization prevents or reduces the severity of varicella if given
  within 72 hours of exposure.
- Active immunization: varicella virus vaccine (Varivax): live attenuated
  vaccine recommended by ACIP for immunization of healthy patients ≥12
  months who have not had chickenpox
  - 12 months to 12 years: initial dose 0.5 mL SC at age 12 to 15 months;
    second dose at age 4 to 6 years. Single dose is 85–94% effective in
    preventing severe disease. The 2-dose regimen is 96–98% effective.
    Breakthrough disease generally has <50 lesions, shorter duration, and lower
    fever incidence (3)[A].

[3][A]
– ≥13 years: two 0.5 mL SC doses 4 to 8 weeks apart, seroconversion rates 78–82% after 1 dose, 99% after 2 doses; adult efficacy in lower end of this range
– 2014 U.S. estimate: 91% one or more-dose vaccine coverage for children 19 to 35 months (4)
– Vaccine side effects are pain and redness at the vaccine site (19% of children; 24% of teens and adults). 1 in 10 develops fever. 1 in 25 will develop a mild varicella-like rash up to 1 month after vaccination.
– Vaccine contraindications
  o Severe allergic reaction (e.g., anaphylaxis) to a previous dose or vaccine component
  o Severe immunodeficiency (e.g., HIV patients with very low CD4 counts, chemotherapy, congenital immunodeficiency, long-term immunosuppressive therapy)
  o Pregnancy
● MMRV vaccine, combines the measles, mumps, and rubella vaccine with varicella, is equally effective. There are rare reports of an increased risk of febrile seizures 5 to 12 days after vaccination in 1/2,300 to 2,600 patients.
● May be considered for a subset of HIV-positive children in CDC class I with CD4 >25%
  – Vaccine recipients who develop a rash should avoid contact with immunocompromised people, pregnant women who have never had chickenpox, and their newborns.
  – Allow at least 3 months between doses 1 and 2 in children needing catch-up vaccination.

DIAGNOSIS

HISTORY
● Prodromal symptoms: fever, malaise, anorexia, mild headache
● Malaise, muscle aches, arthralgias, and headache are more common in adults.
● Subclinical in ~4% of cases
● Characteristic rash

PHYSICAL EXAM
● Characteristic rash: crops of vesicles on erythematous bases (“dew drops on a rose petal”)
Lesions erupt in successive crops.
Progress from macule to papule to vesicle, then begin to crust
Pruritic rash is present in various stages of development.
Lesions may be present on mucous membranes, both oral and vaginal.

DIFFERENTIAL DIAGNOSIS
- Herpes simplex: herpes zoster
- Smallpox
- Impetigo
- Coxsackievirus infection
- Scabies
- Dermatitis herpetiformis
- Drug rash
- Rickettsial pox infection

DIAGNOSTIC TESTS & INTERPRETATION
The diagnosis of chickenpox is primarily clinical; testing generally for complicated cases or epidemiologic studies.

Initial Tests (lab, imaging)
- VZV polymerase chain reaction (PCR) is the current method of choice (best is fluid from intact vesicle).
- Leukocyte count varies; marked leukocytosis suggests secondary infection.
- Multinucleated giant cells on Tzanck smear from vesicle scrapings
- Isolate virus from human tissue culture.

Follow-Up Tests & Special Considerations
- Serologies show acute (IgM) or prior (IgG) infection.
- Visualization by electron microscopy, tissue culture (costly), and various methods of acute and convalescent sera collection: latex agglutination (most available), enzyme immunoassay, indirect immunofluorescence antibody, fluorescent antibody to membrane assay, or PCR assay, which can detect wild from vaccine viral strains
- Vaccine-modified cases can be more difficult to diagnose; PCR testing of skin lesions is most sensitive and specific for diagnosing varicella, especially in vaccinated persons.
TREATMENT
Outpatient, except for complicated cases

GENERAL MEASURES
- Supportive/symptomatic treatment
- Antihistamines and/or oatmeal baths for itch
- Acetaminophen and/or ibuprofen for pain and fever
- Clipping nails can help prevent scarring or secondary infection from excessive itching.

MEDICATION

First Line
- Supportive: antipyretics for fever; avoid aspirin in children.
- Local and/or systemic antipruritic agents for itching
- VZIG available for passive immunization for:
  - Immunocompromised patients, newborn infants of mothers who have signs and symptoms of varicella at the time of delivery; premature infants born at 28 weeks or more whose mothers do not have evidence of immunity to varicella; premature infants <28 weeks’ gestation or who weigh <1,000 g regardless of maternal immunity
  - Give VZIG within 96 hours after exposure (5).
- Acyclovir: decreases duration of fever and shortens time of viral shedding; recommended for adolescents, adults, and high-risk patients; most beneficial if initiated early in the disease (≤24 hours)
  - 2- to 16-year-old patients: 20 mg/kg/dose (max 800 mg/dose) QID for 5 days
  - Adults: 800 mg 5 times daily for 5 days
- Contraindication
  - Hypersensitivity to the drug
- Precautions
  - Renal insufficiency with acyclovir
  - Concurrent administration of probenecid increases half-life; increased effects with zidovudine (e.g., drowsiness, lethargy)

Second Line
- Famciclovir: 500 mg TID for 7 to 10 days (adults)
- Valacyclovir: 1 g TID for 7 to 10 days (adults)

**ONGOING CARE**  
**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Not needed in mild cases. Intensive supportive care may be required in the setting of complications.
- Activity as tolerated. Children may return to school when lesions have completely scabbed.

**DIET**
No special diet

**PATIENT EDUCATION**
- In otherwise healthy children, chickenpox is rarely serious and the recovery is almost always complete.
- Native chickenpox typically confers lifelong immunity.
- A second attack is rare, but subclinical infection can occur; this happens occasionally after vaccination in children.
- Latent infection may recur years later as herpes zoster in adults (and sometimes in children).
- Fatalities are rare.

**COMPLICATIONS**
- Although only 2% of cases are reported after 2nd decade, 35% of deaths occur in this age group.
- Secondary bacterial infection: cellulitis, abscess, erysipelas, sepsis, septic arthritis/osteomyelitis, or staphylococcal pyomyositis
- Pneumonia: 20–30% of adults with chickenpox have lung involvement; 1/400 is hospitalized.
- Encephalitis (the most common CNS complication)
- Meningitis; Reye syndrome
- Purpura, thrombocytopenia
- Glomerulonephritis; arthritis; hepatitis
REFERENCES

ADDITIONAL READING

SEE ALSO

Herpes Zoster (Shingles)

CODES

**ICD10**

- B01.9 Varicella without complication
- B02.9 Zoster without complications
- P35.8 Other congenital viral diseases

CLINICAL PEARLS

- Varicella zoster infection is more likely to produce serious illness in adults than in children.
Introduction of the varicella vaccine has reduced morbidity and mortality. Currently, 2 doses of vaccine are recommended.

Herpes zoster vaccine is recommended for persons ≥60 years of age to prevent shingles.
CHILD ABUSE
Karen A. Hulbert, MD

BASICS

DESCRIPTION
- Types of abuse: neglect (most common and highest mortality), physical abuse, emotional/psychological abuse, sexual abuse
- Neglect includes physical (e.g., failure to provide necessary food or shelter or lack of appropriate supervision), medical (e.g., failure to provide necessary medical or mental health treatment), educational (e.g., failure to educate a child or attend to special education needs), and emotional (e.g., inattention to a child’s emotional needs, failure to provide psychological care, or permitting the child to use alcohol or other drugs).
- System(s) affected: gastrointestinal (GI), endocrine/metabolic, musculoskeletal, nervous, renal, reproductive, skin/exocrine, psychiatric
- Synonym(s): suspected nonaccidental trauma; child maltreatment; child neglect

EPIDEMIOLOGY

Incidence
- Using the stringent “harm standard” definition, >1.25 million children experience maltreatment (1 in 58).
- Using the “endangerment standard,” 3 million children experienced maltreatment (1 child in 25).

Prevalence
Children’s Bureau report for federal fiscal year (FFY) 2015 (1):
- CPS agencies received an estimated 4.0 million referrals (national referral rate of 53.2 referrals per 1,000 children).
- Approximately 3.4 million children received either an investigation or
alternative response. Of those investigated, 9.2 per 1,000 children were found to be victims of abuse or neglect.

- The overall rate of child fatalities was 2.25 deaths per 100,000 children in the national population.
- The majority of perpetrators were parents—one or both parents maltreated 91.6% of victims.
- Types of maltreatment:
  - 75.3% neglect
  - 17.2% physical abuse
  - 8.4% sexual abuse

RISK FACTORS

- African American children had the highest rates of victimization at 14.5 per 1,000 children (1).
- Children in the age group of birth to 1 year had the highest rate of victimization (1).
- Slightly more than one half of the child victims were girls and 48.6% were boys.
  - Risk of physical abuse increases with age.
  - Risk of fatal abuse is more common in those <3 years (74.8% of children who died were <3 years old).
- Poverty, drug abuse, lower educational status, parental history of abuse, mentally ill parent/maternal depression, poor support network, and domestic violence:
  - Child abuse is 4.9 times more likely in family with spouse abuse.
  - Children in households with unrelated adults, 50 times more likely to die of inflicted injuries
  - Adults who were abused as children are at higher risk of becoming abusers than those not abused.

GENERAL PREVENTION

- Know your patients and document their family situations; have increased suspicion to screen for risk factors at prenatal, postnatal, and pediatric visits.
- Physicians can educate parents on range of normal behaviors to expect in infants and children:
  - Anticipatory guidance on ways to handle crying infants; methods of discipline for toddlers
- Train first responders—teachers, childcare workers—to look for signs of abuse.
Some studies suggest developing screening tools to identify high-risk families early and offer interventions such as early childhood home visitation programs.

**COMMONLY ASSOCIATED CONDITIONS**
- Failure to thrive
- Prematurity
- Developmental deficits
- Poor school performance
- Poor social skills
- Low self-esteem, depression

**DIAGNOSIS**
- Relatively minor injuries, frenulum tears, or bruising in precrurising infants may be the first indications of child physical abuse; these minor, suspicious injuries have been termed “sentinel injuries” (2)[B].
- In a retrospective study of infants who were definitely abused, 27.5% had a sentinel injury (80% had a bruise), and in 41.9% of those cases, the parent reported that a medical provider was aware of the injury (2)[B].
- Patients may present with seemingly unrelated complaints; multiple studies have documented repeated visits (to the PCP, to the emergency department [ED]) before child abuse is suspected.
- Infants with injuries caused by child abuse often present with vague complaints; important to have high index of suspicion when evaluating infants for fussiness
- Documentation
  - The medical record is an important piece of evidence for investigation and litigation (3)[C].
  - Critical elements include the following (3)[C]:
    - Brief statement of child’s disclosure or caregiver’s explanation, including any alternate explanations offered
    - Time the incident occurred and date/time of disclosure
    - Whether witnesses were present
    - Developmental abilities of child
    - Objective medical findings
- DO NOT use terms such as “rule out,” “R/O,” and “alleged.” They may cause ambiguity; clearly state physician opinion (3)[C].
The child should be separated from the parent for the interview if at all possible.

Any description of abuse given by the child should be recorded word for word using quotation marks in the child’s own language and attributed to the child.

The child should not be rewarded after a disclosure (e.g., “Tell me what happened and you can go back to your mom . . . ”).

Remember this is a medical interview and physician is obtaining information needed for diagnostic and treatment decisions.

Documentation should include disposition of patient and record any report made to CPS (3)[C].

**HISTORY**

History of a sentinel injury should prompt consideration of abuse; it may be the first and only abusive injury; there may be escalating and repeated violence instead of a single event of momentary loss of control (2)[B].

Use nonjudgmental, open-ended questions (ask: who, what, when, and where; NEVER why).

Use quotes whenever possible.

Document past medical and developmental history, child’s temperament, and family interactions.

Suggestive of intentional trauma

– No explanation or vague explanation
– Important detail of explanation changes dramatically.
– Explanation is inconsistent with pattern, age, or severity.
– Explanation is inconsistent with child’s physical or developmental abilities.
– Different witnesses provide different history.
– Considerable delay in seeking treatment

Nonspecific symptoms of abuse:

– Behavior changes; self-destructive behavior
– Anxiety and/or depression
– Sleep disturbances, night terrors
– School problems

**PHYSICAL EXAM**

Explain what the exam will involve and why procedures are needed. Examine child in a comfortable setting.

Allow child to choose who will be in the room.

Use appropriate positions to examine the anal and genital areas of children.
General assessment for signs of physical abuse, neglect, and self-injurious behaviors

Thorough physical exam
  – Skin, head, eyes, ears, nose, and mouth
  – Chest/abdomen
  – Genital (consider exam under sedation) or refer to ED
  – Extremities, with focus on inner arms and legs
  – Growth data

Maintain high index of suspicion for occult head, chest, and abdominal trauma.

Physical abuse
  – Skin markings (e.g., lacerations, burns, ecchymoses, linear/shaped contusions, bites)
  – Immersion injuries with clearly distinguished outlines (e.g., from boiling water)
  – Oral trauma (e.g., torn frenulum, loose teeth)
  – Ear trauma (e.g., signs of ear pulling)
  – Eye trauma (e.g., hyphema, hemorrhage)
  – Head/abdominal blunt trauma
  – Fractures

Sexual abuse
  – Unexplained penile, vaginal, hymenal, perianal, or anal injuries/bleeding/discharge
  – Pregnancy or STIs
  – Sperm is a definitive finding of child abuse.

Neglect
  – Low weight for height, unclean, unkempt.
  – Rashes
  – Fearful or too trusting
  – Clinging to or avoiding caregiver
  – Flat or balding occiput
  – Abnormal development or growth parameters

Measurements, photographs, and careful descriptions are critical for accurate diagnosis.

Collaboration with specialist and child abuse assessment team

**DIFFERENTIAL DIAGNOSIS**

Physical trauma
  – Accidental injury; toxic ingestion
– Bleeding disorders (e.g., classic hemophilia)
– Metabolic or congenital conditions
– Conditions with skin manifestations (e.g., mongolian spots, Henoch-Schönlein purpura, meningococcemia, erythema multiforme, hypersensitivity, car seat burns, staphylococcal scalded skin syndrome, chickenpox, impetigo)
– Cultural practices (e.g., cupping, coining)

• Neglect
  – Endocrinopathies (e.g., diabetes mellitus)
  – Constitutional
  – GI (clefts, malabsorption, irritable bowel)
  – Seizure disorder
  – Sudden infant death syndrome (SIDS)

• Skeletal trauma
  – Obstetrical trauma
  – Nutritional (scurvy, rickets)
  – Infection (congenital syphilis, osteomyelitis)
  – Osteogenesis imperfecta

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

• Directed by history and physical exam:
  – Urinalysis (e.g., abdominal/flank/back/genital trauma), urine DNA probe for STIs
  – CBC, disorder, abdominal trauma
  – Electrolytes, creatinine, BUN, glucose
  – Liver and pancreatic function tests (e.g., abdominal trauma)
  – Guaiac stool (abdominal trauma)

• In cases of suspected neglect:
  – Stool exam, calorie count, purified protein derivative and anergy panel, sweat test, lead and zinc levels

• In cases of suspected sexual abuse:
  – STI testing: gonorrhea, chlamydia, *Trichomonas*; also consider HIV, herpes simplex virus (HSV), hepatitis panel, syphilis.
  – The American Academy of Pediatrics (AAP) recommends the use of NAATs when evaluating children and adolescents for *Chlamydia trachomatis* and *Neisseria gonorrhoeae*.
  – Serum pregnancy test
Skeletal survey is a mainstay of child abuse evaluation; 22 radiographs. It is recommended for:
- Infants <6 months with bruising, regardless of pattern (given rarity of accidental bruising in young nonmobile infants)
- Children with bruising attributed to abuse or domestic violence
- Children <12 months with bruising on the cheek, eye area, ear, neck, upper arm, upper leg, hand, foot, torso, buttocks, or genital area
- All children with fractures and children with suspicious injuries <2 years:
  - Consider bone scan for acute rib fractures and subtle long bone fractures.
- Intracranial and extracranial injury:
  - CT scan of head
  - Consider MRI of head/neck for better dating of injuries, looking at subtle findings, intercerebral edema, or hemorrhage.
- Intra-abdominal injuries:
  - CT scan of abdomen

**Follow-Up Tests & Special Considerations**

- Bruising is a common presenting feature:
  - Bruising in babies who are not independently mobile is very uncommon (<1%).
- Patterns suggestive of abuse
  - Bruises seen away from bony prominences
  - Bruises to face, back, abdomen, arms, buttocks, ears, hands
  - Multiple bruises in clusters or uniform shape
  - Patterned injuries (such as bite marks or the imprint of an object like a belt or cord) should be considered inflicted until proven otherwise.
- Red flags
  - History that is inconsistent with the injury
  - No explanation offered for the injury or injury blamed on sibling or another child
  - History that is inconsistent with the child’s developmental level
- Sexual abuse
  - Consider whether child should be triaged to facility such as children’s hospital where collection of forensic samples can be performed.

**Test Interpretation**

- Spiral fractures in nonambulatory patients (children who are not walking or cruising should not have bruising or fractures from “falls”)
- Chip or bucket-handle fractures
• Epiphyseal/metaphyseal rib fractures in infants
• Rupture of liver/spleen in abdominal blunt trauma
• Retinal hemorrhages in shaken baby syndrome
• Recent literature notes a greater risk of abuse with skull and femur fractures, unexplained injuries, and a delay in seeking care.

**TREATMENT**

**GENERAL MEASURES**

• If diagnosed with STI, treat promptly.
• If HIV exposure possible, consider prophylaxis.

**MEDICATION**

*First Line*

Antibiotics as indicated for STIs

**ALERT**

Emergency contraception reduces rate of pregnancy after sexual assault:

• Levonorgestrel (Plan B): single dose of 1.5 mg or two 0.75 mg doses taken together or 12 hours apart; effective up to 72 hours
• Ulipristal (Ella): 30-mg single dose as soon as possible; effective up to 120 hours

**ISSUES FOR REFERRAL**

Responding to possible abuse consider:

• The child’s safety; is the child at imminent risk or additional harm if sent back to environment where possible perpetrator has access to child?
• Health professionals report suspected abuse/neglect.
• Child’s mental health
  – Need for a physical exam and need for forensic collection; consider referral to ER.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Admission if:
Moderate to severe injuries or unstable
Acute psychological trauma
Safety of child outside the hospital cannot be guaranteed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
As clinically indicated

Patient Monitoring
- Monitor injury healing over time.
- Follow up assessment for STIs that may not present acutely (e.g., HPV).

PROGNOSIS
Without intervention, child abuse is often a chronic and escalating phenomenon.

COMPLICATIONS
Sexual, physical, and emotional abuse in childhood are risk factors for poorer adult mental and physical health. Includes maltreatment and depressive disorder, drug use, suicide attempts, and risky sexual behaviors.

REFERENCES

ADDITIONAL READING
November 14, 2017.

**CODES**

**ICD10**

- T74.12XA Child physical abuse, confirmed, initial encounter
- T74.32XA Child psychological abuse, confirmed, initial encounter
- T74.22XA Child sexual abuse, confirmed, initial encounter

**CLINICAL PEARLS**

- When a bruise is present, it should be considered as potentially sentinel for physical abuse if no plausible explanation is given.
- High index of suspicion is important for prevention and recognition of abuse. Vague complaints and repeated visits to the office and/or ED should prompt further investigation.
- Neglect is the most common and lethal form of abuse and should be aggressively reported.
- Detailed exam with documentation is key.
- Mandated reporting is required for *suspected* child abuse and neglect; the physician does not have to prove abuse before reporting.
CHLAMYDIA INFECTION (SEXUALLY TRANSMITTED)

Casandra Cashman, MD, FAAFP

BASICS

DESCRIPTION

- *Chlamydia trachomatis* is an intracellular membrane-bound prokaryotic organism. Chlamydia derives from the Greek word for “cloak.”
- Chlamydia is the most common bacterial sexually transmitted infection (STI) in the United States (1)[A].
- Transmitted through vaginal, anal, or oral sex; transmitted vertically during vaginal delivery
- Most cases are asymptomatic, especially in females. Untreated disease can lead to pelvic inflammatory disease (PID), ectopic pregnancy, and infertility.
- System(s) affected: reproductive

Pregnancy Considerations

Perinatal acquisition may result in neonatal pneumonia and/or conjunctivitis.

EPIDEMIOLOGY

Incidence

- Mandatory reporting started in 1985; steady increase in incidence has been noted since.
- 1.5 million *reported* cases in 2014. Increasing incidence reflects broader screening, improved testing, and better reporting (rather than a large increase in disease burden). A 6% increase in the United States was noted from 2014 to 2015 (1)[A].
- Swedish new variant *C. trachomatis* (nvCT) first reported in 2006; often produces false-negative tests; largely confined to Nordic countries

Prevalence

- 479/100,000 in United States for 2015 (1)[A]
- Young females, ethnic minorities most affected
- Highest prevalence ages 20 to 24 years

mebooksfree.com
Predominant sex: females > males. Females have 2 times higher reported incidence and prevalence than males. This likely reflects increased testing in females. Increasing use of highly sensitive nucleic acid amplification test (NAAT) urine screening may increase identification in males.

- Infection rates 6 times higher in blacks than whites. Rates are higher in larger urban areas.
- Highest male prevalence in heterosexual adolescents
- Estimated to affect ~2% of young sexually active individuals in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

*C. trachomatis* serotypes D to K associated with genital tract infections. Chlamydia is an obligate intracellular organism. Chlamydia has biphasic life cycle. Exists extracellularly as elementary body (EB) that is metabolically inactive and infectious. Once taken up by host cell (typically columnar epithelium of the genital tract), the EB prevents lysosomal phagocytosis and transforms to reticulate body (RB) which requires energy from host cell to synthesize RNA, DNA, and proteins. After taking up residence in host cells, EBs are released to infect neighboring cells or spread through sexual contact.

RISK FACTORS
Risk correlates with:
- Number of lifetime sexual partners and number of concurrent sexual partners
- No use of barrier contraception during intercourse
- Black/Hispanic/Native American and Alaskan Native ethnicity

GENERAL PREVENTION
- Screen populations with annual prevalence >5% *(1)[A]*.
- Screen if new or >1 sex partner in past 6 months; attending an adolescent clinic, family-planning clinic, STD or abortion clinic, jail or other detention center clinic. Screen if rectal pain, discharge or tenesmus, testicular pain; test if urethral or cervical discharge.
- All sexually active women ≤25 years of age should be screened at least yearly. Repeat testing in ~3 months is recommended for those who screen positive because reinfection rate is high regardless of whether the sexual partner is treated *(2)[A]*.
- Consider screening sexually active men ≤25 years of age, particularly in high-risk populations.
• Screen men who have sex with men annually using genital and extragenital screening (3)[A].
• NAAT is the preferred screening test in all circumstances except child sexual abuse involving boys or rectal/oropharyngeal testing in prepubescent girls. In these cases, culture and susceptibility testing is preferred (3)[A].
• Acceptable to screen women for chlamydia on same day as intrauterine device insertion—treat if positive (no need to remove IUD in this circumstance) (4)[B].

COMMONLY ASSOCIATED CONDITIONS

• Females
  – PID: ~10% of infected patients will develop PID within 12 months if untreated.
  – Infertility, ectopic pregnancy
  – Chronic pelvic pain
  – Urethral syndrome (dysuria, frequency, and pyuria in the absence of infection)
  – Arthritis (less common)
  – Spontaneous abortion
• Males
  – Epididymitis and nongonococcal urethritis
  – Reiter syndrome (HLA-B27)
  – Proctitis
• Neonates
  – Inclusion conjunctivitis (occurs in ~40% of exposed neonates)
  – Otitis media
  – Pneumonia
  – Pharyngitis
• Diseases caused by other chlamydial species
  – Lymphogranuloma venereum (LGV): *C. trachomatis* serotypes L1 to L3
  – Trachoma: *C. trachomatis* serotypes A to C

DIAGNOSIS

Many patients are asymptomatic.

**Pregnancy Considerations**

• Test all patients at first prenatal visit.
- Obtain test of cure 3 to 4 weeks after treatment for pregnant patients. Test for reinfection in 3 months.
- Repeat test in 3rd trimester in high-risk patients. 

**HISTORY**
- Complete sexual history, including number of sex partners (lifetime and past year), prior history of STIs, use of barrier protection, commercial sex work, oral or anal receptive intercourse, and partner fidelity
- In females, the most common symptoms are:
  - Mucopurulent vaginal discharge, dysuria (urethral syndrome), Bartholinitis, abdominopelvic pain (endometritis, salpingitis/PID), right upper quadrant pain (Fitz-Hugh-Curtis syndrome)
- In males, the most common symptoms are:
  - Dysuria, urethral discharge (urethritis), scrotal pain (epididymitis), rectal pain or discharge (proctitis), acute arthritis (Reiter syndrome)

**PHYSICAL EXAM**
- Men and women: external genitalia (rash, lesions), urethral discharge, inguinal lymphadenopathy, pharyngeal exudate, and perianal lesions
- Women: cervix (discharge, motion tenderness), bimanual examination for cervical motion tenderness, uterine, ovarian/adnexal tenderness or mass
- LGV (*C. trachomatis* serovars L1, L2, or L3): Primary lesion is a small papule that may ulcerate at the site of transmission after an incubation period of 3 to 30 days. Unilateral tender lymphadenopathy. With rectal transmission, LGV causes an invasive proctocolitis.

**DIFFERENTIAL DIAGNOSIS**
- *Neisseria gonorrhoeae*: urethritis, proctitis, epididymitis, cervicitis, PID, Bartholin abscess
- *Mycoplasma* or *Ureaplasma urealyticum*: urethritis, epididymitis, Reiter disease, PID
- *C. trachomatis* (serotypes L1 to L3): LGV, proctitis
- Trichomoniasis

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- NAAT: sensitivity >95%; specificity >99%
- Urine is as sensitive as cervical swab.
Self-collected vaginal swabs are also effective.
- Labs potentially positive for up to 3 weeks after treatment
- Test for concurrent gonorrhea, HIV, syphilis; cervical cancer (PAP) screening as clinically indicated

**Follow-Up Tests & Special Considerations**
See “Patient Monitoring.”

---

### TREATMENT

#### GENERAL MEASURES
- Offer concurrent testing for gonorrhea, HIV (after counseling and consent), and possibly syphilis. Ensure cervical cancer screening up to date.
- Consider treating gonorrhea empirically.
- Test and treat all partners (most recent partner and all partners within the past 60 days).

#### MEDICATION

**First Line**
- Treatment of chlamydial urethritis, cervicitis (including sexual partners of infected persons)
- Azithromycin 1 g PO single dose or
- Doxycycline 100 mg PO BID for 7 days
- First-line PID treatment (outpatient)
  - Ceftriaxone 250 mg IM × 1 PLUS doxycycline 100 mg PO for 14 days with or without metronidazole 500 mg PO BID for 14 days or
  - Cefoxitin 2 g IM × 1 with probenecid 1 g PO × 1 PLUS doxycycline 100 mg PO for 14 days with or without metronidazole 500 mg PO BID for 14 days
- Azithromycin and ceftriaxone may be given simultaneously in the office to treat both chlamydia and gonorrhea. This reduces nonadherence (2)[A].
- Asymptomatic rectal chlamydia can be treated with doxycycline 100 mg BID × 7 days. Azithromycin 1 g for 1 day is slightly less effective but can also be used, especially if compliance or medication availability is an issue (5,6)[A].

---

**ALERT**
Use azithromycin with caution in patients with known QT prolongation, hypokalemia, hypomagnesemia, bradycardia, or with concurrent antiarrhythmic use.

**Pregnancy Considerations**
- Tetracyclines (doxycycline) and quinolones (ofloxacin, levofloxacin) are contraindicated in pregnant women.
- Consider the following as alternatives:
  - Azithromycin 1 g PO or
  - Amoxicillin 500 mg PO TID for 7 days
  - Erythromycin base 500 mg PO QID for 7 days

**ALERT**
Tetracyclines and quinolones are contraindicated in young children:
- <45 kg: erythromycin base or ethinyl succinate 500 mg/kg/day PO QID for 14 days
- >45 kg but <8 years: azithromycin 1 g PO × 1 day
- >8 years: adult regimen
- Rule out sexual abuse in children with chlamydia.

**Second Line**
For chlamydial urethritis/cervicitis
- Erythromycin base 500 mg PO QID for 7 days OR erythromycin ethylsuccinate 800 mg PO QID for 7 days
- Levofloxacin 500 mg PO daily for 7 days or ofloxacin 300 mg PO BID for 7 days

**ADDITIONAL THERAPIES**
Patient-delivered partner therapy (PDPT) or expedited partner therapy (EPT):
Provide medications or prescriptions to take to sexual partners of persons infected with STIs without clinical assessment.
- EPT reduces recurrence more effectively than traditional partner referral.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Inpatient treatment of PID: pregnancy, lack of response or intolerance to oral
medicines, suspicion of poor compliance, severe clinical illness, pelvic abscess, and possible need for surgical intervention

- Otherwise, treat PID as outpatient unless moderately or severely ill.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Abstain from sexual contact for at least 7 days after treatment (single-dose treatment) or until completion of the full course of other antibiotics.

**Patient Monitoring**

- Test of cure not routinely recommended except in pregnancy. Do not repeat NAAT <3 weeks after testing; may be falsely positive due to nonviable organisms.
- Test of cure in 3 to 4 weeks in pregnancy as well as test for reinfection in 3 months.
- Consider rescreening high-risk pregnant women in 3rd trimester even if initial screening negative.
- Test for reinfection (not cure) 3 months after treatment or, if not possible then, at next presentation to medical care if within 12 months.
- Treat sexual partners.

**PATIENT EDUCATION**

- Safe sexual practices, barrier contraception, abstinence
- Complete antibiotic course (patient and partners)

**PROGNOSIS**

Prognosis is good following therapy.

**COMPLICATIONS**

- Chlamydia infection enhances HIV transmission in both genders.
- Females: tubal infertility (most common cause of acquired infertility), tubal (ectopic) pregnancy, chronic pelvic pain
  - Annual screening of sexually active women would prevent 61% of chlamydia-related PID.
- Males: transient oligospermia and postepididymitis urethral stricture (rare)

CODES
ICD10

- A56.8 Sexually transmitted chlamydial infection of other sites
- A56.01 Chlamydial cystitis and urethritis
- A56.02 Chlamydial vulvovaginitis

CLINICAL PEARLS

- *C. trachomatis* is common in young sexually active individuals. Annual screening is recommended in sexually active women 25 years of age and younger and in other individuals with known risk factors.
- To prevent recurrence, treat patients and their partners concurrently.
- Test of cure is recommended for pregnant patients at 3 to 4 weeks and test for reinfection 3 months afterward.
- Repeat screening in 3rd trimester for high-risk patients, regardless of initial test result.
CHOLELITHIASIS
Hongyi Cui, MD, PhD, FACS, FICS

**BASICS**

**DESCRIPTION**
- The presence of cholesterol, pigment, or mixed stones (calculi) within the gallbladder
- Synonym(s): gallstones

**Pediatric Considerations**
- Uncommon in children <10 years
- Most gallstones in children are pigment stones associated with blood dyscrasias.

**EPIDEMIOLOGY**

**Incidence**
- Increased in Native Americans and Hispanics
- Increases with age by 1–3% per year; peaks at 7th decade; 2% of the U.S. population develops gallstones annually.

**Prevalence**
- Population: 8–10% of the United States; gallstones present in 20% >65 years of age
- Predominant sex: female > male (2 to 3:1)

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Gallstone formation is a complex process mediated by genetic, metabolic, immune, and environmental factors. Gallbladder sludge (a mixture of cholesterol crystals, calcium bilirubinate granules, and mucin gel matrix) serves as the nidus for gallstone formation.
- Production of bile supersaturated with cholesterol (cholesterol stones) precipitates as microcrystals that aggregate and expand. Stone formation is enhanced by biliary stasis or impaired gallbladder motility.
- Decrease in bile content of either phospholipid (lecithin) or decreased bile salt secretion
- Excess unconjugated bilirubin in patients with hemolytic diseases; passage of excess bile salt into the colon with subsequent absorption of excess unconjugated bilirubin in patients with inflammatory bowel disease (IBD) or after distal ileal resection (black or pigment stones)
- Hydrolysis of conjugated bilirubin or phospholipid by bacteria in patients with biliary tract infection or stricture (brown stones or primary bile duct stones; rare in the Western world and common in Asia)

**RISK FACTORS**
- Age (peak in 60s to 70s)
- Female gender, pregnancy, multiparity, obesity, and metabolic syndrome
- Caucasian, Hispanic, or Native American descent
- High-fat diet rich in cholesterol
- Cholestasis or impaired gallbladder motility in association with prolonged fasting, long-term total parenteral nutrition (TPN), s/p vagotomy, long-term somatostatin therapy, and rapid weight loss
- Hereditary (p.D19H variant for the hepatic canalicular cholesterol transporter ABCG5/ABG8)
- Short gut syndrome, terminal ileal resection, IBD
- Hemolytic disorders (hereditary spherocytosis, sickle cell anemia, etc.), cirrhosis (black/pigment stones)
- Medications (birth control pills, estrogen replacement therapy at high doses, and long-term corticosteroid or cytostatic therapy)
- Viral hepatitis, biliary tract infection, and stricture (promotes intraductal formation of pigment stones)

**GENERAL PREVENTION**
- Ursodiol (Actigall) taken during rapid weight loss prevents gallstone formation.
- Regular exercise and dietary modification may reduce the incidence of gallstone formation.
- Lipid-lowering drugs (statins) may prevent cholesterol stone formation by reducing bile cholesterol saturation.

**COMMONLY ASSOCIATED CONDITIONS**
90% of people with gallbladder carcinoma have gallstones and chronic cholecystitis.
DIAGNOSIS

HISTORY

- Mostly asymptomatic (80%): 2% become symptomatic each year. Over their lifetime, <50% of patients with gallstones develop symptoms.
- Episodic right upper quadrant or epigastric pain lasting >15 minutes and sometimes radiating to the back (biliary colic—due to transient cystic duct obstruction), usually postprandial; pain sometimes awakens the patient from sleep; most patients develop recurrent symptoms after a first episode of biliary colic.
- Nausea, vomiting; indigestion or bloating sensation; fatty food intolerance

PHYSICAL EXAM

- Physical exam is usually normal in patients with cholelithiasis in the absence of an acute attack.
- Epigastric and/or right upper quadrant tenderness (Murphy sign) is traditional physical finding—associated with acute cholecystitis.
- Charcot triad: fever, jaundice, right upper quadrant pain
- Reynold pentad: fever, jaundice, right upper quadrant pain, hemodynamic instability, mental status changes; classically associated with ascending cholangitis
- Flank and periumbilical ecchymoses (Cullen sign and Grey-Turner sign) in patients with acute hemorrhagic pancreatitis
- Courvoisier sign: palpable mass in the right upper quadrant in patient with obstructive jaundice most commonly due to malignant tumors within the biliary tree or pancreas

DIFFERENTIAL DIAGNOSIS

- Peptic ulcer diseases and gastritis
- Hepatitis
- Pancreatitis
- Cholangitis
- Gallbladder cancer
- Gallbladder polyps
- Acalculous cholecystitis
- Biliary dyskinesia
- Choledocholithiasis
No lab study is specific for cholelithiasis.

**Initial Tests (lab, imaging)**

- Leukocytosis and elevated C-reactive protein level are associated with acute calculus cholecystitis.
- Ultrasound (US) is the preferred imaging modality. US detects gallstones in 97–98% of patients.
- Thickening of the gallbladder wall (≥5 mm), pericholecystic fluid, and direct tenderness when the probe is pushed against the gallbladder (sonographic Murphy sign) are associated with acute cholecystitis.
- CT scan has no advantage over US except in detecting distal common bile duct (CBD) stones.
- MR cholangiopancreatography (MRCP) is reserved for cases of suspected CBD stones. MRCP is recommended as a secondary imaging study if ultrasonography does not clearly demonstrate acute cholecystitis or gallstones.
- Endoscopic US is as sensitive as endoscopic retrograde cholangiopancreatography (ERCP) for detection of CBD stones in patients with gallstone pancreatitis.
- Hepatobiliary iminodiacetic acid (HIDA) scan is useful in diagnosing acute cholecystitis secondary to cystic duct obstruction. It is also useful in differentiating acalculous cholecystitis from other causes of abdominal pain. False-positive tests can result from a fasting state, insufficient resistance of the sphincter of Oddi, and gallbladder agenesis.
- Cholecystokinin (CCK)-HIDA is specifically used to diagnose gallbladder dysmotility (biliary dyskinesia).
- 10–30% of gallstones are radiopaque calcium or pigment-containing gallstones that are more likely to be visible on plain x-ray. A “porcelain gallbladder” is a calcified gallbladder, visible by x-ray; associated with chronic cholecystitis and gallbladder cancer

**Test Interpretation**

- Pure cholesterol stones are white or slightly yellow.
- Pigment stones may be black or brown. Black stones contain polymerized calcium bilirubinate, most often secondary to cirrhosis or hemolysis; these almost always form within the gallbladder.
- Brown stones are associated with biliary tract infection, caused by bile stasis, and as such may form either in the bile ducts or gallbladder.
TREATMENT

GENERAL MEASURES

- Treat symptomatic cholelithiasis.
- Conservative therapy is preferred during pregnancy. Surgery in the 2nd trimester if necessary.
- Prophylactic cholecystectomy for patients with calcified (porcelain) gallbladder (risk for gallbladder cancer), patients with large stones (≥3 cm), patients with sickle cell disease, patients planning an organ transplant, and patients with recurrent pancreatitis due to microlithiasis.
- In morbidly obese patients, cholecystectomy may be performed in combination with bariatric procedures to reduce subsequent stone-related comorbidities.
- Prophylactic cholecystectomy is recommended for gallstones discovered incidentally during open abdominal surgery.

Geriatric Considerations

Gallstones are more common in the elderly. Age alone should not alter the therapeutic plan.

MEDICATION

First Line

- Analgesics for pain relief
  - NSAIDs are the first-choice treatment for pain control equivalent to opioid therapy.
  - Opioids are an option for patients who cannot tolerate or fail to respond to NSAIDs.
- Antibiotics for patients with acute cholecystitis
- Prophylactic antibiotics in low-risk patients do not prevent infections during laparoscopic cholecystectomy (LC) (1)[A].

ISSUES FOR REFERRAL

Patients with retained or recurrent bile duct stones following cholecystectomy should be referred for ERCP.

SURGERY/OTHER PROCEDURES

- Surgery should be considered for patients who have symptomatic
cholelithiasis or gallstone-related complications (e.g., cholecystitis) or in asymptomatic patients with immune suppression, calcified gallbladder, or family history of gallbladder cancer. Open and LC have similar mortality and complication rates. LC offers less pain and quicker recovery. In well-selected patients, single-incision LC (SILC) and robotic LC are novel methods for the treatment of symptomatic cholelithiasis. SILC has not been shown to be superior to conventional multiport LC in terms of pain and risk of complications (2)[A]. Natural orifice transluminal endoscopic surgery (NOTES) is investigational. Surgery-related complications include CBD injury (0.2%), right hepatic duct/artery injury, retained stones, duct leak, biloma formation, and bile duct stricture.

- Conversion to open procedure is based on clinical judgment. Male gender, previous upper abdominal surgery, thickened gallbladder wall, and acute cholecystitis increase the likelihood of need to convert to an open procedure.
- In 10–15% of patients with symptomatic cholelithiasis, CBD stones are detected by intraoperative cholangiogram (IOC). CBD stone(s) can be removed by laparoscopic CBD exploration or postoperative ERCP.
- IOC helps delineate bile duct anatomy when dissection is difficult. Routine use of IOC is debatable but may be associated with decreased incidence and severity of bile duct injury.

- Early LC (<24 hours after diagnosis of biliary colic) decreases hospital stay and operating time (3)[A].
- For patients with acute cholecystitis, early LC (<7 days of clinical presentation) is safe and may shorten the total hospital stay versus delayed LC (>6 weeks after index admission with acute cholecystitis) (4)[A].
- Percutaneous cholecystostomy (PC) is used in high-risk patients with cholecystitis or gallbladder empyema. Interval cholecystectomy is advisable.
- Symptomatic patients who are not candidates for surgery or those who have small gallstones (5 mm or smaller) in a functioning gallbladder with a patent cystic duct are candidates for oral dissolution therapy (Actigall). However, the recurrence rate is >50% once the medication is discontinued.
- Extracorporeal shock wave lithotripsy is a noninvasive therapeutic alternative for symptomatic patients who are not candidates for surgery. It helps break down large bile duct stones before ERCP. Complications include biliary pancreatitis, hepatic hematoma, incomplete ductal stone clearance, and recurrence.

**ADMISSION, INPATIENT, AND NURSING**
CONSIDERATIONS
For patients with symptomatic cholelithiasis, LC is typically an outpatient procedure. For patients with complications (i.e., cholecystitis, cholangitis, pancreatitis), inpatient care is necessary.
- Acute phase: NPO, IV fluids, and antibiotics
- Adequate pain control with narcotics and/or NSAIDs

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Follow for signs of symptomatic cholelithiasis.
- Follow patients on oral dissolution agents with serial liver enzymes, serum cholesterol, and imaging.

DIET
A low-fat diet may help.

PATIENT EDUCATION
- Change in lifestyle (e.g., regular exercise) and dietary modification (low-fat diet and reduction of total caloric intake) reduce gallstone-related hospitalizations.
- Patients with asymptomatic gallstones should be educated about the typical symptoms of biliary colic and gallstone-related complications.

PROGNOSIS
- <50% of patients with gallstones become symptomatic.
- Cholecystectomy mortality <0.5% in elective cases, 3–5% in emergency cases; morbidity <10% in elective cases, 30–40% in emergency cases
- ~10–15% of patients have associated choledocholithiasis.
- After cholecystectomy, stones may recur within the biliary tree in patients with associated risk factors.

COMPLICATIONS
- Acute cholecystitis (90–95% secondary to gallstones)
- Gallstone pancreatitis (GP). ERCP ± sphincterotomy of no clear benefit in
patients with mild GP but reduces complications in those with severe GP (5) [A]

- CBD stones with obstructive jaundice and acute cholangitis. In patients undergoing ERCP for CBD stones, early LC reduces the risk of recurrent biliary events (6)[B].

- Biliary-enteric fistula and gallstone ileus
- Bouveret syndrome is a variant of gallstone ileus where the gallstone lodges in the duodenum or pylorus causing a gastric outlet obstruction.
- Gallbladder cancer
- Mirizzi syndrome (extrinsic bile duct obstruction caused by gallstones lodged in gallbladder or cystic duct)

REFERENCES

ADDITIONAL READING

**SEE ALSO**

Cholangitis, Acute; Choledocholithiasis

**CODES**

**ICD10**

- K80.20 Calculus of gallbladder w/o cholecystitis w/o obstruction
- K80.21 Calculus of gallbladder w/o cholecystitis with obstruction
- K80.01 Calculus of gallbladder w acute cholecystitis w obstruction

**CLINICAL PEARLS**

- Most patients with gallstones are asymptomatic.
- Transabdominal US is the imaging modality of choice for diagnosis of cholelithiasis (sensitivity, 97%; specificity, 95%).
- LC is the preferred surgical procedure for symptomatic cholelithiasis.
- Acute acalculous cholecystitis is associated with bile stasis and gallbladder ischemia.
- Prophylactic cholecystectomy is not indicated in patients with asymptomatic gallstones.
CHRONIC COUGH

Jacqueline L. Olin, MS, PharmD, BCPS, CDE, FASHP, FCCP • Brian Hertz, MD • J. Andrew Woods, PharmD, BCPS

BASICS

DESCRIPTION

- Chronic cough is defined as a cough that persists for >8 weeks in adults.
- In children, chronic cough is often defined as a cough of >4 weeks in duration.
- Subacute cough describes a cough lasting 3 to 8 weeks.
- Patients present because of fear of the causative illness (e.g., cancer), annoyance, self-consciousness, and hoarseness.
- System(s) affected: gastrointestinal (GI), pulmonary

EPIDEMIOLOGY

- Predominant age: all age groups
- Predominant sex: male = female, with females more likely to seek out medical attention

Incidence

Persistent unexplained cough occurs in up to 10% of patients presenting with chronic cough and up to 46% referred to specialty cough clinics (1).

Prevalence

Chronic cough is one of the most common reasons for primary care visits.

ETIOLOGY AND PATHOPHYSIOLOGY

Varies with findings and disorders implicated

- Often multiple etiologies, but most are related to bronchial irritation. Frequent etiologies (account for >90% of cases) in nonsmokers include the following:
  - Upper airway cough syndrome (UACS) and other upper airway abnormalities, including allergic and vasomotor rhinitis syndromes
  - Asthma
  - Gastroesophageal reflux disease (GERD)
Other causes:
- ACE inhibitors
- Chronic smoking or exposure to smoke or pollutants
- Aspiration
- Bronchiectasis
- Infections (e.g., pertussis, tuberculosis)
- Nonasthmatic eosinophilic bronchitis (NAEB)
- Cystic fibrosis
- Sleep apnea
- Restrictive lung diseases
- Neoplasms: bronchogenic or laryngeal
- Psychogenic (habit cough)

Cough hypersensitivity syndrome defines a syndrome of cough with characteristic trigger symptoms not adequately explained by other medical conditions.

Etiologies of chronic cough in young children differ from those in older children and adults (2).

RISK FACTORS
Although various conditions may contribute to chronic cough, the main causes include smoking and pulmonary diseases.

COMMONLY ASSOCIATED CONDITIONS
Patients with UACS, asthma, and GERD may present with chronic cough as the only symptom and not the usual symptoms associated with the diagnoses.

DIAGNOSIS

HISTORY
- Patient age, associated signs/symptoms, medical history, medication history (i.e., ACE inhibitors), environmental and occupational exposures, potential for aspiration, and smoking history may make some causes more likely.
- The character of cough or description of sputum quality is rarely helpful in predicting the underlying cause.
- Cough diaries have not correlated well with objective measures.
- Hemoptysis or signs of systemic illness preclude empiric therapy.
PHYSICAL EXAM
- Signs and symptoms are variable and related to the underlying cause; usually, a nonproductive cough with no other signs or symptoms
- Possible signs and symptoms of UACS, sinusitis, GERD, congestive heart failure, chronic stressors
- Absence of additional signs/symptoms of a particular condition not necessarily helpful
  - For example, 5% of patients with GERD have no other signs or symptoms and sometimes have poor response to empiric proton pump inhibitor (PPI) trials.

DIAGNOSTIC TESTS & INTERPRETATION
- Evaluation often starts with empiric therapy directed at likely underlying etiology and/or simple testing such as a chest x-ray (CXR).
- Extensive testing only if indicated by the history and physical

Pediatric Considerations
Children with chronic cough not responsive to an inhaled β-agonist and without overt stressors should undergo spirometry (if age-appropriate) and foreign body evaluation (CXR).

Initial Tests (lab, imaging)
- Evaluation will be dictated by findings in the comprehensive history and physical.
- Evaluation of peak flow may be indicated.
- If considering neoplasm, heart failure, or infectious etiologies, CXR or B-type natriuretic peptide (BNP) may be indicated.
- In cases of failure to respond to initial trial of empiric therapy, CXR may also be beneficial.

Follow-Up Tests & Special Considerations
- Examples:
  - If considering chronic obstructive pulmonary disease (COPD), asthma, or restrictive lung disease: spirometry
  - If suspicious of cystic fibrosis: sweat chloride testing
  - If suspicious of hypereosinophilic syndrome, tuberculosis, or malignancy: sputum for eosinophils and cytology
- If abnormal CXR, suspected neoplasm, or underlying pulmonary disorder,
consider a chest CT.
- Consider pulmonary consultation.
- Consider specialist cough clinic.
- Refer to gastroenterologist for endoscopy.

**Diagnostic Procedures/Other**
If diagnosis suggested and inadequate response to initial measures, other procedures can be considered:
- Pulmonary function testing
- Purified protein derivative (PPD) skin testing
- Allergen testing
- 24-hour esophageal pH monitor
- Bronchoscopy, if history of hemoptysis or smoking with normal CXR
- Endoscopic or video fluoroscopic swallow evaluation or barium esophagram
- Sinus CT
- Ambulatory cough monitoring and cough challenge with citric acid, capsaicin, or other bronchodilator (at specialized cough clinic)
- Echocardiogram

**Test Interpretation**
Specific to underlying cause

---

**TREATMENT**

**GENERAL MEASURES**
- With chronic cough, empiric treatment should be directed at the most common causes as clinically indicated (UACS, asthma, GERD) (1,3)[C].
- Empiric trial of nasal steroids and/or antihistamines should be considered if allergic symptoms or postnasal drip is present.
- With concomitant complaints of heartburn and regurgitation, GERD should be considered as a potential etiology (3)[C].
- In patients with cough associated with the common cold, nonsedating antihistamines were not found to be effective in reducing cough (1,3)[C]. 90% of patients will have resolution of cough after smoking cessation (3)[A].
- When indicated, ACE inhibitor therapy should be switched in patients in whom intolerable cough occurs. It may take several days or weeks for cough to resolve after stopping ACE inhibitor therapy.
Empirically treat postnasal drip and GERD.

In infants and children with nonspecific chronic cough, trials of empiric PPI therapy were not effective (3)[C]; empiric PPI not recommended for adults either (3)[C].

Multimodality speech pathology therapy had a positive benefit on cough severity in some adults (1)[C].

Attempt maximal therapy for single most likely cause for several weeks and then search for coexistent etiologies.

MEDICATION

Treatments (nasal steroids, classic antihistamines, antacids, bronchodilators, inhaled corticosteroids, PPIs, antibiotics) should be directed at the specific cause of cough.

If history and physical exam suggest GERD, may want to empiric PPI therapy prior to further diagnostic testing.

The FDA issued a public health advisory stating that OTC cough and cold medicines, including antitussives, expectorants, nasal decongestants, antihistamines, or combinations, should not be given to children <2 years. Subsequently, manufacturers have changed labeling to state “do not use” in children <4 years. In 2017, the FDA issued a contraindication to codeine for cough treatment in children <12 years.

Routine empiric treatment of children with chronic cough with leukotriene receptor antagonists lacks evidence and cannot be recommended.

First Line

In adults:

Nasal steroids: fluticasone, budesonide, others, 1 spray BID for those with allergic rhinitis symptoms or postnasal drip or an empiric trial of PPI (omeprazole, others) once a day

Second Line

A peripherally acting antitussive agent has been used:

– In patients >10 years, benzonatate (Tessalon Perles) 100 to 200 mg PO TID as needed (maximum 600 mg/day)

Gabapentin was evaluated in a randomized, double-blind, placebo-controlled trial of patients with refractory chronic cough. Gabapentin demonstrated improved cough-specific quality of life compared to placebo. Nausea and fatigue occurred in 31%. A therapeutic trial with a risk-benefit assessment at 6
months is suggested (1)[C].

- A comparative effectiveness review of 49 studies with common opioid and nonanesthetic antitussives stated there is some efficiency for treating cough in adults, but evidence is limited (4)[C].
- Studies evaluating inhaled corticosteroid use in chronic cough for patients without additional indication such as asthma did not show consistent benefits (1)[C].

**ISSUES FOR REFERRAL**

Patients with chronic cough may benefit from evaluation by pulmonary, gastroenterology, ear/nose/throat (ENT), and/or allergy specialists. Consider specialist cough clinic.

**SURGERY/OTHER PROCEDURES**

Fundoplication may be effective for cough secondary to refractory GERD.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Consider stepwise withdrawal of medications after resolution of cough.

*Patient Monitoring*

Frequent follow-up is necessary to assess the effectiveness of treatment.

**DIET**

Dietary modification: Patients with GERD may benefit by avoiding ethanol, caffeine, nicotine, citrus, tomatoes, chocolate, and fatty foods.

**PATIENT EDUCATION**

- Reassure patient that most cases of chronic cough are not life-threatening and that the condition can usually be managed effectively.
- Counsel that several weeks to a month may be needed for significant reduction or elimination of cough.
- Prepare the patient for the possibility of multiple diagnostic tests and therapeutic regimens because the treatment is very often empiric.

**PROGNOSIS**
>80% of patients can be effectively diagnosed and treated using a systematic approach.

Cough from any cause may take weeks to months until resolution, and resolution depends greatly on efficacy of treatment directed at underlying etiology.

**COMPLICATIONS**

- Cardiovascular: arrhythmias, syncope
- Stress urinary incontinence
- Abdominal and intercostal muscle strain
- GI: emesis, hemorrhage, herniation
- Neurologic: dizziness, headache, seizures
- Respiratory: pneumothorax, laryngeal, or tracheobronchial trauma
- Skin: petechiae, purpura, disruption of surgical wounds
- Medication side effects
- Other: negative impact on quality of life

CLINICAL PEARLS

- Chronic cough is defined as a cough that persists for >8 weeks in adults.
- In patients with chronic cough, most frequent etiologies include a history of smoking, asthma, UACS, and GERD.
- The FDA issued a public health advisory stating that OTC cough and cold medicines should not be given to children <2 years. OTC cough expectorant and suppressant product labels state “do not use” in children <4 years. Codeine is contraindicated for cough treatment in children <12 years.
CHRONIC FATIGUE SYNDROME (CFS)
Yow-Jeng Franny Pan, MB, BCh, BAO • Naureen Rafiq, MBBS

BASICS

DESCRIPTION
- A complex physical illness characterized by a new or definite onset of debilitating fatigue that persists for >6 months and significantly reduces a person’s ability to perform usual activities. Key features include:
  - Impaired memory or concentration
  - Joint and muscle pain
  - Unrefreshing sleep
  - Postexertional malaise
  - Orthostatic intolerance (i.e., dizziness and light-headedness when standing up)
- Synonyms: myalgic encephalomyelitis, chronic Epstein-Barr virus syndrome, postviral fatigue syndrome, chronic fatigue immune dysfunction, and systemic exertion intolerance disease (1)
- Fatigue is not relieved by rest and results in >50% reduction in previous activities (occupational, educational, social, and personal).
- Other potential medical causes must be ruled out (2).

EPIDEMIOLOGY
- Generally occurs as sporadic or isolated cases, although cluster outbreaks have occurred in different parts of the world—Iceland (1948), London, England (1955), New Zealand (1984), and the United States (1984 and 1985)
  - Onset usually between 30 and 50 years of age, can affect all ages (1)[B]
  - Females affected 3 to 4 times more than male
  - Estimated annual cost from loss of productivity and medical bills ranges from $17 to 24 billion in the United States.

Prevalence
- Affects all racial and ethnic groups; more prevalent in minority and low socioeconomic groups
  - An estimated 836,000 to 2.5 million Americans suffer from chronic fatigue
ETIOLOGY AND PATHOPHYSIOLOGY

- Unknown and likely multifactorial
  - Possible interaction between genetic predisposition, environmental factors, an initiating stressor, and perpetuating factors
- A recent theory attributes possible neuroendocrine immunologic and biochemical effects in CFS to dysbiosis of the gut microbiome.
- Physiologic or environmental stressors are potential precipitants.
- Many patients with chronic fatigue recall significant stressors (e.g., major medical procedure, loss of a loved one, loss of employment) in months before symptoms began. History of childhood trauma is common.
- Systems hypothesized to contribute to altered physiology include:
  - Neuroendocrine (e.g., diminished cortisol response to increased corticotropin concentrations)
  - Immune (e.g., increased C-reactive protein and β-2 microglobulin)
  - Neuromuscular (e.g., dysfunction of oxidative metabolism)
  - Autonomic (Orthostatic hypotension is reported in a proportion of CFS patients.)
  - Serotonergic (e.g., hyperserotonergic mechanisms or upregulation of serotonin receptors)

Genetics

Higher concordance among monozygotic twins compared with dizygotic twins

RISK FACTORS

Possible predisposing factors include (3):

- Personality characteristics (neuroticism and introversion)
- Lifestyle
  - Childhood inactivity or over activity
  - Inactivity in adulthood after infectious mononucleosis
  - Familial predisposition
  - Comorbid depression or anxiety
- Long-standing medical conditions in childhood
- Childhood trauma (emotional, physical, sexual abuse)
- Prolonged idiopathic chronic fatigue
- Postinfectious fatigue and CFS have been noted to follow mononucleosis, Ross River virus, Coxiella burnetii, herpes zoster, Q fever, and Giardia
Due to concern for a possible “as yet undiscovered” infectious etiology, CFS patients excluded from donating blood by the American Red Cross in 2010.

**COMMONLY ASSOCIATED CONDITIONS**

Common comorbidities include:
- Fibromyalgia (more common in women)
- Irritable bowel syndrome
- Gynecologic conditions (pelvic pain, endometriosis) and GYN surgeries (hysterectomy, oophorectomy) (2)
- Anxiety disorders
- Major depression
- Posttraumatic stress disorder (including physical and/or past sexual abuse)
- Domestic violence
- Attention deficit hyperactivity disorder (ADHD)
- Postural orthostatic tachycardia syndrome (POTS)
- Sleep disorders, including OSA
- Reduced left ventricular size and mass

**DIAGNOSIS**

**HISTORY**

A thorough medical history and psychosocial history is required for accurate diagnosis. Box 1 shows updated diagnostic criteria proposed by the Institute of Medicine.

**ALERT**

Box 1. 2015 IOM Criteria for Diagnosis of Myalgic Encephalomyelitis/CFS (1)

Each of the following three symptoms at least half of the time, to at least a moderately severe degree:
- A substantial reduction or impairment in the ability to engage in pre-illness levels occupational, educational, social, or personal activities that persists for >6 months and is accompanied by fatigue, which is often profound, is of new or definite onset (not lifelong), is not a result of ongoing excessive exertion, and is not substantially alleviated by rest
- Postexertional malaise*
• Unrefreshing sleep*  
Plus at least one of the two following manifestations (chronic, severe):
• Cognitive impairment*  
• Orthostatic intolerance  

*Frequency and severity of symptoms should be assessed.

• Common illnesses to exclude (2):
  – Anemias  
  – Autoimmune diseases (rheumatoid arthritis, lupus)  
  – Significant cardiac or pulmonary disease  
  – Endocrine disorders (diabetes, Addison disease, thyroid disorder)  
  – Infectious disease (tuberculosis, HIV/AIDS, chronic hepatitis, Lyme disease)  
  – Intestinal diseases (celiac or Crohn)  
  – Neurologic disorders (such as multiple sclerosis, Parkinson disease, myasthenia gravis)  
  – Primary psychiatric disorders and substance abuse (clinical depression not included)  
  – Primary sleep disorders such as sleep apnea  
  – Malignancies

PHYSICAL EXAM  
Complete physical exam to rule out other medical causes for symptoms. A complete mental status examination should be performed as well.

DIFFERENTIAL DIAGNOSIS  
• Idiopathic chronic fatigue (i.e., fatigue of unknown cause for >6 months without meeting criteria for CFS)  
• Psychiatric disorders  
  – Major depression  
  – Somatization disorder  
• Physiologic fatigue (sleep disturbance, menopause)  
• Pregnancy until 3 months postpartum  
• Insomnia: primary (no clear etiology) versus secondary (e.g., due to anxiety, depression, environmental factors, poor sleep hygiene)  
• Other known or defined systemic disease  
• Endocrine disorder (hypothyroidism, Addison disease, Cushing syndrome, diabetes mellitus)  

mebooksfree.com
- Localized infection (e.g., occult abscess)
- Chronic or subacute bacterial disease (e.g., endocarditis)
- Lyme disease
- Fungal disease (e.g., histoplasmosis, coccidioidomycosis)
- Parasitic disease (e.g., amebiasis, giardiasis, helminth infestation)
- HIV or related disease
- Iatrogenic (e.g., medication side effects)
- Toxic agent exposure
- Obesity
- Malignancy
- Autoimmune disease
- Chronic inflammatory disease (sarcoidosis, Wegener)
- Neuromuscular disease (MS, myasthenia gravis)

**DIAGNOSTIC TESTS & INTERPRETATION**

No validated diagnostic test available and finding an abnormal result is not always the same as discovering the cause of fatigue. Be prepared to renew the search for the cause if the problem is treated and the patient remains fatigued.

**Initial Tests (lab, imaging)**

- Standard laboratory tests are recommended to rule out other causes for symptoms:
  - CBC; complete metabolic panel
  - Urinalysis
  - Thyroid-stimulating hormone (TSH) and free T$^4$
  - ESR or C-reactive protein
  - Magnesium and phosphorus level
  - Screen for drugs of abuse.
  - Age-/gender-appropriate cancer screening
- Additional studies, if clinical findings are suggestive or patient at risk:
  - Creatine kinase
  - Anti-nuclear antibodies and rheumatoid factor
  - Tuberculin skin test
  - Serum cortisol
  - HIV; RPR; VDRL
  - Lyme serology
  - IgA tissue transglutaminase
- As domestic violence is a common component of the differential diagnosis,
screen using:
- “Have you ever been hit, kicked, punched, or otherwise, hurt by someone within the past year? If so, by whom?”
- “Do you feel safe in your current relationship?”
- “Is there a partner from a previous relationship who is making you feel unsafe now?”

- No applicable imaging tests available; however, EEG and/or MRI may be useful if patient has CNS symptoms; polysomnography, if patient has increased somnolence (4)

**Follow-Up Tests & Special Considerations**
- Assess for comorbid psychiatric disorders.
- Assess for personality and psychosocial factors and maladaptive coping styles.
- In patients with sleep disturbance, polysomnography may reveal a treatable comorbid disease.

**TREATMENT**
- No treatment yet proven effective by large randomized trials; recommendations based on expert opinion and standard symptom management (1,2)
- Focus on changes in lifestyle and insight, with a goal to avoid complicating treatments (e.g., addictive medications, invasive testing) or interventions that support secondary gain.
- A multi-disciplinary approach is recommended.

**GENERAL MEASURES**

**ALERT**
No definitive cure. Treatment involves symptom management and guided self-management. The aim is to reduce symptoms and improve quality of life by establishing a good therapeutic relationship. It is helpful to identify troublesome symptoms (pain and insomnia) and address those first. Both cognitive-behavioral therapy (CBT) and graded exercise therapy (GET) are effective. Medication is often of little value.

- **Individual CBT**: Challenge fatigue-related cognition; plan social and occupational rehabilitation.
GET: Track amount of exercise patient can do without exacerbating symptoms and gradually increase intensity and duration. Both involve a careful balance between activity and rest. Fear of movement and avoidance of physical activity are common in CFS.

Patients learn how to gradually increase activity in a way that will not exacerbate their illness. Vigorous exercise can trigger relapse, perhaps related to immune dysregulation.

Improves functional capacity and diminishes fatigue

GET is more effective with educational interventions using telephone reminders.

Duration of illness does not predict treatment outcome; aggressive combined care indicated for all

MEDICATION

- No established pharmacologic treatments
- If medications are needed, use the lowest effective dose and increase cautiously.
- Studies have been conducted with antivirals, antidepressants, immunoglobulins, hydrocortisone, and modafinil; none show clear benefit
- Agomelatine, an antidepressant with agonist activity at melatonin receptors, is promising in early studies.
- If insomnia is present, use of nonaddicting sleep aids (hydroxyzine, trazodone, doxepin, etc.) may improve outcomes.

ISSUES FOR REFERRAL

- Psychiatrist to help manage comorbid behavioral disorders
- Rehabilitative medicine
- Sleep or pain management specialist

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Treatment such as acupuncture, massage, and chiropractic have been shown to be beneficial for some patients suffering from pain (2)[B].
- Other helpful nonpharmacologic interventions may include physical therapy, stretches, hydrotherapy, yoga, Tai Chi, and meditations. Hot or cold packs, warm baths as well as electrical massagers, transcutaneous electrical nerve stimulations can also be considered.
- Equivocal evidence for homeopathy and biofeedback
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Although no consensus exists, periodic reevaluation is appropriate for support, relief of symptoms, and assessment for other possible causes of symptoms.

DIET
- Good nutrition and well balanced diet is advisable.
- Ensure patient obtains at least the recommended daily allowance of vitamins and minerals.
- No particular diet program has been shown to be effective for treatment of CFS.
- Whether weight loss improves symptoms in obese CFS patients, it has yet to be tested.

PATIENT EDUCATION
- Gradual increase in physical exercise
- Avoid extended periods of rest but ensure adequate rest between sessions.
- Patient education is an important part of treatment of CFS, such as education on the benefits of cognitive therapies, lifestyle changes, and pharmacologic therapy directed at specific-associated symptoms. Job modification should also be proposed as needed.
- Chronic Fatigue and Immune Dysfunction Syndrome Association of America: http://solvecfs.org/
- CDC, Chronic Fatigue Syndrome: http://www.cdc.gov/cfs/

PROGNOSIS
- Fluctuating course is common.
- Generally, improvement is slow, with a course of months to years.
- An estimated 15% full recovery rate
- Patients with poor social adjustment, a strong belief in an organic etiology, financial secondary gain, or age >50 years are less likely to improve.

COMPLICATIONS
- CFS patients may reduce physical activity out of fear that it may worsen symptoms.
• Depression
• Unemployment: Although studies document improvement with treatment, <1/3 of patients in trials return to work.
• The Social Security Administration considers CFS to be a disability.
• Receipt of third-party disability payments (secondary gain) has been associated with treatment nonresponse.

Polypharmacy
• Chronic immune activation or an associated infection may play a role in an increased risk for non-Hodgkin lymphoma in elderly (>80 years) CFS patients.

REFERENCES

ADDITIONAL READING

• Social Security Administration. Providing medical evidence to the social security administration for individuals with chronic fatigue syndrome fact sheet. [https://www.socialsecurity.gov/disability/professionals/cfs-pub063.htm](https://www.socialsecurity.gov/disability/professionals/cfs-pub063.htm).
CLINICAL PEARLS

- No pharmacologic agents (e.g., antidepressants, immune modulators) have been shown to be consistently effective in treating CFS.
- ~70% of patients show improvement with CBT; 55% with GET; in many cases, the combination of these two treatments is helpful.
- There are many more patients with idiopathic chronic fatigue than true CFS. To diagnose CFS, use the IOM diagnostic criteria.
- Standardized instruments (SF-36, symptom index, and Multidimensional Fatigue Inventory [MFI]) are of use in the diagnosis of CFS and help to follow patient progress.
CHRONIC KIDNEY DISEASE

Crystal Verdick, DO, MS • James E. West, MD

BASICS

Chronic kidney disease (CKD) is defined as structural or functional abnormalities of the kidney for ≥3 months, as determined by either pathologic abnormalities or markers of damage—including abnormalities in blood or urine tests, histology, imaging studies, or history of kidney transplant—or a GFR <60 mL/min/1.73 m² for ≥3 months.

DESCRIPTION

• In 2012, Kidney Disease: Improving Global Outcome (KDIGO) classified CKD in six categories by GFR estimation (in mL/min/1.73 m²):
  – G1: kidney damage with normal or increased GFR ≥90
  – G2: mild ↓ GFR 60 to 89
  – G3a: mild to moderate ↓ GFR 45 to 59
  – G3b: moderate to severe ↓ GFR 30 to 44
  – G4: severe ↓ GFR 15 to 29
  – G5: kidney failure: GFR <15 or dialysis
• CKD per albumin-to-creatinine ratio (ACR) category:
  – A1: normal to mildly increased: <30 mg/g or <3 mg/mmol
  – A2: moderately increased: 30 to 300 mg/g or 3 to 30 mg/mmol
  – A3: severely increased: >300 mg/g or >30 mg/mmol
• Risk of progression depends on comorbid conditions.
• System(s) affected: renal/urinary, cardiovascular, skeletal, endocrine, metabolic, hematologic, lymphatic, immune, neurologic
• Synonym(s): chronic renal failure; chronic renal insufficiency

Geriatric Considerations

GFR normally decreases with age, despite normal creatinine (Cr). Adjust renally cleared drugs for GFR in the elderly.

Pediatric Considerations

CKD definition is not applicable for children <2 years because of lower GFR even when corrected for body surface area. Calculated GFR based on serum Cr
is used in this age group.

**Pregnancy Considerations**
Renal function in CKD may deteriorate during pregnancy. Cr >1.5 and hypertension (HTN) are major risk factors for worsening renal function.

- Increased risk of premature labor, preeclampsia
- ACE inhibitors and angiotensin receptor blockers (ARBs) are contraindicated due to teratogenicity. Use diuretics with caution.

**Epidemiology**
- African Americans are 3.6 times more likely to develop CKD than Caucasians.
- Predominant sex: similar in both sexes; however, incidence rate of end-stage renal disease (ESRD) is 1.6 times higher in males than females.

**Incidence**
Estimated annual incidence of 1,700/1 million population

**Prevalence**
Overall prevalence of CKD is 14.2%. Unadjusted prevalence/incidence rates of ESRD (stage 5) are 1,752 and 362.4/1 million, respectively. Numbers do not reflect the burden of earlier stages of CKD (stages 1 to 4), which are estimated to affect 13.1% of the population nationwide or 26.3 million in the United States.

**Etiology and Pathophysiology**
Progressive destruction of kidney nephrons; GFR will drop gradually, and plasma Cr values will approximately double, with 50% reduction in GFR and 75% loss of functioning nephrons mass. Hyperkalemia usually develops when GFR falls to <20 to 25 mL/min. Anemia develops from decreased renal synthesis of erythropoietin.

- Renal parenchymal/glomerular
  - Nephritic: hematuria, RBC casts, HTN, variable proteinuria
    - Focal proliferative: IgA nephropathy, systemic lupus erythematosus (SLE), Henoch-Schönlein purpura, Alport syndrome, proliferative glomerulonephritis, crescentic glomerulonephritis
    - Diffuse proliferative: membranoproliferative glomerulonephritis, SLE, cryoglobulinemia, rapidly progressive glomerulonephritis (RPGN), Goodpasture syndrome
- Nephrotic: proteinuria (>3.5 g/day), hypoalbuminemia, hyperlipidemia, and edema
  - Minimal change disease, membranous nephropathy, focal segmental glomerulosclerosis
  - Amyloidosis, diabetic nephropathy
- Vascular: HTN, thrombotic microangiopathies, vasculitis (Wegener), scleroderma
- Interstitial-tubular: infections, obstruction, toxins, allergic interstitial nephritis, multiple myeloma, connective tissue disease, cystic disease
- Postrenal: obstruction (benign prostatic hyperplasia), neoplasm, neurogenic bladder

**Genetics**
- Alport syndrome, Fabry disease, sickle cell anemia, SLE, and autosomal dominant polycystic kidney disease can lead to CKD.
- Polymorphisms in gene that encodes for podocyte nonmuscle myosin II A are more common in African Americans than Caucasians and appear to increase risk for nondiabetic ESRD.

**RISK FACTORS**
- Type 1 or 2 diabetes mellitus (DM); most common
- Age > 60 years
- Cardiovascular disease (e.g., HTN [common], renal artery stenosis, atheroemboli)
- Previous kidney transplant
- Urinary tract obstruction (e.g., BPH)
- Autoimmune disease, vasculitis/connective tissue disorder
- Family history of CKD
- Nephrotoxic drugs (lithium, salicylate, high-dose or chronic NSAIDs, sulfonamide)
- Congenital anomalies, obstructive uropathy, renal aplasia/hypoplasia/dysplasia, reflux nephropathy
- Hyperlipidemia
- Low income/education/ethnic minority status
- Obesity/smoking/heroin use
- Chronic infection (hepatitis B, hepatitis C, HIV)

**GENERAL PREVENTION**
- Treat reversible causes: hypovolemia, infections, diuretics, drugs (NSAIDs, aminoglycosides, IV contrast).
- Treat risk factors: DM, HTN, hyperlipidemia, smoking, and obesity; adjust medication doses to prevent renal toxicity.

COMMONLY ASSOCIATED CONDITIONS
HTN, DM, cardiovascular disease

DIAGNOSIS

HISTORY
Patients with CKD stages 1 to 3 are usually asymptomatic; can present with
- Oliguria, nocturia, polyuria, hematuria, change in urinary frequency
- Bone disease
- Edema, HTN, dyspnea
- Fatigue, depression, weakness
- Pruritus, ecchymosis
- Metallic taste in mouth, anorexia, nausea, vomiting
- Hyperlipidemia, claudication, restless legs
- Erectile dysfunction, decrease libido, amenorrhea

PHYSICAL EXAM
- Volume status (pallor, BP/orthostatic; edema; jugular venous distention; weight)
- Skin: sallow complexion, uremic frost
- Ammonia-like odor (uremic fetor)
- Cardiovascular: Assess for murmurs, bruits, pericarditis.
- Chest: pleural effusion
- Rectal: enlarged prostate
- CNS: asterixis, confusion, seizures, coma, peripheral neuropathy

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- GFR can be estimated using the Modification of Diet in Renal Disease (MDRD) and Chronic Kidney Disease-Epidemiology Collaboration (CKD-EPI) equations. A recent meta-analysis found the MDRD has greater accuracy
at GFR 60, whereas the CKD-EPI is more accurate at GFR >60 (1)[A].

- Cr clearance (CrCl) can be calculated using Cockcroft-Gault formula to determine medication adjustments.
- Urine analysis to assess for evidence of damage
  - Urine microscopy: WBC casts in pyelonephritis, RBC casts in glomerulonephritis/vasculitis
  - Urine electrolytes: sodium, Cr, urea (if on loop diuretics)
- Albuminuria is more sensitive than proteinuria at detecting disease (2)[B].
  - Report as a ratio of albumin concentration to Cr concentration (mg/mmol or mg/g)

- Ultrasound (initial imaging test of choice): small, echogenic kidneys; may see obstruction (e.g., hydroureter); cysts; kidneys may be enlarged with HIV and diabetic nephropathy.
- Doppler ultrasound to assess for renovascular disease, thrombosis
- Noncontrast CT scan: obstruction, calculi, cysts, neoplasm, renal artery stenosis
- MRI/MRA: Avoid gadolinium because of the risk of nephrogenic systemic fibrosis.
- Renal arteriogram for renal artery stenosis can be therapeutic (angioplasty or stenting).
- Renal scan to screen for differential function between kidneys
- Retrograde pyelogram: if strong suspicion for obstruction despite negative finding on ultrasound

**Follow-Up Tests & Special Considerations**
Additional evaluation may be indicated to assess for complications or cause, as clinically indicated:

- Hematology: normochromic, normocytic anemia; increased bleeding time
- Chemistry: elevated BUN, Cr, hyperkalemia, metabolic acidosis, increased PTH, HLD, hyperphosphatemia, decreased 25-(OH) vitamin D, hypocalcemia, decreased albumin
- Serology: antinuclear antibody (ANA); double-stranded DNA, antineutrophil cytoplasmic antibody; complements (C3, C4, CH50); anti-glomerular basement membrane (GBM) antibodies; hepatitis B, C; and HIV screening
- Serum and urine immunoelectrophoresis

**Follow-Up Tests and Special Considerations**
Monitoring the parameters with frequency based on GFR and risk of progression:
- Urine albumin and GFR at least annually
- Hb: clinically indicated for GFR ≥60, annually for 30 to 59, twice per year for <30 (3)[B]
- Calcium, phosphate, PTH, alkaline phosphate actively beginning at CKD Stage G3a (4)[C]
- 25(OH)D (calcidiol) levels with repeated testing determined by baseline values and therapeutic interventions (4)[C]
- Therapeutic decisions should be based on trends rather than on a single laboratory value, taking into account all available CKD-MBD assessments (4)[C].

**ALERT**
Drugs that may alter lab result:
- Cimetidine: inhibits Cr tubular secretion
- Trimethoprim: inhibits Cr and K⁺ secretion and may cause/worsen hyperkalemia
- Cefoxitin and flucytosine: increases serum Cr
- Diltiazem and verapamil (like ACE/ARBs) have significant antiproteinuric effects in patients with CKD.

**Diagnostic Procedures/Other**
Biopsy: hematuria, proteinuria, acute/progressive renal failure, nephritic or nephrotic syndrome

**TREATMENT**
**GENERAL MEASURES**
- Lowering salt intake to <2 g/day of sodium in adults, unless contraindicated (5)[C]
- Minimize radiocontrast exposure; prehydrate; N-acetylcysteine use is controversial. Avoid nephrotoxins (NSAIDs, aminoglycosides, etc.).
- Encourage smoking cessation, encourage weight loss (if applicable), and limit alcohol consumption (5)[C].
- Protein restriction to 0.8 g/kg/day is recommended in CKD G4 to G5 (2)[B]. CKD at risk of progression should avoid dietary protein >1.3 g/kg/day to
**MEDICATION**

- **HTN:** Goal in adults is BP <130/80 mm Hg if urine albumin excretion is ≥30 mg/24 hr and <140/90 mm Hg if urine albumin excretion is <30 mg/24 hr. Goal in children is <90th percentile for age, sex, weight (5)[B].
  - ACE-I or ARB recommended for diabetic and nondiabetic adults with albumin excretion >30 mg/24 hr based on evidence of reductions in proteinuria, improved CVD outcomes, and decreased progression of CKD (5)[A]. Monitor potassium and serum Cr (tolerate up to 30% rise unless hyperkalemia develops).
  - Additional antihypertensive agents should be selected based on the type of CKD and comorbid factors.

- **Secondary hyperparathyroidism**
  - For GFR <45, monitor for hyperphosphatemia, hypocalcemia, and vitamin D deficiency if intact PTH is elevated beyond lab normals (2)[C].
  - Cinacalcet, paricalcitol (decrease PTH levels)

- **Hyperphosphatemia:** Maintain phosphate according to reference lab normals (2)[C]. Recommended serum phosphate maintenance levels for CKD patients:
  - Stages 3 to 5 CKD (not on dialysis): Restrict dietary phosphate to 800 to 1,000 mg/day.
    - Calcium-containing phosphate binders (with meals): calcium carbonate, calcium acetate (risk of hypercalcemia)
    - Noncalcium phosphate binders (with meals): sevelamer, lanthanum
    - Vitamin D: inactive vitamin D 25 (ergocalciferol or cholecalciferol), calcitriol (active vitamin D 1,25 [OH]): Vitamin D may increase absorption of phosphate by intestines and should not be started until serum phosphate concentration is controlled.

- **Anemia:** Hb <13 g/dL in adult males or <12 g/dL in adult females. Treat with iron replacement therapy with or without erythropoietin-stimulating agents (ESAs) (3)[B]. Consider ESA if Hb >9 g/dL and <10 g/dL. ESA initiation not recommended for Hb >10 g/dL. If using ESA, goal Hb range 10 to 11 g/dL, not to exceed 11.5 g/dL (3)[B].

- **Hyperlipidemia:** Statins with low-density lipoprotein (LDL) goal is similar to coronary heart disease patients (LDL <70 to 100).

- **Glycemic control:** Target for HbA1c should be adjusted based on risk of hypoglycemia, comorbid conditions, and life expectancy (2)[B]. HbA1c may be falsely low in patients with decreased RBC; glucose logs may be more
accurate reflection of glycemic control (2)[C]. Metformin use should be reconsidered for GFR between 30 and 44 and discontinued if GFR <30 mL/min/1.73 m² (2)[C].

- Metabolic acidosis: Start treatment when bicarbonate <22 mEq/L with goal to maintain in normal range (2)[C].

ISSUES FOR REFERRAL
- Nephrology consult: GFR <15: immediate
- GFR 15 to 29: urgent
- GFR 30 to 59: nonurgent referral
- GFR 60 to 89: not required unless with comorbidities
- Renal replacement: Prepare for dialysis or transplant when GFR <30 mL/min/1.73 m².

SURGERY/OTHER PROCEDURES
Placement of dialysis access or transplantation

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Uremia: nausea/vomiting, fluid overload, pericarditis, uremic encephalopathy, resistant HTN, hyperkalemia, metabolic acidosis, hyperphosphatemia

ONGOING CARE

DIET
Nutrition consult for CKD diet (2)[C]

PATIENT EDUCATION
- Annual influenza vaccine unless contraindicated (2)
- Polyvalent pneumococcal vaccine if GFR <30 mL/min/1.73m² and those at high risk of pneumococcal infection (2)
- Hepatitis B vaccine with serologic confirmation if high risk of CKD progression and GFR <30 mL/min/1.73 m² (2)

PATIENT EDUCATION
PROGNOSIS

Risk of progression and complications is based on cause, GFR category, albuminuria category, and comorbid conditions (2)[B]. Progression defined as decline in GFR category with 25% decrease in GFR from baseline (2). Rapid progression is decrease in GFR by >5 mL/min/1.73 m²/year (2). Patients with CKD gradually progress to ESRD, with bad prognoses. 5-year survival rate for U.S. patients on dialysis is ~35%.

COMPLICATIONS

HTN, anemia, secondary hyperparathyroidism, renal osteodystrophy, sleep disturbances, infections, malnutrition, electrolyte imbalances, platelet dysfunction/bleeding, pseudogout, gout, metabolic calcification, sexual dysfunction

REFERENCES

SEE ALSO

- Hydronephrosis; Nephrotic Syndrome; Polycystic Kidney Disease; Proteinuria
- Algorithm: Anuria or Oliguria
CODES

ICD10
- N18.9 Chronic kidney disease, unspecified
- Q63.9 Congenital malformation of kidney, unspecified
- N18.3 Chronic kidney disease, stage 3 (moderate)

CLINICAL PEARLS
- CKD is defined based on >3 months of kidney functional or structural abnormalities and classified based on GFR and albuminuria.
- ACE-I and ARB are first line for HTN treatment in CKD with albuminuria.
- Care should be taken in prescribing medication in CKD due to reduced renal clearance of certain medications.
- Consider nonurgent nephrologist referral for GFR ≤59 and urgent nephrologist referral for GFR ≤29.
CHRONIC OBSTRUCTIVE PULMONARY DISEASE AND EMPHYSEMA

Alan Cropp, MD, FCCP • Michael A. Apostolis, MD

BASICS

DESCRIPTION
- Chronic obstructive pulmonary disease (COPD) usually describes a mixture of chronic bronchitis and emphysema. It is characterized by airflow limitation that is not fully reversible, inflammation, and is progressive (1,2).
- Chronic bronchitis is defined clinically by increased mucus production and recurrent cough present on most days for at least 3 months per year during at least two consecutive years without another cause.
- Emphysema, the destruction of interalveolar septa, occurs in the distal or terminal airways and involves both airways and lung parenchyma.

EPIDEMIOLOGY

Incidence
Affects >5% of adults in the United States and is the 12th leading cause of morbidity (1)

Prevalence
- Third leading cause of death in the United States (1)
- Projected to be the third leading cause of death globally by 2020 (2); 3.2 million deaths worldwide (2)

ETIOLOGY AND PATHOPHYSIOLOGY
Cigarette and/or cannabis smoking, air pollution (including indoor), antiprotease deficiency (α₁-antitrypsin), occupational exposure (firefighters), infection (viral), occupational pollutants (cadmium, silica)
- Impaired gas (carbon dioxide and oxygen) exchange
- Chronic bronchitis: airway obstruction (3)
- Emphysema: destruction of lung parenchyma
Genetics
- Chronic bronchitis is not a genetic disorder.
- Antiprotease deficiency (due to $\alpha_1$-antitrypsin deficiency) is an inherited, rare disorder due to two autosomal codominant alleles.

RISK FACTORS
- Smoking: passive smoking, especially adults whose parents smoked; cannabis use (one joint is equivalent to 2.5 to 5 cigarettes) (1–3)
- Severe pneumonia early in life including viral (4)
- Aging
- Lower level of education and poverty (4)
- Airway hyperactivity
- Indoor pollution (open fire for cooking or heating) (4)
- Occupational organic or inorganic dusts (4)

GENERAL PREVENTION
- Avoidance of smoking is the most important preventive measure.
- Early detection through pulmonary function tests (PFTs) in high-risk patients may be useful in preserving remaining lung function.

COMMONLY ASSOCIATED CONDITIONS
- Pulmonary: lung cancer, chronic respiratory failure, acute bronchitis, sleep apnea, pulmonary hypertension (HTN), asthma
- Cardiac: coronary artery disease, arrhythmia
- Ear/nose/throat (ENT): chronic sinusitis, laryngeal carcinoma
- Miscellaneous: malnutrition, osteoporosis, muscle dysfunction, depression

DIAGNOSIS
HISTORY
- Discuss patient’s use of tobacco and cannabis.
- Consider indoor pollution (coal furnace) (4).
- Review possible causes of exacerbation (e.g., recent infection) and history of cough, sputum, dyspnea.
- Chronic bronchitis: cough, sputum production, frequent infections, intermittent dyspnea, wheeze, hemoptysis, morning headache, pedal edema
- Emphysema: minimal cough, scant sputum, dyspnea, weight loss, occasional
infections

**PHYSICAL EXAM**
- Rarely diagnostic for COPD (2)
- Chronic bronchitis: cyanosis, wheezing, weight gain, diminished breath sounds, distant heart sounds
- Emphysema: barrel chest, minimal wheezing, accessory muscle use, pursed lip breathing, cyanosis slight or absent, breath sounds diminished

**DIFFERENTIAL DIAGNOSIS**
- Asthma (including occupational)
- Bronchiectasis
- Lung cancer
- Acute bronchitis
- Normal aging of lungs
- Chronic pulmonary embolism
- Sleep apnea
- Primary alveolar hypoventilation
- Chronic sinusitis
- Reactive airways dysfunction syndrome (RADS)
- Congestive heart failure (CHF)
- Bronchiolitis obliterans
- Gastroesophageal reflux disease
- Cystic fibrosis

**DIAGNOSTIC TESTS & INTERPRETATION**

*Spirometry (the most reliable/objective measurement of airflow obstruction) (1–3)[A]*

*Initial Tests (lab, imaging)*
- Spirometry (1–3) (see “Diagnostic Procedures”)
- Chronic bronchitis
  - Arterial blood gases (ABGs) may show hypercapnia and hypoxia.
  - Hemoglobin may be increased.
- Emphysema
  - Normal serum hemoglobin or polycythemia
  - Normal PaCO₂ on ABGs unless forced expiratory volume in 1 second (FEV₁) <1 L, in which case it can be elevated
– Mild hypoxia
– Chronic bronchitis CXR: increased bronchovascular markings and cardiomegaly
– Emphysema CXR: small heart, hyperinflation, flat diaphragms, and possibly bullous changes

**Follow-Up Tests & Special Considerations**
– Check continuous overnight oximetry in selected patients.
– \( \alpha_1 \)-Antitrypsin screening for those with COPD age <45 years, have a blood relative with this disease, or spirometry out of proportion to tobacco use
– Chest CT may show diffuse bullous changes or upper lobe predominance. Also, small lung nodules may be identified (5).

**Diagnostic Procedures/Other**
– PFTs (1,2)[A] – Not indicated during acute exacerbation (3)
– Decreased FEV\(_1\) and resulting reduction in FEV\(_1\):FVC (forced vital capacity) ratio
– Poor or absent reversibility to bronchodilator
– Normal or reduced FVC
– Normal or increased total lung capacity
– Increased residual volume and functional residual capacity
– Diffusing capacity is normal or reduced.
– Staging: Global Initiative for Obstructive Lung Disease (GOLD) criteria (3)
  – Mild COPD: FEV\(_1\) ≥80% predicted
  – Moderate COPD: FEV\(_1\) 50–80% predicted
  – Severe COPD: FEV\(_1\) 30–50% predicted
  – Very severe COPD: FEV\(_1\) <30% predicted or FEV\(_1\) <50% predicted plus chronic respiratory failure

**Test Interpretation**
– Chronic bronchitis: bronchial mucous gland enlargement, increased number of secretory cells in surface epithelium, thickened small airways from edema and inflammation, smooth muscle hyperplasia, mucus plugging, bacterial colonization of airways
– Emphysema: entire lung affected, bronchi usually clear of secretions, anthracotic pigment, alveoli enlarged with loss of septa, cartilage atrophy,
TREATMENT
GENERAL MEASURES

- Smoking cessation: This is the most important intervention to decrease risk (1,2)[A].
- Aggressive treatment of infections (3)[B]
- Treat any reversible bronchospasm.
- Home oxygen: may improve survival; should be initiated partial pressure of arterial oxygen (PaO\textsubscript{2}) \textless 55 mm Hg or pulse oximetry trends \textless 88% (1)[A]
- Influenza and pneumococcal immunizations (2)[B]
- Tiotropium (Spiriva) may slow disease progression (6)[B].

MEDICATION
Medications help reduce symptoms and exacerbations (1).

First Line
- All patients should have a short-acting \( \beta \)-agonist (albuterol) to use as a rescue drug (1).
- Anticholinergics (2)[A]
  - Ipratropium (Atrovent), tiotropium (Spiriva), aclidinium bromide (Tudorza) and/or
- Long-acting \( \beta \)-agonists
  - Salmeterol (Serevent), formoterol (Foradil), one inhalation q12h; or arformoterol (Brovana), formoterol (Perforomist), nebulized q12h (1,2)[A]

ALERT
Acute exacerbation: Use oxygen, inhaled \( \beta \)-agonists, inhaled anticholinergic agents, and oral or IV corticosteroids prednisone (up to 1 mg/kg/day commonly 40 mg/day for 5 days) (7)[A]. Antibiotics should be given for those with moderate/severe exacerbations showing clinical signs of bacterial infection (increased sputum volume, increased sputum purulence); optimal antibiotic therapy has not been determined (3)[B].

Second Line
- Trial of inhaled corticosteroids for moderate or severe disease (2)[A]
– May initiate earlier if suggestion of asthmatic component to disease
– Systemic corticosteroids: Prednisone (Deltasone) can be given orally 7.5 to 15.0 mg/day in selected patients.
– Long-term monotherapy with steroids (oral or inhaled) is not recommended (2,3)[A].
– Inhaled corticosteroids are associated with an increased risk of pneumonia (3).

Continuous home oxygen: may improve survival; should be initiated for severe resting hypoxemia (PaO₂ ≤ 55 mm Hg or oxygen saturation ≤ 88%) or PaO₂ 56 to 59 mm Hg with evidence of hypoxia (i.e., polycythemia or pulmonary HTN) or pulse oximetry trends ≤ 88% (1)[A]
– Theophylline if other long-term treatment is unavailable or unaffordable: 400 mg/day; increase by 100 to 200 mg in 1 to 2 weeks, if necessary (4)[B].
– Reduce dosage in patients with impaired renal or liver function, age > 55 years, or CHF.
– Monitor serum level. Therapeutic range is 8 to 13 μg/mL.
– Low-dose theophylline may help inflammatory component (4)[B].
– Combination of inhaled corticosteroid, long-acting β-agonist, and anticholinergic indicated for severe disease. Several combination medications are now available (2)[A].
– Combined LABA/LAMA is indicated for GOLD stage II COPD (2).
– Mucolytic agents may improve secretions but do not improve outcomes.
– Phosphodiesterase-4 inhibitor (PDE4) inhibitor (roflumilast) in severe chronic bronchitis may reduce exacerbations (2)[B].
– α₁-Antitrypsin, if deficient: 60 mg/kg/week to maintain level > 80 mg/dL
– Precautions
  – Sympathomimetics: excessive use may be dangerous. May need to reduce dosage or use levalbuterol (Xopenex) in patients with cardiovascular disease, HTN, hyperthyroidism, diabetes, or seizures.
  – Anticholinergics: narrow-angle glaucoma, benign prostatic hyperplasia, bladder neck obstruction
  – Corticosteroids: weight gain, diabetes, adrenal suppression, osteoporosis, infection (pneumonia)
– Sympathomimetics may be aerosolized.
– Anticholinergics: Ipratropium (Atrovent) may be aerosolized or combined with albuterol (Combivent Respimat).

ISSUES FOR REFERRAL
Severe exacerbation, frequent hospitalizations, age <40 years, rapid progression, weight loss, severe disease, or surgical evaluation

**ADDITIONAL THERAPIES**
- Adequate hydration and pulmonary hygiene
- Consider postural drainage, flutter valve, or other devices to assist mucus clearance.
- Pulmonary rehabilitation (1–3)[A]
- Intermittent, noninvasive ventilation (NIV) may help in severe chronic respiratory failure.
- Short course of antibiotics (5 to 10 days) for acute exacerbations (2)[B]
- Immunizations
- Supplemental oxygen if indicated

**SURGERY/OTHER PROCEDURES**
- Lung reduction surgery (selected cases)
- Lung transplantation (selected cases)

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Outpatient treatment is usually adequate.
- Exacerbation with acute decompensation (hypoxemia, hypercarbia)
- Serious comorbidities (i.e., decompensated CHF)
- Systemic steroids reduce recovery time and improve hypoxia (2,7)[A]
- Supplemental oxygen and short-acting bronchodilators should be given (3).

**ALERT**
If not already in place, have patient delineate an advance directive.

- Progressive nature of disease and severity of treatment methods (ventilation, etc.) make revisiting patient preferences beneficial.
- Acute respiratory failure may require ICU and invasive or NIV (2)[A].
- Systemic steroids (prednisone 40 mg/day for 5 days or equivalent) have been shown to reduce recovery time and improve hypoxia (7)[A].
- Teach proper inhaler use.
- Discharge criteria
  - Ability to ambulate (3)
  - Hypoxia can be treated with home oxygen (may only be temporary) (2)[A].
– Inhaled short-acting β-agonist therapy no more frequently than q4h (3)
– Ability to eat and sleep without interruption caused by dyspnea (3)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- May taper or stop oral steroids as outpatient
- If pneumonia caused exacerbation, need to follow CXR or chest CT until clear or stable
- Pulmonary rehabilitation for exertional dyspnea (1)[A]

Patient Monitoring

- Severe or unstable patients should be seen monthly. When stable, see every 6 months.
- Check theophylline level with dose adjustment and then check every 6 to 12 months.
- With use of home oxygen, check ABGs yearly or with change in condition. Frequently monitor saturation (pulse oximetry). Some patients only desaturate at night, thus only need nocturnal oxygen.
- Yearly spirometry
- Travel at high altitude with supplemental oxygen if necessary.

- Baseline chest CT for patients aged 55 to 74 years with a 30 pack/year smoking history to look for lung nodules (5)[B]
- Discuss advance directive and health care proxy.

DIET

A high-protein low-carbohydrate diet may benefit those with hypercarbia.

PATIENT EDUCATION

American Lung Association: www.lung.org/lung-disease/copd/

PROGNOSIS

- Patient’s age and postbronchodilator FEV₁ are the most important predictors of prognosis.
- Supplemental O₂, when indicated, is shown to increase survival (may only need at night) (1)[A].
Smoking cessation improves prognosis—consider E-cigarettes (2).
Malnutrition, cor pulmonale, hypercapnia, and pulse >100 indicate a poor prognosis.

COMPLICATIONS
- Malnutrition, poor sleep quality, infections, secondary polycythemia
- Acute or chronic respiratory failure, bullous lung disease, pneumothorax
- Arrhythmias, cor pulmonale, pulmonary HTN

REFERENCES
ADDITIONAL READING

SEE ALSO

Bronchitis, Acute

CODES

ICD10

- J44.9 Chronic obstructive pulmonary disease, unspecified
- J43.9 Emphysema, unspecified
- J42 Unspecified chronic bronchitis

CLINICAL PEARLS

- Consider screening PFTs on any high-risk patient.
- Overnight oximetry if daytime SaO₂ is borderline.
- Influenza/pneumococcal vaccines should be current.
- Advance directive before patient is seriously ill.
- Consider chest CT for patients age 55 to 74 years with a 30 pack/year smoking history for lung cancer screening.
CHRONIC PAIN MANAGEMENT: AN EVIDENCE-BASED APPROACH

Jennifer Reidy, MD, MS, FAAHPM • Delila Katz, PharmD, BCOP

BASICS

- Chronic pain is pain persisting beyond the time of normal tissue healing, usually >3 months.
- Over time, neuroplastic changes in the CNS transform pain into a chronic disease. Pain levels exceed pathology observed on exam or imaging.
- Pain experience is inherently related to emotional, psychological, and cognitive factors.
- Use an evidence-based, systems-based practice to safely and effectively prescribe any opioid medication, and only when indicated for chronic, nonmalignant pain.

EPIDEMIOLOGY

Incidence
Incidence is rising, but exact rate is unclear. The annual economic cost of chronic pain in the United States is estimated at $560 to $635 billion (1)[B].

Prevalence
In the United States, an estimated 50 million adults live with significant chronic or severe pain, according to the National Institutes of Health. People with severe pain are more likely to have worse health status, use more health care, and suffer more disability (2)[B].

ALERT
Caution: More people died from drug overdoses in 2016 than in any year on record. The majority of drug overdose deaths (more than 6 out of 10) involve an opioid. From 2000 to 2016, over half a million people died from drug overdoses (http://www.cdc.gov/drugoverdose/index.html) (3)[B].
ETIOLOGY AND PATHOPHYSIOLOGY

- With intense, repeated, or prolonged stimulation of damaged or inflamed tissues, the threshold for activating primary afferent pain fibers is lowered, the frequency of firing is higher, and there is increased response to noxious and/or normal stimuli (peripheral and central sensitization). The amygdala, prefrontal cortex, and cortex relay emotions related to the pain experience, and these areas undergo structural and functional changes with chronic pain.
- Patients often have an identifiable etiology (most commonly musculoskeletal problems or headache), but pain levels are often worse than observable tissue injury. Many patients have no obvious cause of chronic pain.

**Genetics**
Current research suggests a genetic polymorphism in opioid receptors; may affect patient’s response and/or side effects to individual opioids

**RISK FACTORS**
- Traumatic: motor vehicle accidents, repetitive motion injuries, sports injuries, work-related injuries, and falls
- Postsurgical: especially back surgeries, amputations, and thoracotomies
- Psychiatric comorbidities: substance abuse, depression, posttraumatic stress disorder (PTSD), personality disorders
- Aging: increased incidence with age but should not be considered a “normal” part of aging

**GENERAL PREVENTION**
- Prevent work-related injuries through the use of ergonomically correct workplace design.
- Exercise and physical therapy to help prevent work-related low back pain.
- Varicella vaccine and rapid treatment of shingles to lower risk of postherpetic neuralgia
- Tight glycemic control for diabetic patients, prevention of alcohol abuse, smoking cessation

**COMMONLY ASSOCIATED CONDITIONS**
Any chronic disease and/or its treatment can cause chronic pain, including diabetes, cardiovascular disease, HIV, progressive neurologic conditions, lung disease, cirrhosis, autoimmune disease, cancer, renal failure, depression, and mental illness.
DIAGNOSIS

Two general categories of pain:

- Nociceptive pain (two types)
  - Somatic: skin, bone, soft tissue disease; described as well localized, sharp, stabbing, aching
  - Visceral: visceral inflammation/injury; described as poorly localized, dull, aching; may refer to sites remote from lesion; can wax and wane
- Neuropathic pain: damaged peripheral or central nerves; described as burning, tingling, and/or numbness
  - Sympathetically mediated pain: Peripheral nerve injury can cause severe burning pain, swelling of the affected limb, and focal changes in sweat production and skin appearance (e.g., complex regional pain syndrome).

HISTORY

- Pain history: location, onset, intensity, duration, quality, temporal pattern, exacerbating agents, alleviators, prior treatments
- Screen for personal or family history of substance abuse (including tobacco addiction), mental health conditions, domestic violence, or sexual abuse.
- Standardized tools: pain severity—Brief Pain Inventory (short form); mood—Patient Health Questionnaire-9 (PHQ-9); substance abuse—Screener and Opioid Assessment for Patients with Pain (SOAPP), multiple versions
- Stratify patients for risks of chronic opioid therapy and need for increased monitoring; a positive screen does not automatically exclude patients from opioid therapy.

PHYSICAL EXAM

Exam is guided by history and includes functional and behavioral assessments.

DIFFERENTIAL DIAGNOSIS

- Multiple medical and surgical conditions can lead to chronic pain.
- Aberrant drug-taking behaviors:
  - Inadequate analgesia (“pseudoaddiction”), disease progression, opioid-resistant pain, opioid-induced hyperalgesia, addiction, opioid tolerance, self-medication of nonpain symptoms, criminal intent (diversion)
DIAGNOSTIC TESTS & INTERPRETATION
Base testing on history, exam, and differential diagnosis.

Initial Tests (lab, imaging)
- Urine drug screen: qualitative analysis for drugs of abuse and quantitative analysis for individual drugs (e.g., as part of prescription opioid contract)
- Most tests are immunoassays, which detect morphine and heroin but often not other opioids. Laboratory-based chromatography/spectrometry can identify specific drugs. Uses and limitations of laboratory testing are reviewed here: http://www.aafp.org/afp/2010/0301/p635.html.

Follow-Up Tests & Special Considerations
For chronic opioid therapy, order random urine drug screens (see “Ongoing Care”).

Diagnostic Procedures/Other
- Consider interventional pain clinic for complex injections and nerve blocks, which can be diagnostic.
- If complex regional pain syndrome is suspected, a sympathetic block can be diagnostic and possibly prevent chronic pain.

TREATMENT
- Goals of treatment are to restore function and decrease pain while balancing risks and benefits of therapies.
- Interdisciplinary teams offer the most effective approach to treating the physical, emotional, and behavioral aspects of chronic pain. These teams may include the patient, family, primary care doctor, nurse, pain management specialist, pharmacist, psychologist, psychiatrist, physical and occupational therapists, physiatrist, complementary medicine practitioners, social worker, and an addiction medicine specialist.
- Treatment should always include nonpharmacologic therapies such as exercise, cognitive-behavioral therapy (CBT), patient and family education, yoga, massage, relaxation techniques, support groups, meditation, and acupuncture.

GENERAL MEASURES
Keep a pain and function diary to record pain and activity level and medication use.

**MEDICATION**

- Always begin with exercise, physical therapy, CBT, and self-management skills. Use sequential time-limited trials of medications, start at low doses, and gradually increase until effect or dose-limiting side effects reached; rational polypharmacy (such as an opioid + neuropathic agent) if indicated (consult as necessary)
- For mild to moderate chronic pain
  - Acetaminophen: daily dose not to exceed total 4 g in healthy adults and 2 g in the elderly or those with hepatic disease or active or past history of alcohol use
  - NSAIDs: COX-2 selective inhibitors should be used with caution because of cardiac risks but may have less gastric risk. If high cardiac risk, consider nonselective COX inhibitor (such as naproxen) with or without gastric prophylaxis (depending on ulcer risk).
  - Tramadol: Caution: Opioid analgesic combinations can lead to serious acetaminophen or NSAID toxicities if patients exceed safely prescribed doses.
  - Topical agents: NSAIDs, lidocaine (gel is less expensive than patch), ketamine, capsaicin
- For neuropathic pain
  - Classes of medications include (i) tricyclic antidepressants (desipramine and nortriptyline have fewer side effects); (ii) serotonin-norepinephrine reuptake inhibitor (SNRI) antidepressants (duloxetine); (iii) anticonvulsants (alpha 2-delta ligands, gabapentin, and pregabalin); and (iv) opioids, including tramadol; example: combination of nortriptyline + gabapentin
  - See “Diagnosis.”
- For moderate to severe chronic pain
  - Morphine, oxycodone, hydromorphone, oxymorphone, fentanyl. Check opioid equianalgesic tables for dosing by route of administration.
  - No evidence supports any of these opioids as superior or having improved side effect profile.
  - In patients with chronic back pain, aberrant medication-taking behaviors range from 5% to 24%.
    - Avoid morphine in patients with renal insufficiency.
    - Methadone should be prescribed by experienced providers. The only opioid that also acts as N-methyl-D-aspartate receptor antagonist,
methadone has many drug interactions and can contribute to potentially fatal cardiac arrhythmias.

– Once stable dose of opioids is established, change to sustained-release formulations if pain is constant or very frequent. Short-acting formulations are only for breakthrough or episodic pain.

– Common side effects: constipation: Senna should be prescribed at time opioids are started; also nausea, sedation, mental status changes, and pruritus

– Coprescribe nasal naloxone for at-risk patients on chronic opioids (see “Ongoing Care”) (4)[C].

**ALERT**
Patients on chronic opioid therapy must agree to monitoring. Clinicians should use universal precautions and systems-based practice, including written agreements, random urine drug screens (testing for drugs of abuse and specifically for the drug prescribed), pill/patch counts, and other measures (see “Ongoing Care”) (4)[C].

**SURGERY/OTHER PROCEDURES**
Consider interventional procedures, including joint injections, nerve blocks, spinal cord stimulation, and intrathecal medication among others, as needed.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Acupuncture: efficacy in chronic neck and back pain and fibromyalgia
- Exercise: efficacy in low back pain and fibromyalgia
- Among adults with chronic low back pain, treatment with mindfulness-based stress reduction (MBSR) or CBT, compared with usual care, resulted in greater improvement in back pain and functional limitations at 26 weeks, with no significant differences in outcomes between MBSR and CBT (5)[A].
- Mind–body interventions: yoga, tai chi, hypnosis, progressive muscle relaxation, meditation

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
**Patient Monitoring**

- It can be difficult to identify appropriate pain relief–seeking behavior from inappropriate drug seeking, but consistent patient–clinician relationships over time can often discern the difference.
- Maintain a nonjudgmental, risk–benefit approach.
- Assess and document benefits, pain levels, functioning, and quality of life. In general, patients successfully taking opioids for pain become more engaged (better relationships and productive work).

**Universal precautions** is a systems-based approach that includes:
  - Informed consent for opioid therapy
  - Written or electronic agreement between patient and clinician
  - One prescribing clinician (or designee) and one pharmacy
  - No after-hours prescriptions or early refills
  - Mandatory police reporting for medication thefts
  - Random urine drug tests, pill/patch counts
  - Requirements for patient to continue with physical therapy, counseling, psychiatric medications, or other necessary treatments
  - Taper and discontinue medications (10% dose reduction per week) if patient does not benefit, if side effects outweigh benefits, or if medications are abused or diverted. If addiction is suspected, always offer treatment for substance abuse (4)[C].

- Nasal naloxone
  - Offer naloxone for patients at increased risk of opioid overdose: history of overdose, history of substance use disorder, concurrent benzodiazepine use, higher opioid doses.
  - Naloxone kit: two 1 mg/mL prefilled syringes with intranasal mucosal atomization device; takes effect in 2 to 5 minutes, lasts 30 to 90 minutes

**PATIENT EDUCATION**

American Chronic Pain Association: [https://theacpa.org](https://theacpa.org)

**COMPLICATIONS**

- Rate of addiction in chronic pain patients is estimated to be 3–19%.
- Definitions
  - Addiction: chronic biopsychologic disease characterized by impaired control over drug use, compulsive use, and continued use despite harm
– Physical dependence: withdrawal syndrome produced by abrupt cessation or rapid dose reduction; is not addiction but a physiologic phenomenon
– Tolerance: state of adaptation when a drug induces changes that diminish its effects over time
– Diversion: selling drugs or giving them to persons other than for whom they are prescribed

SCOPE of Pain (Safe and Competent Opioid Prescribing Education)—free online modules from Boston University School of Medicine:
https://www.scopeofpain.com

CODES
ICD10
- G89.29 Other chronic pain
- G89.21 Chronic pain due to trauma
- G89.28 Other chronic postprocedural pain
CLINICAL PEARLS

- Start with the presumption that a patient’s pain is real, even if pathophysiologic evidence is initially lacking.
- Emphasize that a pain-free life may not be possible but that better function and quality of life are shared goals.
- Use a multidisciplinary approach with nonpharmacologic therapies, exercise, self-management and thoughtful medication use with clear goals, expectations, and documentation of care plan.
- Universal precautions are a systems-based practice to safely and effectively prescribe opioids for chronic pain.
CIRRHOSIS OF THE LIVER
Kathleen M. Donahue, DO • Daniel B. MacHue, MD

BASICS
DESCRIPTION
A chronic hepatocellular disease with inflammation, necrosis, and fibrosis potentially leading to liver failure and/or cancer

EPIDEMIOLOGY
- Predominant age: 40 to 50 years old
- Predominant sex: male > female; more women get cirrhosis from alcohol abuse.
- Ninth leading cause of death among U.S. adults

ETIOLOGY AND PATHOPHYSIOLOGY
- Chronic hepatitis C (26%)
- Alcohol abuse (21%)
- Hepatitis C with alcoholic liver disease (15%)
- Nonalcoholic steatohepatitis (NASH)/obesity (~10%)
- Hepatitis B plus hepatitis D infection (15%)
- Other: hemochromatosis, autoimmune hepatitis, primary biliary cirrhosis, secondary biliary cirrhosis, primary sclerosing cholangitis, Wilson disease, α₁-antitrypsin deficiency, granulomatous disease (e.g., sarcoidosis); drug-induced liver disease (e.g., methotrexate, α-methylldopa, amiodarone); venous outflow obstruction (e.g., Budd-Chiari syndrome, veno-occlusive disease); chronic right-sided heart failure; tricuspid regurgitation; and rare genetic, metabolic, and infectious causes

Genetics
Hemochromatosis, Wilson disease, and α₁-antitrypsin deficiency in adults are associated with cirrhosis.

RISK FACTORS
Alcohol abuse, intravenous drug abuse, obesity, blood transfusion
GENERAL PREVENTION
- Mitigate risk factors (e.g., alcohol abuse); >80% of chronic liver disease is preventable.
- Limit alcohol consumption and advise weight loss in overweight or obese patients.
  - Elevated BMI and alcohol have an additive effect on liver disease (1).

COMMONLY ASSOCIATED CONDITIONS
Diabetes, alcoholism, drug abuse, depression, obesity

DIAGNOSIS

HISTORY
- Review risk factors (alcohol abuse, viral hepatitis, family history of primary liver cancer, other liver disease, or autoimmune disease)
- Symptoms
  - Fatigue, malaise, weakness
  - Anorexia, weight loss (weight gain if ascites/edema)
  - Right upper abdominal pain
  - Absent/irregular menses, chronic anovulation
  - Diminished libido, erectile dysfunction
  - Tea-colored urine, clay-colored stools
  - Edema, abdominal swelling/bloating
  - Bruising, bleeding, hematemesis, hematochezia, melena, pruritus
  - Night blindness

PHYSICAL EXAM
Physical exam may be normal until end-stage disease.
- Skin changes: spider angiomas, palmar erythema, jaundice, scleral icterus, ecchymoses, caput medusa, hyperpigmentation
- Hepatomegaly (small, fibrotic liver in end-stage disease)
- Splenomegaly (if portal hypertension)
- Central obesity
- Abdominal fluid wave, shifting dullness (ascites)
- Gynecomastia
- Dupuytren contractures
- Pretibial, presacral pitting edema and clubbing (especially in
hepatopulmonary syndrome)

- Asterixis, mental status changes
- Muscle wasting, weakness
- Fetor hepaticus with severe portal-systemic shunting

**DIFFERENTIAL DIAGNOSIS**
Steatohepatitis, other causes of portal hypertension (e.g., portal vein thrombosis, lymphoma); metastatic or multifocal cancer in the liver; vascular congestion (e.g., cardiac cirrhosis); acute alcoholic hepatitis

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- Aspartate aminotransferase/alanine aminotransferase (AST/ALT): mildly elevated, typically AST > ALT; enzymes normalize as cirrhosis progresses.
- Elevated alkaline phosphatase (ALP), gamma-glutamyl transpeptidase (GGT), and total/direct bilirubin
- Anemia from hemolysis, folate deficiency, and/or splenomegaly
- Decreased platelet count
- Impaired synthetic liver function
  - Low albumin and cholesterol
  - Prolonged prothrombin (PT), international normalized ratio (INR), partial thromboplastin time (PTT); vitamin K–dependent clotting factors (II, VII, IX, X)
- Progressive cirrhosis
  - Elevated ammonia level, BUN, sodium, and potassium
- α-Fetoprotein level to screen for hepatocellular carcinoma
- Abdominal ultrasound q6–12mo to screen for hepatocellular carcinoma
- Doppler ultrasound to assess liver parenchyma and hepatic/portal veins
- MRI best follow-up test for HCC if α-fetoprotein elevated and/or liver mass found on ultrasound

*Follow-Up Tests & Special Considerations*
Consider:

- Hepatitis serologies (particularly B and C)
- Serum ethanol and GGT if alcohol abuse suspected
- Antimitochondrial antibody to screen for primary biliary cirrhosis
- Anti-smooth muscle and antinuclear antibodies to screen for chronic active (autoimmune) hepatitis
Iron saturation (>50%) and ferritin (markedly increased) to screen for hemochromatosis; if abnormal, check hemochromatosis (HFE) genetics/mutation analysis.

- α₁-Antitrypsin phenotype screen
- Ceruloplasmin level to screen for Wilson disease; if low, check copper excretion (serum copper plus 24-hour urine copper).

**Diagnostic Procedures/Other**
- Liver biopsy: required for definitive diagnosis, percutaneous if INR <1.5 and no ascites; otherwise, transjugular; serologic testing gaining use as a surrogate for biopsy
- Ultrasound-based elastography: noninvasive alternative to liver biopsy, not widely available; relies on increased “stiffness” of abnormal tissue to evaluate for fibrosis
- Endoscopy if portal hypertension to rule out esophageal varices/portal hypertensive gastropathy (2)[C]

**Test Interpretation**
- Fibrous bands and regenerative nodules are classic biopsy features of cirrhosis.
- Other histologic findings vary with etiology.
  - Alcoholic liver disease: steatosis, polymorphonuclear (PMN) leukocyte infiltrate, ballooning degeneration of hepatocytes, Mallory bodies, giant mitochondria
  - Chronic hepatitis B and C: periportal lymphocytic inflammation
  - NASH: identical to alcoholic liver disease; steatosis may be absent in advanced disease (“burned-out NASH”).
  - Biliary cirrhosis: PMN infiltrate in wall of bile ducts, inflammation increased in portal spaces, progressive loss of bile ducts in portal spaces
  - Hemochromatosis: intrahepatic iron stores increased (iron stain or weighted biopsy tissue)
  - α₁-Antitrypsin deficiency: positive periodic acid–Schiff (PAS) bodies in hepatocytes

**TREATMENT**
Outpatient care except for major GI bleeding, altered mental status,
sepsis/infection, rapid hepatic decompensation, and renal failure

GENERAL MEASURES

- Abstain from alcohol, drugs, hepatotoxic medications, and hepatotoxic herbs.
- Pneumococcal, hepatitis A/B, and influenza vaccines
- NASH: weight reduction, exercise, optimal control of lipids/glucose

MEDICATION

First Line

Treat the underlying cause first (note prescribing precautions in decompensated cirrhosis).

- Hepatitis C: Goal is to eradicate hepatitis C virus (HCV) RNA in serum. Combination therapy of pegylated interferon (PEG-IFN) with ribavirin is the standard for most genotypes. Latest therapies are genotype dependent. Typical regimens with or without cirrhosis include sofosbivir-ledipasivir and elbasivir-grazopavir for up to 12 weeks duration.
- Hepatitis B: Goal of treatment is to achieve HBeAg seroconversion. Adefovir 10 mg PO daily, entecavir 0.5 to 1.0 mg PO daily, telbivudine 600 mg PO daily, or lamivudine 100 mg PO daily for minimum of 1 year or continue for at least 6 months after HBeAg seroconversion; alternatively, PEG-IFN α-2a 180 μg SC weekly for 48 weeks. Lamivudine is no longer recommended as first-line agent due to high rates of resistance.
- Alcoholic hepatitis: Treat ethyl alcohol (EtOH) withdrawal; calculate Maddrey discriminant function score for risk stratification; >32 indicates poor prognosis, and patients may benefit from prednisolone 40 mg/day for 28 days with 2 to 4 weeks taper to reduce short-term mortality; pentoxifylline for patients who cannot tolerate steroids.
- Biliary cirrhosis: ursodeoxycholic acid (ursodiol) 13 to 15 mg/kg PO divided BID–QID with food (3)[A]; bile acid sequestrants (BAS) are first-line therapy for pruritus: cholestyramine 4 to 8 g PO BID; antihistamines; rifampicin 150 to 300 mg PO BID or opiate antagonists such as naltrexone 50 mg/day can be used for pruritus if ursodiol is ineffective.
- Wilson disease: initial treatment with penicillamine 1,000 to 1,500 mg/day PO BID–QID or trientine 750 to 1,500 mg/day PO BID–TID on empty stomach. Trientine (Syprine) is better tolerated. After 1 year, zinc acetate 150 mg/day PO BID–TID for maintenance; zinc for presymptomatic, pregnant, and pediatric populations
- Autoimmune (chronic active) hepatitis: prednisolone 30 to 60 mg/day initially,
maintenance 5 to 20 mg/day with or without azathioprine (Imuran) 0.5 to 1.0 mg/kg; adjust to keep transaminase levels normal. The combination is preferred. Discontinue maintenance after at least 24 months of treatment if AST and ALT are normal.

- **Esophageal varices:** for primary prophylaxis of variceal bleed, propranolol 40 to 160 mg or nadolol 40 mg daily, to lower portal pressure by 20 mm Hg, systolic pressure from 90 to 100 mm Hg, and pulse rate by 25% (2)[A]
- **Ascites/edema:** low-sodium (<2 g/day) diet and spironolactone 100 to 400 mg/day with or without furosemide 40 to 160 mg/day PO; torsemide may substitute for furosemide. If new onset, rule out SBP. If history of SBP, consider SBP prophylaxis (TMP-SMX DS daily, norfloxacin 400 mg PO daily).
- **Encephalopathy:** lactulose 15 to 45 mL BID; titrate to induce three loose bowel movements daily. Combination therapy with rifaximin (550 mg PO BID) is recommended regimen to prevent recurrent hepatic encephalopathy (4)[B].
- **Pruritus:** ursodiol, cholestyramine, or antihistamines (e.g., hydroxyzine)
- **Renal insufficiency:** Stop NSAIDs, diuretics, and nephrotoxic drugs; normalize electrolytes; and hospitalize for plasma expansion or dialysis.
- **Prophylactic antibiotics for invasive procedures, GI bleeding, or history of spontaneous bacterial peritonitis (2)[A]
- **Proton pump inhibitor for esophageal varices requiring banding or portal hypertensive gastropathy (5)[A]

**ISSUES FOR REFERRAL**
Evaluate for liver transplant at onset of complications (ascites, variceal bleeding, encephalopathy), jaundice, or liver lesion suggestive of hepatocellular carcinoma and/or when evidence of hepatic dysfunction develops (Child-Turcotte-Pugh >7 and Model for End-stage Liver Disease [MELD] >10).

**SURGERY/OTHER PROCEDURES**
- **Varices:** endoscopic ligation, 4 to 6 treatments (if acute bleed, use pre-esophagogastroduodenoscopy [EGD] octreotide as vasoconstrictor); transjugular intrahepatic shunt (TIPS) second-line or salvage therapy for acute bleed (2)
- **Ascites:** if tense, therapeutic paracentesis every 2 weeks PRN; caution if pedal edema absent.
- **Fulminant hepatic failure:** liver transplantation
Hepatocellular carcinoma: curable if small with radiofrequency ablation or resection and transplant

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Zinc sulfate 220 mg BID may improve dysgeusia and appetite; adjunct for hepatic encephalopathy
- Milk thistle may lower transaminases and improve symptoms.
- Danshen and huang qi injections may promote improvement; further studies needed

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Major GI bleeding, altered mental status, sepsis/infection, rapidly progressing hepatic decompensation, renal failure

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Regular physical conditioning may help with fatigue.

Patient Monitoring
- Once stable, monitor liver enzymes, platelets, and PT q6–12mo.
- Patients >55 years with chronic hepatitis B or C, elevated INR, or low platelets are at highest risk for HCC; serial α-fetoprotein and liver ultrasound screening q6–12mo in patients with cirrhosis
- Endoscopy at diagnosis and every 3 years (compensated) and every 1 year (decompensated) to screen for varices

DIET
Protein (1.0 to 1.5 g/kg body weight), high fiber, daily multivitamin (without iron), sodium restriction (<2 g/day), combined with fluid restriction, essential if ascites/edema

PATIENT EDUCATION
- Educate about when to seek emergency care (e.g., hematemesis, altered
mental status).
- Maintain sobriety and smoking cessation (no cannabis).
- Update required immunizations; hepatitis C transmission precautions

PROGNOSIS
- 5 to 20 years of asymptomatic disease from time of initial diagnosis
- After onset of complications, death typically within 5 years without transplant
  - 5% per year develop HCC.
  - 50% of cirrhotics develop ascites over 10 years; 50% 5-year survival after ascites develop
  - Acute variceal bleeding is the most common fatal complication; 30% mortality
  - Median survival after complications (ascites, variceal bleeding, encephalopathy) develop is 1.5 years.
  - With transplant, 85% survive 1 year; after transplant, ~5% annual mortality
- <25% of eligible patients receive a transplant because of donor organ shortage.

COMPLICATIONS
Ascites, edema, infections, encephalopathy, GI bleeding, esophageal varices, gastropathy, colopathy, hepatorenal syndrome, hepatopulmonary syndrome, hepatocellular carcinoma, fulminant hepatic failure, complications after transplant (e.g., surgical, rejection, infections)

Algorithm: *Cirrhosis*

**CODES**

**ICD10**

- K74.60 Unspecified cirrhosis of liver
- K70.30 Alcoholic cirrhosis of liver without ascites
- K74.69 Other cirrhosis of liver

**CLINICAL PEARLS**

- 80% of chronic liver disease that leads to cirrhosis is preventable (primarily alcohol abuse).
- After diagnosis of cirrhosis, abdominal ultrasound every 6 months for early detection of hepatocellular carcinoma
- Update necessary immunizations and treat underlying cause (hepatitis C, alcohol abuse, etc.).
CLOSTRIDIUM DIFFICILE INFECTION
Sally-Ann L. Pantin, MD, FAAFP • Thomas A. Waller, MD

BASICS

DESCRIPTION
- A gram-positive, spore-forming anaerobic bacillus that releases toxins to produce clinical disease
- Infection caused by Clostridium difficile is frequently associated with antibiotic use, hospitalization, residence at long-term care facilities, and age.
- Severity of infection can range from diarrhea to pancolitis, perforation, and death.
- System(s) affected: gastrointestinal
- Synonyms(s): C. difficile–associated disease or diarrhea (CDAD); C. difficile infection; C. difficile colitis; C. diff

EPIDEMIOLOGY

Incidence
- C. difficile is a common hospital-acquired infection. The incidence is rising (1).
- There are ~15 new cases per 1,000 clinical discharges; higher with increased age (2)
- Rates of complications are also increasing (1).

Prevalence
- C. difficile causes ~25% of all cases of antibiotic-associated diarrhea.
- Prevalence of community-acquired C. difficile infection is increasing. Up to 40% of patients require hospitalization (2).
- C. difficile is a commensurate organism in 2–5% of the adult U.S. population.

ETIOLOGY AND PATHOPHYSIOLOGY
- C. difficile is an anaerobic toxin-producing, gram-positive bacillus bacteria existing in vegetative and spore forms.
- Spores can survive for months in harsh conditions and outside of the body.
Spread by fecal–oral contact. Acid-resistant spores pass through stomach to reside mostly in the colon.

Colonic colonization causes disruptions in barrier functions of the normal microbiome (2).

C. difficile is noninvasive. Toxins mediate disease:
– Toxins A (enterotoxin) and B (cytotoxin) attract neutrophils and monocytes, degrading colonic epithelial cells and causing clinical disease.

The hypervirulent strain BI/NAP1/027 of C. difficile produces a much more virulent form of disease. It is associated with higher rates of colectomy and death.

Genetics
No known genetic factors

RISK FACTORS

Host risk factors
– Age >65 years
– Hospitalization or long-term health care facility
– Comorbidities, including inflammatory bowel disease, immunosuppression, chronic liver disease, and end-stage renal disease
– Enteral feeding
– Previous C. difficile infection

Factors that disrupt normal colonic microbiota:
– Exposure to antibiotics (including perioperative prophylaxis) increases risk for C. difficile infection.
– Commonly implicated antibiotics: ampicillin, amoxicillin, clindamycin (most common), cephalosporins, and fluoroquinolones
– Chronic acid suppression may allow more bacteria to reach the colon (2).

Recurrence from prior infection
– Recurrence rates are ~20%; recurrence more likely with each additional episode (2)

Can colonize ileum in patients with prior colectomy

Community-acquired C. difficile infections (no overnight admission in >12 weeks) are more frequent in patients without other risk factors (younger, no recent antibiotic exposure).

Geriatric Considerations
C. difficile is the most common cause of acute diarrheal illness in long-term care
facilities. Elderly patients often have multiple risk factors (comorbid disease, antibiotic exposure, medication use).

**Pediatric Considerations**
- Neonates have a higher rate of *C. difficile* colonization (25–80%) but are generally less symptomatic than adults (possibly due to immature toxin receptors).
- Frequently serve as carrier for infection in adults

**GENERAL PREVENTION**
- Antibiotic stewardship program decreases the incidence of *C. difficile* infection.
- 2010 Society for Healthcare Epidemiology of America (SHEA)/Infectious Diseases Society of America (IDSA) guidelines (3):
  - For health care workers, patients, and visitors:
    - Contact precautions, including gloves and gowns, on entry to room
    - Alcohol-based hand sanitizers are not effective. Hand washing with soap and water before and after patient interaction is recommended.
    - Accommodate patients with *C. difficile* infection in private rooms, if possible.
  - Environmental cleaning and disinfection
    - Disinfect with hypochlorite or other spore-killing solution.
    - Identify and reduce environmental sources of *C. difficile*, including the use of nondisposable rectal thermometers
  - Antimicrobial restrictions
    - Minimize the frequency and duration of antibiotic therapy. Use particular care when prescribing commonly implicated antibiotics.

**COMMONLY ASSOCIATED CONDITIONS**
Pseudomembranous colitis, toxic megacolon, sepsis, colonic perforation

**DIAGNOSIS**

**HISTORY**
- Age and underlying comorbidities
- Recent antibiotic use
- Diarrhea (defined as >3 stools in 24 hours) that is watery, foul-smelling, and
sometimes bloody (1)
- Fever (<10%), anorexia, nausea
- Recent hospitalization or stay at nursing facility

**PHYSICAL EXAM**
- Mild or moderate: cramping and lower abdominal pain
- Severe: fever, nausea/vomiting, dehydration
- Severe, complicated: shock, peritonitis, ileus

**DIFFERENTIAL DIAGNOSIS**
- Acute abdomen
- Antibiotic-associated diarrhea
- Inflammatory bowel disease
- Enteric infections
- Foodborne illness

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- The optimal diagnostic test is unclear (4).
- **C. difficile** can be identified by polymerase chain reaction (PCR)-based testing; rapid, highly sensitive, and highly specific (2)[B]
- **C. difficile** products can be identified by immunoassays or nucleic acid amplification test (NAAT):
  - Glutamate dehydrogenase (GDH) antigen, in both toxic and nontoxic strains of **C. difficile** (sensitivity, 85–95%; specificity, 89–99%)
  - Toxins (A/B or A); rapid, inexpensive, easy to use (sensitivity 63–94%)
- Stool culture is the most sensitive; non–toxin-producing strains are also detected.
- Repeat testing during the same episode of diarrhea is not recommended. Stool carriage persists for 3 to 6 weeks after successful treatment (2)[A].
- Routine radiologic examination is not recommended in the absence of signs of systemic disease or clinical suspicion for complicated/severe disease.
  - Plain films may show thumbprinting and colonic distension.
  - CT may show mucosal thickening, colonic wall thickening, pericolonic inflammation, or signs of complicated infection in severe cases (i.e., extraluminal air).

**Diagnostic Procedures/Other**
Endoscopy can evaluate for presence of pseudomembranes and exclude other conditions.

- Although not all patients with *C. difficile* infection have pseudomembranes, their presence is pathognomonic for *C. difficile*.
- Flexible sigmoidoscopy may miss 15–20% of pseudomembranes (from the proximal colon).

**Test Interpretation**

SHEA/IDSA guidelines (3)

- Mild or moderate disease: leukocytosis with white blood cell (WBC) count <15,000 cells/μL and a serum creatinine level <1.5× the premorbid level
- Severe, uncomplicated disease: leukocytosis with WBC count >15,000 cells/μL or a serum creatinine level >1.5× the premorbid level
- Severe, complicated disease: hypotension, sepsis, markedly elevated WBC count, and imaging findings of complicated disease

**TREATMENT**

**GENERAL MEASURES**

- Antimotility agents are contraindicated.
- Avoid indiscriminate use of antibiotics.
- Proton pump inhibitors are associated with recurrent infection but have not been shown to be causal.
- Discontinue offending antibiotic, whenever possible.

**MEDICATION**

**First Line**

- Mild or moderate infection (4)[A]
  - Oral metronidazole is the drug of choice for mild to moderate *C. difficile* infection:
    - 500 mg PO three times daily for 10 to 14 days
    - If patient is unable to take oral medications, then intravenous (IV) metronidazole or intraluminal (oral) vancomycin can be used.
- Severe infection (4)[A]
  - Enteral vancomycin is first-line therapy in patients with severe *C. difficile* infection:
125 mg PO 4 times daily for 10 to 14 days
- Vancomycin retention enema if unable to take PO or if there is evidence of poor gastrointestinal motility

### Severe, complicated infection—consider surgical and critical care consultation (4)[A]
- Vancomycin: 500 mg PO 4 times daily and metronidazole 500 mg PO 3 times daily. Consider vancomycin retention enemas.

### First recurrence
- Treat the same as first episode.

### Second recurrence
- Vancomycin taper and/or pulse: vancomycin 125 mg PO QID for 10 to 14 days, then 125 mg PO BID for 7 days, then 125 mg PO once daily for 7 days, and then 125 mg PO every 2 to 3 days for 2 to 8 weeks:
  - Pulse dosing every 2 to 3 days allows spores to germinate and then be killed.

### ALERT
When using vancomycin to treat *C. difficile* infection, use oral or rectal formulations. IV formulations (not excreted into the colonic lumen) are ineffective.

### Second Line
- Vancomycin: for patients who cannot tolerate or have failed metronidazole therapy and for pregnancy
- Fidaxomicin 200 mg PO BID × 10 days; similar cure rates to vancomycin with lower recurrence rates due to its narrow antimicrobial spectrum (4)[A]
- Fecal transplant: stool from healthy, screened donor. Administered via either rectal or oral route. Highly effective for recurrent infections (80–90% cure rate) after offending antibiotic stopped. Recipient gut flora transformed in as few as 3 days following fecal transplantation (5)[A].

### SURGERY/OTHER PROCEDURES
- Severe abdominal pain or signs of hemodynamic instability in the setting of known infection should prompt surgical and critical care consultation.
- Perforation of the colon (4)[A]

### ALERT
BI/NAP1/027 strain is commonly associated with fulminant colitis, often requiring surgical intervention in younger patients with severe disease.
COMPLEMENTARY & ALTERNATIVE MEDICINE

- Adjunctive therapy with IV immunoglobulin (IVIG) has shown promise. More data are required before routine clinical use.
- Probiotics *Lactobacillus acidophilus* and *Saccharomyces boulardii* have inhibitory effects on *C. difficile* and can help prevent.
- Other investigational treatments:
  - Newer antibiotics (rifalazil, tolevamer, and ramoplanin)
  - Monoclonal antibodies to modulate toxin effects
  - Vaccine form of *C. difficile* antitoxin antibody

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization
  - Hypovolemia
  - Inability to keep up with enteric losses
  - Hematochezia
  - Electrolyte disturbances
- IV fluids to maintain volume status
- Discharge criteria
  - Decreased diarrhea severity and frequency
  - Tolerating oral diet and medications

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Do not repeat testing for toxins, as patients may shed for weeks following an acute infection.

*Patient Monitoring*

- Relapses of colitis occur in 15–30%.
- Relapses typically occur 2 to 10 days after discontinuing antibiotics.

DIET

- Regular diet
- NPO if severe colitis and surgical evaluation pending
PATIENT EDUCATION
Educate patients about *C. difficile* transmission, the importance of hand washing and not relying on alcohol-based sanitizers, and the appropriate use of antibiotics.

PROGNOSIS
- Most patients improve with conservative management and oral antibiotics.
- 1–3% of patients develop severe/fulminant colitis requiring emergency colectomy.

REFERENCES

ADDITIONAL READING

CODES

ICD10
A04.7 Enterocolitis due to Clostridium difficile

CLINICAL PEARLS

• C. difficile is spread by fecal–oral contact.
• Alcohol-based hand sanitizers are ineffective against C. difficile. Wash hands with soap and water.
• Testing and treatment of asymptomatic patients is not recommended.
• C. difficile and organismal by-products (e.g., toxin) are identifiable from stool samples.
• Patients may shed organism or toxin for weeks after treatment. Repeat toxin assays following treatment are not helpful.
• Metronidazole remains the drug of choice for mild to moderate disease.
COLIC, INFANTILE

Daniel T. Lee, MD, MA • Arthur Ohannessian, MD

BASICS

DESCRIPTION

- Colic is defined as excessive crying in an otherwise healthy baby.
- A commonly used criteria is the Wessel criteria or the Rule of Three, when crying lasts for:
  - >3 hr/day
  - >3 days/week
  - Persists >3 weeks
- Many clinicians do not strictly adhere to the criterion of persistence for >3 weeks, as few parents or clinicians will wait that long before evaluation or intervention.
- Some clinicians feel that colic represents the extreme end of the spectrum of normal crying, whereas most feel that colic is a distinct clinical entity.

EPIDEMIOLOGY

Incidences

- Predominant age group is between 2 weeks and 4 months of age.
- Equal predominance among males and females

Prevalence

Wide range between 8% and 40% of infants, however more likely affects between 10% and 25% of infants

Pediatric Considerations

This is a problem during infancy.

ETIOLOGY AND PATHOPHYSIOLOGY

The cause is unknown. Factors that may play a role include the following:

- Infant gastroesophageal reflux disease
- Allergy to cow’s milk, soy milk, or breast milk protein
- Fruit juice intolerance
Swallowing air during the process of crying, feeding, or sucking
- Overfeeding or feeding too quickly; underfeeding has also been proposed.
- Inadequate burping after feeding
- Family tension
- Parental anxiety, depression, and/or fatigue
- Parent–infant interaction mismatch
- Baby’s inability to console him- or herself when dealing with stimuli
- Increases in the gut hormone motilin, causing hyperperistalsis
- Functional lactose overload (i.e., breast milk that has a lower lipid content can have faster transit time in the intestine, leading to more lactose fermentation in the gut and hence gas and distension)
- Tobacco smoke exposure

RISK FACTORS
- Physiologic predispositions in an infant may play a role, but no definitive risk factors have been established.
- Emerging data suggest maternal smoking or exposure to nicotine replacement therapy during pregnancy is associated with higher incidence of infantile colic.
- Infants with a maternal history of migraine headaches are twice as likely to have colic.

GENERAL PREVENTION
Colic is generally not preventable.

DIAGNOSIS

HISTORY
- Evaluation for Wessel criteria: Crying lasts for >3 hr/day, >3 days/week, and persists >3 weeks.
- Episodes usually have a clear beginning and end.
- The crying is generally spontaneous, without preceding events triggering the episodes.
- The crying is typically different from normal crying. Colicky crying may be louder, more turbulent, variable in pitch, and appears more like screaming.
- The infant may be difficult to soothe or console despite all of the parents’ efforts.
- The infant acts normally when not colicky.
- Assess the support system of caregivers and families, including coping skills.

**PHYSICAL EXAM**
- A comprehensive physical exam is normal.
- Because excessive crying may be a risk factor for abuse, be sure to examine the child carefully for signs of shaken baby syndrome or other types of child abuse.

**DIFFERENTIAL DIAGNOSIS**
Any organic cause for excessive or qualitatively different crying in infants such as:
- Infectious causes such as meningitis, sepsis, otitis media, or UTI
- Gastrointestinal causes such as gastroesophageal reflux disease, intussusception, lactose intolerance, constipation, anal fissure, or strangulated hernia
- Trauma, which includes foreign bodies, corneal abrasion, occult fracture, digit or penile hair tourniquet syndrome, or child abuse

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
Infantile colic is a clinical diagnosis. No testing is typically performed unless clinical symptoms imply other causes (UTI, weight loss, etc.).

*Diagnostic Procedures/Other*
A thorough history and physical exam should be performed to rule out other causes. Otherwise, no diagnostic procedures or imaging are indicated.

**TREATMENT**

**GENERAL MEASURES**
- Soothe by holding and rocking the baby (1)[B].
- Use a pacifier (1)[B].
- Use of gentle rhythmic motion (e.g., strollers, infant swings, car rides) (1)[B]
- Place near white noise (e.g., vacuum cleaner, clothes dryer, white noise machine) (1)[B].
Crib vibrators or car ride simulators have not proven to be helpful (1)[B].
Increased carrying or use of infant carrier has not been shown to improve colic (1)[B].
Burping does not significantly lower colic events.
Employ the 5 Ss (need to be done concurrently):
- Swaddling: tight wrapping with blanket; may be especially beneficial in infants <8 weeks old (2)[B]
- Side: laying baby on side
- Shushing: loud white noise
- Swinging: rhythmic, jiggle motion
- Sucking: on a nipple, finger, or pacifier

MEDICATION
- No medication has been found to be universally beneficial in treating infantile colic. Probiotics are safe and effective. Their use is discussed in the “Complementary & Alternative Medicine” section.
- Dicyclomine (Bentyl) has been proven beneficial, but the potential serious adverse effects, such as apnea, seizures, and syncope, have precluded its use. Furthermore, the manufacturer has made the medication contraindicated for infants <6 months (3)[B].
- Simethicone has not been shown to be beneficial (3)[B].
- Omeprazole has not been shown to be beneficial.

ISSUES FOR REFERRAL
Excessive vomiting, poor weight gain, recurrent respiratory diseases, or bloody stools should prompt referral to a specialist.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Recent data from a large randomized controlled study involving nine neonatal units in Italy found that prophylactic use of *Lactobacillus reuteri* was beneficial. At 3 months of age, the mean duration of crying time (38 vs. 71 minutes; *p* < .01), the mean number of regurgitations per day (2.9 vs. 4.6; *p* < .01), and the mean number of evacuations per day (4.2 vs. 3.6; *p* < .01) for the *L. reuteri* DSM 17938 and placebo groups, respectively, were significantly different (4)[A]. A possible mechanism of action for this intervention may be related to the fact that colic in infants is associated with low-grade systemic inflammation. Thus, specific bacterial species beyond conventional probiotics...
may have anti-inflammatory properties that may help to modulate microbiota and alleviate colic-related inflammation.

- However, the effect of *L. reuteri* has not been as robust in infants already diagnosed with colic. A placebo-controlled study of 50 infants given *L. reuteri* had significantly reduced median daily crying times throughout the study (370 to 35 min/day vs. 300 to 90 min/day in placebo group). However, weight gain, stooling frequency, and incidence of regurgitation were similar in both groups (5)[B].

- *L. reuteri* is available as over-the-counter drops; however, it is not regulated by the FDA.

- Anecdotal evidence that car rides, both real and simulated, can be effective. You can find a 10-hour recording of a simulated car ride at the following link: [https://www.youtube.com/watch?v=8KAXmIe-T_4](https://www.youtube.com/watch?v=8KAXmIe-T_4).

- Running a vacuum cleaner near the baby may be effective.

- Herbal teas and supplements may help but are not recommended because of limited, inconclusive evidence.
  - Herbal teas containing mixtures of chamomile, vervain, licorice, and balm-mint used up to TID may be beneficial. However, the study used high dosages, raising clinical concerns that this therapy may impair needed milk consumption in infants and be impractical to administer. In addition, preparations used in the study may not be commercially available in the United States.
  - There is evidence supporting the effectiveness of different preparations of fennel, such as oils, teas and herbal compounds, in treating infantile colic (6)[A].

- A home-based intervention focusing on reducing infant stimulation and synchronizing infant sleep–wake cycles with the environment, as well as parental support, has been shown to be effective.

- Use of music may help.

- Chiropractic treatment has shown no benefit over placebo.

- Infant massage has not been shown to be helpful.

---

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Frequent outpatient visits as needed for parental reassurance, education, and monitoring and to ensure the health of the infant and parents.
**Patient Monitoring**
Follow for proper feeding, growth, and development.

**DIET**
- **If breastfeeding:**
  - Continue breastfeeding; switching to formula unlikely to help
  - Possible therapeutic benefit from eliminating milk products, eggs, wheat, nuts, soy, and/or fish from the maternal diet of breastfeeding mothers (1)[B]
- **If formula feeding:**
  - Feeding the infant in a vertical position using a curved bottle or bottle with collapsible bag may help to reduce air swallowing.
  - If no intervention or dietary change has been effective, consider a 1-week trial of hypoallergenic formulas such as whey hydrolysate (e.g., Good Start) or casein hydrolysate (e.g., Alimentum, Nutramigen, Pregestimil) (1)[B],[3][C].
  - Adding fiber to formula also has not been shown to be helpful (1)[B].
- Supplementing with sucrose solution may be helpful, but the effect may be short-lived (<1 hour) (1,3)[B].
- Despite the proposed mechanism of functional lactose overload, use of lactase enzymes in formula or breast milk or given directly to the infant has no therapeutic benefit (1)[B].

**PATIENT EDUCATION**
- Reassure parents that colic is not the result of bad parenting, and advise parents about having proper rest breaks, adequate sleep, and help in caring for the infant.
- Explain the spectrum of crying behavior.
- Avoid over- or underfeeding.
- Instruct parents regarding beneficial feeding techniques such as improved bottles (low air, curved) and sufficient burping after feeding.
- Information for parents of colicky infants can be found at the following link from the American Academy of Family Physician:

**PROGNOSIS**
- Usually subsides by 3 to 6 months of age, often on its own
- Despite apparent abdominal pain, colicky infants eat well and gain weight normally.
A few studies indicate temper tantrums may be more common among formerly colicky infants as studied in toddlers up to 4 years old. Colic has no bearing on the baby’s intelligence or future development.

COMPLICATIONS

- Colic is self-limiting and does not result in lasting effects to infant or maternal mental health.
- However, case-control studies have shown an increased incidence of diagnosing childhood migraine headaches in patients with a history of colic during infancy.

CODES

ICD10
R10.83 Colic

CLINICAL PEARLS

- Colic is defined as excessive crying in an otherwise healthy baby (3 hr/day, 3 day/week, persists >3 weeks).
- Excessive crying may be a risk factor for shaken baby syndrome or other forms of child abuse.
- Usually subsides spontaneously by 3 to 6 months of age
- Provide advice, support, and reassurance to parents.
- Prevent caregiver burnout by advising parents to get proper rest breaks, sleep, and help in caring for the infant.
- Employ the 5 Ss (need to be done concurrently):
  - Swaddling: tight wrapping with blanket
  - Side: laying baby on side
  - Shushing: loud white noise
  - Swinging: rhythmic, jiggle motion
  - Sucking: on a nipple, finger, or pacifier
BASICS

Ischemic colitis (IC) results from decreased blood flow to the colon with resultant inflammation and tissue damage.

DESCRIPTION

- More common in the elderly; can affect patients of all ages
- Patients present in several ways:
  - Nonacute IC from a chronic process with irreversible ischemic injury
  - Acute IC—self-limited transient mucosal ischemia
- IC is self-limited and reversible in 80% of patients:
  - 20% of patients progress to full-thickness necrosis requiring surgical intervention.
- Most commonly, ischemia is related to a nonocclusive reduction in blood flow.
- Presentation varies, but patients with acute IC typically present with localized abdominal pain and tenderness. Frequent loose, bloody stools may be seen within 12 to 24 hours of onset.
- Laboratory and radiographic findings are nonspecific and must be correlated with clinical presentation.
- Colonoscopy is the gold standard for diagnosis of IC.
- In the absence of complications, most patients recover with supportive care including IV fluids, bowel rest, and clinical monitoring.

EPIDEMIOLOGY

- Men and women are at equal risk.
- Evidence of IC seen in 1 of every 100 endoscopies

Geriatric Considerations

Rare in patients <60 years old. 70 years is the average age at diagnosis.

Incidence
4.5 to 44 cases per 100,000 in the general population
1 of every 2,000 hospital admissions
True incidence may be underestimated due to nonspecific clinical manifestations.

**Prevalence**
19 cases per 100,000 in the general population

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Local hypoperfusion in the colon compromises the ability to meet metabolic demands. Reperfusion injury may also play a role.
- Most commonly, an acute, self-limited process
- The colon is perfused by both the superior and inferior mesenteric arteries (SMAs and IMAs) and branches of the internal iliac arteries. Occlusion of branches of the SMA or IMA rarely leads to ischemic consequences due to extensive collateral circulation.
- Watershed areas of the colon (splenic flexure and rectosigmoid junction) are most susceptible to ischemic damage. Blood is carried by narrow branches of the SMA and IMA to these areas, putting them at increased risk for ischemia. The splenic flexure is supplied by the terminal branches of the SMA, and the rectosigmoid junction is supplied by the terminal branches of the IMA.
- Left colon is more commonly affected than the right.
- The rectum is often spared because of additional blood supply from the internal iliac arteries.
- Poor perfusion may result from systemic disease, local vascular compromise, and anatomic or functional changes in the colon itself. An occlusion of large vessels is usually not identified.
  - Hypoperfusion from shock, trauma
  - Embolic occlusion of mesenteric vessels
  - Hypercoagulable states, vasculitis
  - Sickle cell disease
  - Arterial thrombosis; venous thrombosis
  - Mechanical obstruction of the colon (e.g., tumor, adhesions, hernia, volvulus, prolapse, diverticulitis)
  - Surgical complications
  - Medications (intestinally active vasoconstrictive substances, medications that induce hypotension and thus, hypoperfusion)
  - Cocaine abuse
  - Aortic dissection
– Strenuous physical activity (e.g., long-distance running)
• Repeated episodes of ischemia and inflammation may result in chronic colonic ischemia, possible stricture formation, recurrent bacteremia, and sepsis. These patients may have unresolving areas of colitis and require segmental colonic resection.

RISK FACTORS
• Age >60 years (90% of patients)
• Smoking (most common cause of recurrent IC) (1)
• Hypertension, diabetes mellitus (1)
• Rheumatologic disorders/vasculitis
• Cerebrovascular disease, ischemic heart disease (1)
• Recent abdominal surgery
• Constipation-inducing medications (1)
• History of vascular surgery (1)
• History of ileostomy
• Chronic obstructive pulmonary disease
• Hypoalbuminemia; hemodialysis
• Hypercoagulability, oral contraceptive (1)
• AAA repair (IMA ligation) (1)
• IBS (1)

DIAGNOSIS
• Diagnosis is based on history, risk factors, and physical examination (2)[A].
• Laboratory values and radiographic findings are usually nonspecific (2)[A].
• Colonoscopy is diagnostic (2)[A].

HISTORY
• Abdominal pain is the most common symptom (3).
• Symptoms vary depending on severity (4)[A].
• Sudden-onset, mild to moderate abdominal pain with tenderness over the affected segment of bowel (4)[A]
• Sudden urge to defecate followed by passage of either bright red or maroon stool (4)[A]
• Lower GI bleeding is rarely heavy (2)[A].
• Loose, bloody bowel movements may occur, typically within 12 to 24 hours of abdominal pain onset (4)[A].
PHYSICAL EXAM

- Individual signs and symptoms are poorly predictive of IC (5)[A].
- Vital signs: hypotension; tachycardia
- Tenderness over the involved segment of bowel (4)[A]
- Abdominal distention with vomiting (due to an associated ileus) (2)[A]
- In the uncommon setting of transmural ischemia, patients may develop peritoneal signs such as rebound and guarding (6)[A].

DIFFERENTIAL DIAGNOSIS

- Infectious colitis (6)[A]
- Inflammatory bowel disease (ulcerative colitis, Crohn disease) (6)[A]
- Colon cancer (6)[A]; diverticulitis (6)[A]
- Pseudomembranous colitis (5)[A]

DIAGNOSTIC TESTS & INTERPRETATION

- Depends on clinical presentation, extent of colonic involvement, transmural involvement, acuity (2)[A]
- CT scan is the initial diagnostic test for patients with nonspecific abdominal pain (5)[A].
- Colonoscopy most sensitive for diagnosis (2)[A]
- Radiographic tests and laboratory values are otherwise nonspecific (5)[A].

Initial Tests (lab, imaging)

- The following lab markers of ischemia are not specific to IC but can help determine disease severity (5)[A]:
  - CBC (leukocytosis) (5)[A]
  - BMP, ABG (signs of metabolic acidosis) (5)[A]
  - Lactate, LDH, CPK, amylase (5)[A]
  - Alkaline phosphatase (5)[A]
  - Albumin (4)[B]
- Abdominal plain film should be obtained to look for:
  - 20% of patients show signs of IC such as thumbprinting and mural thickening; may predict worse prognosis (6)[A]
  - Bowel perforation and pneumoperitoneum (6)[A]
- Abdominal CT scan with contrast if suspected IC (2)[A]:
  - The most common CT findings are thickening of the colonic wall and pericolonic fat stranding (4).
  - Other common CT findings include hyperdense mucosa, submucosal
edema, and mesenteric inflammation (2)[A].
- Pneumatosis, pneumoperitoneum, and free peritoneal fluid suggest advanced ischemia (2)[A].

**Follow-Up Tests & Special Considerations**

- Stool cultures, fecal leukocytes, stool ova, and parasites to rule out infection (5)[A]
- Patients undergoing aortic surgery may benefit from postoperative colonoscopy within 2 to 3 days to look for signs of IC (4)[A].
- Cardiac workup including electrocardiogram, Holter monitoring, or transthoracic echocardiogram to exclude cardiogenic embolism as indicated (5)[A]
- Drug and toxicology screening (4)[A]

**Diagnostic Procedures/Other**

- Colonoscopy is gold standard; sigmoidoscopy used to evaluate postoperative left sided ischemia (2)[A].
- Cyanotic hemorrhagic tissue and edematous mucosa suggest ischemia (4)[A].
  - Segmental distribution (watershed), hemorrhagic nodules, and rectal sparing (4)[A]
  - “Colon single-stripe sign” is a single line of erythema, with a 75% histopathologic yield (4)[A].
  - Routine biopsy no longer advised, as results are typically nonspecific (2) [A]
- In cases of isolated right colon ischemia, noninvasive vascular imaging studies are recommended to evaluate acute SMA occlusion (4)[A].

**Test Interpretation**

- Fulminant gangrenous IC seen in 15% of cases requires surgical intervention (2)[A].
- Acute transient IC seen in 85% of cases requires clinical evaluation for further workup (2)[A].
- Biopsied specimens reveal mucosal infarction and ghost cells, which show normal cellular outlines but lack intracellular contents (2)[A].

**TREATMENT**
Treatment depends on disease severity (2)[A].
Continuous clinical monitoring, including vital signs and serial abdominal exams (6)[A]
In the absence of colonic necrosis or perforation, most patients respond to supportive care (1)[A]:
- Bowel rest (4)[A]
- IV fluids to maintain hemodynamic stability (4)[A]
- Broad-spectrum antibiotics covering aerobic and anaerobic bacteria to avoid bacterial translocation secondary to colonic mucosal damage (4)[A]
  - Ciprofloxacin 400 mg IV BID or 500 mg PO BID
  - Metronidazole 500 mg PO/IV TID
- Avoid intestinally active vasoconstrictive medications (4)[A].
- Avoid systemic corticosteroids—may worsen ischemia and increase risk of perforation (2)[A].
- If ileus is present, place nasogastric tube (2)[A].
If radiographic abnormalities present, serial abdominal x-rays help follow improvement (4)[A]
If signs of clinical deterioration are present despite supportive care (increased abdominal pain, peritoneal signs, persistent diarrhea, bleeding, or sepsis), consider surgery (2)[A].

MEDICATION
- Broad-spectrum antibiotics (i.e., metronidazole, ciprofloxacin) (4)[A]
- If cardiac workup reveals CHF or cardiac arrhythmias, initiate appropriate medical treatment (4)[A].

SURGERY/OTHER PROCEDURES
- 20% of patients require surgical intervention (3)[A].
- Pneumatosis intestinalis, portal vein air, or free peritoneal air are indications for urgent surgery (2)[A].
- Surgery may be indicated for:
  - Peritoneal signs, increased abdominal tenderness, new-onset shock, lactic acidosis, or acute renal failure (2)[A]
  - Diarrhea, lower GI bleeding, or exudative colitis persisting past 14 days (2) [A]
- Most common surgical intervention is colectomy with end ileostomy (5)[A].
  - Cholecystectomy may prevent resuscitation-related acute acalculous cholecystitis (2)[A].
ONGOING CARE

DIET
- Bowel rest until symptoms resolve
- Parenteral nutrition for patients needing prolonged bowel rest who have contraindications to surgery

PROGNOSIS
- In most patients, IC symptoms resolve in 24 to 48 hours.
- Radiographic or endoscopic resolution within 2 weeks
- Right-sided IC is the most significant predictor of outcome. Patients with right-sided IC have a 2-fold increase in mortality and a 4-fold increase in morbidity (4).
- Secondary cardiovascular prevention minimizes recurrence.
- Male gender, low hemoglobin, low serum albumin, high BUN, and presence of metabolic acidosis are poor prognostic factors (1).
- Chronic kidney disease, COPD, long-term care facilities increase mortality in IC (1).

COMPLICATIONS
20–30% of patients develop chronic IC, with persistent diarrhea or stricture formation requiring surgery.

REFERENCES
ADDITIONAL READING

CODES

ICD10

- K55.9 Vascular disorder of intestine, unspecified
- K55.0 Acute vascular disorders of intestine
- K55.1 Chronic vascular disorders of intestine

CLINICAL PEARLS

- Suspect IC in patients with multiple risk factors who present with abdominal pain and loose bloody stools.
- Colonoscopy is the diagnostic gold standard.
- Most often, IC is self-limited, responding well to conservative management with IV fluids, bowel rest, and empiric broad-spectrum antibiotics.
- Peritoneal signs or lack of clinical improvement suggests more extensive ischemia and need for surgical intervention.
- Right-sided IC is associated with higher morbidity and mortality.
COLON CANCER
Jaine McKenzie, MD • Asif Talukder, MD • Daniel Albo, MD, PhD

BASICS
DESCRIPTION
- Colon and rectal cancers (CRC) are often grouped together but are two distinct clinical entities that differ in their prognosis, presentation, staging, and management.
- CRC is the second leading cause of cancer deaths and is the third most common cancer in men and women in the United States.
- Screening for colon cancer reduces the incidence of and mortality from colon cancer.

EPIDEMIOLOGY
Incidence
- 93,090 new cases of colon cancer in 2015
- 49,700 deaths from CRC combined were estimated in the United States in 2015 (1).
- Incidence is equal between men and women.

Prevalence
- The lifetime risk for developing colon cancer in the United States is about 1 in 21 (4.8%).
- Incidence and death rates have been declining due to improved screening, prevention, and treatment.

ETIOLOGY AND PATHOPHYSIOLOGY
- Progression from the first abnormal cells to the appearance of colon cancer usually occurs over 10 to 15 years, a disease characteristic that contributes to the effectiveness of prevention.
- High-risk polyp findings include multiple polyps, villous polyps, and larger polyps.
- Hyperplastic polyps are less likely to evolve into CRC.
Multiple genetic and environmental factors have been linked to the development of CRC.

**Genetics**
- <10% of CRC cases are linked to an inherited gene.
  - APC, a tumor suppressor gene, is altered in familial adenomatous polyposis (FAP).
  - Genes encoding DNA mismatch repair (MMR) enzymes are implicated in hereditary nonpolyposis colon cancer (HNPCC): MLH1, MSH2, MSH6, PMS1, PMS2, and others.
  - STK11, a tumor suppressor gene, is altered in Peutz-Jeghers syndrome.
- Sporadic cases of CRC have been linked to oncogenes: Kras, c-Myc, c-Src, HER-2/neu, and others.

**RISK FACTORS**
- Age: >90% of people diagnosed with colon cancer are >50 years of age.
- Personal history of colorectal polyps
  - Risk increases with multiple polyps, villous polyps, larger polyps, and presence of dysplasia.
- Personal history of cancer
  - 30% increase in risk of developing metachronous (new primary tumors unrelated to the patients’ previous cancers) colon cancer
  - 2–4% incidence of local recurrence with colon cancer, 3–5% incidence of synchronous colon cancer
- History of inflammatory bowel disease (IBD)
  - Prevalence of CRC in ulcerative colitis and Crohn disease is ~3%, with a cumulative risk of CRC of 2% at 10 years, 8% at 20 years, and 18% at 30 years.
- Family history of CRC
  - Having a single first-degree relative with a history of CRC increases risk 1.7-fold.
  - Risk is more than double for those who have a history of CRC or polyps in:
    - Any first-degree relative <60 years of age
    - ≥2 first-degree relatives, regardless of age
- Inherited syndromes
  - HNPCC (formerly Lynch syndrome)
    - Often develops at young age (average age at diagnosis of CRC is 44 years)
    - Lifetime risk of CRC is 52–69%.
Accounts for ~2% of all CRCs

- FAP
  - Affected individuals develop hundreds to thousands of polyps in colon and rectum.
  - CRC usually present by age 40 years
  - Accounts for <1% of CRCs

- Peutz-Jeghers syndrome
  - Individuals may have hyperpigmented mucocutaneous lesions (mouth, hands, feet) and large polyps in GI tract.
  - 81–93% risk for CRC and increased risk for other cancers

Race and ethnicity

- African Americans have the highest CRC incidence and mortality rates in the United States. It is unclear whether this is biologic or due to lower rates of access to screening.
- Colonoscopy is underutilized, particularly in minorities.
- Several different gene mutations have been identified among Ashkenazi Jews.

Lifestyle factors that increase risk

- Smoking, obesity, diet high in fat and low in fiber

GENERAL PREVENTION

- Optimal screening method for colon cancer is unclear. Stool based testing such as guaiac fecal occult blood test (gFOBT) and fecal immunochemical test (FIT), or FIT-DNA tests are less invasive, but endoscopic testing such as flexible sigmoidoscopy or colonoscopy offers ability to provide intervention if polyp discovered.
- Compared to no endoscopic screening, screening colonoscopy has been associated with 67% relative risk reduction in death from any colorectal cancer.
- Lifestyle factors that may reduce risk:
  - Low-fat, high-fiber diet (rich in fruits and vegetables)
  - Supplementation with vitamin D, calcium, folate, and fiber may lower CRC risk; more research is needed to understand how diet affects risks of CRC.

ALERT

The U.S. Preventive Services Task Force (USPSTF) strongly recommends screening adults, beginning at age 50 years and continuing until age 75 years and gives this an “A” Grade, meaning screening’s benefits far outweigh its harms.
Screening methods include
- Colonoscopy every 10 years
- Flexible sigmoidoscopy every 5 to 10 years (2)[C]
- FIT annually (1)[C]
- Fecal occult blood testing annually (1)[A]
- Stool DNA test (sDNA) every 3 years (2)[C]
- Note: The USPSTF does not recommend barium enema as a screening test and concludes the evidence is insufficient to assess the benefits and harms of CT colonography and stool DNA testing as screening modalities for CRC. The USPSTF also recommends AGAINST screening routine screening for CRC in adults 76 to 85 years of age but acknowledges there may be considerations that support screening in certain patients and recommends AGAINST screening those age >85 years.

American Cancer Society recommends screening with colonoscopy every 10 years. For those patients refusing colonoscopy, an alternative cancer detection tests method is recommended.

Screening in high-risk groups:
- The American Gastroenterology Society recommends screening African American patients starting at age 45 years.
- People with a history of polyps need frequent colonoscopy screening, depending on risk.
- People who have a first-degree relative or two second-degree relatives with CRC or adenomatous polyps before age 60 years should begin colonoscopy at age 40 or 10 years younger than the age of relative at cancer diagnosis, whichever is earlier.
- People with IBD should have regular surveillance colonoscopy with biopsies to detect dysplasia; guidelines generally indicate starting surveillance by 8 to 10 years of onset of symptoms followed by surveillance every 1 to 2 years.
- Genetic testing may be appropriate for individuals with a strong family history of CRC or polyps:
  - Family members of a person affected by HNPCC should start colonoscopy surveillance at age 25 years.
  - Individuals with suspected FAP should have yearly flexible sigmoidoscopy beginning at age 10 to 12 years; those who test positive for the gene linked to FAP may consider colectomy.
DIAGNOSIS

HISTORY
- Most patients with colon cancer are asymptomatic.
- Microcytic anemia in men of any age and postmenopausal women is CRC until proven otherwise, evaluation must include diagnostic colonoscopy.
- Symptoms may indicate advanced disease. Common presenting symptoms include:
  - Abdominal pain or cramping
  - Change in bowel habits (constipation, diarrhea, narrowing of stool)
  - Rectal bleeding, dark stools, or blood in stool
  - Weakness or fatigue
  - Unintentional weight loss
- Other presentations may include symptoms due to the presence of metastatic lesions (lymph nodes, liver, lung, peritoneum), fever of unknown origin, and *Streptococcus bovis* or *Clostridium septicum* sepsis.

PHYSICAL EXAM
- Signs of anemia
- Weight loss
- Palpable abdominal mass (late presentation)
- Must include digital rectal exam

DIFFERENTIAL DIAGNOSIS
- >95% of colon cancers are adenocarcinomas. Other colonic tumors include carcinoid tumors, lymphomas, and Kaposi sarcoma in HIV.
- Many conditions can mimic CRC, including other cancers, hemorrhoids, IBD, infection, and extrinsic masses (i.e., cysts, abscesses).

DIAGNOSTIC TESTS & INTERPRETATION

*Initial Tests (lab, imaging)*
- Should any screening method identify an increased risk, colonoscopy must be performed as it can be both diagnostic and therapeutic.
- For confirmed colorectal cancer, obtain:
  - CBC, ferritin to evaluate iron deficiency anemia
  - CEA, LFTs
Follow-Up Tests & Special Considerations
- If CT chest, abdomen, and pelvis to evaluate presence of metastatic disease
- Intraoperative US may be used to evaluate solid organs (e.g., the liver) after tumor resection.
- In selected cases, positron emission tomography (PET) may be used to detect metastatic disease.
- Biopsy is usually performed (most often during colonoscopy) if cancer is suspected.
- CT-guided biopsy may be needed to evaluate a suspected tumor or metastasis.
- Staging of colon cancer
  - The American Joint Committee on Cancer (AJCC) TNM staging is preferred.
    - **Stage 0**: limited to the mucosa (carcinoma in situ or intramucosal carcinoma (Tis, N0, M0)
    - **Stage I**: invades mucosa (T1) or muscularis propria (T2); no invasion of lymph nodes or distant sites (T1, N0, M0 or T2, N0, M0)
    - **Stage IIA**: invades pericolectal tissues; no lymph nodes or distant sites (T3, N0, M0)
    - **Stage IIB**: penetrates to surface of visceral peritoneum; no lymph nodes or distant sites (T4a, N0, M0)
    - **Stage IIC**: directly invades or adherent to other organs or structures (T4b, N0, M0)
    - **Stage IIIA**: invades submucosa or muscularis propria with spread to 1 to 3 lymph nodes; no distant sites (T1, N1, M0 or T2, N1, M0)
    - **Stage IIIB**: invades pericolorectal tissues or surface of visceral peritoneum + spread to 1 to 3 lymph nodes; no distant sites (T3, N1, M0, or T4a, N1, M0)
    - **Stage IIIC**: invades pericolorectal tissues or peritoneum or other organs and to ≥4 nearby lymph nodes; no distant sites (any T3 or T4, N2, M0)
    - **Stage IVA**: any level of invasion with spread to one organ or site (any T, any N, M1a)
    - **Stage IVB**: any level of invasion with spread to more than one organ or site or peritoneum (any T, any N, M1b)

TREATMENT
- Colon cancer is typically treated with surgery and chemotherapy.
Data suggest multidisciplinary communication among providers of colon cancer patients can improve cancer survival.

SURGERY/OTHER PROCEDURES

- Surgery is the primary treatment for localized colon cancer.
  - Minimally invasive (i.e., laparoscopic) surgery has fewer complications, less blood loss, shorter hospital stay, less time to bowel movement, and lower 30-day mortality when compared to open surgery with equivalent oncologic outcomes. This approach allows patients to have less pain and faster recovery. For health systems, decreased length of stay and fewer complications improves the cost of care (3).
  - There are no significant differences between minimally invasive and open colorectal surgery in long-term survival and recurrence rates (3).

- Radiation therapy is most often used for peritoneal cancers; it may also be used to relieve symptoms.

ADDITIONAL THERAPIES

Adjuvant chemotherapy is most clearly beneficial for stage III (node-positive) disease, in which improvements of 30% can be achieved in both disease recurrence and overall survival, compared with untreated controls. Chemotherapeutic regimens for metastatic disease may extend overall survival from 6 months to 2 years (2)[B].

- First-line therapy includes combination chemotherapy with oxaliplatin, irinotecan, fluorouracil, leucovorin, and capecitabine.
- Targeted therapies may be used alongside first-line agents or alone if first-line agents are ineffective.
- Bevacizumab (Avastin) is a monoclonal antibody that targets vascular endothelial growth factor (VEGF); inhibits angiogenesis
- Cetuximab (Erbitux) and panitumumab (Vectibix) are monoclonal antibodies that target epidermal growth factor receptor (EGFR).
- Aflibercept and regorafenib are newer agents with actions on VEGF.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Risk of recurrence is greatest in the first 2 to 4 years after treatment; 80% occur in first 2.5 years from date of surgery.
H&P and CEA should be performed every 3 to 6 months for 5 years.
Annual CT scan of chest, abdomen, and pelvis for 3 years
Surveillance colonoscopy 1 year after initial surgery. Subsequent colonoscopies should generally be every 5 years if findings are normal.
In obstructive colon cancer precluding from preoperative colonoscopy, recommend colonoscopy within 3 to 6 months after surgery to detect synchronous cancer and complete resection of precancerous polyps.
CEA is used to detect recurrences after resection of primary colon cancer. CEA levels decrease and normalize within 4 to 6 weeks after surgery. Persistent elevation of CEA levels can suggest incomplete resection or occult metastasis. Elevated CEA should raise suspicion for recurrent disease, and adjustments of routine surveillance program should be undertaken (4,5).

PROGNOSIS
5-year relative survival rate after surgical resection alone (6):
- Stage I: 85–95%
- Stage II: 60–80%
- Stage III: 30–60%
- Stage IV: 25–40% following resection of hepatic metastases with clear margins

COMPLICATIONS
- Surgery: pain, deep vein thrombosis (DVT), anatomic leaks, wound infection, incisional hernia. Incidence complications are lower with minimally invasive (i.e., laparoscopic) approach.
- Chemotherapy: hair loss, nausea, vomiting, bruising, fatigue, increased risk for infections
- Radiation therapy: skin irritation, nausea, rectal pain, incontinence, bladder irritation, fatigue, and sexual problems

PATIENT EDUCATION

- AAFP: Colorectal Cancer: http://www.aafp.org/afp/2015/0115/p93-s1.html
REFERENCES

ADDITIONAL READING

CODES
ICD10

- C18.9 Malignant neoplasm of colon, unspecified
- C18.2 Malignant neoplasm of ascending colon
- C18.8 Malignant neoplasm of overlapping sites of colon

CLINICAL PEARLS

- Microcytic anemia in men of all ages and postmenopausal women is CRC until proven otherwise.
- Colon cancer screening decreases mortality from colon cancer, but optimal screening method is unclear.
- Colonoscopy offers ability for diagnosis of colon cancer and intervention if polyp is discovered.
- Multidisciplinary communication in the treatment of colorectal cancer patients improves outcomes.
- Minimally invasive surgery leads to less pain and faster recovery for patients with equivalent oncologic outcomes.
COLONIC POLYPS

Marcelle Meseeha, MD • Maximos Attia, MD, FAAFP

BASICS

DESCRIPTION
- Intraluminal colonic tissue growth; most commonly sporadic or part of polyposis syndromes
- Size classification:
  - Diminutive ≤5 mm, small 6 to 9 mm, large ≥10 mm
- Morphologic classification:
  - Depressed, flat, sessile, or pedunculated
- Clinical significance:
  - >95% of colon adenocarcinoma arise from polyps.

EPIDEMIOLOGY

Colorectal polyps are more common in non-Caucasian men in Western countries.

Incidence
Incidence increases with age.

Prevalence
- 15–20% of all adults
- 30% of U.S. population >50 years
- 6% of children
- 12% of children with lower GI bleed

ETIOLOGY AND PATHOPHYSIOLOGY
- Mucosal
  - Neoplastic
    - Adenomatous polyps (tubular >80%, villous 5–15%, tubulovillous 5–15%)
    - Serrated polyps
    - Sessile serrated polyps are common, more in proximal colon, with low malignant potential if no dysplasia and significant malignant potential if dysplastic.
Traditional serrated adenoma is uncommon, more often noted in distal colon, with significant malignant potential.

- Nonneoplastic polyps (hyperplastic, juvenile polyps, hamartomas, inflammatory pseudopolyps)
  - Hyperplastic polyps are very common, more in distal colon, with very low malignant potential.
  - Juvenile polyps are common in childhood, benign hamartomas, more in rectosigmoid, and not premalignant.
- Submucosal (lipomas, lymphoid aggregates, carcinoids)

**Genetics**
- Inactivation of tumor suppressor genes as adenomatous polyposis coli (APC) or mismatch repair genes (MLH1) causes polyps to grow into cancer.
- Familial adenomatous polyposis (FAP) is autosomal dominant. By age 40 years, almost all patients develop colorectal cancer (CRC).
- MUTYH-associated polyposis (MAP) is autosomal recessive caused by biallelic mutations in MUTYH gene.
- Juvenile polyposis syndrome (JPS) is autosomal dominant. 50–60% of patients have a mutation in the SMAD4 or BMPR1A gene. By age 35 years, 20% of patients develop CRC.

**RISK FACTORS**
- Family history of intestinal polyposis, polyps, or CRC
- Advancing age; male
- High-fat, low-fiber diet; tobacco use
- Excessive alcohol intake: >8 drinks a week
- Inflammatory bowel disease is associated with a decreased prevalence of colon polyps (but with higher risk of colon cancer).

**GENERAL PREVENTION**
- Low-fat, high-fiber diet
- Avoid smoking.
- Decrease alcohol intake.
- Use of NSAIDs and calcium is associated with decreased incidence and recurrence of polyps.
- No lower rates of CRC with azathioprine, 6-mercaptopurine, folate, calcium, multivitamins, or statins
COMMONLY ASSOCIATED CONDITIONS
Hereditary polyposis syndromes:
- Adenomatous
  - FAP
    - Classic (CFAP)
    - Attenuated (AFAP)
  - MAP
  - FAP variants:
    - Gardner syndrome
    - Turcot syndrome
- Hamartomatous
  - Peutz-Jeghers syndrome (PJS)
  - JPS
  - Familial juvenile polyposis
  - Cowden syndrome

ALERT
JPS imposes a higher risk of CRC, although juvenile polyps are not premalignant.

DIAGNOSIS
HISTORY
- Generally asymptomatic
- Painless rectal bleeding, bright or dark red, mixed with stools, dripping, or on wiping
- Diarrhea or mucous stool
- Abdominal pain
- Constipation
- Chronic bleeding resulting in iron deficiency anemia
- McKittrick-Wheelock syndrome; large hypersecretory rectosigmoid villous adenoma, resulting in persistent severe diarrhea, electrolyte disorder, dehydration, and prerenal acute renal failure
- Social and family history

PHYSICAL EXAM
- Usually normal
Rectal polyps noted as prolapsed or palpated on digital rectal examination (DRE)
Fecal occult blood test (FOBT) by DRE is less effective than FOBT by stool passed spontaneously.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- CBC; anemia with chronic bleeding
- Basic metabolic panel; electrolyte disorder with hypersecretory adenomas
- FOBT, insensitive screening test, as small polyps don’t usually bleed:
  - Guaiac (gFOBT)—uses a chemical indicator with color change in presence of blood
  - Immunochemical (iFOBT or fecal immunochemical test [FIT])—uses antibodies against human hemoglobin
- Stool DNA test is more sensitive and less specific than FIT.

**Diagnostic Procedures/Other**
- Colonoscopy is the gold standard test for detection of polyps and polypectomy. Not a perfect screening test, with increased miss rate with right-sided colon polyps, smaller polyp size, low quality of colon prep, less endoscopist experience
- Computed tomographic colonography (CTC) is less sensitive with flat polyps and requires excellent bowel preparation.
- Double-contrast barium enema
- Colon capsule endoscopy
- Enhanced optical technologies can potentially differentiate between neoplastic and nonneoplastic colonic lesions (1)[A].
- Enhanced optical technologies include:
  - Narrowed spectrum endoscopy (narrow-band imaging [NBI])
  - Image-enhanced endoscopy (i-scan)
  - Fujinon intelligent chromoendoscopy (FICE)
  - Confocal laser endomicroscopy (CLE)
- Patients with >10 colorectal adenomas should undergo genetic testing for APC and MUTYH (2)[C].

**Test Interpretation**
- Tubular adenoma
  - Gross: tend to be polypoid
– Micro: dysplastic epithelium with a tubular architecture

Villous adenoma:
– Gross: tends to be sessile
– Micro: dysplastic epithelium with fine fingerlike projections

Tubulovillous adenomas have a combination of tubular and villous architecture.

Hyperplastic polyps are composed of hyperplastic colonic mucosa.

Hamartomatous polyps include muscularis mucosa.

Juvenile polyp
– Gross: pedunculated, smooth, red mass, 1 to 3 cm (3)

**TREATMENT**

**SURGERY/OTHER PROCEDURES**

– Colonic polypectomy; diagnostic, therapeutic:
  – Snare polypectomy with electrocautery for pedunculated polyps
  – Endoscopic mucosal resection for sessile polyps
  – Endoscopic submucosal dissection

– Colorectal surgery; prophylactic in FAP and MAP and when there are numerous polyps or persistent bleeding (2,3)[C]:
  – Total colectomy ileorectal anastomosis
  – Proctocolectomy ileal pouch anal anastomosis

– Chemoprevention: NSAIDs and calcium may reduce incidence and recurrence of polyps in patients with FAP and MAP (4)[A].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Follow-up colonoscopy in:

– 10 years if no polyps or distal small hyperplastic polyps (<10 mm) (5)[B]
– 5 to 10 years if 1 to 2 small tubular adenomas (<10 mm) (5)[B]
– 3 years if 3 to 10 adenomas if any polyp ≥6 mm (5)[B] or if all polyps <6 mm (5)[C]
– <3 years if >10 adenomas (5)[B]
– 3 years if one or more adenomas ≥10 mm (5)[A]
3 years if one or more adenomas with villous features of any size or with HGD (5)[B]
5 years if sessile serrated polyp(s) <10 mm with no dysplasia (5)[C]
3 years if sessile serrated polyp(s) ≥10 mm or with dysplasia or traditional serrated adenoma (5)[C]
1 year if serrated polyposis syndrome (5)[B]

**Patient Monitoring**
- Colonoscopy for CRC screening starts at age 50 years and earlier for at-risk patients.
- Stop screening if life expectancy is <10 years.
- In CFAP and AFAP, screen for extracolonic manifestations: thyroid cancer, desmoid tumors, and gastroduodenal polyposis (every 6 months to 5 years) (2)[C].
- In families, lifetime screening is indicated in mutation carriers (2)[C]:
  - In CFAP: with sigmoidoscopy or colonoscopy every 1 to 2 years starting at age of 10 to 11 years
  - In AFAP and MAP: with colonoscopy every 1 to 2 years starting at age of 18 to 20 years
- After colorectal surgery, surveillance of the rectum (every 6 to 12 months) or pouch (every 6 months to 5 years) is indicated (2)[C].
- First-degree relatives of patients with JPS require screening by colonoscopy and upper endoscopy after age 12 years (3)[C].

**DIET**
Low-fat, high-fiber diet (insufficient evidence)

**PATIENT EDUCATION**
Importance of colonoscopy as a screening tool

**PROGNOSIS**
- Regression or no change in size, more with small hyperplastic polyps and with patients on NSAIDs
- Recurrence: Juvenile polyps recur in 45% of children with multiple polyps and 17% of children with solitary polyps (3).
- Risk factors for colon cancer (6)[A]:
  - Polyp pathology
    - Adenomatous
- Serrated
  - With high-grade dysplasia
  - With >25% villous histology
  - Polyp size >1 cm in diameter
  - Polyps located in proximal colon
  - More than three polyps
- Recurrence rates <10% postpolypectomy

**COMPLICATIONS**
- Polyps: progression to cancer
- Polypectomy: bleeding 2–11%, perforation 0–1%, higher with endoscopic submucosal dissection
- Colonoscopy: complications related to anesthesia and procedure itself

**REFERENCES**

SEE ALSO

Colon Cancer; Rectal Cancer

CODES

ICD10

- K63.5 Polyp of colon
- D12.6 Benign neoplasm of colon, unspecified
- K51.40 Inflammatory polyps of colon without complications

CLINICAL PEARLS

- Colonoscopy is the gold standard tool for diagnosis of polyps.
- Small hyperplastic polyps should be biopsied to differentiate adenomatous and serrated polyps.
- Use of NSAIDs and calcium is associated with decreased incidence and recurrence of polyps.
- The progression from normal mucosa to polyp to carcinoma takes years to develop.
BASICS

- Complementary and alternative medicine (CAM) are medical and health care systems, practices, and products not presently considered part of conventional medicine.
- The National Center for Health Statistics (NCHS) reports nonvitamin, nonmineral dietary supplements, chiropractic or osteopathic manipulation, yoga, and massage therapy are the most common complementary health approaches.
- Medical professionals who incorporate CAM into their medical practice often refer to this model as “integrative medicine.”

DESCRIPTION

- Definitions and additional terms
  - *Complementary medicine* is used in conjunction with conventional medicine to address a health concern. For example, massage plus physical therapy for low back pain or medication plus osteopathic manipulation for recurrent headaches.
  - *Alternative medicine* is used in place of conventional medicine to promote healing of conditions not fully explained by the conventional biomedical model or for which the effectiveness of therapy is not yet established by clinical research.
  - *Integrative medicine* is the combination of allopathic medicine with CAM and may be provided to the patient by a single licensed medical professional trained in CAM or by a group of diverse health care providers.
  - *Holistic* is a descriptive term for a practitioner’s approach to patient care. Holistic care assesses the emotional, spiritual, mental, and physical state of wellness of the patient and works to provide comprehensive care. A holistic practice may include practitioners of different disciplines to address multiple aspects of wellness or illness.
- *Biologically based therapies*: diets, herbals, vitamins, supplements, flower essences
Manipulative and body-based methods

- Massage therapy is manipulation of the body’s soft tissues, using knowledge of anatomy and physiology to restore function, promote relaxation, and relieve pain. There are different types of massage.
- Osteopathic manipulative medicine includes indirect techniques (e.g., muscle energy, myofascial release, osteopathy in the cranial field, and strain–counterstrain approach) as well as direct action techniques (high-velocity thrusts).
- Craniosacral therapy is a gentle release of bony and fascial restrictions in the craniosacral system (cranium, sacrum, spinal cord, meninges, CSF).
- Chiropractic therapy focuses on the musculoskeletal and nervous systems and how imbalances in these systems can affect general health. It is used to treat back, neck, and joint pain. Doctors of chiropractic (DCs) complete 4 to 5 years of intensive training in anatomy, physiology, and manipulation.

Mind–body medicine

- Meditation is a practice of detachment in which a person sits quietly, generally focusing on the breath, while releasing thoughts from the mind with the intention to center the self, restore balance, and enhance well-being. Mindfulness meditation involves making oneself aware of the most immediate of activities in order to gain control over actions and anxiety.
- Spiritual practices (e.g., prayer)
- Yoga is an exercise of mindfulness, meditation, strength and balance, composed of asanas (postures) and pranayamas (focused breathing).
- Aromatherapy uses highly concentrated plant extracts to stimulate healing. Aromatic oils are rubbed on the skin, aerosolized, or used in compresses.
- Relaxation techniques include breathing exercises, progressive muscle relaxation, and guided imagery.
- Tai chi and qi gong are Chinese exercise systems that combine meditation, regulated breathing, and flowing dance-like movements to enhance and balance chi (qi)—life force energy.

Alternative medical systems

- Traditional Chinese medicine incorporates Chinese herbs and acupuncture. Acupuncture is the practice of regulating chi by inserting thin needles at specific points along meridian pathways of the body. Chi movement is responsible for animating and protecting the body; relieving pain; and regulating cellular blood flow, oxygen delivery, and nourishment.
- Ayurvedic medicine originated in India and is one of the world’s oldest medical systems. It uses healing modalities and herbs to integrate and balance the body, mind, and spirit.
– Homeopathy is based on the concept that very dilute quantities of an offending agent can stimulate innate immunity. In general, homeopathic remedies are considered safe and unlikely to cause serious adverse reactions. Only three states license homeopaths.
– Naturopathy regimens include herbs, vitamins, supplements, dietary counseling, homeopathic remedies, manipulative therapies, acupuncture, and hydrotherapy. 4-year doctoral training programs are available; however, only 20 states/territories have licensing laws for naturopathic practitioners.

• Energy therapies
  – *Reiki*, which means “source energy,” is a healing practice from Japan. Laying hands lightly on the patient or holding the hands just above the body, the *reiki* practitioner facilitates spiritual and physical healing by stimulating life force energy.

• Common reasons patients choose CAM
  – Additive therapy to address issues not covered by conventional medical treatment
  – Conventional medicine has been unsuccessful in fully addressing ailment.
  – Preventive health care
  – Desire for a holistic or natural approach to well-being
  – Preference for noninvasive treatment options
  – Concern about medication side effects
  – Desire to include spiritual support into healing
  – Cultural or familial belief system more aligned with “natural” solutions not provided for or supported by the standard allopathic model of health care

**Epidemiology**
• All ages use CAM, but it is most prevalent among adults aged 30 to 69 years.
• Gender ratio: female > male
• College graduates and residents of western states are more likely to use CAM.
• Cancer survivors are more likely than the general population to use CAM.
• Six most used CAM therapies:
  – Nonvitamin, nonmineral dietary supplements (18%)
  – Chiropractic and osteopathic manipulation (8.5%)
  – Yoga (8%)
  – Massage (7%)
  – Meditation (4%)
  – Special diets (3%)
TREATMENT

- Variable evidence supports safety and efficacy of
  - Meditation for lowering BP
  - Acupuncture for chronic low back pain (1)[B]
    - Acupuncture to improve fertility
    - Spinal manipulative therapy for prophylactic treatment of headaches
    - Ginger for nausea, including that associated with chemotherapy
    - Manipulation, massage, and mobilization for acute low back and posterior neck pain
  - Massage therapy to promote weight gain in preterm infants
  - Massage (30 minutes × 3) during labor shortens the second stage and reduces pain.
  - Acupuncture for chemotherapy-induced nausea and vomiting
  - Tai chi for improving balance and decreasing the risk of and fear of falling in elderly
  - Mind–body techniques for migraines, chronic pain, and insomnia
    - Cognitive-behavioral therapy is highly effective for the treatment of insomnia (2)[A].
  - Homeopathic remedy for the treatment of chemotherapy-induced stomatitis in children
  - Riboflavin for migraine prophylaxis
  - Horse chestnut seed extract to improve lower leg venous tone, pain, and edema
  - Glucosamine for osteoarthritis and knee pain
  - Yoga and meditation appear to improve endothelial function in patients with CAD and can have potential beneficial effects on depressive disorders.
  - Yoga throughout pregnancy shortens labor by 140 to 190 minutes.
  - Exercise in both preconception and early pregnancy reduces chance of gestational diabetes mellitus.
  - Exercise has a small to moderate effect in reducing symptoms in persons with diagnosed anxiety disorders.
  - Breast stimulation in late pregnancy increases successful induction of labor (NNT 3.2) and reduces postpartum hemorrhage (NNT 19).
    - Oral probiotics in preterm infants to decrease necrotizing enterocolitis and reduce mortality (3)[A]
      - Oral probiotics to prevent URIs in children and influenza in the elderly
      - Oral probiotics to shorten the duration of acute and antibiotic-associated...
diarrhea and as prophylaxis for traveler’s diarrhea
– Vitamin D 800 IU/day may reduce falls and fractures in the elderly.
– Acupuncture for recurrent headache
  – *Ginkgo biloba* extract EGb 761 improves cognition in patients with dementia (4)[A].

● Evidence supports safety, but evidence regarding efficacy is inconclusive:
  – *Homeopathy* for induction and augmentation of labor
  – Chondroitin sulfate is ineffective for osteoarthritis.
  – *Sterile water injections* do not reduce labor pain.
  – Fish oil might be an effective treatment for hypertriglyceridemia.
  – Omega-3 fatty acids may reduce inflammation and anxiety in young healthy adults.
  – *Dietary fat reduction* for certain types of cancer
  – *Mind–body techniques* for metastatic cancer
  – *Copper and magnetic bracelets* for pain
  – *Vitamin D levels* >30 ng/mL correlate with lower risk of some cancers.
    Adequate vitamin D intake may decrease atopy and asthma symptoms.

● Evidence supports efficacy, but evidence regarding safety is inconclusive or poor:
  – St. John’s wort extract for short-term treatment of depression in adults
  – Licorice for gastritis
  – Goldenseal

● Evidence indicates serious risk:
  – Black cohosh, blue cohosh, and evening primrose oil are unsafe to induce labor.
  – Delay in seeking medical care or replacement of curative conventional treatment
  – Use of toxic herbs or substances
  – Known herb–drug interactions

ONGOING CARE

PATIENT EDUCATION
The National Center for Complementary and Integrative Health
(https://nccih.nih.gov/)

COMPLICATIONS
ALERT
Ginkgo, goldenseal, and St. John’s wort account for most reported herb–drug interactions.

- Herbs with possible adverse effects
  - Serious adverse events from herbal remedies remain uncommon.
  - Some ethnic medicines, as those prescribed by practitioners of Ayurveda or traditional Chinese medicine, may intentionally contain heavy metals or other toxic substances. These are usually listed by their pharmacopeial names, for example, Qian Dan = lead oxide.
  - Bitter orange (Citrus sinensis): sympathomimetic; increases heart rate (HR), BP
  - Black cohosh (Actaea racemosa) reduces effectiveness of statins.
  - California poppy (Eschscholzia californica): may cause respiratory depression, drowsiness; contains opioids
  - Cascara sagrada (Frangula purshiana): depletes serum potassium
  - Chaparral (Larrea tridentata): hepatotoxic
  - Ephedra (Ephedra spp.): sympathomimetic; increases HR, BP; insomnia, gastric distress
  - Ginkgo (Ginkgo biloba): extravasation, increased bleeding time
  - Goldenseal (Hydrastis canadensis) interferes with nearly all prescription drugs.
  - Guarana (Paullinia cupana): tachycardia, hypertension; contains caffeine
  - Kava (Piper methysticum): decreases use of niacin; possibly hepatotoxic
  - Licorice (Glycyrrhiza spp.): Long-term use depletes serum potassium.
  - Lily of the valley (Convallaria majalis): contains cardiac glycosides
  - Poke root (Phytolacca species): strong gastric irritant; may cause sedation
  - Senna (Cassia senna): depletes serum potassium
  - Snakerooot (Aristolochia spp.): nephrotoxic
  - St. John’s wort (Hypericum perforatum): numerous drug interactions; induces CYP(3a4) pathway, speeding metabolism of cyclosporine, tacrolimus, warfarin, protease inhibitors, theophylline, venlafaxine, digoxin, and oral contraceptives
  - Wormwood (Artemisia absinthium): elevates serotonin level, may raise BP
  - Yohimbe (Pausinystalia yohimbe): elevates BP

Geriatric Considerations
Ginkgo biloba commonly interacts with Coumadin.
Pediatric Considerations
Iron is a leading cause of accidental poisoning in children <6 years of age. Minerals (i.e., potassium, calcium, magnesium, zinc, copper, and selenium) may cause toxicity.
- Vitamin A is the most common cause of hypervitaminosis.
- β-Carotene has a limited potential for overdose.

REFERENCES

CODES
ICD10
Z76.89 Persons encountering health services in other specified circumstances

CLINICAL PEARLS
- Oral probiotics reduce respiratory and diarrheal infections and reduce mortality in preterm infants.
- Acupuncture is effective for back pain, headaches, and infertility.
- Cognitive-behavior therapy reduces insomnia.
- Yoga and breast stimulation shorten labor.
- Ginkgo, goldenseal, and St. John’s wort account for most herb–drug interactions described in the medical literature.
COMPLEX REGIONAL PAIN SYNDROME

Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION

- Complex regional pain syndrome (CRPS) is a pain syndrome that can be chronic and debilitating. It is divided into two subtypes and can have significant physical and psychosocial short- and long-term disability. Most cases are a result of a physical insult to an extremity such as trauma or surgery.
  - Type I: no nerve injury (reflex sympathetic dystrophy [RSD])
  - Type II: associated with a demonstrable nerve injury (causalgia)

- Synonym(s): traumatic erythromelalgia; Weir Mitchell causalgia; causalgia; RSD; posttraumatic neuralgia; sympathetically maintained pain

EPIDEMIOLOGY

- Incidence of 5.46/100,000 for type I and 0.82/100,000 for type II in United States (1)
- Peak age 50 to 70 years
- Predominant gender: female > male (3:1, 60–81%), favoring postmenopausal
- Recent studies found 3.8% occurrence after wrist fracture and 7% occurrence after intra-articular ankle fracture—both independent strong risk for CRPS (2) [B].
- More prevalent in patients that report higher than usual expected pain in early phases of trauma (2)

ETIOLOGY AND PATHOPHYSIOLOGY

- Poorly understood activation of abnormal sympathetic reflex that lowers pain threshold
  - Increased excitability of nociceptive neurons in the spinal cord; “central sensitization”
  - Exaggerated responses to normally nonpainful stimuli (hyperalgesia, allodynia)
- Other than known nerve injury (type II or causalgia), no known definitive pathogenesis
*Genetics*
No known genetic pattern

**RISK FACTORS**
- Minor or severe trauma (upper extremity fracture noted in 44%)
- Surgery (particularly carpal tunnel release)
- Lacerations
- Burns
- Frostbite
- Casting/immobilization after extremity injury
- Penetrating injury
- Polymyalgia rheumatica
- Myocardial infarction (MI)
- Cerebral vascular accident

**GENERAL PREVENTION**
- Early mobilization after fracture, stroke, and MI has proven benefit in reducing incidence of CRPS.
- One study of wrist fractures found that addition of 500 mg/day of vitamin C lowered rates of CRPS.
- There is evidence that limiting use of tourniquets, liberal regional anesthetic use, and ensuring adequate perioperative analgesia can reduce the incidence of CRPS-I.

**COMMONLY ASSOCIATED CONDITIONS**
- Serious injury to bone and soft tissue
- Herpes zoster
- Postherpetic neuralgia results from partial or complete damage to afferent nerve pathways.
- Pain occurs in dermatomes as a sequela of herpes zoster.

**DIAGNOSIS**
Unprovoked pain is the hallmark of the condition, and the diagnosis of CRPS is excluded by the existence of conditions that would otherwise account for the degree of symptoms. Clinical diagnostic criteria (1)
HISTORY
- Continuing pain which is disproportionate to any inciting event
- One reported symptom in three of the four following categories:
  - Sensory: hyperalgiesia and/or allodynia
  - Vasomotor: skin, temperature, color asymmetry
  - Sudomotor/edema: edema, sweating changes, or sweating asymmetry
  - Motor/trophic: decreased range of motion or motor dysfunction and/or trophic changes (hair, nail, skin) (2)

PHYSICAL EXAM
At least one sign at evaluation in two of the following:
- Sensory: hyperalgiesia (to pinprick) or allodynia (to light touch, pressure, or joint movement)
- Vasomotor: evidence of temperature, skin, color asymmetry
- Sudomotor/edema: evidence of edema or sweating changes or asymmetry
- Motor/trophic: decreased range of motion; motor dysfunction; or trophic changes in hair, nails, skin (2)

DIFFERENTIAL DIAGNOSIS
- Infection
- Hypertrophic scar
- Bone fragments
- Neuroma
- CNS tumor or syrinx
- Deep vein thrombosis or thrombophlebitis
- Thoracic outlet syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- CBC
- Erythrocyte sedimentation rate (ESR)
- Plain radiographs may show patchy demineralization within 3 to 6 weeks of onset of CRPS that are more pronounced than would be seen from disuse alone.
- Three-phase bone scanning has varying sensitivity but is most accurate for support of the diagnosis when there is diffuse activity (especially on phase 3).
- Bone density
**Diagnostic Procedures/Other**
- Electromyelography (EMG) shows nerve injury with type II CRPS.
- Sudomotor function testing (resting sweat testing, resting skin temperature, quantitative sudomotor axon reflex testing; all related to increased autonomic activity of the affected limb)

**Test Interpretation**
- Partial or complete damage to afferent nerve pathways and probably reorganized central pain pathways
- Nerves most commonly involved are median and sciatic.
- Atrophy in affected muscles
- Incomplete nerve plexus lesion

**TREATMENT**

**GENERAL MEASURES**
Discourage maladaptive behaviors (pain medication seeking, secondary gain). Principal of functional restoration is a stepwise and multidisciplinary approach.

**MEDICATION**

**First Line**
- NSAIDs recommended early in course but mixed support in literature
- The following have literature support of either limited or suggestive benefit in treatment of CRPS-I:
  - Corticosteroids (prednisone 30 mg/day \( \times \) 2 to 12 weeks with taper) are the only class of drugs that have direct clinical trial support early in the course. A recent retrospective case review found that patients showed significant improvement with various measurable physical parameters after treatment with prednisolone (30 mg starting dose tapering by 5 mg every 3 days for a total of 3 weeks treatment) (3)[C].
  - Gabapentin 600 to 1,800 mg/day for 8 weeks following diagnosis
  - 50% DMSO cream applied to affected extremity up to 5 times daily
  - \( N \)-Acetylcysteine 600 mg TID
  - Bisphosphonates (alendronate) at 40 mg/day (however, optimal dose uncertain)
  - Nifedipine 20 mg/day showed benefit early in the course of the condition.
Although many have advocated the use of tricyclic antidepressants in the treatment of CRPS, there is no credible evidence of improvement of pain. They may be helpful in controlling depressive symptoms that develop with disease progression (1)[B].

ISSUES FOR REFERRAL
- After 2 months of the illness, psychological evaluation generally is indicated to identify and treat any comorbid conditions.
- Physical therapy and occupational therapy early for guided motor and mirror therapy (1)

ADDITIONAL THERAPIES
Type I
- Physical and occupational therapy (beneficial to the overall prognosis for recovery) and should be initiated early in the course of treatment
  - “Mirror therapy” has shown good results.
- Transcutaneous nerve stimulation
- Psychotherapy
- Use of subdissociative (0.2 to 0.5 mg/kg) infusions of ketamine has shown some promise, but effects seem to be time limited; systemic literature review failed to find and high quality support for ketamine treatment (4)[C]

SURGERY/OTHER PROCEDURES
- Type II responds more favorably to nerve-directed treatment.
  - Sympathetic blocks
  - Cervicothoracic or lumbar sympathectomies have little data to support their use and should be used judiciously and after all other therapies have failed.
- Anesthetic blockade (chemical or surgical) of sympathetic nerve function
  - Transient relief suggests that chemical or surgical sympathectomy will be helpful.
  - Little in the way of quality clinical trials exist to support local sympathetic blockage as the gold standard of therapy.
- IV regional sympathetic block with guanethidine or reserpine by pain specialist or anesthetist
- Transcutaneous electric nerve stimulation (controversial)
- Inject myofascial painful trigger points.
- Dorsal root ganglion (DRG) stimulation higher rate of success than spinal cord stimulation in recent comparative study; more specific target as DRG
Intrathecal analgesia
Amputation as a last resort in severe cases, with patients reporting improved quality of life
Single case study of topical 5% lidocaine revealed significant pain reduction and improved range of motion and function (6).

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Vitamin C (500 mg/day) may help to prevent CRPS in those with wrist fracture.
- Briskly rub the affected part several times per day.
- Acupuncture
- Hypnosis can be suggested.
- Relaxation training (alternate muscle relaxing and contracting)
- Biofeedback
- Whirlpool baths

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Only for proposed surgical therapy

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Weekly, to monitor progress and initiate additional modalities as needed

PATIENT EDUCATION
- Stress need to remain active physically.
- Instruct carefully about any prescribed medications.
- Reflex Sympathetic Dystrophy Syndrome Association: http://rsds.org/; 203-877-3790
- American RSD Hope Group: www.rsdhope.org; 207-583-4589

PROGNOSIS
Most improve with early treatment, but symptoms may be lifelong if there is
limited response to initial treatments.

**COMPLICATIONS**
- Depression
- Disability
- Opioid dependence

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- G90.50 Complex regional pain syndrome I, unspecified
- G90.519 Complex regional pain syndrome I of unspecified upper limb
- G90.529 Complex regional pain syndrome I of unspecified lower limb
CLINICAL PEARLS

- A pain syndrome disproportioned to injury
- Pain control and early mobility are the key to recovery.
- Avoid use of opiate analgesics.
- Use a multidisciplinary approach.
CONDYLOMATA ACUMINATA

Morgan A. Brown, DO  •  Tayseer Husain Chowdhry, MD  •  E. James Kruse, DO

BASICS

DESCRIPTION

- Condylomata acuminata are soft, skin-colored, fleshy lesions (commonly called genital warts) that are caused by human papillomavirus (HPV):
  - Warts appear singly or in groups (a single wart is a “condyloma”; multiple warts are “condylomas” or “condylomata”); small or large; typically appear on the anogenital skin (penis, scrotum, introitus, vulva, perianal area); and may occur in the anogenital tract (vagina, cervix, rectum, urethra, anus); also conjunctival, nasal, oral, and laryngeal warts
- System(s) affected: skin/exocrine, reproductive, occasionally respiratory
- HIV considerations:
  - Treatment of external genital warts should not be different for HIV-infected persons (1).
  - Lesions may be larger or more numerous (1).
  - May not respond as well to therapy as immunocompetent persons (1)

Pediatric Considerations

- Consider sexual abuse if seen in children, although children can be infected by other means (e.g., transfer from wart on another child’s hand or prolonged latency period) (2).
- American Academy of Pediatrics recommends all school-aged children who present with lesions be evaluated for abuse and screened for other STDs (2).

Pregnancy Considerations

- Warts often grow larger during pregnancy and regress spontaneously after delivery.
- Virus does not cross the placenta. Treatment during pregnancy is somewhat controversial. Cesarean section is not absolutely indicated for maternal condylomata (3).
- Cervical infection has been found to be a risk factor for preterm birth (3).
- Few documented cases of laryngeal papillomas due to HPV transmission at
the time of delivery. Although rare, the condition is life-threatening.

- HPV vaccination is contraindicated in pregnancy.
- The safety of imiquimod, sinecatechins, podophyllin, and podofilox during pregnancy has not been established (3).

EPIDEMIOLOGY

- HPV types 6 and 11 associated with 90% of condylomata acuminata. Types 16, 18, 31, 33, and 35 may be found in warts and may be associated with high-grade intraepithelial dysplasia in immunocompromised states such as HIV.
- Highly contagious; incubation period may be from 1 to 8 months. Initial infections may very well go unrecognized, so a “new” outbreak may be a relapse of an infection acquired years prior.
- Predominant age: 15 to 30 years
- Predominant sex: 1:1 male to female
- Most infections are transient and clear spontaneously within 2 years.

Incidence

One study population demonstrated that from 2007 to 2010, with the introduction of HPV vaccines, the incidence of genital warts decreased 35% (from 0.94% per year to 0.61% per year) in females <21 years and decreased 19% in males <21 years.

Prevalence

- Most common viral sexually transmitted infection (STI) in the United States. Most sexually active men and women will have acquired a genital HPV infection, usually asymptomatic, at some time.
- Estimated 6.2 million Americans become infected with genital HPV each year.
- Peak prevalence in ages 17 to 33 years
- 10–20% of sexually active women may be actively infected with HPV. Studies in men suggest a similar prevalence.
- Pregnancy and immunosuppression favor recurrence and increased growth of lesions.

ETIOLOGY AND PATHOPHYSIOLOGY

HPV is a circular, double-stranded DNA molecule. There are >120 HPV subtypes. HPV types that cause genital warts do not cause anogenital cancers.
RISK FACTORS

- Usually acquired by sexual activity
  - Young adults and adolescents
  - Multiple sexual partners; short interval between meeting new sex partner and first intercourse
  - Not using protective barriers
  - Young age of commencing sexual activity
  - History of other STI
- Immunosuppression (particularly HIV)
- Cigarette smoking
- Radiation therapy

GENERAL PREVENTION

- Sexual abstinence or monogamy
- HPV vaccination is for prevention of HPV infections and HPV-associated cancers. This vaccine is targeted to adolescents before the period of their greatest risk for exposure to HPV. The vaccine does not treat previous infections:
  - A 2-dose schedule (0, 6 to 12 months) will have efficacy equivalent to a 3-dose schedule (0, 1 to 2, 6 months) if the HPV vaccination series is initiated before the 15th birthday (4).
  - The 9-valent HPV vaccine (Gardasil 9) protects against the two most common HPV serotypes (types 6 and 11, which cause most anogenital warts) and the two most cancer-promoting types (16 and 18) as well as 31, 33, 45, 52, and 58 (4).
  - Quadrivalent and 9-valent HPV vaccines (4vHPV and 9vHPV, Gardasil and Gardasil 9) are licensed for use in females and males aged 9 through 26 years (4).
  - The Advisory Committee on Immunization Practices (ACIP) has recommended routine vaccination at age 11 or 12 years for females since 2006 and since 2011 for males (4).
- Use of condoms is partially effective, although warts may be easily spread by lesions not covered by a condom (e.g., 40% of infected men have scrotal warts).
- Abstinence until treatment completed

COMMONLY ASSOCIATED CONDITIONS

- >90% of cervical cancer associated with HPV types 16, 18, 31, 33, and 35
- 60% of oropharyngeal and anogenital squamous cell carcinomas are associated with HPV.
- STIs (e.g., gonorrhea, syphilis, chlamydia), AIDS

**DIAGNOSIS**

**HISTORY**
- Explore sexual history, contraception use, and other lifestyle topics.
- Most warts are asymptomatic but symptoms include
  - Pruritus, burning, redness, pain, bleeding
  - Vaginal discharge
  - Large warts may cause obstructive symptoms in the anus (with defecation) or vaginal canal (with intercourse or childbirth).

**PHYSICAL EXAM**
- Lesions often have a typical rough, warty appearance with multiple fingerlike projections but may be soft, sessile, and smooth.
- Large lesions are cauliflower-like and may grow to >10 cm.
- Most common sites: penis, vaginal introitus, and perianal region
- May be seen anywhere on the anogenital epithelium or in the anogenital tract
- Warts often occur in clusters.
- Bleeding or irritation of the lesions may be noted.

**DIFFERENTIAL DIAGNOSIS**
- Condylomata lata (flat warts of syphilis)
- Lichen planus
- Normal sebaceous glands
- Seborrheic keratosis
- Molluscum contagiosum
- Keratomas, micropapillomatosis
- Scabies
- Crohn disease
- Skin tags
- Melanocytic nevi
- Vulvar intraepithelial neoplasia
- Squamous cell carcinoma
DIAGNOSTIC TESTS & INTERPRETATION

- Diagnosis is usually clinical, made by unaided visual examination of the lesions.
- Biopsy
- Acetowhiteness test: Subclinical lesions can be visualized by wrapping the penis with gauze soaked with 5% acetic acid (vinegar) for 5 minutes. Using a 10× hand lens or colposcope, warts appear as tiny white papules. A shiny white appearance of the skin represents foci of epithelial hyperplasia (subclinical infection), but because of low specificity, the CDC recommends against routine use of this test to screen for HPV mucosal infection.

Initial Tests (lab, imaging)

- Usually not required for diagnosis
- Serologic tests for syphilis may be helpful to rule out condylomata lata.
- Other testing for STIs
- Pap smear may be indicated.

Follow-Up Tests & Special Considerations

Because squamous cell carcinoma may resemble or coexist with condylomata, biopsy may be considered for lesions refractory to therapy.

Diagnostic Procedures/Other

- Biopsy with highly specialized identification techniques, such as HPV DNA detected through polymerase chain reaction, is rarely useful.
- Colposcopy, antroscopy, anoscopy, and urethroscopy may be required to detect anogenital tract lesions.
- Screening men who have sex with men (MSM) with anal Pap smears is controversial.

TREATMENT

GENERAL MEASURES

- May resolve spontaneously
- Change therapy if no improvement after three treatments, not complete clearance after six treatments, or therapy’s duration or dosage exceeds manufacturer’s recommendations.
- Appropriate screening/counseling of partners
MEDICATION

First Line

- No single therapy for genital warts is ideal for all patients or clearly superior to other therapies.
- Recommendations for external genital warts, patient-applied:
  - Podofilox (Condylox): antimitotic action; apply 0.5% solution or gel to warts twice daily (allowing to dry) for 3 consecutive days at home followed by 4 days of no therapy; may repeat up to 4 total cycles; maximum of 0.5 mL/day or area <10 cm² (3)[A]
  - Imiquimod (Aldara): immune enhancer; self-treatment with a 5% cream applied once daily at bedtime 3 times weekly until warts resolve for up to 16 weeks. Wash off with soap and water 6 to 10 hours after application. Imiquimod has been noted to weaken condoms and diaphragms; therefore, patients should refrain from sexual contact while the cream is on the skin (3)[A].
  - Sinecatechins (Veregen): immune enhancer and antioxidant, extract from green tea; apply a 0.5-cm strand of ointment 3 times daily for up to 16 weeks. Do not wash off after use (3)[A].
- Recommendations for external genital warts, provider-applied:
  - Cryotherapy: liquid nitrogen applied to warts for two 10-second bursts with thawing in between; usually requires 2 to 3 weekly sessions (3)[A]
  - Podophyllin 10–25% in tincture of benzoin. Apply directly to warts, air-dry in office before coming into contact with clothes. Wash off in 1 to 4 hours. Repeat every 7 days in office until gone (3)[A].
  - Trichloroacetic acid (TCA): 80% solution. Apply only to warts; powder/talc to remove unreacted acid. Repeat in office at weekly intervals; ideal for isolated lesions in pregnancy (3)[A]
- Recommendations for exophytic cervical warts: biopsy to exclude high-grade squamous intraepithelial lesion (SIL) (3)[A]
- Recommendations for vaginal warts: cryotherapy or TCA or bichloracetic acid (BCA) 80–90% (3)[A]
- Recommendations for urethral meatus warts: cryotherapy or podophyllin 10–25% in compound tincture of benzoin (3)[A]
- Recommendations for anal warts: cryotherapy, TCA or BCA 80–90%, or surgery; specialty consultation for intra-anal warts (3)[A]

Pregnancy Considerations
Cryotherapy, surgery, or TCA; medications contraindicated in pregnancy: podophyllin, podophyllotoxin, sinecatechins, interferon, and imiquimod (3)[C]

**Second Line**
Intralesional interferon, photodynamic therapy, topical cidofovir (3)[A]

**SURGERY/OTHER PROCEDURES**
- Larger warts may require surgical excision, laser treatment, or electrocoagulation (including infrared therapy):
  - Precaution: Laser treatment may create smoke plumes that contain HPV. CDC recommendation is for the use of a smoke evacuator no <2 inches from the surgical site. Masks are recommended; N95 the most efficacious (5,6)[A]
- Intraurethral, external (penile and perianal), anal, and oral lesions can be treated with fulgurating CO₂ laser. Oral or external penile/perianal lesions can also be treated with electrocautery or surgery.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
No restrictions, except for sexual contact

**Patient Monitoring**
- Patients should be seen every 1 to 2 weeks until lesions resolve.
- Patients should follow up 3 months after completion of treatment.
- Persistent warts require biopsy.
- Sexual partners require monitoring.

**PATIENT EDUCATION**
- Provide information on HPV, STI prevention, and condom use.
- Explain to patients that it is difficult to know how or when a person acquired an HPV infection; a diagnosis in one partner does not prove sexual infidelity in the other partner.
- Emphasize the need for women to follow recommendations for regular Pap smears.

**PROGNOSIS**
Asymptomatic infection persists indefinitely.
Treatment has not clearly been shown to decrease transmissible infectivity.
Warts may clear with treatment or resolve spontaneously. However, recurrences are frequent, particularly in the first 3 months, and may necessitate repeated treatments.

COMPLICATIONS
- Cervical dysplasia (probably does not occur with type 6 or 11, which cause most warts)
- Malignant change: Progression of condylomata to cancer rarely, if ever, occurs, although squamous cell carcinoma may coexist in larger warts.
- Urethral, vaginal, or anal obstruction from treatment
- The prevalence of high-grade dysplasia and cancer in anal canal is higher in HIV-positive than in HIV-negative patients, probably because of increased HPV activity.

REFERENCES
ADDITIONAL READING

CODES

ICD10
A63.0 Anogenital (venereal) warts

CLINICAL PEARLS

- Condylomata acuminata are soft, skin-colored, fleshy lesions caused by HPV subtypes 6, 11, 16, 18, 31, 33, and 35.
- The majority of sexually active men and women will have acquired a genital HPV infection, usually asymptomatic, at some time.
- No single therapy for genital warts is ideal for all patients or clearly superior to other therapies.
- 9vHPV vaccine is effective in preventing HPV infection, particularly if administered prior to the onset of engaging in sexual activity. Gardasil is approved and recommended for use in males and females aged 9 to 26 years.
CONJUNCTIVITIS, ACUTE
Frances Yung-tao Wu, MD

BASICS

DESCRIPTION
- Inflammation of the bulbar and/or palpebral conjunctiva of <4 weeks’ duration
- System(s) affected: nervous, skin/exocrine
- Synonym(s): pink eye

Geriatric Considerations
- Suspect autoimmune, systemic, or irritative conditions.
- If purulent, risk of bacterial cause increases with age, the combo of age >65 years and bilateral lid adherence equates to risk for bacterial infection >70%.

Pediatric Considerations
- Neonatal conjunctivitis may be gonococcal, chlamydial, irritative, or related to dacryocystitis.
- Pediatric ER study; 78% positive bacterial culture, mostly *Haemophilus influenzae*; 13% no growth; other studies showed >50% adenovirus.
- Children <5 years were 7 times more likely to be bacterial than were older children or adults.
- Daycare regulations sometimes require any child with presumed conjunctivitis to be treated with a topical antibiotic, despite lack of evidence (1)[A].

EPIDEMIOLOGY
- Predominant age
  - Pediatric: viral, bacterial
  - Adult: viral, bacterial, allergic
- Predominant sex: male = female

Incidence
In the United States accounts for 1–2% of ambulatory office visits

ETIOLOGY AND PATHOPHYSIOLOGY
- Viral
– Adenovirus (common cold), coxsackievirus (implicated in recent hemorrhagic conjunctivitis epidemics in Asia and Middle East)
– Enterovirus (acute hemorrhagic conjunctivitis)
– Herpes simplex
– Herpes zoster or varicella
– Measles, mumps, or influenza

• Bacterial
  – *Staphylococcus aureus* or *Staphylococcus epidermidis*
  – *Streptococcus pneumoniae*
  – *H. influenzae* (children)
  – *Pseudomonas* spp. or anaerobes (contact lens users)
  – *Acanthamoeba*-contaminated contact lens solution may cause keratitis (rare; ~30 cases/year in United States).
  – *Neisseria gonorrhoeae* and *Neisseria meningitidis*
  – *Chlamydia trachomatis*: gradual onset >4 weeks

• Allergic
  – Hay fever, seasonal allergies, atopy

• Nonspecific
  – Irritative: topical medications, wind, dry eye, UV light exposure, smoke
  – Autoimmune: Sjögren syndrome, pemphigoid, Wegener granulomatosis
  – Rare: *Rickettsia*, fungal, parasitic, tuberculosis, syphilis, Kawasaki disease, chikungunya, Graves, gout, carcinoid, sarcoid, psoriasis, Stevens-Johnson, Reiter syndrome

**RISK FACTORS**

• History of contact with infected persons
• Sexually transmitted disease (STD) contact: gonococcal, chlamydial, syphilis, or herpes
• Contact lenses: pseudomonal or acanthamoeba keratitis
• Epidemic bacterial (streptococcal) conjunctivitis reported in school settings

**GENERAL PREVENTION**

• Wash hands frequently.
• Eyedropper technique: While eye is closed and head back, several drops over nasal canthus and then open eyes to allow liquid to enter. Never touch tip of dropper to skin or eye.

**COMMONLY ASSOCIATED CONDITIONS**
• Viral infection (e.g., common cold)
• Possible STD

**DIAGNOSIS**

**HISTORY**

**ART**
Red flag: Any decrease in visual acuity is not consistent with conjunctivitis alone; must document normal vision for diagnosis of isolated conjunctivitis

• Viral: contact or travel
  – May start with one eye and then both
  – If herpetic, recurrences or vesicles on skin
• Bacterial: difficult to distinguish from viral, unless contact lens user. Assume bacterial in contact lens wearer unless cultures are negative. If recent STD, suspect chlamydia or gonococcus.
• Allergic: itching, atopy, seasonal, dander
• Irritative: Feels dry, exposure to wind, tear film deficit may persist 30 days after acute conjunctivitis, chemicals, or drug: atropine, aminoglycosides, iodide, phenylephrine, antivirals, bisphosphonates, retinoids, topiramate, chamomile, COX-2 inhibitors
• Foreign body: Redness may persist 24 hours after removal.

**PHYSICAL EXAM**

• General: common to all types of conjunctivitis
  – Red eye, conjunctival injection
  – Foreign body sensation
  – Eyelid sticking or crusting, discharge
  – Normal visual acuity and pupillary reactivity
• Viral
  – Palpable preauricular lymphadenopathy may be present.
  – Hemorrhagic coxsackievirus-related epidemics were reported.
  – Severe viral: herpes simplex or zoster:
    o Burning sensation, rarely itching
    o Unilateral, herpetic skin vesicles in zoster
    o Palpable preauricular node
• Bacterial (non-STD): may be epidemic
- Mild pruritus, discharge mild to heavy
- Conjunctival chemosis/edema
- If contact lens user, must rule out pseudomonal (or other bacterial) keratitis

- **Bacterial:** gonococcal (or meningococcal) hyperacute infection
  - Rapid onset 12 to 24 hours
  - Severe purulent discharge
  - Chemosis/conjunctival/eyelid edema
  - Rapid growth of superior corneal ulceration
  - Preauricular adenopathy
  - Signs of STDs (chlamydia, GC, HIV, etc.)

- **Allergic**
  - Itching predominant, chemosis, edema
  - Seasonal or dander allergies

- **Nonspecific irritative**
  - Dry eyes, intermittent redness, chemical/drug exposure
  - Foreign body: may have redness and discharge 24 hours after removal

- Must document normal visual acuity
- Cornea should be clear and without fluorescein uptake. Cloudy or ulcerated signifies keratitis; consult ophthalmologist.
- Recommend fluorescein exam: Evert lid to inspect for foreign bodies.
- Skin: Look for herpetic vesicles, nits on lashes (lice), scaliness (seborrhea), or styes.
- Limbal flush at corneal margin if uveitis
- If pupil is irregular (i.e., penetrating foreign body), emergent referral is warranted.
- Discharge but no conjunctival injection: blepharitis

**DIFFERENTIAL DIAGNOSIS**

- **Uveitis** (iritis, iridocyclitis, choroiditis): limbal flush (red band at corneal margin), hazy anterior chamber, and decreased visual acuity
- **Penetrating ocular trauma:** emergently hospitalize
- **Acute glaucoma** (emergency): headache, corneal clouding, poor visual acuity
- **Corneal ulcer,** keratitis, or foreign body: lesions or tear-film deficits on fluorescein exam
- **Dacryocystitis:** tenderness and swelling over tear sac (below medial canthus)
- **Scleritis and episcleritis:** red injected vessels radially oriented, sectoral (pie wedge), nodularity of sclera
- **Pingueculitis:** inflammation of a yellow nodular or wedge-like area of chronic conjunctival degeneration (pinguecula)
- **Ophthalmia neonatorum:** neonates in the first 2 days of life (gonococcal; 5 to 12 days of life): chlamydial, herpes simplex virus (HSV), very rare *N. meningitidis*. Consider specialty consultation for required systemic therapy.
- **Blepharitis:** Lid margins are inflamed producing itching, scale, or discharge, but no conjunctival injection.

### DIAGNOSTIC TESTS & INTERPRETATION
- Usually not needed initially for most common causes
- Culture swab if STD is suspected, very severe symptoms, or patient is a contact lens user
- Viral swab (10-minute test) for adenovirus is costly, requires 6 passes to acquire sample, and may not be tolerated by children.

#### Diagnostic Procedures/Other
- Fluorescein exam for corneal ulcer or abrasion
- Remove small, superficial foreign bodies with irrigation or moistened swab.

### TREATMENT
#### GENERAL MEASURES
- Viral conjunctivitis does not require antibiotics and resolves spontaneously.
- Clean eyelid with wet cloth up to QID.
- Stop use of contact lenses while eye is red.
- Patching of eye is not beneficial.

#### MEDICATION

**First Line**
- Viral (nonherpetic)
  - Artificial tears for symptomatic relief
  - Vasoconstrictor/antihistamine (e.g., naphazoline/pheniramine) QID for severe itching
  - May consider topical antibiotic (see bacterial below) if return to daycare requires treatment
- Viral (herpetic) (ophthalmology consultation)
  - Ganciclovir gel: 0.15%, 5 times per day for 7 days
  - Acyclovir: PO 400 mg 5 times per day for HSV; 800 mg for zoster for 7 days
Bacterial (non-STI): 3 days of cool compresses before starting antibiotic is associated with no adverse effects and reduces unnecessary antibiotic use.
- After 3 days, consider topical antibiotics (NNT 7 at day 6) (immediate antibiotics shortened course by only 3 days in children): Polymyxin B–Bacitracin ophthalmic ointment: Apply 4 times per day for 5 to 7 days.
- Polymyxin B-trimethoprim solution 1 gtt 4 times per day for 5 to 7 days
- Erythromycin ophthalmic ointment: 1/2 inch BID–QID for 5 days
- Sodium sulfacetamide (10% solution) (Bleph-10): 2 drops q4h (while awake) for 5 days
- Tobramycin or gentamicin: 0.3% ophthalmic drops/ointment q4h (drops) to q8h (ointment) for 7 days

Bacterial (gonococcal)
- Neonates: Hospitalize for IV therapy.
- Adults: ceftriaxone: 1 g IM as single dose and topical bacitracin ophthalmic ointment 1/2 inch QID. Neonates 25 to 50 mg/kg IV or IM, not to exceed 125 mg, as a single dose. Chlamydia in neonates requires oral erythromycin ethylsuccinate: 50 mg/kg/day divided q6h PO for 14 days, max 3 g/day.

Allergic and atopic over-the-counter (OTC) medications are efficacious, no evidence favoring one over another (3).[A.]
- Ketotifen (Zaditor, Alaway, and other generics OTC): 0.25% 1 drop BID
- Cromolyn (Opticrom): 4% QID
- Azelastine: 0.05% 1 gtt BID
- Pemirolast (Alamast): 0.1% 1 gtt QID
- Alcaftadine (Lastacaft): 0.25% 1 gtt QD
- Emedastine: 0.05% 1 drop QID
- Epinastine (Elestat): 0.05% BID
- Ketorolac (Acular): 0.1% 1 drop QID
- Olopatadine (Pataday, Patanol): 0.1% 1 drop BID or 0.2% 1 drop daily
- Bepotastine (Bepreve): 1.5% 1 gtt BID
- Lodoxamide tromethamine (Alomide): 0.1% 1 gtt QID
- Nedocromil (Alocril): 2% 1 gtt BID
- Oral nonsedating antihistamines (cetirizine [Zyrtec] 10 mg/day, fexofenadine [Allegra] 60 mg BID, etc.) may treat nasal symptoms but cause ocular drying; oral antihistamine (e.g., diphenhydramine 25 mg TID) in severe cases of itching

Contraindications: Steroids NOT beneficial in treatment of bacterial keratitis (4).[A]. Topical immune modulators (tacrolimus, cyclosporine) should be reserved for specialist use only in the most difficult cases.

Precautions
– Do not allow dropper to touch the eye.
– Case reports of eye irritation from gentamicin in infants, moxifloxacin in adults, sulfacetamide in allergic individuals
– Vasoconstrictor/antihistamine: rebound vasodilation after prolonged use

**Second Line**
- Viral and allergic: numerous OTC products
- Bacterial: second line (quinolones used as postop or known resistant organisms)
  - Ofloxacin: 0.3% 1 gtt 4 times per day for 7 days
  - Ciprofloxacin: 0.3% 1 gtt 4 times per day for 7 days
  - Levofloxacin: 0.3% 1 gtt 4 times per day for 7 days
  - Gatifloxacin: 0.3% 1 gtt 3 times per day for 7 days
  - Moxifloxacin: 0.5% 1 gtt 3 times per day for 7 days
  - Besifloxacin: 0.6% 1 gtt 3 times per day for 7 days
  - Azithromycin: 1.5% 2 times per day for 3 days

**ISSUES FOR REFERRAL**
- Refer to ophthalmology for any significantly decreased visual acuity, herpetic keratitis, or contact lens–related conjunctivitis or immunocompromised (HIV).
- Refer for symptoms or worsening over 7 days (concern for severe adenoviral keratitis) (5).

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Usually benign and self-limited; saline flushes, cool compresses, and similar treatments help
- Mandarin orange yogurt showed improvement over 2 weeks for allergic conjunctivitis in a small study.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Acute gonococcal conjunctivitis (or very rare case of meningococcal conjunctivitis) requires inpatient treatment with ceftriaxone 50 mg/kg IV everyday (pediatric), 1 g IM for one (adult) along with ophthalmologic consultation.
- Admission criteria/initial stabilization
– Penetrating ocular trauma, gonococcal conjunctivitis

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- If not resolved within 5 to 7 days, alternate diagnoses should be considered or consultation obtained, although some epidemic keratoconjunctivitis and other adenoviral conjunctivitis typically last 1 to 2 weeks.
- Children may be excluded from school until eye is no longer red, if viral or bacterial, depending on school policy. Allergic conjunctivitis should be able to return to school with doctor’s note.

**PATIENT EDUCATION**
- Patients should not wear contacts until their eyes are fully healed (typically 1 week).
- Patients should discard current contacts.
- Patients should discard eye makeup they had been using, especially mascara.
- Cool, moist compress can ease irritation and itch.

**PROGNOSIS**
- Viral: 5 to 10 days of symptoms for pharyngitis with conjunctivitis, 2 weeks with adenovirus
- Herpes simplex: 2 to 3 weeks of symptoms
- Most common bacterial—*H. influenzae, Staphylococcus, Streptococcus*: self-limited; 74–80% resolution within 7 days, whether treated or not

**COMPLICATIONS**
- Corneal scars with herpes simplex
- Lid scars or entropion with varicella zoster and chlamydia
- Corneal ulcers or perforation, very rapid with gonococcal
- Hypopyon: pus in anterior chamber
- Chlamydial neonatal (ophthalmic): could have concomitant pneumonia
- Otitis media may follow *H. influenzae* conjunctivitis.
- Very rarely *N. meningitidis* conjunctivitis may be followed by meningitis.

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

- Rhinitis, Allergic
- Algorithm: Eye Pain

**CODES**

**ICD10**

- H10.30 Unspecified acute conjunctivitis, unspecified eye
- H10.33 Unspecified acute conjunctivitis, bilateral
- H10.32 Unspecified acute conjunctivitis, left eye

**CLINICAL PEARLS**

- Conjunctivitis does *not* alter visual acuity; decreased acuity or photophobia should prompt consideration of more serious ophthalmic disorders.
- Culture the discharge in all *contact lens wearers*, consider referral, and remind patient to throw away current contacts and avoid contacts until eyes are fully
healed.
- Antibiotics are of no value in viral conjunctivitis (most cases of infectious conjunctivitis) and do not significantly alter the course of most types of bacterial conjunctivitis.
- Treating symptomatically for 3 days before prescribing an antibiotic is appropriate for adults and children >1 month.
CONSTIPATION
S. Mimi Mukherjee, PharmD • Sandra Marwill, MD, MPH

BASICS
Unsatisfactory defecation characterized by infrequent stools, difficult stool passage, or both. Characteristics include <3 bowel movements a week, hard stools, excessive straining, prolonged time spent on the toilet, a sense of incomplete evacuation, and abdominal discomfort/bloating.

DESCRIPTION
- System(s) affected: gastrointestinal (GI)
- Synonym(s): obstipation

Geriatric Considerations
Colorectal neoplasms may be associated with constipation; new-onset constipation after age 50 years is a “red flag.” Use warm water enemas for impaction instead of sodium phosphate enema in geriatric patients. Sodium phosphate enemas have been associated with fatalities and severe electrolyte disturbances (1)[B].

Pediatric Considerations
Consider Hirschsprung disease (absence of colonic ganglion cells): 25% of all newborn intestinal obstructions, milder cases diagnosed in older children with chronic constipation, abdominal distension, decreased growth; 5:1 male-to-female ratio; associated with inherited conditions (e.g., Down syndrome)

Pregnancy Considerations
Avoid misoprostol. Always consider risks versus benefits when deciding on treatment.

EPIDEMIOLOGY
- More pronounced in children and elderly
- Predominant sex: female > male (2:1)
- Nonwhites > whites
Incidence

- 5 million office visits annually
- 100,000 hospitalizations

Prevalence

- 16% of adults >18 years, rising to 33% of adults >60 years of age
- 3% of physician visits in children relate to constipation.

ETIOLOGY AND PATHOPHYSIOLOGY

- As food leaves the stomach, the ileocecal valve relaxes (gastroileal reflex) and chyme enters the colon (1 to 2 L/day) from the small intestine. In the colon, sodium is actively absorbed in exchange for potassium and bicarbonate. Water follows the osmotic gradient. Peristaltic contractions move chyme through the colon into the rectum. Chyme is converted into feces (200 to 250 mL).
- Normal transit time is 4 hours to reach the cecum and 12 hours to reach the distal colon.
- Defecation reflexively follows once stool reaches the rectal vault. This reflex can be inhibited by voluntarily contracting the external sphincter or facilitated by straining to contract the abdominal muscles while voluntarily relaxing the anal sphincter. Rectal distention initiates the defecation reflex. The urge to defecate occurs as rectal pressures increase. Distention of the stomach also initiates rectal contractions and a desire to defecate (gastrocolic reflex).
- Primary and secondary defecation disorders result from delay in colonic transit, altered rectal motor activity, and structural or functional problems with pelvic floor muscles (including paradoxical contractions, diminished ability to relax sphincter, and/or poor propulsion).

Genetics

Unknown but may be familial

RISK FACTORS

- Very young and very old
- Polypharmacy
- Sedentary lifestyle or condition
- Improper diet and inadequate fluid intake

GENERAL PREVENTION

High-fiber diet, adequate fluids, exercise, and training to “obey the urge” to
COMMONLY ASSOCIATED CONDITIONS

- General debilitation (disease or aging)
- Dehydration
- Hypothyroidism
- Hypokalemia
- Hypercalcemia
- Nursing home resident

DIAGNOSIS

ALERT

Red flags:

- New onset after age of 50 years
- Hematochezia/melena
- Unintentional weight loss
- Family history of colon cancer
- Anemia
- Neurologic defects

HISTORY

- Assess onset of symptoms, number of bowel movements per week, straining, completeness of evacuation, use of manual manipulation.
- Identify red flags; evaluate diet, lifestyle, prescription, and OTC medication use; identify reversible causes; ask about history of sexual abuse, illicit opioid use.
- Bristol Stool Form Scale—seven categories of consistency (2)
- Bowel and diet diary help to measure treatment response.
- Rome III criteria (3)[C]:
  - At least two of the following for 12 weeks in the previous 6 months:
    - <3 stools per week
    - Straining at least 1/4 of the time
    - Hard stools at least 1/4 of time
    - Need for manual assist at least 1/4 of time
    - Sense of incomplete evacuation at least 1/4 of time
    - Sense of anorectal blockade at least 1/4 of time
– Loose stools rarely seen without use of laxatives
– Frequent constipation but does not meet irritable bowel syndrome (IBS) criteria
– Although there can be overlap, the history of primary constipation differs from constipation-predominant IBS.
  o In primary constipation, pain and bloating are relieved by adequate defecation. In IBS, pain and bloating predominate and are not readily relieved by defecation.

**PHYSICAL EXAM**
- Vital signs
- Abdominal exam, previous surgical scars, hypoactive bowel sounds, tenderness and masses
- Gynecologic exam: Evaluate for masses and rectocele.
- Digital rectal exam: Evaluate for masses, pain, stool, fissures, hemorrhoids; assess sphincter tone.
- Neurologic exam

**DIFFERENTIAL DIAGNOSIS**
- Primary constipation (primary problem is within the GI tract) four subtypes
  - Normal colonic transit time most common subtype; can be difficult to differentiate from constipation-predominant IBS
  - Slow colonic transit time
  - Pelvic floor/anal sphincter dysfunction
  - Combination pelvic floor/anal sphincter dysfunction and slow transit
- Secondary constipation (outside the GI tract)
  - Endocrine dysfunction (diabetes mellitus, hypothyroid)
  - Metabolic disorder (increased calcium, decreased potassium)
  - Mechanical (obstruction, rectocele)
  - Pregnancy
  - Neurologic disorders (Hirschsprung, multiple sclerosis, spinal cord injuries, Parkinson disease)
- Congenital
  - Hirschsprung disease/syndrome
  - Hypoganglionosis
  - Congenital dilation of the colon
  - Small left colon syndrome
- Medication effect
  - Anticholinergic effects (antidepressants, opioids antipsychotics)
– Antacids (calcium, aluminum)
– Nondihydropyridine calcium channel blockers, especially verapamil
– Iron and multivitamins with iron
– Diuretics
– Overuse of antidiarrheal medications

**DIAGNOSTIC TESTS & INTERPRETATION**
Identify red flags, secondary causes, and reversible conditions. If none present, go to first-line treatment.

*Initial Tests (lab, imaging)*
- CBC to screen for iron deficiency anemia
- Consider tox screen if suspect illicit opioid use
- Calcium, glucose, and thyroid function testing (TSH) based on history and exam. If red flags are present, refer for sigmoid/colonoscopy.

*Follow-Up Tests & Special Considerations*
For patients with pelvic floor dysfunction or exam abnormalities (e.g., rectocele) and/or patients who are refractory to initial treatment, refer to an experienced subspecialist. An experienced biofeedback physical therapist can be very helpful.

*Diagnostic Procedures/Other*
- Anorectal manometry (ARM)
- Balloon expulsion testing (BET)
- Scintigraphy
- MRI
- Defecography
- Colonic marker studies

*Test Interpretation*
- ARM and BET recommended for all refractory cases
- If ARM and BET are negative, scintigraphy may help evaluate transit time. Some recommend biofeedback prior to scintigraphy.

**TREATMENT**
Address immediate concerns:
- Bloating/discomfort/straining: osmotic agents
- Postoperative, after childbirth, hemorrhoids, fissures: stool softener to aid defecation
- If impacted: manual disimpaction, then treat any underlying conditions.

**GENERAL MEASURES**
In patients with no known secondary causes, conservative nonpharmacologic treatment is recommended.

- Eliminate medications that cause constipation.
- Increase fluid intake.
- Increase soluble fiber in diet.
- Encourage regular defecation attempts after eating.
- Regular exercise
- Enemas if other methods fail (avoid sodium phosphate enemas in geriatric patients)

**MEDICATION**
Nonprescription medications are first line. If patient goals are not reached, advance to prescription medications.

**First Line**
Bulking agents (accompanied by adequate fluids):

- Hydrophilic colloids (bulk-forming agents)
  - Psyllium (Konsyl, Metamucil, Perdiem Fiber): 1 tbsp in 8-oz liquid PO daily up to TID
  - Methylcellulose (CitruCel): 1 tbsp in 8-oz liquid PO daily up to TID
  - Polycarbophil (Mitrolan, FiberCon): 2 caplets with 8-oz liquid PO up to QID
- Stool softeners
  - Docusate sodium (Colace): 50 to 100 mg PO TID
- Osmotic laxatives
  - Polyethylene glycol (PEG) (MiraLax) 17 g/day PO dissolved in 4 to 8 oz of beverage (current evidence shows PEG to be superior to lactulose) (4)[B]
  - Lactulose (Chronulac, Enulose) 15 to 60 mL PO QHS (flatulence, bloating, cramping)
  - Sorbitol: 15 to 60 mL PO QHS (as effective as lactulose)
  - Magnesium salts (milk of magnesia) 15 to 30 mL PO once daily; avoid in
renal insufficiency.

**Second Line**

- Stimulants (irritate bowel, causing muscle contraction; usually combined with a softener; work in 8 to 12 hours)
  - Senna/docusate (Senokot-S, Ex-lax, Peri-Colace): 1 to 2 tablets or 15 to 30 mL PO at bedtime
  - Bisacodyl (Dulcolax, Correctol): 1 to 3 tablets PO daily
- Lubricants (soften stool and facilitate passage of the feces by its lubricating oily effects)
  - Mineral oil (15 to 45 mL/day)
  - Short-term use only; can bind fat-soluble vitamins, with the potential for deficiencies; may similarly decrease absorption of some drugs
  - Avoid in those at risk for aspiration (lipoid pneumonia).
- Suppositories
  - Osmotic: sodium phosphate
  - Lubricant: glycerin
  - Stimulatory: bisacodyl
  - Enemas: saline (Fleet enema)
- Lubiprostone (Amitiza): a selective chloride channel activator; 24 μg PO BID
- Guanylate cyclase-C agonists (adult use only)
  - Linaclotide (Linzess): dose: 145 μg PO once daily;
  - Plecanatide (Trulance): dose: 3 mg PO once daily
- Peripherally acting μ-opioid receptor antagonists, indicated for opioid-induced constipation
  - Methylnaltrexone (Relistor): dose: 38 to <62 kg: 8 mg; 62 to 114 kg: 12 mg SC every other day PRN
  - Naloxegol (Movantik): dose: 12.5 to 25.0 mg PO daily; discontinue other laxatives for 3 days when initiating naloxegol; avoid in patients on strong Cyp3A4 inhibitors due to increased naloxegol levels and risk of opioid withdrawal.
  - Naldemedine (Symproic): dose: 0.2 mg PO daily; monitor for opioid withdrawal in patients on strong Cyp3A4 inhibitors or P-gp inhibitors.
- Prokinetic agents (partial 5-HT4 agonists) have been withdrawn due to cardiac side effects; only available via IND protocols: tegaserod (Zelnorm), cisapride (Propulsid)
- Other agents not approved by the FDA:
  - Misoprostol (Cytotec): a prostaglandin that increases colonic motility
  - Colchicine: neurogenic stimulation to increase colonic motility
ADDITIONAL THERAPIES
- Other nonpharmacologic therapies include biofeedback, a first-line recommendation for patients with refractory constipation due to functional conditions involving dyssynergic defecation or inadequate propulsive force.
- Behavior therapy

SURGERY/OTHER PROCEDURES
Surgery rarely indicated; sometimes required for anatomic findings (rectocele or enterocele)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Toxic megacolon
- Manual disimpaction occasionally required in chronic refractory cases

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Encourage exercise and physical activity.

Patient Monitoring
If functional constipation persists, revisit secondary causes.

DIET
Increase soluble fiber (bloating and gas can be problematic with insoluble fiber):
- Gradually increase intake to 25 g/day over a 6-week period.
- Oat bran (hard outer layer of cereal grains)
- Peas; onions; lentils; beans; seeds; nuts; and fruits including bananas, apples, and strawberries
- Encourage liberal intake of fluids.

PATIENT EDUCATION
- Occasional mild constipation is normal.
- Bowel training: The best time to move bowels is in the morning, after eating breakfast, when the normal bowel transit and defecation reflexes are functioning.
PROGNOSIS

- Occasional constipation responds well to simple measures.
- Habitual constipation can be a lifelong nuisance.
- Patients with neurologic compromise can suffer from obstipation, impaction, and toxic megacolon.
- No evidence for laxative dependence or harm from stimulant use; melanosis coli may develop but is a benign condition.

COMPLICATIONS

- Volvulus
- Toxic megacolon
- Acquired megacolon in severe, long-standing cases
- Fluid and electrolyte depletion: laxative abuse
- Rectal ulceration (stercoral ulcer) related to recurrent fecal impaction
- Anal fissures

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**

- K59.00 Constipation, unspecified
- K59.01 Slow transit constipation
- K59.09 Other constipation

**CLINICAL PEARLS**

- Constipation (especially with normal transit time) is common. Reversible risk factors include inadequate hydration, sedentary lifestyle, poor dietary habits, and medication side effects.
- Red flags: onset >50 years, hematochezia/melena, unintentional weight loss, anemia, neurologic defects
- Osmotic agents (PEG) are most clinically effective.
CONTRACEPTION

Kim M. Stein, MD • Melissa J. Fullerton, MD

BASICS

DESCRIPTION

- Medications or procedures that control timing of pregnancies and prevent unintended pregnancies
- Contraception options are divided into two major categories: hormonal and nonhormonal.
- The most effective methods of contraception are vasectomy, female sterilization, and the long-acting reversible contraceptives (LARC).

EPIDEMIOLOGY

Incidence

- The estimated prevalence of contraception use among women age 15 to 44 years is 61% in the United States (1).
- 49% of all pregnancies in the United States are unintended, and half of these occur in women using a form of reversible contraception.
- 43% of all unintended pregnancies in the United States result in termination.
- The most frequently used forms of contraception in the United States (in order of prevalence) are oral contraceptive pills (OCPs), female sterilization, male condom, male sterilization, and depot injectables.
- Although LARC is one of the most effective forms of contraception, they are among the least used methods in the United States.

RISK FACTORS

Unintended pregnancy: higher rates among women ages 18 to 24 and >40 years, unmarried/cohabitating women, women with less than a college education, and minority women

DIAGNOSIS

HISTORY
Review past medical, family, social, obstetric, and gynecologic histories including menstrual history, prior experience with contraceptives, and prior sexually transmitted diseases (STDs).

Contraindications: See CDC medical eligibility criteria (MEC) (2).

- Estrogen-progestin contraceptives
  - Absolute: age ≥35 years and smoking ≥15 cigarettes per day, <21 days postpartum, SBP ≥160 mm Hg or DBP ≥100 mm Hg, multiple CAD risk factors, current/prior venous thromboembolism (VTE), thrombophilia, long-standing/complicated diabetes, ischemic heart disease, stroke, complicated valvular disease, systemic lupus, migraine with aura, breast cancer, severe cirrhosis, solid organ transplant, hepatocellular adenoma, or malignant hepatoma
  - Relative: age ≥35 years and smoking <15 cigarettes per day, breastfeeding <42 days postpartum, SBP 140 to 159 mm Hg or DBP 90 to 99 mm Hg (or well-controlled on medications), symptomatic choledolithiasis, certain anticonvulsants, bariatric surgery, migraines without aura but ≥35 years, or breast cancer history in remission >5 years

- Progestin-only (pill/Depo/implant)
  - Absolute: current breast cancer
  - Relative: bariatric surgery, ischemic heart disease, history of stroke, lupus, migraine with aura, severe cirrhosis, certain anticonvulsants, hepatocellular adenoma, or malignant hepatoma

- Levonorgestrel (LNG)-intrauterine device (IUD)
  - Absolute: postseptic abortion, postpartum sepsis, gestational trophoblastic disease, current breast/cervical/endometrial cancer, unexplained vaginal bleeding, distorted uterine cavity, current pelvic inflammatory disease (PID), purulent cervicitis, gonorrhea/chlamydia infection, pelvic tuberculosis (TB)
  - Relative: ischemic heart disease, lupus, severe cirrhosis, hepatocellular adenoma or malignant hepatoma, increased risk of STDs, solid organ transplant

- IUD—copper (“ParaGard”)
  - Absolute: same as LNG-IUD except use in cancer of breast, possibly cervix OK
  - Relative: severe thrombocytopenia, increased risk of STDs, solid organ transplant

**DIAGNOSTIC TESTS & INTERPRETATION**

- A negative pregnancy test (urine or serum) is advised prior to initiating
contraception.
- Consider testing for gonorrhea and chlamydia prior to IUD insertion especially if age <25 years or multiple sexual partners. Testing can be done at time of insertion if symptomatic infection is ruled out.
- Perform Pap smear if otherwise indicated.
- Screen for hypertension.
- In family history of thrombophilia, testing can be considered before initiation of estrogen-containing contraception, especially if specific defect is known.

**TREATMENT**

**GENERAL MEASURES**
- Method(s) should be selected based on patient preference, effectiveness, need for STD prevention, side effects, and contraindications.
- General categories included hormonal and nonhormonal methods.
  - Nonhormonal methods include condoms, diaphragm, cervical cap, copper IUD, vasectomy, female sterilization, fertility awareness, sponge, spermicides, and abstinence.
  - Hormonal methods include oral contraceptives, patch, ring, injectables, IUDs, and implants.

**MEDICATION**
- Estrogen-progestin contraceptives
  - Mechanism of action: work by suppression of ovulation, thickening cervical mucus, and endometrial changes that interfere with transport of sperm to egg and with implantation
  - Efficacy: failure rate of about 4.8% at 1 year
  - Side effects: nausea, bloating, headaches, mastalgia, depression, acne, and hirsutism
  - Side effect management: Breakthrough bleeding is usually self-limiting after 3 months; if persists, change pill. Amenorrhea: Rule out pregnancy.
  - Combined oral contraceptives (COCs): pill
    - All COCs contain the same type of estrogen (ethinyl estradiol) but differ in the amount of estrogen (range of 10 to 50 μg) and the type of progestin.
    - Newer progestins (such as norgestimate and desogestrel) are less androgenic but may have increased rate of VTE.
o Start with a pill that is inexpensive (generic); contains an average amount of estrogen (30 to 35 μg)
o Dosing: Most pills have a 21/7 regimen (21 active days and 7 placebo); alternatively, can take active pills continuously with four yearly scheduled withdrawal bleeds
o Initiation: 1st day start (begin the pill on the 1st day of menses), quick start (begin pill on day medication is obtained), or Sunday start (begin pill on first Sunday)
  - Weekly hormonal patch (Ortho Evra):
    o Releases 20 μg/day ethinyl estradiol and 150 μg/day norelgestromin
    o Applied transdermally and changed weekly
    o Produces higher serum estrogen levels than oral 20 μg pill and may be associated with a slightly increased risk of blood clot
    o Patch may cause local skin irritation; not as reliable in women >90 kg
  - Vaginal contraceptive ring (NuvaRing):
    o Flexible polymer ring with 15 μg/day of ethinyl estradiol and 120 μg/day of etonogestrel absorbed via vaginal wall
    o Insert into vagina for 3 weeks/cycle or use continuous cycling for 4 weeks then replace immediately with a new ring (off-label).
    o Although systemic exposure to estrogen is about 50% of exposure with COCs, the risk of blood clots is about the same.

● Progestin-only birth control
  - Mechanism of action: thickening cervical mucus and thinning endometrial lining
  - Progestin-only pill (Micronor)
    o Efficacy: failure rate of about 0.3% with perfect use, 9% with typical use at 1 year
    o Can be used in women with contraindication to estrogen, including breastfeeding women after 6 weeks postpartum
    o Dosing: 1 pill at the same time daily, no placebo days
    o Side effects: irregular bleeding
  - Injectable contraceptive (medroxyprogesterone) ”Depo-Provera”
    o Efficacy: failure rate of 0.2% with perfect use, 6% with typical use at 1 year
    o Dosing: 150 mg IM or Depo-SubQ Provera 104 mg SC, both are given every 3 months. Contraceptive levels of hormone persist for up to 4 months (2- to 4-week margin of safety).
    o Side effects include irregular bleeding, weight gain (average of 5 lb/year of use), and amenorrhea.
LARC: IUDs and implantable devices

- **Mirena (52-mg levonorgestrel-releasing IUD):**
  
  - Mechanism of action: sterile inflammatory reaction due to foreign body that is toxic to sperm and ova, thickens cervical mucus, endometrial deciduation and glandular atrophy, inhibiting sperm-egg binding, partial inhibition of ovarian follicular development, and ovulation
  
  - Efficacy: failure rate of 0.2% with both perfect and typical use at 1 year
  
  - Dosing: releases 20 μg/day (very low serum levels) initially and subsequently reduces to 10 μg/day
  
  - Approved for use up to 5 years; has been used off-label for up to 7 years
  
  - Safe in nulliparous women/teenagers
  
  - Can be inserted immediately postpartum or immediately following dilation and curettage for miscarriage or abortion, but these are associated with higher rates of expulsion compared to delayed placement (6 to 10 weeks)
  
  - Side effects: irregular menstrual spotting for the first 3 to 6 months that usually resolves after 6 months of use; may see absence of menses after 1 year
  
  - Side effect management: Consider COCs or estrogen alone for spotting and cramps.
  
  - Can reduce heavy bleeding in menorrhagia

- **Liletta (52-mg levonorgestrel-releasing IUD):**
  
  - Releases 18.6 μg/day initially; approved for 3 years, at which time it releases 12.6 μg/day

- **Kyleena (19.5-mg levonorgestrel-releasing IUD):**
  
  - Releases 17.5 μg/day for the 1st year, down to 7.5 μg/day. Approved for 5 years. Smaller insertion tube with 3.8 mm diameter offers potential for easier insertion in nulliparous women.

- **Skyla (13.5-mg levonorgestrel-releasing IUD):**
  
  - Releases 14 μg/day initially, down to 5 μg/day, approved for 3 years. Smaller insertion tube (3.8 mm diameter); more bleeding days than Mirena

- **ParaGard (copper IUD):**
  
  - Mechanism of action: In addition to sterile inflammatory reaction due to foreign body, free copper and copper salts enhance the cytotoxic inflammatory reaction—toxic to sperm and ova.
  
  - Efficacy: failure rate of 0.6% with perfect use, 0.8% with typical use at 1 year
  
  - Approved for up to 10 years
o Same insertion timing as LNG-IUD
o Side effects: blood loss and cramping
  – Nexplanon (etongestrel implant):
    o Mechanism of action: thickening cervical mucus and thinning endometrial lining
    o Efficacy: failure rate of 0.05% with perfect use, 0.3% with typical use at 1 year
    o Dosing: 40 mm × 2 mm semirigid plastic rod containing 68 mg of etonogestrel; initially releases 60 to 70 μg/day, down to 25 to 30 μg/day at the end of the 3rd year
    o Effective for up to 3 years
    o Must be inserted only by certified providers
    o Side effects: menstrual irregularities (common first 6 to 12 months, often continue for full 3 years)

• Emergency contraception: should be initiated as soon as possible post-unprotected intercourse. Copper IUD is the most effective, followed by ulipristal, levonorgestrel, and Yuzpe method (least effective) (3)[A].
  – Copper-bearing IUD (ParaGard): Insert up to 5 days after intercourse; failure rate of 0.04–0.19%
  – Ulipristal acetate (Ella): 30 mg × 1 dose; selective progesterone modulator, effective up to 5 days after unprotected intercourse with minimal decline in efficacy; about 2% failure rate
  – Levonorgestrel: 1.5 mg taken as two 0.75-mg tablets (Plan B) or one 1.5-mg tablet (Plan B 1-Step). Failure rate: 1.1–2.4%. Less nausea than “Yuzpe regimen.” Available over the counter; may be less expensive if prescribed. Most effective within 72 hours, efficacy declines with time. May be ineffective for women with BMI >30. Estradiol/levonorgestrel (Preven, Lo Ovral, Ogestrel): “Yuzpe regimen” 50 μg/0.25 mg, 2 tablets q12h (4 tablets total). Any OC may be used as long as the dose of estrogen component ≥100 μg/dose. Failure rate: 3.2%. Note: Antiemetic should be given 1 to 2 hours before each dose.

**ADDITIONAL THERAPIES**

• Condoms: failure rate of 2% with perfect use, 18% with typical use at 1 year
• Spermicides: All contain nonoxynol-9; may alter vaginal flora and mucosal barrier. Failure rate: 28% at 1 year with typical use.
• Sponge (Today Sponge): Soft foam disk contains nonoxynol-9. Moisten with water before use; effective for 24 hours; must leave in for 6 hours after use; less effective in parous women. Failure rate: 12–24% at 1 year with typical
Diaphragm: latex or silicone dome-shaped device with flexible spring-activated rim, works by preventing sperm from entering cervix; used with spermicides. Failure rate: 12–16% at 1 year with typical use.

SURGERY/OTHER PROCEDURES
Permanent sterilization
- Female: tubal ligation or Essure (micro-insert system placed hysteroscopically). Essure requires confirmation of tubal occlusion with hysterosalpingogram 3 months postprocedure. Failure rate: 0.5% at 1 year
- Male: vasectomy. Less complicated than female. Failure rate: 0.15% at 1 year

COMPLEMENTARY & ALTERNATIVE MEDICINE
Fertility awareness methods: calendar method, cervical mucus method, temperature method. Low cost but generally not as effective as other methods. Failure rate: 24% at 1 year with typical use.
- Withdrawal method: Male partner withdraws from vagina before ejaculation. Failure if not timed accurately. Failure rate: 22% at 1 year with typical use
- Lactational amenorrhea method: Breastfeeding is effective contraception only if (i) the infant is <6 months old, (ii) the infant is exclusively breastfeeding, and (iii) the mother has not resumed regular menses. Failure rate: 7% at 1 year with typical use

Pediatric Considerations
- AAP and ACOG recommend LARCs as the most effective in sexually active adolescents.
- Contraception counseling should include anticipated adverse effects, need to use condoms for STD prevention, and indications for emergency contraception (including options and how to obtain).

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Pelvic exam, Pap smear, and STI testing per guidelines and routine follow-up
2 to 3 months postinitiation of all methods to assess tolerance

- Check for IUD strings 1 month after insertion; spontaneous expulsion rate highest in the 1st month
- BP check within 3 months of initiation in patients on estrogen-containing methods

**DIET**

St. John’s wort may alter estrogen levels, reducing efficacy or causing breakthrough bleeding.

**PATIENT EDUCATION**

- Diaphragm: device inspected prior to each use, 1 tablespoon of spermicide in hollow of the dome, diaphragm is inserted into the vagina, additional applicator of spermicide placed in vagina. If placed >6 hours prior to intercourse need additional applicator of spermicide. Position needs to be checked post intercourse, and additional spermicide applied prior to each new episode of intercourse. Diaphragm should remain in place for at least 6 hours after the last episode of intercourse to maximize effectiveness.
- Male condoms: New condom is placed on the penis before genital contact, remains intact until the penis is withdrawn; new condom needs to be used with every act of intercourse.
- IUD: Patient should monitor presence of the string monthly following menses.
- OCP: Pill should be taken at approximately the same time each day. Backup birth control method is needed for the first 7 days with quick start and Sunday start methods.

**COMPLICATIONS**

- Estrogen-progestin contraceptives:
  - Serious (requires discontinuation): stroke, thromboembolism, hypertension, myocardial infarction, and cholestatic jaundice
  - Overall 5-fold increased risk of venous thrombosis compared to nonusers, comparable to the 4-fold increased risk of venous thrombosis during pregnancy ([4][B]), but absolute risk is low
- Injectable contraceptive:
  - Potential for decreased bone mineral density (BMD) if used for ≥2 years. Mostly recovers after discontinuation. Consider calcium/vitamin D supplementation if prolonged use.
- Nexplanon: insertion site reaction including pain, bleeding, paresthesias, and
infection

- IUDs:
  - PID: Treat without removal unless serious infection or failure to respond to therapy.
  - Uterine perforation
  - Absolute risk of ectopic pregnancy is reduced with IUD, but if pregnancy does occur, there is a higher risk that it will be ectopic.

- Sponge and diaphragm: rarely associated with toxic shock syndrome

- “Chart comparing contraceptive methods: ARHP Method Match at http://www.arhp.org/methodmatch/

CODES

ICD10

- Z30.9 Encounter for contraceptive management, unspecified
- Z30.41 Encounter for surveillance of contraceptive pills
- Z30.431 Encounter for routine checking of intrauterine contraception
CLINICAL PEARLS

- Hormonal and IUD contraceptives may be initiated immediately if the likelihood of preexisting pregnancy is low “Quick start” and improves adherence compared with traditional start.
- LARC methods provide high efficacy and convenience for patients.
- All patients should be counseled on emergency contraception options.
BASICS

DESCRIPTION

- The term “cor pulmonale” derives from the Latin cor: heart and pulmonale: lungs. Hence, cor pulmonale is a cardiac complication of primary pulmonary disease.
- Acute or chronic pulmonary processes can lead to increased right-sided cardiac pressures. Resultant pulmonary hypertension (PH) subsequently induces structural alterations and/or impairs right ventricle (RV) function.
- PH may be secondary to abnormalities of the pulmonary system including disorders of the lung parenchyma, pulmonary circulation, chest wall, and/or ventilatory mechanisms. The pathophysiologic mechanisms of pulmonary arterial hypertension (WHO Group I) and PH secondary to pulmonary processes are biologically and clinically distinct. Therefore, for the purposes of this review, pulmonary arterial hypertension (WHO Group I) will not be considered as a cause of cor pulmonale.
- Cor pulmonale may occur in acute or chronic setting.
  - Acute: rapid increase of pulmonary arterial pressure resulting in RV overload, dysfunction, and potential cardiovascular collapse
  - Chronic: progressive hypertrophy and dilation of the RV over months to years, leading to dysfunction, and potentially failure

EPIEDEMOLOGY

- ~6–7% of all types of adult heart disease in United States
- Estimated 10–30% of heart failure admissions in the United States are the result of cor pulmonale, most commonly related to chronic obstructive pulmonary disease (COPD).

Incidence

Difficult to assess: Best estimate is 1/10,000 to 3/10,000/year.

Prevalence

Difficult to assess: Best estimate is 2/1,000 to 6/1,000.
ETIOLOGY AND PATHOPHYSIOLOGY

- **Acute:** A sudden event, such as large pulmonary embolism (PE), increases resistance to blood flow in the pulmonary vasculature, causing a quick and significant increase of pressure proximal to the right ventricular outflow tract. The RV may not be able to generate adequate force to overcome this pressure, leading to low RV cardiac output, which ultimately leads to a decreased left ventricle (LV) cardiac output. Increased RV pressures in conjunction with a low cardiac output may cause coronary ischemia, further impairing cardiac output and potentially causing complete cardiovascular collapse.

- **Chronic:** A disorder of the pulmonary system leading to chronic hypoxia results in progressive vasoconstriction of the pulmonary vasculature. Over time, the pulmonary arterial system hypertrophies and intrinsic vasoactive mechanisms (mediated by nitric oxide, cyclooxygenase, and endothelin) become dysregulated, leading to an increase in pulmonary vasculature resistance.

  Increased pulmonary vascular resistance yields PH. PH transmits increased pressures and volumes to the thin-walled, low-pressure RV causing maladaptive remodeling (concentric hypertrophy, followed by eccentric dilation and frequently associated tricuspid regurgitation) and subsequent impairment in RV systolic and diastolic function.

- Indicators for the presence of PH in these patients may include a disproportionally low diffusion capacity of the lungs for carbon monoxide (DLCO) and a low pCO₂.

  **Pulmonary disorders**
  - Lung parenchymal disease: COPD (most common), interstitial lung disease (ILD), and pulmonary fibrosis
  - Pulmonary circulation: thromboembolic disease (associated with WHO Group IV PH)
  - Chest wall: severe obesity, kyphoscoliosis
  - Ventilation: obstructive sleep apnea (OSA) and obesity hypoventilatory syndrome, neuromuscular diseases such as Guillain-Barré syndrome, muscular dystrophy, myasthenia gravis, spinal cord injuries

- Left ventricular failure is not considered a cause of cor pulmonale.

RISK FACTORS

- Acute cor pulmonale (most commonly caused by PE)
- Chronic cor pulmonale (most commonly caused by underlying pulmonary disorder)
– Risk factors associated with pulmonary disorders
  o Tobacco use (COPD)
  o Occupational exposures (ILD)
  o Hypercoagulable state (chronic thromboembolic disease)
  o Obesity, age (chest wall abnormalities)

**GENERAL PREVENTION**
Management of underlying pulmonary disorders, including aggressive correction of hypoxia and acidosis, which may contribute to worsening PH

**COMMONLY ASSOCIATED CONDITIONS**
PH, defined as the presence of a resting mean pulmonary artery pressure (PAP) >25 mm Hg

**DIAGNOSIS**

**HISTORY**
- Dyspnea is the most common symptom, although nonspecific; may be present at rest, with exertion, or occur as paroxysmal nocturnal dyspnea
- Other pulmonary symptoms: pleuritic chest pain, cough, hemoptysis
- General heart failure symptoms: fatigue, lethargy, syncope; exertional angina less likely
- Right-sided heart failure symptoms: anorexia, early satiety, digital cyanosis, clubbing, right upper quadrant discomfort (hepatic congestion), lower extremity edema
- Hoarseness secondary to compression of the left recurrent laryngeal nerve by enlarged pulmonary vessels
- Cardiovascular collapse, shock, and/or cardiac arrest may occur in acute or advanced chronic setting.

**PHYSICAL EXAM**
- Peripheral edema is the most common sign of right-sided heart failure, although it is nonspecific.
- General: pallor, diaphoresis, clubbing, cyanosis, tachypnea
- Neck: jugular venous distension, with prominent a-wave
- Lungs: tachypnea, wheezing
- Heart
– Increased intensity of pulmonic component of second heart sound (P₂)
– Splitting of S₂ over the cardiac apex with inspiration
– Audible right-sided S₃ or S₄
– RV heave
– Pansystolic murmur heard best at right midsternal border increasing with inspiration, consistent with tricuspid regurgitation (typically a late sign)

- Abdomen: hepatomegaly
- Extremities: clubbing, cyanosis, bilateral lower extremity edema, may also signs of deep vein thrombosis (DVT) such as tenderness or unilateral swelling

**DIFFERENTIAL DIAGNOSIS**
Other causes of right-sided failure:
- Left-sided heart failure
- WHO Groups I, II, and V PH
- Right-sided intrinsic cardiomyopathy

**DIAGNOSTIC TESTS & INTERPRETATION**
- 2D echocardiogram (1)[C]
  – Initial diagnostic test of choice
  – Elevated pulmonary arterial pressures
  – Right ventricular hypertrophy
  – Bulging of the interventricular septum into the LV with systole
  – Flattening of the interventricular or interatrial septum
  – Dilation and hypokinesis of the RV
  – Tricuspid regurgitation
  – Dilation of the right atrium
  – Acute thromboembolic pulmonary disease as evidenced by right ventricular hypokinesis with sparing of the apex (McConnell sign)
  – Echocardiography can over- or underestimate the pulmonary arterial pressures depending on image quality or operator. Pulmonary arterial pressures should therefore be verified by right heart catheterization.

- MRI
  – If echocardiography is inconclusive or as a substitute
  – Most accurate modality for diagnosing emphysema and ILD
  – Can assess cardiac pressures, size, function, myocardial mass, and viability

- Right heart catheterization (1)[C]
  – Gold standard for diagnosis of PH and therefore critical for diagnosis of cor pulmonale
– Elevated central venous pressure (CVP)
– Mean PAP ≥25 mm Hg at rest

**Initial Tests (lab, imaging)**
- CBC may show signs of polycythemia due to chronic hypoxia.
- Basic metabolic panel (BMP) may demonstrate elevated creatinine secondary to poor cardiac output.
- Liver function tests (LFTs) may be abnormal due to proximal hepatic congestion or poor distal cardiac output secondary to RV failure.
- Brain natriuretic peptide (BNP) and cardiac troponin can be elevated secondary to right ventricular strain.
- D-dimer may be positive as evidence of underlying thromboembolic pulmonary disease.
- Arterial blood gas may show hypercapnia due to COPD or hypoxemia due to ILD.
- Arterial blood gases of COPD patients show a decreased PaO₂ with normal or increased PaCO₂.
- ECG often shows signs of right-sided enlargement.
  – Right axis deviation
  – An R/S wave ratio >1 in V₁
  – Right ventricular hypertrophy (R wave in V₁ and V₂ with S waves in V₅ and V₆)
  – Right atrial enlargement as evidenced by P pulmonale (increased amplitude of P wave in lead II)
  – Incomplete or complete right bundle branch block
  – S₁S₂S₃ pattern or S₁Q₃T₃ inverted pattern
- Chest x-ray
  – Cardiomegaly
  – Enlargement of the central pulmonary arteries and reduced size of peripheral vessels (oligemia)
  – Reduced retrosternal space due to right ventricular enlargement on lateral views
  – Enlargement of the right atrium resulting in prominence of the right heart border
  – Evidence of COPD, ILD, and structural disease (i.e., kyphosis)
  – Evidence of PE (Westermark sign, Fleischner sign, and Hampton hump)
- Spiral CT scan of chest
  – Diagnosis of acute PE
– Diagnosis of COPD and ILD

- Ventilation/perfusion scan (V/Q)
  - High specificity and sensitivity for acute and chronic thromboembolic disease
  - Screening method of choice for chronic thromboembolic PH because of its higher sensitivity compared with computed tomography pulmonary angiogram
  - May be used for diagnosis of acute thromboembolic disease if contraindication to chest spiral CT
  - Diagnosis of chronic thromboembolic disease (WHO Group IV PH) may warrant confirmation by pulmonary angiography.

- Pulmonary angiography
  - Gold standard in diagnosis of chronic thromboembolic pulmonary disease

- Polysomnography
  - Gold standard for diagnosis of OSA

- Pulmonary function tests (PFTs)
  - DLCO: A decrease in lung volume combined with decreased diffusion capacity for carbon monoxide may indicate ILD. COPD is associated with a decreased DLCO.
  - Obstructive or restrictive ventilatory defects (ILD, chest wall abnormalities, and COPD)

![TREATMENT]

Reduce symptoms, improve quality of life, and increase survival. Reduce disease burden via oxygenation, preservation of cardiac function, and attenuation of PH.

**GENERAL MEASURES**

- Treat underlying disease (2)[A].
  - For underlying pulmonary disease, bronchodilators and/or steroids may be beneficial.
  - For underlying chronic thromboembolic disease, anticoagulation may be indicated.

- Supportive therapy as necessary
  - Continuous positive airway pressure/bilevel positive airway pressure may be used for hypoxia/sleep disorders.
  - Ventilation using positive-pressure masks, negative-pressure body suits, or mechanical ventilation is suggested for patients with neuromuscular
disease.
- Phlebotomy may be indicated for severe polycythemia or signs and symptoms of hyperviscosity (hematocrit >55%).

**MEDICATION**

- **Oxygen (3)[A]**
  - Long-term continuous oxygen therapy improves the survival of hypoxemic patients with COPD and cor pulmonale.
  - All patients with PH whose PaO₂ is consistently <55 mm Hg or saturation ≤88% at rest, during sleep, or with ambulation should be prescribed oxygen to keep O₂ >92 mm Hg.
  - Exposure to high altitude should be avoided. Supplemental oxygen should be used during altitude exposure or air travel as needed to maintain oxygen saturations >91%.

- **Preservation of cardiac function (4)[B]**
  - Inotropes: Dobutamine and milrinone may improve cardiac output.
  - Diuretics: decrease RV filling pressures and reduces peripheral edema secondary to RHF
    - Excessive volume depletion should be avoided.
    - Monitor closely for metabolic alkalosis, as this may suppress ventilatory drive and contribute to hypoxia.

- **Ameliorate PH (1,4)[C]**
  - Treatment of underlying disease is hallmark of management.
  - When refractory to traditional medical treatment, advanced therapies may be beneficial, although evidence is lacking.
  - For chronic thromboembolic associated PH (WHO Group IV), riociguat and macitentan may be used.

**ISSUES FOR REFERRAL**

Patients with cor pulmonale should be referred to a specialized center for expert consultation.

**SURGERY/OTHER PROCEDURES**

- Endarterectomy for chronic thromboembolic disease (WHO Group IV)
- Moderate to severe disease refractory to medication may require lung and/or heart transplantation.
ONGOING CARE

DIET
Salt and fluid restriction

PATIENT EDUCATION
- Smoking cessation and avoidance of exposure to secondary smoke is strongly recommended.
- Level of physical activity should be discussed with physician.
- Pregnancy should be avoided.

PROGNOSIS
Patients with cor pulmonale resulting from COPD have a greater likelihood of dying than do similar patients with COPD alone. In patients with COPD and mild disease (PAP 20 to 35 mm Hg), 5-year survival is 50%.

CODES

ICD10
- I27.81 Cor pulmonale (chronic)
- I26.09 Other pulmonary embolism with acute cor pulmonale

CLINICAL PEARLS

- Treatment of cor pulmonale requires treatment of the underlying disease. Therefore, accurate diagnosis of primary pulmonary disease is critical to clinical management and treatment therapy.
- Continuous, long-term oxygen therapy improves life expectancy and quality of life in cor pulmonale.
- Referral of patients with cor pulmonale to a specialized center is strongly recommended.
CORNEAL ABRASION AND ULCERATION

Patrick F. Cleary, DO • Christine S. Persaud, MD

 BASICS

DESCRIPTION

- Corneal abrasions: result from cutting, scratching, or abrading the thin, protective, clear coat of the exposed anterior portion of the ocular epithelium. These injuries cause pain, tearing, photophobia, foreign body sensation, and a gritty feeling (1).
- Corneal ulceration: break in the epithelial layer of the cornea leading to exposure of the underlying corneal stroma, which results in a corneal ulcer. Superficial ulcers, limited to loss of the corneal epithelium, are the most common form of ulceration (2).
- Corneal abrasion and ulceration can both lead to impaired vision from scarring.

EPIDEMIOLOGY

Incidence

- Corneal abrasions are commonly seen in primary care. Eye-related diagnoses make up 8% of total ER visits. Of those eye-related visits, 45% are corneal abrasions. Abrasions are the third leading cause of red eye, following conjunctivitis and subconjunctival hemorrhage (3).
- Associated with significant morbidity and loss of productivity

ETIOLOGY AND PATHOPHYSIOLOGY

- Corneal abrasions are most often caused by mechanical trauma but may also result from foreign bodies, contact lenses wear, or chemical and flash burns.
- Corneal ulceration: Contact lenses use, HIV, trauma, ocular surface disease, and ocular surgery increase the incidence. Edema plays a major role in epithelial defect. Edema can lead to trauma, ischemia, and increased intraocular pressure. Excessive fluid disrupts the normal architecture of the epithelial layer (4).
- Causes of ulcerations include the following:
– Infection with gram-positive organisms ~29–53% (*Staphylococcus aureus* and coagulase-negative *Streptococcus* are common ones)
– Infection with gram-negative organisms ~47–50% (*Pseudomonas* being most common, followed by *Serratia marcescens, Proteus mirabilis*, and gram-negative enteric bacilli)

- Increased risk of corneal ulceration in HIV and diabetes mellitus (DM) patients and immunocompromised

**RISK FACTORS**
- History of trauma (direct blunt trauma, chemical burn, radiation exposure, etc.)
- Contact lenses wear
- Male gender
- Age: 20 to 34 years old
- Job (construction, manufacturing)
- Lack of eye protection

**GENERAL PREVENTION**
Protective eyewear during work (automechanics, metal workers, miners, etc.) and during sports

**COMMONLY ASSOCIATED CONDITIONS**
- Vitamin A deficiency is associated with corneal ulcers.
- Neuropathy of cranial nerve (CN) V
- DM, thyroid dysfunction, immunocompromised states, connective tissue disease

**DIAGNOSIS**

**HISTORY**
Corneal abrasion is a clinical diagnosis. It includes a history of recent ocular trauma and acute pain. Other symptoms include photophobia, pain with extraocular muscle movement, excessive tearing, blepharospasm, foreign body sensation, gritty feeling, blurred vision, and headache.

**PHYSICAL EXAM**
- Gross examination of the anatomy: eyelids, surface of the eye, pupils, and
extraocular muscles

- Snellen chart
- Tonometry
- Penlight
- Blepharospasm: fluorescein stain
- Wood lamp (5)

**DIFFERENTIAL DIAGNOSIS**

- Corneal abrasion
  - Acute angle-closure glaucoma
    - Conjunctivitis
  - Infective keratitis
    - Uveitis
      - Keratoconjunctivitis (3,5)
- Corneal ulceration
  - Herpes zoster
    - Herpes zoster ophthalmicus

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- Ulcer culture
- Pretreatment with topical antibiotics may alter culture results.

*Diagnostic Procedures/Other*

- Slit lamp and fluorescein dye to identify and evaluate corneal abrasions
- Trauma/foreign body has geographic shape; if due to contact lenses, several punctate lesions (5)
- Document visual acuity.

*Test Interpretation*

Scraping culture/staining identifies bacteria, yeast, or intranuclear inclusions to help narrow diagnosis.

**TREATMENT**

**GENERAL MEASURES**

- Most uncomplicated corneal abrasions heal in 24 to 48 hours.
May not require follow-up if lesion is >4 mm, uncomplicated abrasion, normal vision, and resolving symptoms
- Patching not recommended
  - Does not reduce pain
  - Delays healing (4)[A]

MEDICATION
- Treatment guidelines: pain control, infection prevention, and daily symptom monitoring
- Oral analgesic: narcotics, acetaminophen, NSAIDs
- Topical anesthetics include proparacaine hydrochloride 0.1–0.5%, tetracaine hydrochloride 1%.
  - Proparacaine may be less cytotoxic than tetracaine (4)[B].

First Line
- Ophthalmic NSAIDs: Diclofenac 0.1% QID helps relieve moderate pain:
  - Alternatives include ketorolac 0.5% and bromfenac 0.09%.
  - Caution: Ophthalmic NSAIDs may rarely cause corneal melting and perforation.
- Ophthalmic antibiotics may help prevent further infection and ulceration of corneal abrasions (6)[C].
- Some ophthalmic antibiotics include ciprofloxacin 0.3%, ofloxacin 0.3%, gentamicin 0.3%, erythromycin 0.5%, polymyxin B/trimethoprim (Polytrim), and tobramycin 0.3%.
- Large corneal abrasions (>4 mm) or very painful abrasions should be treated with a combination of topical antibiotic and topical NSAID.
- Fungal keratitis is treated with a protracted course of topical antifungal agents (by ophthalmologist).
- Herpetic keratitis should be referred promptly to ophthalmologist and treated initially with trifluridine:
  - Vidarabine and acyclovir are alternatives.

ISSUES FOR REFERRAL
- Indications for referral include:
  - Chemical burn
  - Evidence of corneal ulcer or infiltrate
  - Failure to heal after 3 to 4 days
  - Inability to remove a foreign body
– Increase size of abrasion after 24 hours
– Penetrating injury
– Presence of hyphema (blood) or hypopyon (pus)
– Rust ring
– Vision loss of >20/40

• Worsening symptoms or improvement after 24 hours (5)
  – Immediate ophthalmology consultation for corneal ulceration for culture and initiation of treatment

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

• Most uncomplicated corneal abrasions heal in 24 to 48 hours.
• Follow-up not necessary for small (<4 mm), uncomplicated abrasions, normal vision, and resolving symptoms
• Lesions >4 mm, decreased vision, and abrasions due to contact lenses need follow-up within 24 hours (3)[C].

PATIENT EDUCATION

Prevention of abrasions and proper handling of contact lenses can prevent recurrence of corneal ulcers.

PROGNOSIS

• Corneal abrasions heal within 24 to 48 hours.
• Ophthalmology consult with penetrating eye injury

COMPLICATIONS

• Recurrence
• Scarring of the cornea
• Loss of vision

REFERENCES

**CODES**

**ICD10**

- S05.00XA Inj conjunctiva and corneal abrasion w/o fb, unsp eye, init
- H16.009 Unspecified corneal ulcer, unspecified eye
- H16.049 Marginal corneal ulcer, unspecified eye

**CLINICAL PEARLS**

- Contact lenses use should be discontinued until corneal abrasion or ulcer is healed and pain is fully resolved.
- Eye patching is not recommended.
- Prescribe topical and/or oral analgesic medication for symptom relief and consider ophthalmic antibiotics.
- Prompt referral to an ophthalmologist should be made with suspicion of an ulcer, recurrence of abrasion, retained foreign body, viral keratitis, significant visual loss, or lack of improvement despite therapy.
CORNS AND CALLUSES
Sangili Chandran, MD • Valerie Rygiel, DO

BASICS

DESCRIPTION
- A callus (tyloma) is a diffuse area of hyperkeratosis, usually without a distinct border.
  - Typically, the result of exposure to repetitive forces, including friction and mechanical pressure; tend to occur on the palms of hands and soles of feet (1)
- A corn (heloma) is a circumscribed hyperkeratotic lesion with a central conical core of keratin that causes pain and inflammation. The conical core in a corn is a thickening of the stratum corneum.
- Hard corn or heloma durum (more common): often on toe surfaces, especially 5th toe (proximal interphalangeal [PIP]) joint
- Soft corn or heloma molle: commonly in the interdigital space (1)
- Digital corns are also known as clavi or heloma durum.
- Intractable plantar keratosis is usually located under a metatarsal head (1st and 5th most common), is typically more difficult to resolve, and often is resistant to usual conservative treatments.

EPIDEMIOLOGY
Corns and calluses have the largest prevalence of all foot disorders.

Incidence
- Incidence of corns and calluses increases with age.
- Less common in pediatric patients
- Women affected more often than men
- Blacks report corns and calluses 30% more often than whites.

Prevalence
- 9.2 million Americans
- ~38/1,000 people affected

ETIOLOGY AND PATHOPHYSIOLOGY
Increased activity of keratinocytes in superficial layer of skin leads to hyperkeratosis. This is a normal response to excess friction, pressure, or stress.

- Calluses typically arise from repetitive friction, motion, or pressure to skin. The increased pressure is often secondary to a metatarsal deformity (long metatarsal or plantarflexed metatarsal) or another bone spur or deformity.
- Hard corns are an extreme form of callus with a keratin-based core. Often found on the digital surfaces and commonly linked to bony protrusions, causing skin to rub against shoe surfaces.
- Soft corns arise from increased moisture from perspiration leading to skin maceration, along with mechanical irritation, especially between toes.

**Genetics**

No true genetic basis was identified because most corns and calluses are due to mechanical stressors on the foot/hands.

**RISK FACTORS**

- Extrinsic factors producing pressure, friction, and local stress
  - Ill-fitting shoes or walking barefoot
  - Not using socks/gloves
  - Activities that increase stress applied to skin of hands or feet (manual labor, running, walking, sports)
- Intrinsic factors
  - Bony prominences: bunions, hammertoes, mallet deformities, deformed metatarsals
  - Motor or sensory neuropathy such as secondary to diabetes

**GENERAL PREVENTION**

External irritation and pressure are by far the most common cause of calluses and corns. General measures to reduce friction or pressure on the skin are recommended to reduce incidence of callus formation. Examples include wearing shoes that fit well and using socks and gloves.

**Geriatric Considerations**

In elderly patients, especially those with neurologic or vascular compromise, skin breakdown from calluses/corns may lead to increased risk of infection/ulceration. 30% of foot ulcers in the elderly arise from eroded hyperkeratosis. Regular foot exams are emphasized for these patients as well as diabetic patients (2).
COMMONLY ASSOCIATED CONDITIONS
- Foot ulcers: especially noted in diabetic patients or patients with neuropathy or vascular compromise
- Infection: look for warning signs including
  - Increasing size, redness, pain, or swelling
  - Purulent drainage
  - Fever
  - Change in color of fingers or toes
- Signs of gangrene (color change, coolness)

DIAGNOSIS
- Most commonly a clinical diagnosis based on visualization of the lesion
- Examination of footwear may also provide clues.

HISTORY
- Careful history can usually pinpoint cause.
- Ask about neurologic and vascular history and diabetes. These may be risk factors for progression of corns/calluses to frank ulcerations and infection.

PHYSICAL EXAM
- Calluses
  - Thickening of skin without distinct borders
  - Often on feet, hands; especially over palms of hands, soles of feet
  - Colors range from white to gray-yellow, brown, red
  - May be painless or tender
  - May throb or burn
- Corns
  - Hard corns
    - Commonly on feet: dorsum of toes or 5th PIP joint
    - Varied texture: dry, waxy, and transparent to a hornlike mass
    - Distinct borders
    - Often painful
  - Soft corns
    - Commonly between toes, especially between 4th and 5th digits at the base of the web space
    - Often yellowed, macerated appearance
Often extremely painful

**DIFFERENTIAL DIAGNOSIS**
- Plantar warts (typically a loss of skin lines within the wart), which are viral in nature
- Porokeratoses (blocked sweat gland)
- Underlying ulceration of skin, with or without infection (important to rule out especially with diabetic patients)

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Radiographs may be warranted if no external cause is found. Look for abnormalities in foot structure, bone spurs.
- Use of metallic radiographic marker and weight-bearing films often highlight the relationship between the callus and bony prominence.

*Diagnostic Procedures/Other*
Biopsy with microscopic evaluation in rare cases

*Test Interpretation*
Abnormal accumulation of keratin in epidermis, stratum corneum

**TREATMENT**

**GENERAL MEASURES**
- Most therapy for corns and calluses can be done as self-care in the home (1).
- Use bandages, soft foam padding, or silicone sleeve over the affected area to decrease friction on the skin and promote healing with digital clavi.
- Use socks or gloves regularly.
- Padding to offload bony prominences
- Low-heeled shoes; soft upper with deep and wide toe box
- Avoidance of activities that contribute to painful lesions
- Prefabricated or custom orthotics

**MEDICATION**
- Keratolytic agents, such as urea or ammonium lactate, can be applied safely.
Intralesional bleomycin injections have shown improvement in size and pain of warts.
In office débridement of affected tissue and use of protective padding
Use sandpaper discs or pumice stones over hard, thickened areas of skin; can be done safely at home

**Geriatric Considerations**
Use of salicylic acid corn plasters can cause skin breakdown and ulceration in patients with thin, atrophic skin; diabetes; and those with vascular compromise. The skin surrounding the callus will often turn white and can become quite painful. Sometimes the acids are weak enough to not penetrate the thick skin but they can burn the adjacent skin, making the condition worse. Aggressive use of pumice stones can also lead to skin breakdown, especially surrounding the callus.

**ISSUES FOR REFERRAL**
- May benefit from referral to podiatrist if use of topical agents and shoe changes are ineffective
- Abnormalities in foot structure may require surgical treatment.
- Diabetic, vascular, and neuropathic patients may benefit from referral to podiatrist for regular foot exams to prevent infection or ulceration.

**SURGERY/OTHER PROCEDURES**
- Surgical treatment to areas of protruding bone where corns and calluses form
- Rebalancing of foot pressure through functional foot orthotics
- Shaving or cutting off hardened area of skin using a chisel or 15-blade scalpel. For corns, remove keratin core and place pad over area during healing.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- May benefit from urea-based lotions, creams, or ointments
- Warm water/Epsom salt soaks

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission usually not necessary, unless progression to ulcerated lesion with signs of severe infection, gangrene
- May require aggressive débridement in operating room if an abscess or deep-
space infection is suspected. Deep-space infections can develop where an abscess can penetrate into tendon sheaths and/or deep compartments within the foot or hand, potentially leading to rapid sepsis. Vascular status must be assessed and vascular referral considered.

- Nursing
  - Wound care, dressing changes for infected lesions

**ONGOING CARE**

**PATIENT EDUCATION**

- American Podiatric Medical Association: [http://www.apma.org](http://www.apma.org)

**PROGNOSIS**

Complete cure is possible once factors causing pressure or injury are eliminated.

**COMPLICATIONS**

Ulceration, infection

**REFERENCES**

**ADDITIONAL READING**

- American College of Foot and Ankle Surgeons: [http://www.acfas.org/](http://www.acfas.org/)

**CODES**
CLINICAL PEARLS

Most therapy for corns and calluses can be done as self-care in the home using padding over the affected area to decrease friction or pressure. However, if simple home care is not helpful, then removal of the lesions is often immediately curative.
CORONARY ARTERY DISEASE AND STABLE ANGINA

Adam R.S. Bainey, DO • Merrill Krolick, DO, FACC, FACP, FSCAI

BASICS

DESCRIPTION

- Coronary artery disease (CAD) refers to the atherosclerotic narrowing of the epicardial coronary arteries. It may manifest insidiously as angina pectoris or as an acute coronary syndrome (ACS).
- Stable angina is a chest discomfort due to myocardial ischemia that occurs predictably at a certain level of exertion or emotional stress.
- The spectrum of ACS includes unstable angina (UA), non–ST elevation myocardial infarction (NSTEMI), and ST elevation myocardial infarction (STEMI). See chapters on ACS for further information.

Definitions
- Typical angina: exhibits three classical characteristics: (i) substernal chest tightness, pressure, or heaviness that frequently radiates to the jaw, back, or arms and generally lasts from 2 to 15 minutes; (ii) occurs in a consistent pattern at a certain level of myocardial oxygen demand from exertion, emotional stress, or increased sympathetic tone; and (iii) relieved with rest or sublingual nitroglycerin
- Atypical angina: exhibits two of the above typical characteristics
- Noncardiac chest pain: exhibits ≤1 of the above typical characteristics
- Anginal equivalent: Patients may present without chest discomfort but with nonspecific symptoms such as dyspnea, diaphoresis, fatigue, belching, nausea, light-headedness, or indigestion that occur with exertion or stress. In patients with diabetes mellitus, women, and the elderly, one must maintain a high clinical index of suspicion as they may present with more atypical features compared with the general population.
- UA: anginal symptoms that are new or changed in character to become more frequent, more severe, or both; it is considered an ACS but does not present with cardiac biomarker elevation.
- NSTEMI: typically presents with symptoms similar to UA; however,
cardiac biomarker elevation is noted. Ischemic ECG changes may be present, but there is no ST segment elevation.

- **STEMI**: presents with typical symptoms as mentioned above with ST elevations noted on ECG and elevated cardiac biomarkers; generally caused by acute plaque rupture and complete obstruction of the culprit vessel.

- **Canadian Cardiovascular Society grading scale:**
  - **Class I**: Angina does not limit ordinary physical activity, occurring only with strenuous or prolonged exertion (7 to 8 metabolic equivalents [METs]).
  - **Class II**: Angina causes slight limitation of ordinary activity. It occurs when walking rapidly, uphill, or >2 blocks; climbing >1 flight of stairs; or with emotional stress (5 to 6 METs).
  - **Class III**: Angina causes marked limitation of ordinary physical activity. It occurs when walking 1 to 2 blocks or climbing one flight of stairs (3 to 4 METs).
  - **Class IV**: Angina occurs with any physical activity and may occur at rest (1 to 2 METs).

**Geriatric Considerations**
- Elderly may present with atypical symptoms.
- Other physical limitations may delay recognition of angina until it occurs with minimal exertion or at rest.
- Maintain a high degree of suspicion during evaluation of dyspnea and other nonspecific complaints.
- Geriatric patients may be very sensitive to the side effects of medications used to treat angina.

**EPIDEMIOLOGY**
- CAD is the leading cause of death for adults both in the United States and worldwide.
- CAD is responsible for about 31% of all deaths and averages 1 in every 4 deaths in the United States alone.
- Global cost of CAD in 2010 was $863 billion and is estimated to rise to $1,044 billion by 2030.
- ~80% of CAD is preventable with a healthy lifestyle.

**Incidence**
In the United States, the lifetime risk of a 40-year-old developing CAD is 49%
for men and 32% for women.

**Prevalence**
In the United States, 28.4 million people carry a diagnosis of CAD, whereas 7.12 million have angina pectoris (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Anginal symptoms occur during times of myocardial ischemia caused by a mismatch between coronary perfusion and myocardial oxygen demand.
- Atherosclerotic narrowing of the coronary arteries is the most common etiology of angina, but it may also occur in those with significant aortic stenosis, pulmonary hypertension, hypertrophic cardiomyopathy, coronary spasm, or volume overload.
- Sensory nerves from the heart enter the spinal cord at levels C7–T4, causing diffuse referred pain/discomfort in the associated dermatomes.

**RISK FACTORS**
- Traditional risk factors: hypertension, ↓ HDL, ↑ LDL, smoking, diabetes, premature CAD in first-degree relatives (men <55 years old; women <65 years old), age (>45 years for men; >55 years for women)
- Nontraditional risk factors: obesity, sedentary lifestyle, chronic inflammation, abnormal ankle-brachial indices, renal disease

**GENERAL PREVENTION**
- Smoking cessation
- Regular aerobic exercise program
- Weight loss for obese patients (goal BMI <25 kg/m\(^2\))
- BP control (goal <140/90 mm Hg; <150/90 mm Hg for those ≥60 years old) (2)
- Diabetes management
- Statin therapy for those with diabetes age 40 to 75 years and those with 10-year risk ≥7.5–10% (recommendations vary)
- Low-dose aspirin may be considered in those with 10-year risk ≥10% and without aspirin-use risks.

**COMMONLY ASSOCIATED CONDITIONS**
Hyperlipidemia, peripheral vascular disease, cerebrovascular disease, hypertension, obesity, diabetes
DIAGNOSIS

HISTORY
- Careful history is important to elicit symptoms.
- Pain may be described with a clenched fist over the center of the chest (Levine sign).
- Discomfort is usually not affected by position or deep inspiration.
- Episodes of angina are generally of the same character and in the same location.
- Recent decrease in level of physical activity may be due to worsening anginal symptoms.
- Dyspnea on exertion may present as the only symptom. Atypical symptoms are more likely in women, the elderly, and diabetic patients.
- May present with symptoms similar to gastric reflux or GI upset (indigestion, nausea, diaphoresis)

PHYSICAL EXAM
- Normal physical exam does not exclude the diagnosis of angina or CAD.
- Cardiac exam may reveal dysrhythmias, heart murmurs indicative of valvular disease, gallops, or signs of congestive heart failure.
- Evidence of peripheral vascular disease (diminished pulses, bruits, abdominal aortic aneurysm [AAA]) may or may not be noted.

DIFFERENTIAL DIAGNOSIS
- Vascular: aortic dissection, pericarditis, myocarditis, myocardial infarction (MI), vasospasm
- Pulmonary: pleuritis, pulmonary embolism, pneumothorax
- Gastroesophageal: gastric reflux, esophageal spasm, peptic ulcer
- Musculoskeletal: costochondritis, arthritis, muscle strain, rib fracture
- Other: anxiety, psychosomatic, cocaine abuse

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Serial cardiac troponins to rule out MI in those presenting with prolonged pain or other symptoms compatible with ACS
- CBC, lipid profile, HgbA1c (1)[C]
- Basic metabolic panel to rule out electrolyte abnormalities and assess renal
Follow-Up Tests & Special Considerations
- Goal is to detect possible high-risk coronary lesions where intervention would improve long-term mortality or alleviate anginal symptoms.
- Stress testing is most helpful for patients at intermediate risk of heart disease.
  - Exercise testing for those who can physically exercise (≥5 METs) (1)[A]
    - Standard exercise ECG for those with normal baseline ECG
    - Exercise stress testing with echo or perfusion imaging for those with abnormal baseline ECG or in premenopausal women
  - In patients who cannot tolerate exercise, consider pharmacologic stress testing (1)[A].
- Echocardiogram should be obtained in patients with a new or loud (≥III/VI) murmur, evidence of MI, symptoms of heart failure, concern for hypertrophic cardiomyopathy or pericardial effusion, and in those with new arrhythmias (1)[A].
- Echocardiogram can be considered in patients with hypertension or diabetes and abnormal ECG (1).
- CT coronary angiography or cardiac MRI can be considered as a supplement/alternative to stress testing in patients with continued symptoms despite negative stress testing, inconclusive stress testing, or need for better anatomic definition of disease (1)[A].

Diagnostic Procedures/Other
- Cardiac catheterization with coronary angiography is the gold standard for confirmation and delineation of coronary disease and direction of interventional therapy or surgery. It is indicated if noninvasive testing suggests a high-risk lesion or if patient fails to respond to appropriate medical management.
- Significant CAD is defined as ≥50% stenosis of the left main coronary artery.
or ≥70% stenosis of other major coronary arteries by angiography.
- Borderline lesions may be assessed with a pressure wire. Fractional flow reserve (FFR) of ≤0.8 demonstrates a hemodynamically significant lesion.

**TREATMENT**

**GENERAL MEASURES**

- **BP control goal:** <140/90 mm Hg for most, except in elderly (2)[A]. Selected high-risk nondiabetic patients may benefit from a systolic blood pressure target of <120 mm Hg (3)[B].
- **Smoking cessation goal:** complete cessation, no exposure to secondhand smoke or e-cigarettes
- **Physical activity goal:** 30 to 60 minutes of moderate aerobic activity, at least 5 (preferably 7) days/week
- **Weight management goal:** BMI 18.5 to 24.9 kg/m²; waist circumference <35 inches (women) or <40 inches (men)
- **Glycemic control in diabetics:** Avoid hypoglycemic episodes.

**MEDICATION**

**First Line**

- **β-Blockers:** decrease myocardial oxygen demand by lowering heart rate, BP, and contractility
  - Improve mortality in patients with MI or heart failure and should be used as initial therapy (1)[A]
  - Can improve symptoms of angina
  - Metoprolol (25 to 400 mg daily [succinate] or divided BID [tartrate]) or carvedilol (3.125 to 25 mg BID). Adjust doses according to clinical response. Maintain resting heart rate 50 to 60 bpm.
  - Side effects: bradycardia, fatigue, and sexual dysfunction
- **Calcium channel blockers (CCBs):** cause arterial vasodilation, decreased myocardial oxygen demand, and improved coronary blood flow. Similar effectiveness to β-blockers; may be used instead of, or in addition to β-blockers (1)[A]. Only long-acting CCBs should be used:
  - Dihydropyridine CCBs: Nifedipine (30 to 90 mg/day), amlodipine (5 to 10 mg/day), or felodipine (2.5 to 10 mg/day) work predominantly on arterial vasodilation and can improve coronary blood flow.
- Nondihydropyridine CCBs: Diltiazem (120 to 480 mg/day) or verapamil (120 to 480 mg/day) also have negative inotropic effects and should not be used in those with EF <40% as they may precipitate heart failure. Side effects include constipation and peripheral edema.

- Nitrates: dilate systemic veins and arteries (including coronary vessels) and cause decreased preload. At higher doses, they decrease BP and thus increase myocardial flow.
  - Sublingual nitroglycerin (0.4 mg every 5 minutes for 2 to 3 doses) may be used for acute anginal episodes (1)[A].
  - Long-acting nitrates such as isosorbide mononitrate (30 to 240 mg daily [extended release]) can be used for angina prophylaxis.
  - Side effects include headache and hypotension but tend to improve with continued usage.
  - Contraindicated with concomitant PDE5 inhibitor use

- Lipid-lowering agents:
  - High-intensity statin therapy is indicated for all patients with CAD regardless of lipid levels (4)[A].
  - Statin therapy should also be encouraged for those with high CAD risk (lifetime risk ≥7.5–10%).
  - Atorvastatin (20 to 80 mg/day) and rosuvastatin (10 to 40 mg/day) are high-intensity statins.
  - Statins reduce risk of MI and revascularization need. Side effects include myalgias, transaminitis, rhabdomyolysis (rare), and impaired glucose tolerance.
  - Ezetimibe may be added to statin therapy, although evidence for improved clinical outcomes remains weak.
  - Evolocumab and possibly other PCSK-9 inhibitors can further reduce LDL levels when used in combination with statins for high-risk patients and may reduce cardiovascular events (3) but are very expensive. Clinical trials are ongoing.

- Antiplatelets: decrease risk of thrombosis
  - Aspirin (75 to 162 mg/day) decreases risk of first MI and reduces adverse cardiovascular events in those with stable angina (1)[A].
  - Clopidogrel (75 mg/day) may be used in patients with contraindications to aspirin (1)[A].
  - Dual antiplatelet therapy with aspirin + clopidogrel, prasugrel, or ticagrelor is indicated after MI or percutaneous coronary intervention (PCI) (use prasugrel only after PCI).

- Angiotensin-converting enzyme inhibitors (ACEIs): act on the renin-
angiotensin-aldosterone system to reduce BP and afterload. They also have effects on cardiac remodeling after MI.

- ACEIs such as lisinopril (5 to 40 mg/day) and enalapril (2.5 to 20.0 mg BID) have been shown to reduce both cardiovascular death and MI in patients with CAD and left ventricular systolic dysfunction (1)[A].
- Angiotensin receptor blockers such as candesartan (4 to 32 mg daily) may be used in patients intolerant to ACEIs.
- Side effects include cough (ACEIs only), hyperkalemia, and angioedema.

**Second Line**
Ranolazine (500 to 1,000 mg BID) decreases calcium overload in myocytes, acting as an antianginal/anti-ischemic agent.

- Does not affect heart rate or BP
- Use as adjunctive therapy when symptoms persist despite optimal doses of other antianginals
- Side effects can include nausea, constipation, dizziness, QT prolongation, and headache.

**SURGERY/OTHER PROCEDURES**
- Revascularization should be considered when noninvasive testing suggests a high-risk lesion. It can also be performed if optimal medical therapy is inadequate to control symptoms.
- PCI with balloon angioplasty and/or stent placement (with drug-eluting or bare-metal stent) is performed for significant lesions. Additional techniques include laser therapy and atherectomy.
- PCI does not decrease mortality or risk of MI versus aggressive medical management in those with stable angina.
- Coronary artery bypass graft (CABG) is preferred over PCI for those with severe left main coronary stenosis, significant lesions in ≥3 major coronary arteries, and for lesions not amenable to PCI.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Relaxation/stress reduction therapy for angina
FOLLOW-UP RECOMMENDATIONS

- Lifestyle modifications should be aggressively stressed at every visit.
- Patients should be followed clinically; routine stress testing is not necessary for asymptomatic patients.

Patient Monitoring

Frequent follow-up after initial event: every 4 to 6 months in first year and then 1 to 2 times per year

DIET

- Reduced intake of trans-fatty acids (1)[C]
- Adherence to dietary modification for comorbid conditions (diabetes, heart failure, hypertension)

PROGNOSIS

Variable; depends on severity of symptoms, extent of CAD, and left ventricular function.

COMPLICATIONS

ACS, arrhythmia, cardiac arrest, heart failure

REFERENCES

SEE ALSO
Algorithm: Chest Pain/Acute Coronary Syndrome

CODES

ICD10
- I25.119 Athscl heart disease of native cor art w unsp ang pctrs
- I25.118 Athscl heart disease of native cor art w oth ang pctrs
- I20.9 Angina pectoris, unspecified

CLINICAL PEARLS

- Maximize antianginal therapy: Combine $\beta$-blockers, CCBs, and nitrates as tolerated, along with high-intensity statin therapy.
- Lifestyle changes and optimal medical therapy must be emphasized to prevent progression of atherosclerosis and to control contributing risk factors.
COSTOCHONDRITIS
Smriti Ohri, MD • Scott A. Fields, MD, MHA

BASICS

DESCRIPTION
- Anterior chest wall pain and tenderness of the costochondral and costosternal regions
- System(s) affected: musculoskeletal
- Synonym(s): costosternal syndrome; parasternal chondrodynia; anterior chest wall syndrome (1)

EPIDEMIOLOGY
- Predominant age: 20 to 40 years
- Predominant gender: female

Incidence
- 30% emergency room visits for chest pain
- 20% of chest pain visits in primary care are for musculoskeletal causes (13% for costochondritis).

ETIOLOGY AND PATHOPHYSIOLOGY
Not fully understood

RISK FACTORS
- Unusual physical activity or overuse stressing the upper extremity
- Recent trauma (including motor vehicle accident, domestic violence) or new-onset physical activity
- Recent upper respiratory infection (URI) with coughing

DIAGNOSIS
- Pain is usually sharp, achy, or pressure-like, involving multiple (and mostly unilateral 2nd to 5th) costal cartilages.
- Exacerbated by upper body movements and exertional activities
Reproduced by palpation of the affected cartilage segments
Chest tightness is often associated with the pain.

**HISTORY**
- A complete and thorough history is mandatory for the diagnosis, with special emphasis on cardiac risk factor evaluation.
- Social history: careful screening and evaluation for domestic violence and substance abuse

**PHYSICAL EXAM**
- Focus on excluding other serious conditions that may present with chest pain.
- Tenderness over the costochondral junctions is necessary to establish the diagnosis but does not completely exclude other causes of chest pain.
- If swelling or redness of costal cartilage is present, the presentation is often termed Tietze syndrome.
- Movement of upper extremity of the same side may reproduce the pain (1).
- Epigastric (gastroesophageal reflux disease) and right upper quadrant (gallbladder disease) palpation

**Pediatric Considerations**
- Consider psychogenic chest pain in children who perceive family discord.
- Consider slipping rib syndrome in children with chronic chest and abdominal pain (2).

**Geriatric Considerations**
- Multiple problems cause chest pain, emphasizing the importance of a thorough history and physical exam.
- Consider herpes zoster in elderly patients.

**DIFFERENTIAL DIAGNOSIS**
- Cardiac
  - Coronary artery disease (CAD)
  - Cardiac contusion from trauma
  - Aortic aneurysm
  - Pericarditis
  - Myocarditis
- Gastrointestinal
  - Gastroesophageal reflux
– Peptic esophagitis
– Esophageal spasm
– Cholecystitis

**Musculoskeletal (2)**
– Fibromyalgia
– Slipping rib syndrome
– Costovertebral arthritis
– Painful xiphoid syndrome
– Rib trauma
– Ankylosing spondylitis
– Precordial catch syndrome

**Psychogenic**
– Anxiety disorder
– Panic attacks
– Hyperventilation

**Respiratory**
– Asthma
– Pulmonary embolism
– Pneumonia
– Chronic cough
– Pneumothorax

**Other**
– Domestic violence and abuse
– Herpes zoster
– Spinal tumor
– Metastatic cancer
– Substance abuse (cocaine)

**DIAGNOSTIC TESTS & INTERPRETATION**

– Primarily a clinical diagnosis
– Use laboratory exams and imaging to exclude other diagnoses.
– ESR is inconsistently elevated.

*Initial Tests (lab, imaging)*

No imaging is indicated for the diagnosis of costochondritis; chest x-ray and rib films are often normal.

*Diagnostic Procedures/Other*
None indicated for the diagnosis of costochondritis
Consider ECG in patients age >35 years and for patients with history or risk of CAD.
Consider chest x-ray in patients with cardiopulmonary symptoms.
Consider spiral CT for pulmonary embolism and D-dimer if history or risk factors are present.

Test Interpretation
Costochondral joint inflammation

TREATMENT
Reassurance of benign nature of condition and potential for long, slow recovery from pain

GENERAL MEASURES
- Rest, and heat (or ice) massage
- Stretching exercises
- Minimize symptom-provoking activities (e.g., reduce frequency or intensity of exercise/work activity).

MEDICATION
- Pain relief with NSAIDs (ibuprofen, naproxen, or diclofenac), acetaminophen or other analgesics
- Use of skeletal muscle relaxants may be beneficial if associated with muscle spasm.

ISSUES FOR REFERRAL
- Consider referral to physical therapy for pain reduction and improvement in function (3)[B].
- Refractory cases of costochondritis can be treated with local injections of combined lidocaine/corticosteroid into costochondral areas; rarely necessary (4)[C]

COMPLEMENTARY & ALTERNATIVE MEDICINE
Limited data on use of manipulation or ice massage but may be safely tried if
patient interested

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Only if differential diagnosis is unclear and cardiac or other serious etiology of chest pain is being considered

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Follow-up within 1 week if diagnosis is unclear or symptoms do not abate with conservative treatment

PATIENT EDUCATION
- Educate regarding the self-limited (although potentially recurrent) nature of the illness.
- Instruct patient on proper physical activity regimens to avoid overuse syndromes.
- Avoid sudden, significant changes in activity.

PROGNOSIS
- Self-limited illness lasts for weeks to months and usually abates by 1 year: sometimes chronic particularly in adolescents
- Often recurs

COMPLICATIONS
Incomplete attention to differential diagnosis or overly aggressive interventions to ensure a more life-threatening diagnosis is not missed.

REFERENCES

**CODES**

**ICD10**
M94.0 Chondrocostal junction syndrome [Tietze]

**CLINICAL PEARLS**

- A common disorder, accounting for up to 30% of all cases of chest pain
- Diagnosis is primarily clinical. Lab and other testing is done to exclude other conditions based on patient risk.
- Self-limited (potentially recurrent) condition. Activity modification helps prevent recurrence.
Psychotherapeutic and counseling interventions play an important role in the management of chronic and acute-onset diseases and disorders. They are typically the primary initial mode of evaluation and/or treatment for most mild to moderate psychiatric disorders that reach criteria using the *DSM-5* (1) or *ICD-10* (2) diagnostic classification systems. It should be noted that the *DSM* system has recently been revised with significant changes in several disorder categories and their criteria. Treatment and successful control of either medical or psychological conditions require some form of professional counseling experience. Best outcomes occur when they are employed by a skilled practitioner. However, psychotherapy differs from generic counseling, which can take many forms and is delivered commonly in nonmedical settings, with mixed results.

Counseling approaches are usually tailored to the specific presenting problem or issue and serve educational and emotional support functions. Typically, such counseling in medical settings will be time-limited and problem-focused and often not intended to lead to major medical symptom relief or major behavioral changes.

The goals of psychotherapy range from increasing individual psychological insight and motivation for change to reduction of interpersonal conflict in the marriage or family, reduction of chronic or acute emotional suffering, and reversal of dysfunctional or habitual behaviors. There are several general types of psychotherapy, starting with individual, marital, or family approaches. In addition, a number of psychological theories guide various methods and treatment philosophies. The following is a brief overview of commonly used psychotherapeutic and counseling methods.

- **Psychodynamic therapy**: Unconscious conflict manifests as patient’s symptoms/problem behaviors:
  - Short-term (4 to 6 months) and long-term (≥1 year)
  - Focus is on increasing insight of underlying conflict or processes to initiate symptomatic change.
- Therapist actively helps patient identify patterns of behavior stemming from existence of an unconscious conflict or motivations that may not be accurately perceived.

- Cognitive-behavioral therapy (CBT): Patterns of thoughts and behaviors can lead to development and/or maintenance of symptoms. Thought patterns may not accurately reflect reality and may lead to psychological distress:
  - Therapy aims at modifying thought patterns by increasing cognitive flexibility and changing dysfunctional behavioral patterns.
  - Encourages patient self-monitoring of symptoms and the precursors or results of maladaptive behavior.
  - Uses therapist-assisted challenges to patient’s basic beliefs/assumptions.
  - May use exposure, a procedure derived from basic learning theories, which encourages gradual steps toward change.
  - Can be offered in group or individual formats.
  - Therapist’s role is suggestive and supportive.

- Dialectical behavior therapy (DBT): Techniques such as social skills training, mindfulness, and problem solving are used to modulate impulse control and affect management:
  - Derivative of CBT.
  - Originally used in treatment of patients with self-destructive behaviors (e.g., cutting, suicide attempts).
  - Seeks to change rigid patterns of cognitions and behaviors that have been maladaptive.
  - Uses both individual and group treatment modalities.
  - Therapist takes an active role in interpretation and support.

- Interpersonal psychotherapy: Interpersonal relationships in a patient’s life are linked to symptoms. Therapy seeks to alleviate symptoms and improve social adjustment through exploration of patient’s relationships and experiences. Focus is on one of four potential problem areas:
  - Grief.
  - Interpersonal role disputes.
  - Role transitions.
  - Interpersonal deficits: Therapist works with the patient in resolving the problematic interpersonal issues to facilitate change in symptoms.

- Family therapy: focuses on the family as a unit of intervention.
  - Uses psychoeducation to increase patient’s and family’s insight.
  - Teaches communication and problem-solving skills.

- Motivational interviewing: focuses on motivation as a key to successful
change process
  - Short-term and problem-focused
  - Focuses on identifying discrepancies between goals and behavior
  - “5 A’s” model is a brief counseling framework developed specifically for physicians to effect behavioral change in patients:
    - Assess for a problem.
    - Advise making a change.
    - Agree on action to be taken.
    - Assist with self-care support to make the change.
    - Arrange follow-up to support the change.

– Counseling (heterogeneous treatment)
  - Often focuses on situational factors maintaining symptoms
  - Often encourages the use of community resources
– Behavioral therapy: relatively nontheoretical approach to behavioral change or symptom reduction/eradication through application of principles of stimulus and response

**Pediatric Considerations**

- Important distinctions are made between psychotherapy and counseling for children/teens compared to adults/couples.
- The focus of evaluation must include attention to parent and family processes and factors. Interventions typically include interactions and sessions with parents as well as collateral work with teachers and other school personnel.
- Younger children will often be evaluated and diagnosed through behavioral descriptions provided by parents and other adults who know them well as well as through direct observation and/or play techniques. Children of all ages should be screened using behavioral checklists that are norm-referenced for age.
- Any child or teenager who requests counseling should be interviewed initially by the primary care provider and referred appropriately. Most referrals will be in response to parental request, however.
- Psychotherapeutic interventions with the strongest empirical basis with children include behavior therapy/modification, CBT, and family/parenting therapy. Play therapy has the least empirical support, and insight-oriented therapies appear to be more effective with older children (>11 years).
- There is controversy regarding the efficacy of psychopharmacologic treatment in preadolescents, although clear benefits have been demonstrated in some studies. Treatment guidelines for mild to moderate depressed mood and/or anxiety disorders typically recommend pediatric CBT initially, and studies
have typically supported this approach in preteen and milder cases.

**EPIDEMIOLOGY**
- ~18.8 million adults suffer from clinical depression, and 20 million suffer from a diagnosable anxiety disorder.
- One in four Americans report seeking some form of mental health treatment in their adult life. This includes generic counseling in nonmedical settings such as work, clergy, or school settings and also includes visits to primary care providers. It is estimated that between 3.5% and 5% of adults in the United States actually participate in formal mental health psychotherapy annually.
- Public health experts report that the majority of those adults with diagnosable psychiatric disorders, however, do not receive professional mental health services. This is due to multiple factors, including failure to identify, noncompliance with psychiatric referral, regional shortages of providers, economic barriers, and excessive time duration from referral to available service.
- A large study conducted between 1987 and 1997 concluded that the percentage of adults in psychotherapy remained relatively stable over that decade, the use of psychopharmacology doubled, and older adults (aged 55 to 64 years) increasingly sought psychotherapy services. In that same study, it was found that psychotherapy duration (number of sessions) decreased substantially and about 1/3 of psychotherapy patients only attended one or two sessions.

**RISK FACTORS**
The need for psychotherapy or counseling services is directly and indirectly associated with a host of socioeconomic and biogenetic factors, including the general effects of poverty, family or marital dysfunction, life stressors, medical diseases or conditions, and individual biologic predisposition to mental health disorders.

**GENERAL PREVENTION**
It is generally assumed that early identification and intervention of child and adolescent psychopathology increases the likelihood of reducing the risk for adult psychopathology, but this has not been sufficiently validated in all categories of psychological disorders. Data support such claims in disorders such as childhood ADHD, anxiety disorders, and habit disorders of childhood, however.
TREATMENT

GENERAL MEASURES
There is evidence of a “dose effect” in psychotherapy outcomes research, with some investigators suggesting that 6 to 8 sessions are necessary to yield positive initial effects and upward of 15 to 20 sessions for longer term, sustainable therapeutic effects. This dose effect may not be applicable to counseling services with primarily informational or emotional/supportive functions. Also, long-term therapy should be evaluated at 6- to 12-month intervals to determine efficacy.

MEDICATION
- Psychotherapy is most likely to be accompanied by use of pharmaceutical adjuncts in moderate to severe cases of psychological dysfunction that do not respond to other therapies or in cases of extremely poor quality of life or high risk. The most common examples are in cases of clinical depression or anxiety that clearly incapacitates the patient or significantly reduces his or her quality of life. Patients at risk for suicide or who represent a danger to others are also candidates for acute psychopharmacotherapy. Studies suggest that verbal and behaviorally oriented therapies can add efficacy to medication treatment in both depression and anxiety.
- There is controversy in the research field regarding the efficacy of medication alone versus psychotherapy alone versus combined treatments. The most recent consensus has been that combined treatments in moderate to severe psychological dysfunction are most likely to render positive short-term results and increase the likelihood that such effects can be sustained over time.

ADDITIONAL THERAPIES
- Anxiety disorders
  - Panic disorder with and without agoraphobia: CBT, psychodynamic therapy
  - Generalized anxiety disorder: CBT
  - Obsessive-compulsive disorder: CBT
  - Posttraumatic stress disorder: CBT
  - Specific phobia: CBT
  - Social phobia: CBT
- Mood disorders
  - Unipolar depression: CBT, interpersonal therapy, psychodynamic therapy
  - Bipolar disorder: family therapy, interpersonal therapy, CBT
  - Schizophrenia: psychodynamic therapy, family therapy, CBT
• Eating disorders
  – Binge eating disorder: CBT, interpersonal therapy
  – Bulimia nervosa: CBT, interpersonal therapy
• Personality disorders
  – Borderline: DBT, CBT
• Substance-use disorders
  – Alcohol: counseling, CBT, motivational interviewing
  – Cocaine: CBT, counseling
  – Heroin: CBT, counseling
  – Smoking: 5 A’s
• Somatoform disorders:
  – Hypochondriasis: CBT
  – Body dysmorphic disorder: CBT

COMPLEMENTARY & ALTERNATIVE MEDICINE

A host of nonempirically based psychological and nutritional therapies can be found outside of mainstream medicine and psychological science. Very little or no evidence exists to support such experimental therapies, but all have the considerable power of the placebo effect fueling their anecdotal supports or claims. Placebo effects are also thought to be powerfully enhanced by the use of ingested or applied substances that create real physiologic, although not therapeutic, changes in the patient. If it makes them feel different, they are more likely to believe it helps.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

There is evidence of a “dose effect” in psychotherapy outcomes research, with some investigators suggesting that 6 to 8 sessions are necessary to yield positive initial effects and upward of 15 to 20 sessions for longer term, sustainable therapeutic effects. This dose effect may not be applicable to counseling services with primarily informational or emotional/supportive functions. Because many patients cease attendance to psychotherapy sessions after one or a few sessions, most interventions of this type cannot be accurately evaluated by the referring
provider. Long-term therapy should also be evaluated for effectiveness at regular periods.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- Z71.9 Counseling, unspecified
- Z71.89 Other specified counseling
- Z63.9 Problem related to primary support group, unspecified

CLINICAL PEARLS

- Combined medication and psychotherapeutic treatments in moderate to severe
psychological dysfunction are most likely to render positive short-term results and increase the likelihood such effects can be sustained over time.  
- Relapse is common over time and/or as treatments are discontinued.  
- Children <10 years may benefit significantly from counseling or psychotherapy alone for symptom relief.  
- Older children and those with more severe symptoms typically require psychopharmacologic options in concert with counseling or verbal therapy approaches.
CROHN DISEASE

Eric Ji-Yuan Mao, MD • Samir A. Shah, MD, FACG, FASGE, AGAF

BASICS

DESCRIPTION
A chronic, relapsing inflammatory GI tract disorder, most commonly involving the terminal ileum (80%)

- Hallmark features of Crohn disease (CD)
  - Transmural inflammation resulting in fibrosis, stricture, and fissures with sinus tract, abscess, or fistula formation
  - Noncaseating granulomas (30%), crypt abscesses
  - Skip lesions: segmental distribution of disease; may affect multiple bowel segments, interspersed with areas of normal mucosa; can also be continuous, mimicking ulcerative colitis (UC)
  - Diverse presentations: ileocolitis (50%); isolated colitis (20%) are most common.

- Early disease
  - Ulcerations: focal lesions with surrounding edema, resembling aphthous ulcers
  - Perianal disease (pain, anal fissures, perirectal abscess) may precede intestinal disease.
  - May present as wasting illness or anorexia

- Developed disease
  - Mucosal cobblestoning; luminal stenosis; creeping fat; fissures between mucosal folds result in strictures/adhesions and/or fistulae.

EPIDEMIOLOGY

Incidence

- 8 to 15 cases/100,000 North American adults; incidence rising in North America and Western Europe
- Bimodal age distribution: Predominant age is 15 to 25 years, with a second smaller peak at 50 to 70 years.
- Women slightly more affected than men; increased incidence in northern
climates
- Increased risk in whites versus nonwhites: 2- to 5-fold
- Increased risk in Ashkenazi Jews: 3- to 5-fold

**Prevalence**
U.S. adults: 100 to 200 cases/100,000

**ETIOLOGY AND PATHOPHYSIOLOGY**
- General: Clinical manifestations result from activation of inflammatory cells and subsequent tissue injury.
- Mechanism of diarrhea: excess fluid secretion and impaired fluid absorption; bile salt malabsorption in inflamed ileum, with steatorrhea, bacterial overgrowth
- Multifactorial: Genetics, environmental triggers, commensal microbial antigens, and immunologic abnormalities result in inflammation and tissue injury.

**Genetics**
15% of CD patients have a first-degree relative with inflammatory bowel disease (IBD); first-degree relative of an IBD patient has 3- to 30-fold increased risk of developing IBD by age 28 years; ~200 different genes associated with IBD
- Mutations in susceptibility loci
  - Ileal CD: IBD1 gene (chromosome 16)
  - Early-onset CD (age ≤15 years): mutations in 5q31 to 33 (IBD5), 21q22, and 20q13
  - Extraintestinal manifestations of CD: mutations in HLA-A2, HLA-DR1, HLA-DQw5
  - Others: IL-10, IL-23 receptors; ATG16L1; IRGM
- Associated genetic syndromes: Turner and Hermansky-Pudlak syndromes, glycogen storage disease type 1b

**RISK FACTORS**
- Environmental factors
  - Cigarette smoking doubles the risk of CD; tobacco cessation reduces flares and relapses.
  - Dietary factors: higher incidence if diet high in refined sugars, animal fat, protein (meat, fish)
  - *Salmonella* or *Campylobacter* increases risk of developing IBD.
- Clostridium difficile infection may trigger flare and make treatment more difficult.

- Immunologic abnormalities: an aggressive immune response against commensal enteric bacteria
  - Tumor necrosis factor (TNF): upregulation of inflammatory Th1 cytokines
  - Tissue inflammation may result from increased secretion of cytokines.

COMMONLY ASSOCIATED CONDITIONS

- Extraintestinal manifestations
  - Arthritis (20%): seronegative, primarily involving large joints; axial arthritis or ankylosing spondylitis (AS) and sacroiliitis (SI)
  - Skin disorders (10%): erythema nodosum, pyoderma gangrenosum, psoriasis
  - Ocular disease (5%): uveitis, iritis, episcleritis
  - Kidney stones: calcium oxalate stones (from steatorrhea and diarrhea) or uric acid stones (from dehydration and metabolic acidosis)
  - Fat-soluble vitamin deficiency (A, D, E, K)
  - Osteopenia and osteoporosis; hypocalcemia
  - Hypercoagulability: venous thromboembolism prophylaxis essential in hospitalized patients
  - Gallstones: cholesterol stones resulting from impaired bile acid reabsorption
  - Primary sclerosing cholangitis (5%): more common in men with UC; asymptomatic, elevated alkaline phosphatase as marker
  - Autoimmune hemolytic anemia

- Conditions associated with increased disease activity
  - Peripheral arthropathy (not SI and AS)
  - Episcleritis (not uveitis)
  - SI, AS, and uveitis are associated with HLA-B27.
  - Oral aphthous ulcers and erythema nodosum
  - Other complications: GI bleed, toxic megacolon, bowel perforation, peritonitis, malignancy, sclerosing cholangitis, rectovaginal fistula

DIAGNOSIS

HISTORY

Hallmarks: fatigue, fever, weight loss, prolonged diarrhea, perianal disease,
crampy abdominal pain (+/− bleeding). Children may present with failure to thrive.

- Factors exacerbating CD: concurrent infection, smoking, NSAIDs, and possibly stress

**PHYSICAL EXAM**

Presentation varies with location of disease.

- General: signs of sepsis/disease activity (fever, tachycardia, hypotension) or wasting/malnutrition
- Abdominal: focal or diffuse tenderness, distension, rebound/guarding; rectal bleeding
- Perianal: fistulae, fissures
- Skin: erythema nodosum; psoriasis

**DIFFERENTIAL DIAGNOSIS**

- Acute, severe abdominal pain: perforated viscus, pancreatitis, appendicitis, diverticulitis, bowel obstruction, kidney stones, ovarian torsion
- Chronic diarrhea with crampy pain (colitis like): UC, radiation colitis, infection, drugs, ischemia, microscopic colitis, IBD, celiac disease, malignancy (lymphoma, carcinoma), carcinoid
- Wasting illness: malabsorption, malignancy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- CBC, serum chemistries, LFTs, erythrocyte sedimentation rate, C-reactive protein, serum iron, vitamin B₁₂, vitamin D-25 OH, stool calprotectin
- If diarrhea, stool specimen for routine culture, fecal leukocytes, *C. difficile*, and ova and parasites
- With severe flares, KUB to rule out toxic megacolon
- Colonoscopy with ileoscopy provides the greatest diagnostic sensitivity and specificity for colonic disease and distal small bowel disease.

**Small bowel:** Sensitivity of CT or magnetic resonance enterography (MRE) better than small bowel follow through. MRE has no radiation exposure (important in younger patients). Capsule endoscopy allows small bowel visualization but no biopsy (1)[A].

- Signs of small bowel disease: narrowed lumen with nodularity and/or string sign; cobblestone appearance, fistula and abscess formation, bowel loop
separation (transmural inflammation)

- Gastroduodenal: upper GI endoscopy
  - Signs of gastroduodenal disease: antral narrowing and segmental stricturing; inflammatory mucosa
- Perirectal complications: combination of endoscopic ultrasound (EUS) or MRI with exam under anesthesia
- Contraindications to endoscopy: perforated viscus, recent myocardial infarction, severe diverticulitis, toxic megacolon, or inability to undergo bowel preparation
- In most cases, unprepared limited sigmoidoscopy allows adequate visualization to assess severity, extent, and aspirate stool for *C. difficile*, obtain biopsies to assess histologic severity, and exclude other disorders (e.g., cytomegalovirus).

**Follow-Up Tests & Special Considerations**

Evidence of complications

- Stricture: obstructive signs—nausea, vomiting, pain, weight loss, diarrhea, or inability to pass gas/feces
- Abscess/phlegmon: localized abdominal peritonitis with fever and abdominal pain; diffuse peritonitis suggests perforation or abscess rupture (may be masked by steroids, opiates).
- Fistula:
  - Enteroenteric: asymptomatic or a palpable, commonly indolent abdominal mass
  - Enterovesical: pneumaturia, recurrent UTI
  - Retroperitoneal: psoas abscess, ureteral obstruction
  - Enterovaginal: vaginal passage of gas or feces; clear, nonfeculent drainage from ileal fistula (may be misdiagnosed as primary vaginal infection)

**Diagnostic Procedures/Other**

How to distinguish CD from UC

- CD: small bowel disease, rectal sparing; skip lesions; granulomas, perianal disease, and/or fistulae; no gross bleeding: RLQ pain is common.
  - Anti-*Saccharomyces cerevisiae* antibody (ASCA), Cbir-1, OmpC, I2 (70% sensitive)
- UC: diffuse, continuous involving the rectum; loss of vascularity, friable tissue; perinuclear antineutrophil cytoplasmic antibody (pANCA); LLQ pain; typically only affects colon; rectal bleeding common
**ALERT**
CD can mimic UC with continuous bowel involvement; 10–15% of cases are difficult to differentiate.

**TREATMENT**
- Disease severity: Crohn Disease Activity Index (CDAI)
  - Asymptomatic: spontaneous, after medical/surgical intervention, or while on steroids (CDAI <150)
  - Mild to moderate CD: ambulatory patients able to tolerate PO intake without dehydration, obstruction, or >10% weight loss; no abdominal tenderness, toxicity, or mass (CDAI 150 to 220)
  - Moderate to severe CD: patients who have failed initial treatment or who continue to have mild symptoms such as fever, weight loss, and abdominal pain (CDAI 220 to 450)
  - Severe: persistent symptoms despite therapy with glucocorticoids and/or biologics or fulminant disease (peritonitis, cachexia, intestinal obstruction, abscess) (CDAI >450)
  - Step-up approach: Begin treatment with milder therapy (5-ASA, antibiotics) followed by more aggressive agents (steroids, immunomodulators, anti-TNF agents) as needed.
  - Top-down approach: early management with immunomodulators and/or anti-TNF agents before patients receive steroids, become steroid dependent, or require surgery

**GENERAL MEASURES**
- Oral lesions: triamcinolone acetonide in benzocaine and carboxymethyl cellulose or topical sucralfate for aphthous ulcers, cheilitis, and/or granulomatous sialadenitis
- Gastrointestinal CD: no clinical trials; slow-release mesalamine may be beneficial. Case reports show success of anti-TNF therapies; symptomatic relief possible from proton pump inhibitors, H2-receptor blockers, and/or sucralfate
- Ileitis: Supplemental fat-soluble vitamins, iron, B12, folate, and calcium may be necessary.
- Treatment toxicity: pancreatitis, bone marrow toxicity, lymphoma, nonmelanoma skin cancer, infections (TB, histoplasmosis, others),
malignancy

MEDICATION

First Line

- Asymptomatic patients: observation
- Mild CD
  - 5-Aminosalicylates have minimal role in CD management; used for colonic CD without deep ulcerations or fibrostenosing disease
  - Antibiotics are controversial. Controlled trials have not consistently demonstrated efficacy.
  - Glucocorticoid therapy: controlled ileal release budesonide (9 mg/day for 8 to 16 weeks and then discontinued over 2- to 4-week taper) for distal ileum and/or right colon involvement (2)[A]
  - Adjunctive therapy: antidiarrheals (loperamide); bile acid-binding resin (cholestyramine 4 to 12 g/day); probiotics (either alone or in combination may reduce inflammation/symptoms in acute CD)
  - Induction/maintenance: 5-ASA is not recommended (2)[C]. Controlled ileal release budesonide, 9 mg/day, is effective for maintenance for up to 6 months.
- Moderate to severe CD
  - Induction: prednisone 40 to 60 mg/day or controlled-release budesonide (for isolated, moderate ileitis) or anti-TNF agents as initial induction agent or for lack of response to corticosteroid or immunomodulator (2)[A]
  - Maintenance: no role for mesalamine. If steroids required for induction, use immunomodulator (2)[B] or biologic (anti-TNF agent) (2)[B] for maintenance.
  - Except for budesonide, do not use steroids for maintenance (1)[A].
- Severe disease: immunomodulators, anti-TNF agents ± steroids
  - Azathioprine or 6-mercaptopurine: thiopurine methyltransferase (TPMT) and LFTs prior to initiation. Check CBC/LFTs q2–3mo.
  - Methotrexate: effective for steroid-dependent and steroid-refractory CD
    - Folic acid 1 mg/day; follow LFTs.
  - Anti-TNF: active disease, fistulae, steroid sparing, extraintestinal disease; infliximab, adalimumab, certolizumab pegol
    - Check for evidence of TB and HBV infection prior to initiation of anti-TNF therapy.
    - Avoid live vaccines.
    - Monitoring: Consider antidrug antibody levels to assess for
immunogenicity. Serum concentrations of anti-TNF agents may also correlate with disease activity.

- **Combination therapy**
  - Azathioprine + infliximab is more effective than either alone if no previous treatment with either.
  - Rare complication: hepatosplenic T-cell lymphoma (fatal, mostly seen in young males)

- **Antiadhesion molecules:** prevent inflammatory cells from entering GI tract
  - Vedolizumab: gut-specific, can be used in anti-TNF failures or anti-TNF naive patients as induction and maintenance; given IV, no risk of progressive multifocal leukoencephalopathy (PML)
  - Natalizumab: non–gut-specific, PML risk (1/1,000); can minimize risk by testing for John Cunningham (JC) virus antibody; however, can avoid risk of PML now with vedolizumab

- **Anti–IL-12 and anti–IL-23 monoclonal antibody:** ustekinumab: recently approved for CD

- **Therapeutic drug monitoring:** Optimize biologics to avoid side effects. Measure trough levels of drug, and if drug not present, assess for antibody to the drug. If low or absent drug level and no antibodies, increase dose or frequency. If no drugs and high antibody levels, switch agents. If drug present and no antibodies, switch treatment if active disease (3)[C].

- **New/Investigational therapies:**
  - JAK kinase inhibitor and SMAD-7 inhibitor under investigation

### COMPLICATIONS

- **Peritonitis:** bowel rest and antibiotic therapy (7 to 10 days parenteral antibiotics, followed by 2- to 4-week course of PO ciprofloxacin and metronidazole); surgery as indicated
  - Consider holding steroids which masks sepsis.

- **Abscess:** antibiotics, percutaneous drainage, or surgery with resection of affected segments

- **Small bowel obstruction:** IV hydration, nasogastric (NG) tube for decompression, total parenteral nutrition (TPN) for malnutrition, resolution typically in 24 to 48 hours; surgery for nonresponders

---

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS

**Patient Monitoring**

Vaccinations
- Check titers; avoid live vaccines (MMR, varicella, zoster) in patients on immunosuppressive therapy (steroids, 6MP, AZA, MTX, or biologics).
- Regardless of immunosuppression: HPV, influenza, pneumococcal, meningococcal, hepatitis A, B; Tdap

Cancer prevention
- Colonoscopy with targeted biopsies every 1 to 3 years after 8 to 10 years of CD with colonic involvement; consider chromoendoscopy if available (4) [C].
- Annual PAP smears if immunocompromised
- Annual skin exam if immunocompromised

Bone health
- Calcium and vitamin D supplementation with each course of corticosteroids or if vitamin D deficient
- Bone density assessment if previous steroid use, maternal history of osteoporosis, malnourished, amenorrheic, postmenopausal

PATIENT EDUCATION

Crohn and Colitis Foundation: (800) 343-3637; [www.ccf.org](http://www.ccf.org)

REFERENCES

CODES

ICD10
- K50.919 Crohn’s disease, unspecified, with unspecified complications
- K50.00 Crohn’s disease of small intestine without complications
- K50.10 Crohn’s disease of large intestine without complications

CLINICAL PEARLS
- Cigarette smoking doubles the risk of CD; tobacco cessation reduces flares and need for surgery.
- MRE allows assessment of luminal and extraluminal CD without radiation exposure.
- Assess for TB and HBV infection prior to initiating anti-TNF therapy.
- Test for C. difficile infection when evaluating diarrhea in all CD patients.
- Hospitalized CD patients require deep vein thrombosis prophylaxis.
- Top-down therapy favored for moderate to severe CD
- Anti-TNF therapy effective in delaying or preventing postoperative recurrence in CD
CROUP  
(LARYNGOTRACHEOBRONCHITIS)  
Ryan Paul B. Urbi, MD • Olga L. Nunez, MD • Mark T. Nadeau, MD, MBA

BASICS

DESCRIPTION
- Croup is a subacute viral illness characterized by upper airway symptoms such as seal-like barking cough, inspiratory stridor, and fever. “Croup” is used to refer to viral laryngotracheitis or laryngotracheobronchitis (LTB). It is sometimes used for LTB with pneumonitis, bacterial tracheitis, or spasmodic croup.
- Most common cause of upper airway obstruction or stridor in children
- Spasmodic croup: noninfectious form with sudden resolution
  - No fever or radiographic changes
  - Initially treated as croup
  - Usually self-limiting and resolves with mist therapy at home
  - Often recurs on same night or in 2 to 3 nights
- System(s) affected: respiratory
- Synonym(s): infectious croup; viral croup

EPIDEMIOLOGY
- Predominant age
  - Common among children 6 months to 3 years
  - Most common during the 2nd year of life
  - Rare among those <3 months and >6 years
- Predominant sex: male > female (1.5:1)
- Timing
  - Possible during any time of year but is most common in autumn and winter (with parainfluenza 1 and respiratory syncytial virus [RSV])

Incidence
- Six cases per year per 100 children <6 years old
- 1.5–6% of cases require hospitalization.
2–6% of those require intubation.
Decreasing incidence in the United States and Canada

ETIOLOGY AND PATHOPHYSIOLOGY
• Subglottic region/larynx is entirely encircled by the cricoid cartilage.
• Inflammatory edema and subglottic mucus production decrease airway radius.
• Small children have small airways with more compliant walls.
• Negative-pressure inspiration pulls airway walls closer together.
• The anatomically small airway is more susceptible to compromise and narrowing caused by the combined edema, mucus secretions, and increased compliance. Small decrease in airway radius causes significant increase in resistance (Poiseuille law: resistance proportional to 1/radius$^4$).
• Typically caused by viruses that initially infect oropharyngeal mucosa and then migrate inferiorly
  • Parainfluenza virus
    – Most common pathogen: 75% of cases
    – Type 1 is the most common, causing 18% of all cases of croup.
    – Types 2, 3, and 4 are also common.
    – Type 3 may cause a particularly severe illness.
  • Other viruses: RSV, paramyxovirus, influenza virus type A or B, adenovirus, rhinovirus, enteroviruses (coxsackie and echo), reovirus, measles virus where vaccination not common, and metapneumovirus
  • Haemophilus influenzae type B now rare with routine immunization
• May have bacterial cause: Mycoplasma pneumoniae has been reported.

RISK FACTORS
• Age group 2 to 3 years, with range of 6 months to 6 years
• Seasonality: fall and winter
• Epidemic outbreaks with associated URI symptoms

GENERAL PREVENTION
Seasonal influenza shots may decrease risk.

COMMONLY ASSOCIATED CONDITIONS
• If recurrent (>2 episodes in a year) or during first 90 days of life, consider host factors.
• Underlying anatomic abnormality (e.g., subglottic stenosis)
  – In one study, found to be present in 59% children with recurrent croup
- Paradoxical vocal cord dysfunction
- Gastroesophageal reflux disease
- Neonatal intubation

**DIAGNOSIS**

- Croup is a clinical diagnosis; lab tests and imaging serve only ancillary purposes. Most children who present with acute onset of barky cough, inspiratory stridor, hoarseness, and chest wall indrawing have croup.
- Classic “seal-like” barking, spasmodic cough
- May have biphasic stridor
- Low to moderate grade fever
- Upper respiratory infection prodrome lasting 1 to 7 days
- Severity usually is determined by clinical observation for signs of respiratory effort: nasal flaring, retractions, tripoding, sniffing position, abdominal breathing, and tachypnea; later symptoms: hypoxia/cyanosis or fatigue
- Westley croup severity score is most useful for research purposes.
- Westley croup score looks at five clinical features: level of consciousness, cyanosis, stridor, air entry, and retractions (≤2 mild; 3 to 7 moderate; ≥8 severe).
  - Level of consciousness: normal, including sleep = 0; disoriented = 5
  - Cyanosis: none = 0; with agitation = 4; at rest = 5
  - Stridor: none = 0; with agitation = 1; at rest = 2
  - Air entry: normal = 0; decreased = 1; markedly decreased = 2
  - Retractions: none = 0; mild = 1; moderate = 2; severe = 2
- No change in stridor with positioning
- Nontender larynx
- Inflamed subglottic region with normal-appearing supraglottic region
- Differentiate from epiglottitis: non–toxic-appearing, normal voice, no drooling, is coughing (1).

**HISTORY**

- LT, LTB, and laryngotracheobronchopneumonitis (LTBP) (triad) present with respiratory distress, stridor (often with hoarseness), barky cough, rhinorrhea, and low-grade fevers. After a 2- to 3-day prodrome, often the exacerbations occur at night that suggest hydration may be a factor.
- Lack of prodrome indicates spasmodic croup.
PHYSICAL EXAM
Pulse oximetry often is normal because there is no disturbance of alveolar gas exchange.

- Overall appearance: Is the child comfortable or struggling?
- Work of breathing: labored or comfortable?
- Sound of breathing and voice: hoarse, stridor, inspiratory wheezing, short sentences?
- Observed/subjective tidal volume: sufficient for child’s size?
  - Assessment of the severity of croup
    - Mild (0 to 2 Westley): occasional barking cough; no audible stridor at rest, and either mild or no suprasternal or intercostal retractions
    - Moderate (3 to 5 Westley): frequent barking cough, easily audible stridor at rest, and suprasternal and sternal retractions at rest, but little or no agitation
    - Severe (6 to 11 Westley): frequent barking cough, prominent inspiratory and, occasionally, expiratory stridor, marked sternal retractions, and agitation and distress
    - Impending respiratory failure (12 to 17 Westley): barking cough (often not prominent), audible stridor at rest (occasionally hard to hear), sternal retractions (may not be marked), lethargy or decreased level of consciousness, and often dusky appearance in the absence of supplemental oxygen (2)[B]

ALERT
Decreased breath sounds and respiratory effort may imply the child is progressing into respiratory failure and less able to mount an effort to move air. Even though there may be less obvious sign of distress, clinicians should not miss the clinically deteriorating patient.

DIFFERENTIAL DIAGNOSIS
In order of decreasing frequency:
- Upper respiratory infection including classic LTB
- Foreign body aspiration: toddler to 4 years of age; often requires high index of suspicion
- Bacterial tracheitis; similar to epiglottitis, acute septic onset
- Retropharyngeal or peritonsillar abscess: similar septic appearance with dysphonia
- Allergic reaction (acute angioneurotic edema); includes spasmodic croup with
classic nocturnal exacerbations
- Epiglottitis: associated with rapid onset, high fever, dysphonia, drooling, and prototypical posture of extended chin and leaning forward; *H. influenzae* being replaced by strep and staph organisms
- Subglottic stenosis
- Trauma
- Airway anomalies (e.g., tracheo-/laryngomalacia)
- Other anatomic obstructions: subglottic hemangioma, subglottic cyst

**DIAGNOSTIC TESTS & INTERPRETATION**
- LTB, LTBP, and LT are clinical diagnosis and usually do not require extensive testing.
- Posteroanterior and lateral neck films show funnel-shaped subglottic region with normal epiglottis: “steeple,” “hourglass,” or “pencil point” sign (present in 40–60% of children with LTB).
- CT may be more sensitive for defining obstruction in a confusing clinical picture.
- Patient should be monitored during imaging; airway obstruction may occur rapidly.
- Also evaluate radiographs for:
  - Retropharyngeal abscess: dimensions of the posterior pharynx (should be same AP width as a contingent vertebral body)
  - Epiglottitis: thumb sign: appearance of a thumb pointing posteriorly, respectively
- Blood work may not be required. WBC counts may be mildly elevated with a predominance of lymphocytes; an elevated WBC shift to the left (bandemia) would suggest etiology other than LTB, most likely bacterial. Examples of this would be epiglottitis, bacterial tracheitis, and retropharyngeal abscess.
- Microbiologic studies might be used to identify viral strains and specific bacteriologic species in severe presentations or to track epidemiology. *H. influenzae* and diphtheria as etiologic agents are rarely seen in industrialized countries in the pharynx as the result of immunization practices.
- Rapid antigen or viral culture tests are available in many centers.
  - Guide isolation precautions, not management.

**Test Interpretation**
- Inflammatory reaction of respiratory mucosa
- Loss of epithelial cells
- Thick mucoid secretions
TREATMENT

GENERAL MEASURES

- Symptomatic treatment
- Minimize lab tests, imaging, and procedures that upset the child; agitation worsens tachypnea and can be more detrimental than accepting a clinical diagnosis.
- ECG monitoring and pulse oximetry
- Pulse oximetry not as sensitive as frequent clinical checks in identifying worsening disease

MEDICATION

First Line

- Well established in the literature; cornerstones of treatment are immediate nebulized epinephrine and oral dexamethasone.

<table>
<thead>
<tr>
<th>Racemic or L-epinephrine (equal efficacy and side effect profiles; L-epinephrine is used for most other hospital purposes and is less expensive) (2) [A]</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Reserved for more severe cases with stridor at rest</td>
</tr>
<tr>
<td>- Racemic epinephrine: 0.05 mL/kg/dose (max 0.5 mL) of 2.25% solution nebulized in normal saline to total volume of 3 mL</td>
</tr>
<tr>
<td>- L-epinephrine: 0.5 mL/kg/dose (max 5 mL) of a 1:1,000 dilution nebulized</td>
</tr>
<tr>
<td>- Onset in 1 to 5 minutes, duration of 2 hours</td>
</tr>
<tr>
<td>- Repeat as necessary if side effects are tolerated.</td>
</tr>
<tr>
<td>- Observe child for 2 hours to ensure no recurrence after epinephrine wears off.</td>
</tr>
</tbody>
</table>

- Corticosteroids

<table>
<thead>
<tr>
<th>Dexamethasone (least expensive, easiest), 0.15 to 0.60 mg/kg; higher doses have been traditional care, but studies have shown 0.15 mg/kg has equal efficacy (3)[B]. Single dose; IV/IM/PO has proven equal efficacy.</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Randomized controlled trials show this begins to improve symptoms within 30 minutes (4)[A]; full effect by 4 hours</td>
</tr>
<tr>
<td>- Other steroids (betamethasone, budesonide (5)[A], prednisolone) are beneficial; there may be minimal superiority of dexamethasone; also, dexamethasone carries benefit of single-dose administration (6,7)[A].</td>
</tr>
</tbody>
</table>

- Antibiotics are not indicated as this is a viral illness.
- Oxygen as needed
Humidified air shows no clinical benefit.

**Second Line**
Oseltamivir for influenza A

**SURGERY/OTHER PROCEDURES**
Intubation rarely is required; tube 0.5 to 1.0 mm smaller than normal

- After trial of medical management, intubation may be required for fatigue caused by work of breathing or obstruction.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Outpatient care in mild cases
- Admit patients who do not respond to therapy or have recurrent stridor at rest after epinephrine wears off. Also admit those who have oxygen requirement, pneumonia, or other serious conditions.
- In most cases, observation in the ED after medical management is sufficient.
- Discharge criteria
  - >2 hours since last epinephrine
  - No stridor at rest, no difficulty breathing
  - Child able to tolerate liquids PO
  - No underlying medical condition
  - Caretakers able to assess changes to clinical picture and reaccess medical care

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Most children with croup do not require specific follow-up; should consider PCP follow-up if patient had stridor for >1 week.

**DIET**
- Liquid diet is most comfortable for the patient and better tolerated.
- Cold liquids are often more soothing.
- Frequent small feedings with increased fluids for mild cases
PATIENT EDUCATION

- Croup is usually a self-limited and mild disease, but some children will need more intense medical care in the hospital.
- Generally, be calming and keep your child comfortable. Keep the child cool by dressing lightly and use antipyretics if they are febrile.
- Keep the child well hydrated with ample cool liquids or popsicles.
- Keep the patient quiet; crying may exacerbate symptoms.
- Educate parents about when to seek emergency care if symptoms worsen.
- Provide emotional support and reassurance for the patient.
- Absolute need for medical care:
  - Respiratory distress; rapid breathing; working hard to breathe; prominent chest or neck muscles with each breath
  - The child becomes restless or agitated.
  - The child looks unusually pale.
  - High temperature (fever) lasts longer than 1 to 2 days.
- Emergency ambulance if the child is:
  - Blue (cyanosis)
  - Lethargic
  - Struggling to breathe
  - Drooling and unable to swallow

PROGNOSIS

- Prognosis is generally good. The few cases that are severe respond to intensive respiratory management.
- Recurrence is rare in viral-mediated disease.
- If croup recurs, consider an anatomic, allergic, or obstructive etiology.

COMPLICATIONS

- Rare
- Subglottic stenosis in intubated patients
- Bacterial tracheitis
- Cardiopulmonary arrest
- Pneumonia

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- J05.0 Acute obstructive laryngitis [croup]
- J20.9 Acute bronchitis, unspecified
- J38.5 Laryngeal spasm

**CLINICAL PEARLS**

- LT and LTB outbreaks are most common in fall and winter time for population aged 6 months to 3 years. Symptoms often occur at night.
- Recurrent episodes should be followed up with a search for anatomic or allergic etiology.
- Foundation of treatment is oxygen, oral/IM steroids and nebulized epinephrine.
- Consider other diagnoses in acute presentations with toxic appearance:
epiglottitis, abscess, bacterial tracheitis.
- Be aware of severity should the child become less noisy; less air movement can be sign of respiratory failure.
- Croup is a clinical diagnosis, thus medical management and stabilization of the patient take priority over lab testing or radiographic images.
CRYPTORCHIDISM
Pamela Ellsworth, MD

BASICS

DESCRIPTION
- Incomplete or improper descent of one or both testicles; also called undescended testes (1)
- Normally, descent is in the 7th to 8th month of gestation. The cryptorchid testis may be palpable or nonpalpable.
- Types of cryptorchidism
  - Abdominal: located inside the internal ring
  - Canalicular: located between the internal and external rings
  - Ectopic: located outside the normal path of testicular descent from abdominal cavity to scrotum; may be ectopic to perineum, femoral canal, superficial inguinal pouch (most common), suprapubic area, or opposite hemiscrotum
  - Retractile: fully descended testis that moves freely between the scrotum and the groin
  - Iatrogenic: Previously descended testis becomes undescended secondary to scar tissue after inguinal surgery, such as an inguinal hernia repair or hydrocelectomy.
  - Also may be referred to as palpable versus nonpalpable (1)
- System(s) affected: reproductive
- Synonym(s): undescended testes (UDT)

EPIDEMIOLOGY

Incidence
- Predominant age: premature newborns
- Predominant sex: male only

Prevalence
- In the United States, cryptorchidism occurs in 1–3% of full-term and 15–30% of premature newborn males (2).
- Spontaneous testicular descent occurs by age 1 to 3 months in 50–70% of full-term males with cryptorchidism.
Descent at 6 to 9 months of age is rare (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Not fully known
- May involve alterations in
  - Mechanical factors (gubernaculum, length of vas deferens and testicular vessels, groin anatomy, epididymis, cremasteric muscles, and abdominal pressure), hormonal factors (gonadotropin, testosterone, dihydrotestosterone, and müllerian-inhibiting substance [MIS]), and neural factors (ilioinguinal nerve and genitofemoral nerve)
  - Major regulators of testicular descent from intra-abdominal location into the bottom of the scrotum are the Leydig cell–derived hormones, testosterone, and insulin-like growth factor 3 (IGF-3).
  - Mutations in the gene for IGF-3 and in the androgen receptor gene have been evaluated as possible causes of cryptorchidism as well as chromosomal alterations (1).
  - Environmental factors acting as endocrine disruptors of testicular descent also may contribute to the etiology of cryptorchidism.
- Risk of ascent may be as high as 32% in retractile testis.

**Genetics**
Occurrence of UDT in siblings as well as fathers suggests a genetic etiology.

**RISK FACTORS**
- Family history of cryptorchidism: highest risk if brother had UDT, followed by uncle and then father
- Low birth weight, prematurity, and small for gestational age are associated with a substantial increase in incidence of cryptorchidism (1). Retractile testes are at increased risk for ascent.

**COMMONLY ASSOCIATED CONDITIONS**
- Inguinal hernia/hydrocele
- Abnormalities of vas deferens and epididymis
- Intersex abnormalities
- Hypogonadotropic hypogonadism
- Germinal cell aplasia
- Prune-belly syndrome
- Meningomyelocele
- Hypospadias
- Wilms tumor
- Prader-Willi syndrome
- Kallmann syndrome
- Cystic fibrosis

**DIAGNOSIS**

**HISTORY**
- ≥1 testicles in a site other than the scrotum
- May be an isolated defect or associated with other congenital anomalies

**PHYSICAL EXAM**
- Performed with warm hands, with child in sitting, standing, and squatting position
- A Valsalva maneuver and applied pressure to lower abdomen may help to identify the testes, especially a gliding testis.
- Failure to palpate a testis after repeated exams suggests an intra-abdominal or atrophic testis.
- An enlarged contralateral testis in the presence of a nonpalpable testis suggests testicular atrophy/absence.
- Testes should be palpated for quality and position at each recommended well-child visit (1)[B].

**DIFFERENTIAL DIAGNOSIS**
- Retractile testis (hypermobile testis), a normally descended testis that ascends into the inguinal canal because of an active cremasteric reflex (more common in males 4 to 6 years of age)
- Atrophic testis: may occur as a result of neonatal torsion
- Vanished testis may be the result of a lack of development or in utero torsion.

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- In phenotypic male newborn with bilateral, nonpalpable UDTs, hormone levels are helpful to determine whether the testes are present and should be evaluated for possible disorder of sexual development (1)[A].
  - Luteinizing hormone (LH)
- Follicle-stimulating hormone (FSH)
- MIS
- Testosterone
- Serum electrolytes
- Karyotype

If bilateral nonpalpable testes and presenting >3 months of age, a human chorionic gonadotropin (hCG) stimulation test to determine presence or absence of testicular tissue (hCG 2,000 IU/day for 3 days, and check testosterone before and after stimulation) as well as gonadotropins—to say testes are absent—needs negative stimulation test and elevated gonadotropins (3).

Ultrasound or other imaging modalities should not be performed in the evaluation of boys with cryptorchidism prior to referral to a specialist, as they are rarely needed in decision making (1)[B].

**Follow-Up Tests & Special Considerations**
In newborns and children <6 months of age, periodic examination to determine if testis is palpable and descended prior to considering further intervention (1)

**Pediatric Considerations**
In the absence of spontaneous testicular descent by 6 months of age (gestational age adjusted), infant should be referred to appropriate specialist, and surgery should be performed within 1 year (1)[B].

- In children with retractile testes, examination should be performed at least yearly to rule out subsequent ascent (1)[B].
- In boys 11 to 30 months of age with unilateral nonpalpable UDT, if the contralateral descended testis is 19 to 20 mm or greater in length measured by caliper, there is a greater likelihood of a vanished/atrophic testis (4)[B].

**Diagnostic Procedures/Other**
Laparoscopy is useful in a child with nonpalpable cryptorchidism to confirm testicular absence or presence accurately and to determine the feasibility of performing a standard orchidopexy.

**Test Interpretation**
Higher incidence of carcinoma in UDT and alterations in spermatogenesis. Histologic changes occur by 1.5 years of age and include smaller seminiferous tubules, fewer spermatogonia, and more peritubular tissue (5).
TREATMENT

GENERAL MEASURES
- Rule out retractile testis.
- Appropriate health care: outpatient until surgery is performed
- Administration of chorionic gonadotropin may cause testicular descent in some boys. Reports of efficacy are inconsistent. American Urological Association (AUA) guidelines on cryptorchidism do not recommend use of hormonal therapy to induce testicular descent due to low response rate and lack of evidence for long-term efficacy (1).

MEDICATION
Medical therapy is not indicated in the United States per the AUA guidelines on cryptorchidism 2014 (1).

ISSUES FOR REFERRAL
- ≥1 testes not descended by 6 months age (1)[B]
- Bilateral nonpalpable UDTs (1)
- Newly diagnosed cryptorchidism after 6 months of age (1)[B]

SURGERY/OTHER PROCEDURES
- Reasons to consider: avoids torsion, averts trauma, decreases but does not eliminate risk of malignancy, and prevents further alterations in spermatogenesis
- In the absence of spontaneous testicular descent by 6 months of age (gestational age–adjusted), surgery should be performed within 1 year (1)[B].
- Prepubertal orchidopexy decreases risk of testicular cancer and results in 2- to 6-fold reduction in relative risk compared to postpubertal orchidopexy (1).
- Laparoscopy/abdominal exploration is performed first if testis is nonpalpable.
- If palpable, an inguinal approach is usually performed. If low-lying, a single incision scrotal approach can also be considered but may increase the risk of hernia.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
• Initial follow-up within 1 month of surgery and periodically thereafter to assess testicular size/growth
• Patients with retractile testes should be examined at least annually to monitor for secondary ascent until testis is no longer retractile (1)[B].

**Patient Monitoring**
• Patients should be followed after surgery to evaluate testicular growth.
• Testicular tumors occur mainly during or after puberty; thus, these children should be taught self-examination when they are older.

**DIET**
No restrictions

**PATIENT EDUCATION**
Discuss with parents about causes, available treatments, and possible effects on patient’s reproductive potential and also increased risk for testicular cancer and need for regular self-examination.

**PROGNOSIS**
• Disorder is usually corrected with medical or surgical therapy; however, there are possible lifelong consequences.
• If testicle is absent or orchiectomy is required, may consider placement of testicular prosthesis.
• Early orchidopexy may decrease risk of testicular damage and risk of malignancy.

**COMPLICATIONS**
• Paternity rates are similar to the general population for men with a unilateral UDT; however, are lower (33–65%) for men with bilateral UDT
• Abnormalities also have been identified in the contralateral descended testis, although less severe.

**REFERENCES**
2. Sijstermans K, Hack WW, Meijer RW, et al. The frequency of undescended

ADDITIONAL READING

**CODES**

**ICD10**
- Q53.9 Undescended testicle, unspecified
- Q53.10 Unspecified undescended testicle, unilateral
- Q53.20 Undescended testicle, unspecified, bilateral

**CLINICAL PEARLS**
- If testicular descent does not occur by 6 months of age, it is unlikely to occur. Therefore, refer patients to a specialist if a testis has not descended by 6 months of age.
- Children with bilateral, nonpalpable UDTs require laboratory evaluation to determine if viable testicular tissue is present and to rule out disorder of sexual differentiation.
- Radiologic imaging has no role in the initial evaluation of cryptorchidism.
- The risk of infertility is increased with bilateral UDTs.
CUSHING DISEASE AND CUSHING SYNDROME

Linda Paniagua, MD

BASICS
DESCRIPTION
- Clinical abnormalities associated with chronic exposure to excessive amounts of cortisol (the major adrenocorticoid)
- Cushing syndrome is defined as excessive corticosteroid exposure from exogenous sources (medications) or endogenous sources (pituitary, adrenal, pulmonary, etc.) or tumor. Exogenous intake of steroids is the primary cause of Cushing syndrome.
- Cushing disease is defined as glucocorticoid excess due to excessive adrenocorticotropic hormone (ACTH) secretion from a pituitary tumor, the most common cause of primary Cushing syndrome.
- System(s) affected: endocrine/metabolic, musculoskeletal, skin/exocrine, cardiovascular; neuropsychiatric

Pediatric Considerations
- Rare in infancy and childhood
- Cushing disease accounts for approximately 75% of all cases of Cushing syndrome in children >7 years.
- In children <7 years, adrenal causes of Cushing syndrome (adenoma, carcinoma, or bilateral hyperplasia) are more common.
- Most common presenting symptom is lack of growth consistent with the weight gain.

Pregnancy Considerations
- Pregnancy may exacerbate disease.
- Cortisol levels increase in normal pregnancy states.

EPIDEMIOLOGY
Incidence
Uncommon: 0.7 to 2.4/1 million per year
Prevalence
2–5% prevalence reported in difficult-to-control diabetics with obesity and hypertension (HTN)

ETIOLOGY AND PATHOPHYSIOLOGY
- Syndrome: excessive corticosteroid exposure from exogenous sources (medications) or endogenous sources (pituitary, adrenal, pulmonary, etc.) or tumor
- Disease: pituitary tumor causing excess ACTH (corticotropin)
- General population
  - Exogenous glucocorticoids
  - Endogenous ACTH–dependent hypercortisolism: 80–85%
    - ACTH-secreting pituitary tumor: 75%
    - Ectopic ACTH production (e.g., small cell carcinoma of lung, bronchial carcinoid): 20%
  - Endogenous ACTH–independent hypercortisolism: 15–20%
    - Adrenal adenoma
    - Adrenal carcinoma
    - Macronodular or micronodular hyperplasia
- Pediatric/adolescent
  - Adrenal hyperplasia secondary to McCune-Albright syndrome: mean age 1.2 years
  - Adrenocortical tumors: mean age 4.5 years
  - Ectopic ACTH syndrome: mean age 10.1 years
  - Primary pigmented nodular adrenocortical disease: mean age 13.0 years
  - Cushing disease: mean age 14.1 years
- Pregnancy
  - Pituitary-dependent Cushing syndrome: 33%
  - Adrenal causes: 40–50%
  - ACTH-independent adrenal hyperplasia: 3%

Genetics
- Multiple endocrine neoplasia
- Carney complex (an inherited multiple neoplasia syndrome)
- McCune-Albright syndrome (mutation of GNAS1 gene)
- Familial isolated pituitary adenomas (mutations in the aryl hydrocarbon receptor–interacting protein gene)
RISK FACTORS
- Prevalent sex: female > male (3:1)
- Most often occurs between the ages of 25 and 40 years
- Prolonged use of corticosteroids

GENERAL PREVENTION
Avoid corticosteroid exposure, when possible.

DIAGNOSIS

HISTORY
- Weight gain: 95%
- Decreased libido: 90%
- Menstrual irregularity: 80%
- Depression/emotional lability: 50–80%
- Easy bruising: 95%
- Diabetes or glucose intolerance: 90%

PHYSICAL EXAM
- Obesity (usually central): 95%
- Facial plethora: 90%
- Moon face (facial adiposity): 90%
- Thin skin: 85%
- HTN: 75%
- Skeletal growth retardation in children (epiphyseal plates remain open): 70–80%
- Hirsutism: 75%
- Proximal muscle weakness: 90%
- Purple striae on the skin
- Increased adipose tissue in neck and trunk
- Acne

DIFFERENTIAL DIAGNOSIS
- Obesity
- Diabetes mellitus
- HTN
- Metabolic syndrome X
Polycystic ovarian disease
- Pseudo-Cushing (e.g., alcoholism, physical stress, severe major depression)

### DIAGNOSTIC TESTS & INTERPRETATION

#### Initial Tests (lab, imaging)

- Recent guidelines (1)[C]
  - The 2008 Endocrine Society guidelines recommend against widespread testing for Cushing syndrome except in patients with the following:
    - Adrenal incidentaloma
    - Multiple progressive features suggestive of Cushing syndrome
    - Unusual features for their age such as osteoporosis and HTN
    - Abnormal growth (children)
- Late-night salivary cortisol, 24-hour urinary free cortisol, or low-dose dexamethasone suppression testing
  - Elevated late-night salivary cortisol: Obtain at least two measurements. Cortisol secretion is highest in the morning and lowest between 11 PM and midnight. The nadir of serum cortisol is maintained in pseudo-Cushing (e.g., obesity, alcoholism, depression) but not in Cushing syndrome. Sensitivity and specificity are >90–95% (2)[B].
  - 24-hour urinary free cortisol level: Obtain ≥2 samples to rule out intermittent hypercortisolism if results are normal and suspicion is high. Also measure 24-hour urinary creatinine excretion to verify adequacy of collection. Results may be falsely low if glomerular filtration rate <30 mL/min. Overall sensitivity and specificity varies, 90–97% and 85–99%, respectively (2)[B]. Avoid drinking excessive amounts of water due to risk of false-positive values. False-positive values can be seen in the presence of pseudo-Cushing states.
  - Low-dose dexamethasone suppression testing: Dexamethasone 1 mg is given between 11 PM and midnight, and fasting plasma cortisol is measured between 8 and 9 AM the following morning. A serum cortisol level below 1.89 μg/dL excludes Cushing syndrome, but specificity is limited. The presence of pseudo-Cushing states (depression, obesity, etc.), hepatic or renal disease, or any drug that induces cytochrome P450 enzymes may cause a false result.
- High-dose dexamethasone suppression test may be useful when baseline ACTH levels are indeterminate:
  - 8 mg overnight dexamethasone suppression test: 8 mg of oral dexamethasone is given at 11 PM, with measurement of an 8-AM cortisol
level the next day. A baseline 8-AM cortisol measurement is also obtained the morning prior to ingesting dexamethasone. Suppression of serum cortisol level to <50% of baseline is suggestive of a pituitary source of ACTH rather than ectopic ACTH or primary adrenal disease. Sensitivity and specificity are 95% and 100%, respectively (3)[B].

- If the initial results are positive or if clinical suspicion is high, perform additional studies to confirm diagnosis. Other tests to consider include the following:
  - Awake midnight plasma cortisol: Obtain samples on three consecutive nights. A late-evening serum cortisol >7.5 μg/dL has a sensitivity of 99% and specificity of 100% (4)[B]. Persistently elevated serum cortisol implies Cushing syndrome; nadir of serum cortisol is maintained in obese patients but not in Cushing.
  - Corticotropin-releasing hormone (CRH) after dexamethasone: used to distinguish Cushing syndrome from pseudo-Cushing syndrome. Dexamethasone 0.5 mg is given q9h for 48 hours starting at noon. CRH (1 μg/kg) is given 2 hours after the last dose of dexamethasone. Plasma cortisol is >1.4 μg/dL 15 minutes after CRH in patients with Cushing syndrome but not in those with pseudo-Cushing.

- Pituitary MRI scan if pituitary tumor is suspected
- Abdominal CT scan if adrenal disease is suspected
- Chest CT scan if ectopic ACTH secretion is suspected
- Octreotide scintigraphy to look for occult ACTH-secreting tumor
- Dual energy x-ray absorptiometry to evaluate for osteoporosis

**ALERT**

- Antiepileptic drugs, progesterone, oral contraceptives (withdraw estrogen-containing drugs 9 weeks before testing), rifampin, and spironolactone may cause a false-positive dexamethasone suppression test.
- Pregnancy (1)[C]: Urine free cortisol is recommended instead of dexamethasone testing in the initial evaluation of pregnant women. Only urine free cortisol in the 2nd or 3rd trimester >3 times the upper limit of normal can be taken to indicate Cushing syndrome.
- Epilepsy (1)[C]: best to use measured cortisol from saliva and urine instead of serum cortisol after dexamethasone. No data to guide length of time needed after withdrawal of such medication to allow dexamethasone metabolism to return to normal; such medication change may not be clinically possible.
Follow-Up Tests & Special Considerations

- Once the diagnosis of Cushing syndrome is confirmed, localization is the next step:
  - ACTH level: elevated in ACTH-dependent Cushing syndrome (e.g., pituitary and ectopic tumor) and low in ACTH-independent Cushing syndrome (e.g., adrenal tumors and exogenous glucocorticoids)
  - High-dose dexamethasone suppression testing: used to distinguish between an ACTH-secreting pituitary tumor and ectopic ACTH-secreting tumors. 0.5 mg dexamethasone is given q9h for 8 doses, with serum cortisol measured at 2 and 9 hours after last dose (sensitivity 79%, specificity 74%) \(^{(3)}[B]\).

- Diagnosis of Cushing syndrome is complicated by the nonspecificity and high prevalence of clinical symptoms in patients without the disorder and involves a variety of tests of variable sensitivity and specificity. Efficient screening and confirmatory procedures are essential before considering therapy.

Diagnostic Procedures/Other

Diagnostic procedure depends on clinical judgment. Inferior petrosal sinus sampling with CRH stimulation can be considered if ACTH-dependent tumor is suspected but not localized.

Test Interpretation

- Thyroid function suppressed
- HTN
- Dyslipidemia
- Polycystic ovarian syndrome/hyperandrogenism
- Oligomenorrhea/hypogonadism
- Myopathy/cutaneous wasting
- Neuropsychiatric problems
- Ipsilateral adrenal gland hyperplasia and contralateral adrenal gland atrophy
- Hypercoagulable state
- Osteoporosis
- Nephrolithiasis
- Growth hormone reduced

TREATMENT
MEDICATION

- Drugs usually not effective for primary long-term treatment; used in preparation for surgery or as adjunctive treatment after surgery, pituitary radiotherapy, or both
- Metyrapone, ketoconazole, and mitotane all lower cortisol by directly inhibiting synthesis and secretion in the adrenal gland. Replacement glucocorticoid therapy is often required. As initial treatment, remission rates up to 85% (5)[C].
- Etomidate also inhibits the adrenals and is the only medical treatment available for severe hypercortisolism who are not immediate surgical candidates and who cannot take oral medication.
- Mifepristone is a potent glucocorticoid receptor antagonist. It is FDA-approved to control hyperglycemia in adults with endogenous Cushing syndrome who have type 2 diabetes or glucose intolerance secondary to hypercortisolism that has not responded to (or who are not candidates for) surgery.
- Pasireotide is a somatostatin receptor ligand with affinity for somatostatin receptor 5. It was approved by the FDA in 2012 for the treatment of Cushing disease when surgery is not successful or cannot be performed.
- Cabergoline is a dopamine agonist that has shown some promise in small studies but still remains off-label use.

SURGERY/OTHER PROCEDURES

- Transsphenoidal surgery
  - Primary treatment for Cushing disease due to remission range of 95–90% (6)[C]
  - Resection of the ACTH-producing ectopic tumor
- Adrenal surgery
  - For unilateral adrenal adenomas, laparoscopic surgery is the treatment of choice.
  - For nodular hyperplasia, bilateral adrenalectomy is usually recommended.
  - For patients with Cushing disease, bilateral laparoscopic adrenalectomy can be considered if the patient has persistent disease even after pituitary surgery and radiotherapy.
- Radiotherapy and stereotactic radiosurgery (SRS) can be used to treat persistent hypercortisolism after transsphenoidal surgery in Cushing disease.
- Fractionated radiotherapy
  - Rates of remission range from 59% to 84%.
– Its related complications of hypopituitarism have limited its usefulness.

- SRS
- Rates of remission range from 17% to 83%.
- Can be used as primary treatment without resection in patients with cavernous sinus tumors

---

**ONGOING CARE**

**PATIENT EDUCATION**

- Teaching regarding diet and monitoring daily weight, early treatment of infections, emotional lability
- National Adrenal Disease Foundation. Great Neck, NY 11021; 519-407-4992

**PROGNOSIS**

- Guardedly favorable prognosis with surgery for Cushing disease; generally chronic course with cyclic exacerbations and rare remissions
- Better prognosis following surgery for benign adrenal tumors; long-term recurrence rate is 20%.
- Poor with small cell carcinoma of the lung producing ectopic hormone; neuroendocrine tumors (bronchial carcinoid) have much better prognosis.

**COMPLICATIONS**

- Osteoporosis
- Increased susceptibility to infections
- Metastases of malignant tumors
- Increased cardiovascular risk even after treatment
- Lifelong glucocorticoid dependence following treatment with bilateral adrenalectomy
- Nelson syndrome (pituitary tumor) after treatment with bilateral adrenalectomy (can occur in 8–38% of patients)

**REFERENCES**

SEE ALSO

Algorithm: Cushing Syndrome

CODES

**ICD10**

- E24.9 Cushing’s syndrome, unspecified
- E24.0 Pituitary-dependent Cushing’s disease
- E24.2 Drug-induced Cushing’s syndrome

CLINICAL PEARLS

- Cushing disease is due to excessive ACTH secretion from a pituitary tumor, resulting in corticosteroid excess.
- Cushing syndrome is due to excessive corticosteroid exposure from exogenous sources (medications) or endogenous sources (pituitary, adrenal, pulmonary, etc.) or tumor.
- Depression, alcoholism, medications, eating disorders, and other conditions can cause mild clinical and laboratory findings similar to those in Cushing syndrome (pseudo-Cushing syndrome).
CUTANEOUS DRUG REACTIONS

Chris Place, MD

BASICS

DESCRIPTION

- An adverse cutaneous reaction in response to administration of a drug. Rashes are the most common adverse drug reactions.
- Severity can range from mild eruptions that resolve within 48 hours after the removal of the inciting agent, to severe skin damage with multiorgan involvement.
- Morbilliform/simple exanthem (75–95%) and urticarial (5–6%) eruptions are most common, but multiple morphologic types may occur.
- System(s) affected: skin/mucosa/exocrine, hematologic/lymphatic/immunologic

EPIDEMIOLOGY

- All ages are affected.
- Predominant sex: female > male
- There is no correlation between development of adverse reaction and patient’s age, diagnosis, or survival.
- Special consideration in the geriatric population who are on multiple medications: increased likelihood of severe cutaneous and systemic reactions; also consider in the pediatric group: difficult to distinguish from viral exanths

Incidence

In the United States, prevalence of 2–3% in hospitalized patients; estimated 1/1,000 hospitalized patients has had a severe cutaneous reaction.

ETIOLOGY AND PATHOPHYSIOLOGY

- Predictable adverse reactions are due to overdose, side effect, or drug interaction.
- Unpredictable reactions include intolerance, drug idiosyncrasy secondary to abnormality in metabolism, or immune reaction. >700 drugs are known to cause a dermatologic reaction:
- Immunologically mediated reaction: immunoglobulin (Ig) E–mediated reaction (type I hypersensitivity), cytotoxic/IgG/IgM induced (type II), immune complex reactions (type III), and delayed-type hypersensitivity (type IV) with T cells, eosinophils, neutrophils, and monocytes
- Acneiform: OCPs, corticosteroids, iodinated compounds, hydantoins, lithium
- Erythema multiforme/Stevens-Johnson syndrome (SJS)/toxic epidermal necrolysis (TEN): >100 drugs reported. Most common include sulfonamides, cephalosporins, NSAIDs, barbiturates, hydantoins, anticonvulsants tetracycline, terbinafine.
- Fixed drug eruptions: NSAIDS, sulfonamides, tetracycline, barbiturates, salicylates, OCPs
- Lichenoid: thiazides, NSAIDs, gold, ACE inhibitors, proton pump inhibitors, antimalarials, sildenafil
- Photosensitivity: doxycycline, thiazides, sulfonylureas, quinolones, sulfonamides, NSAIDs
- Hypersensitivity vasculitis: hydralazine, penicillins, cephalosporins, thiazides, gold, sulfonamides, NSAIDs, propylthiouracil
- Drug rash with eosinophilia and systemic symptoms (DRESS) syndrome: anticonvulsants, sulfonamides, dapsone, minocycline, allopurinol
- Acute generalized exanthematous pustulosis (AGEP): penicillins, cephalosporins, macrolides, calcium channel blockers, antimalarials, carbamazepine, acetylsalicylic acid, radiocontrast media
- Sweet syndrome (acute febrile neutrophilic dermatosis): sulfa drugs, granulocyte colony-stimulating factor (G-CSF), granulocyte-macrophage colony-stimulating factor (GM-CSF), diazepam, minocycline, nitrofurantoin, captopril, penicillamine
- Serum sickness-like reaction: cephalosporins, penicillins, TMP/SMX, propranolol, bupropion, minocycline
- Morbilliform/urticarial/exfoliative erythroderma: numerous medications, including penicillins, cephalosporins, sulfonamides, tetracyclines, ibuprofen, naproxen, allopurinol, acetylsalicylic acid, radiocontrast media

**Genetics**

Genetics may play a role, as certain HLA antigens have been associated with increased predisposition to specific drug eruptions:

- HLA-B*5801, HLA-B*5701, and HLA-B*1502 have been linked to
allopurinol-induced and carbamazepine-induced SJS/TEN, respectively.

- HLA class I antigens, such as HLA-A2, HLA-B12, and HLA-B22, have been linked to TEN and fixed drug eruptions, respectively.

**RISK FACTORS**

Previous drug reaction, multiple medications, concurrent infections, immunocompromised, disorders of metabolism, and certain genetic HLA haplotypes

**GENERAL PREVENTION**

Always ask patients about prior adverse drug events. Be aware of medications with higher incidence of reactions as well as drug cross-reactions.

**DIAGNOSIS**

**HISTORY**

- New medications within the preceding 6 weeks, most commonly within preceding 2 weeks: all oral, parenteral, and topical agents, including over-the-counter drugs, vitamins, and herbal remedies
- Consider other etiologies: unrelated acute or chronic urticaria, bacterial infections, viral exanthems, or underlying skin disease including cutaneous lymphoma.

**PHYSICAL EXAM**

May present as a number of different eruption types, including, but not limited to the following:

- Morbilliform eruptions (exanthems)
  - Most frequent cutaneous reaction (75–95%); difficult to distinguish from viral exanthem; often secondary to an antibiotic
  - Starts on trunk as pruritic red macules and papules, then extends to extremities in confluent fashion, sparing face, palms, soles, and mucous membranes
  - Onset 7 to 21 days after drug initiation (2)

- Urticaria
  - Pruritic erythematous wheals distributed anywhere on the body, including mucous membranes; may progress to angioedema, appears as nonpitting edema without erythema or margins
– Individual lesions fade within 24 hours, but new lesions may develop (2).

- Acneiform eruptions
  - Folliculocentric, monomorphous pustules typically involving the face, chest, and back distinguished from acne vulgaris by absence of gross and/or microscopic comedones
  - Often may become secondarily infected (2)

- Fixed drug eruptions
  - Single/multiple, round, sharply demarcated, violaceous plaques with gray center that may leave postinflammatory hyperpigmentation; occur on skin or on mucous membrane
  - Appear shortly after drug exposure and recur in identical location after reexposure; some patients have a refractory period during which the drug fails to activate lesions.
  - Onset usually is 48 hours after ingestion of drug (2).

- AGEP
  - Multiple nonfollicular sterile pustules on erythematous background with desquamation after 7 to 10 days
  - Involves intertriginous areas but can be generalized and involve the face
  - Appears similar to pustular psoriasis, but AGEP often causes fever and marked leukocytosis with neutrophilia and/or eosinophilia (2)[C].

- DRESS syndrome
  - Classic triad of fever, exanthem, and internal organ involvement with possible pharyngitis and lymphadenopathy
  - Can lead to exfoliative dermatitis, often accompanied by facial edema
  - Internal organ involvement: 80% hepatic, 40% renal, 33% pulmonary, and cardiac lab tests show elevated liver transaminases and eosinophilia
  - Onset 2 to 8 weeks after drug exposure; may develop 3 months or later into therapy (3)[B]

- Erythema multiforme
  - Relatively common, acute, often recurrent
  - Most commonly associated with herpes simplex virus (HSV) and other viral/bacterial etiologies (i.e., mycoplasma); less likely secondary to drug exposure; 50% with unknown etiology
  - Three-zone target lesions and raised atypical two-zone targets with localized erythema
  - Lesions predominant on distal extremities including on acral surface with limited mucosal involvement; <10% epidermal detachment (4)[B]

- SJS/TEN
  - Classification and distinction between SJS and TEN determined by affected
body surface area (BSA)
- SJS: <10% BSA; SJS-TEN overlap: 10–30% BSA; TEN: >30% BSA
  - Unlike erythema multiforme, strong association with preceding drug exposure as opposed to infection except in children where infection is more common (e.g., mycoplasma)
  - Onset is 1 to 3 weeks after starting offending agent: flat atypical two-zone target lesions and erythematous macules that are truncal and generalized with mucosal involvement
  - May develop confluent areas of bullae, erosions, and necrosis; significant risk for infection and sepsis
  - SJS: 5–15% mortality; TEN: 30% mortality (5,6)
- Lichenoid eruptions
  - Flat-topped, violaceous, pruritic papules on extensor surfaces and involving oral mucosa
  - Reticular pattern: Lesions heal with hyperpigmentation.
  - Chronic lesions persist for weeks/months after the drug discontinued (2).
- Photosensitivity reaction
  - Phototoxic reactions: occur within 24 hours of light exposure with exaggerated sunburn reaction; usually confined to sun-exposed areas
  - Photoallergic reactions: caused by UVA exposure; more pruritic than painful; can involve non–sun-exposed areas
- Hypersensitivity vasculitis
  - Petechiae/palpable purpura and/or maculopapular rash concentrated on lower extremities and dependent areas
  - Biopsy shows neutrophils around an arteriole or venule.
  - Possible renal, joint, and CNS involvement with fever, myalgias, arthritis, and abdominal pain (2)
- Sweet syndrome
  - Fever, neutrophilia, tender edematous violaceous papules, plaques, or nodules, with or without pustules/vesicles that spontaneously resolve
  - May have oral ulcers or ocular manifestations, such as conjunctivitis
  - Classically seen in young women after a mild respiratory illness or GI infection, but 7–56% associated with malignancy and pregnancy
- Serum sickness–like reaction
  - Fever, nonspecific cutaneous eruption with possible bullous lesions, arthralgias
  - Onset 7 to 14 days
- Exfoliative dermatitis/erythroderma
  - Generalized erythema with exfoliation and/or fine desquamation >90% of
– Difficult to distinguish between drug, primary cutaneous lymphoma, or inflammatory etiology
– Lymphadenopathy, hepatosplenomegaly, leukocytosis, eosinophilia, or anemia may be present.
– Increased risk of secondary infection and insensible fluid and temperature loss with hemodynamic instability

**DIFFERENTIAL DIAGNOSIS**
- Viral exanthem: Presence of fever, lymphocytosis, and other systemic findings may help in narrowing differential.
- Primary dermatosis: Correlation of drug withdrawal to rash resolution may clarify diagnosis; skin biopsy is helpful.
- Bacterial infection: Cultures of pustules may distinguish primary infection from AGEP and acneiform eruptions.

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
A minimum number of tests are useful in evaluating for internal organ involvement. CBC with differential; significant eosinophilia may be seen in DRESS and other drug-induced allergic reactions. LFT, urinalysis, and serum creatinine; chest x-ray if suspected vasculitis

**Diagnostic Procedures/Other**
- Special tests depend on suspected mechanism:
  - Type I: skin/intradermal testing, radioallergosorbent test (RAST)
  - Type II: direct/indirect Coombs test
  - Type III: ESR, C-reactive protein, ANA, antihistone antibody, tissue biopsy for immunofluorescence studies
  - Type IV: patch testing, lymphocyte proliferation assay (investigational)
  - Anaphylaxis/nonimmunologic mast and basophil cell reaction: serum tryptase levels
- Cultures useful in excluding infectious etiology; skin biopsy is nonspecific but useful in characterizing an eruption and excluding primary skin pathologies.
- Develop a timeline documenting the onset and duration of all drugs, dosages, and onset of cutaneous eruption (1)[A].

*Test Interpretation*
- Nonspecific histologic findings are superficial epidermal and dermal infiltrates composed variably of lymphocytes, neutrophils, and eosinophils.
- SJS/TEN: partial or full-thickness necrosis of the epidermis necrotic keratinocytes, vacuolization leading to subepidermal blister at basal membrane zone

### TREATMENT

#### GENERAL MEASURES

- Do not rechallenge with drugs causing urticaria, bullae, angioedema, DRESS, anaphylaxis, or erythema multiforme.

#### MEDICATION

- Immediate withdrawal of offending drug. Depending on the type of eruption, symptomatic treatment may be useful, but most require no additional therapy except cessation of offending agent.
- Anaphylaxis or widespread urticaria: epinephrine 0.1 to 0.5 mg (1:1,000 [1 mg/mL] solution) IM in the mid-outer thigh every 5 to 15 min; prednisone may be given to prevent recurrence.
- Acute urticaria (<6 weeks) and chronic urticaria (>6 weeks): 2nd-generation antihistamines (preferred, less sedating): cetirizine 10 to 20 mg daily, loratadine 10 to 20 mg daily, fexofenadine 180 mg daily, levocetirizine 5 to 10 mg daily. 1st-generation antihistamines: diphenhydramine 10 to 25 mg QHS, hydroxyzine 10 to 25 mg TID, doxepin 10 to 50 mg QHS H₂ antagonists: cimetidine 400 mg BID, ranitidine 150 mg BID
- Anaphylaxis, severe urticaria: prednisone PO 1 mg/kg in tapering doses
- Erythema multiforme
  - Treatment is generally supportive with management of suspected underlying infection.
  - HSV-associated: prophylaxis with acyclovir 400 mg BID, valacyclovir 500 to 1,000 mg/day, or famciclovir 250 mg BID
- “Magic mouthwash” BID or TID is helpful for mucosal erosions. Consider ophthalmology consult for severe ocular involvement (4)[B].
- SJS/TEN: Treatment is supportive. Consult with a dermatologist and
ophthalmologist. Systemic corticosteroid use remains controversial. Consider IVIG 2 to 3 g/kg for severe disease. In pediatric TEN patients, low-dose IVIG (0.05 to 0.10 g/kg/day) was effective; varied success rates reported with use of antitumor necrosis factor-\( \alpha \) agents, cyclosporine, cyclophosphamide, and plasmapheresis (5)[C],(6)[A]

- DRESS: prompt removal of offending drug and supportive measures; high-potency topical steroids for rash; systemic steroids with severe organ involvement; prednisone 0.5 to 2.0 mg/kg/day with prolonged taper 8 to 12 weeks (3)[B]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

**Patient Monitoring**

- For urticarial, bullous, DRESS, or erythema multiforme spectrum lesions, close follow-up is needed.
- Patients with anaphylaxis/angioedema should be given EpiPens to be kept at home, work, and in the car for secondary prevention and a Med-Alert bracelet; label the patient’s medical record with the agent and reaction.
- If the patient needs to take the inciting drug (e.g., antibiotic) in the future, induction of drug tolerance or graded challenge procedures may be necessary.

PROGNOSIS

- Eruptions generally begin fading within days after removing offending agent. With morbilliform eruptions, eruption may spread distally even when agent is removed, resolving over time.
- Anaphylaxis, angioedema, DRESS, SJS/TEN, and bullous reactions are potentially fatal.

COMPLICATIONS

Anaphylaxis, bone marrow suppression, hepatitis (dapsone, hydantoin), renal failure, and pulmonary and thyroid toxicity

REFERENCES

1. Joint Task Force on Practice Parameters, American Academy of Allergy, Asthma and Immunology, American College of Allergy, Asthma and

**CODES**

**ICD10**
- L27.1 Loc skin eruption due to drugs and meds taken internally
- L50.0 Allergic urticaria
- R21 Rash and other nonspecific skin eruption

**CLINICAL PEARLS**
- Virtually, any drug can cause a rash; antibiotics are the most common culprits that cause cutaneous drug reactions.
- Focus on drug history with new suspicious skin eruptions.
- Usually self-limited after withdrawal of offending agent
- Symptoms such as tongue swelling/angioedema, skin necrosis, blisters, high fever, dyspnea, and mucous membrane erosions signify more severe drug reactions.

CYSTIC FIBROSIS
Fozia Akhtar Ali, MD • Reethu K. Nayak, MD • Deepika Ram, MD

BASICS
DESCRIPTION
- Cystic fibrosis (CF) is an autosomal recessive genetic mutation (CFTR gene) that most prominently affects the pulmonary and pancreatic systems.
- The GI, endocrine, and reproductive systems as well as the liver, sinuses, and skin can all be involved.
- Initially a pediatric disease, CF has become a chronic pediatric and adult medical condition as improvements in medical care have led to a dramatic increase in long-term survival resulting in adults living with the disease outnumbering children in 2014 (1)[A].

EPIDEMIOLOGY
CF is the most common lethal inherited disease in Caucasians and is found in every racial group.

Incidence
Number of infants born with CF in relation to the total number of live births in the United States
- 1 in 3,000 Caucasians
- 1 in 4,000 to 10,000 Latin Americans
- 1 in 15,000 to 20,000 African Americans
- 1 in 30,000 Asian Americans

Prevalence
30,000 patients with CF living in the United States

ETIOLOGY AND PATHOPHYSIOLOGY
- Primary defect is abnormal function of an epithelial chloride channel protein encoded by the CFTR gene on chromosome band 7q31.2. Abnormal CFTR function leads to abnormally viscous secretions that alter organ function.
• The lungs: Obstruction, infection, and inflammation negatively affect lung growth, structure, and function.
  – Decreased mucociliary clearance
  – Infection is accompanied by an intense neutrophilic response.
  – Degradation of supporting tissues causes bronchiectasis and eventual failure.

**Genetics**

*CFTR* gene (CF transmembrane conductance regulator). >1,500 mutations exist that can cause varying severity of phenotypic CF, all of which are recessively inherited. Most common is loss of the phenylalanine residue at 508th position (deltaF508), which accounts for 8.7% of affected alleles in the CF population in the United States. *G551D* mutation accounts for 4.3% of affected alleles.

**RISK FACTORS**

• CF is a single-gene disorder. The severity of the phenotype can be affected by the specific CFTR mutation (most predictive of pancreatic disease), other modifier genes (CFTM1 for meconium ileus), gastroesophageal reflux disease (GERD), severe respiratory virus infection, and environmental factors such as tobacco smoke exposure.
• Preconception counseling
  – American Congress of Obstetricians and Gynecologists (ACOG) recommends preconception or early (1st/2nd trimester) genetic analysis for all North American couples planning a pregnancy, with appropriate counseling to identified carriers and genetic analysis of siblings of known CF patients.
  – Universal newborn screening (NBS) has been integral in early diagnosis (64% of new CF diagnosis in 2014 were found by NBS). Patients diagnosed prior to onset of symptoms have better lung function and nutritional outcomes and should receive referral and early intervention services by an accredited regional CF center.

**Pregnancy Considerations**

• Pulmonary disease may worsen during pregnancy.
• CF may cause increased incidence of preterm delivery, IUGR, and cesarean section ([2][A]).
• Advances in fertility treatments now allow men with CF to father children ([1][A]).
DIAGNOSIS

HISTORY

- Suspect with failure to thrive, steatorrhea, and recurrent respiratory problems.
  - Chronic/recurrent respiratory symptoms, including airway obstruction and infections
  - Persistent infiltrates on chest x-rays (CXR)
  - Hypochloremic metabolic acidosis
- Hx during neonatal period
  - Meconium ileus (20%) (generally considered pathognomonic for CF)
  - Prolonged jaundice
- Hx during infancy
  - Failure to thrive
  - Chronic diarrhea
  - Anasarca/hypoproteinemia
  - Pseudotumor cerebri (vitamin A deficiency)
  - Hemolytic anemia (vitamin E deficiency)
- Hx during childhood
  - Recurrent endobronchial infection
  - Bronchiectasis
  - Chronic pansinusitis
  - Steatorrhea
  - Poor growth
  - Distal intestinal obstruction syndrome (DIOS)
  - Allergic bronchopulmonary aspergillosis (ABPA)
- Hx for adolescence and adulthood (7% diagnosed >18 years old) (3)[A]
  - Recurrent endobronchial infection
  - Bronchiectasis
  - ABPA
  - Chronic sinusitis
  - Hemoptysis
  - Pancreatitis
  - Portal hypertension
  - Azoospermia
  - Delayed puberty

PHYSICAL EXAM

- Respiratory
– Rhonchi and/or crackles
– Hyperresonance on percussion
– Nasal polyps
• GI: hepatosplenomegaly when cirrhosis present
• Other: digital clubbing, growth retardation, and pubertal delay

COMMONLY ASSOCIATED CONDITIONS
• CF-related diabetes (CFRD)
  – May present as steady decline in weight, lung function, or increased frequency of exacerbation
  – Leading comorbid complication (20.7%)
  – Result of progressive insulin deficiency
  – Early screening and treatment may improve reduced survival found in CFRD.
• Upper respiratory
  – Rhinosinusitis is seen in up to 100% of patients with CF.
  – Nasal polyps are seen in up to 86% of patients.
• The GI tract
  – Pancreatic exocrine insufficiency (85–90%)
  – Malabsorption of fat, protein, and fat-soluble vitamins (A, D, E, and K)
  – Hepatobiliary disease (12.6%)
  – Focal biliary cirrhosis
  – Cholelithiasis
  – Meconium ileus at birth (10–15%)
  – DIOS: intestinal blockage that typically occurs in older children and adults (5.3%) (1)[A]
  – GERD (32.7%) (1)[A]
• Endocrine
  – Bone mineral disease (16.6%) (1)[A]
  – Joint disease (3.0%) (1)[A]
  – Hypogonadism
  – Frequent low testosterone levels in men
  – Menstrual irregularities are common.
• Reproductive organs
  – Congenital bilateral absence of the vas deferens: obstructive azoospermia in 98% of males
• Depression (12.8%) (1)[A]
DIFFERENTIAL DIAGNOSIS

- Immunologic
  - Severe combined immunodeficiency
- Pulmonary
  - Difficult-to-manage asthma
  - COPD
  - Recurrent pneumonia
  - Chronic/recurrent sinusitis
  - Primary ciliary dyskinesia
- Gastrointestinal
  - Celiac disease
  - Protein-losing enteropathy
  - Pancreatitis of unknown etiology
  - Shwachman-Diamond syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- NBS tests blood levels of immunoreactive trypsin (IRT) (1)[A].
- Patients must have clinical symptoms of CF involving at least one organ system.
- Sweat test (gold standard)
  - Sweat chloride
    - >60 mmol/L (on 2 occasions) is (+) for CF.
    - <40 mmol/L is normal.
  - CFTR mutation analysis
  - Limited panel testing: Allele-specific polymerase chain reaction (PCR) identifies >90% of mutations; finite chance of false-negative finding. Full-sequence testing is more costly and time-consuming.
  - Nasal potential difference (when sweat test and DNA testing inconclusive)
  - CXR

Follow-Up Tests & Special Considerations

To further investigate the presence of CF-related complications, these tests are generally ordered:

- Sputum culture (common CF organisms)
- Pulmonary function tests (PFTs)
- 72-hour fecal fat, stool elastase
Oral glucose tolerance test (OGTT) annually after age 10 years

Head CT: Abnormal sinus CT findings are nearly universal in CF and may include mucosal thickening, intraluminal sinus polyps, and sinus effusions.

Chest CT (not routine): useful when unusual findings noted on CXR

**Diagnostic Procedures/Other**
- Flexible bronchoscopy
- Bronchoalveolar lavage

**TREATMENT**

**GENERAL MEASURES**
- CF Foundation Guidelines call for yearly evaluation:
  - Four office visits, four respiratory cultures, PFTs q6mo, and at least 1 evaluation by a multidisciplinary team including dietitian, GI, and social worker
  - PFT goals: >75% predicted for adults, >100% predicted for children <18 years old
  - Annual screening for ABPA for patients >6 years with total serum IgE concentration
  - Annual influenza vaccination for all CF patients age >6 months
  - Screen all adults for osteoporosis with a DXA scan.
  - Annual measurement of fat soluble vitamins to r/o vitamin deficiencies
  - Annual LFTs
  - Decrease exposure to tobacco smoke.
- All patients should be followed in a CF center (accredited sites are listed at www.cff.org).
- Infant care:
  - Monthly visits for first 6 months of life and then every 2 months until 1 year of life
  - Fecal elastase testing and salt supplementation after diagnosis
  - Consider palivizumab for RSV prophylaxis in infants with CF <2 years (4) [A].

**MEDICATION**
- Pathogens for pulmonary infections: methicillin-resistant *Staphylococcus aureus* (MRSA) and methicillin-sensitive *S. aureus* (MSSA),
Stenotrophomonas maltophilia, Pseudomonas aeruginosa, Burkholderia cepacia, nontuberculous mycobacteria (NTM)

- Antibiotics for acute pulmonary infections should be prescribed according to most likely pathogen; most antibiotic courses are for 2 weeks.

- **Pulmonary infections:**
  - Antibiotics, oral
    - *S. aureus*: Bactrim (MRSA), doxycycline (MRSA) or cephalaxin
    - *P. aeruginosa*: fluoroquinolones
  - Antibiotics, inhaled
    - Tobi (tobramycin): for *P. aeruginosa*, nebulizer twice daily for 28 days; stop for 28 days, and then resume use (5)[A].
    - Colistin (more commonly used in Europe)
    - Cayston (aerosolized aztreonam) (5)[A]
  - Antibiotics, IV
    - *S. aureus*: cefazolin or nafcillin
    - MRSA: vancomycin or linezolid
    - *P. aeruginosa*: Zosyn or ceftazidime plus aminoglycoside (tobramycin)
    - Dual therapy synergistic (5)[A]

- **Medications recommended for chronic use in pulmonary disease:**
  - Recombinant human DNAse (Dornase alfa) (5)[A]
  - Hypertonic saline
  - High-dose ibuprofen in patients 6 to 17 years old with FEV₁ ≥60 PPV
  - Inhaled tobramycin or aztreonam in *P. aeruginosa*–positive patients
  - Azithromycin in *P. aeruginosa*–positive patients
  - Ivacaftor (VX770) and lumacaftor: CFTR potentiators approved in 2015 for patients with two copies of the F508del mutation. This vastly increases the number of people with CF eligible for this therapy (>50%) (1)[A].

- Inhaled steroids are not recommended for chronic use in the absence of asthma or ABPA.
- Insufficient evidence to recommend for or against chronic use: inhaled β-agonist, inhaled anticholinergics, leukotriene modifiers, inhaled colistin
  - Pancreatic enzymes (87.3%) (1)[A]
    - Often combined with H₂ blocker or PPI to increase effectiveness
  - Fat-soluble vitamin supplementation (A, D, E, and K)
  - Liver disease (cholestasis)
    - Ursodeoxycholic acid has not been proven effective.

**ADDITIONAL THERAPIES**
High-frequency chest wall oscillation vest is the most widely used airway clearance technique.
Aerobic exercise is used as an adjunct therapy for airway clearance.
  - CF-related bone disease: Consider bisphosphonate therapy.

**SURGERY/OTHER PROCEDURES**

- Timing for lung transplantation (bilateral) is polyfactorial [6][A].
- 5-year posttransplant survival is up to 62%.
- Liver transplantation is reserved for progressive liver failure ± portal hypertension with GI bleeding.
- Nasal polypectomy in 4.5% of CF patients [1][A]

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Pulmonary exacerbation (most common reason for admission)
- Bowel obstruction (due to DIOS, previously known as meconium ileus equivalent [MIE])
- Pancreatitis (in pancreatic-sufficient patients)
- CF exacerbations should always be admitted on contact precautions and private rooms.
- Nasal cannula oxygen when the patient is hypoxemic (SaO$_2$ <90%)
- Increased salt loss increases risk of hyponatremic hyp choloremic dehydration.
- Cautious use of IV fluids with worsening lung disease
- Nursing assignments should involve only 1 CF patient per nurse for isolation purposes.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Upon discharge for a pulmonary exacerbation, follow-up with CF provider within 2 to 4 weeks.
- Routine clinic visits every 3 months, with airway cultures and pulmonary function testing
- Annual comprehensive nutritional evaluation [4][A]

**DIET**
High-calorie, high-fat diet titrated to specific BMI goals established by the CF Foundation nutrition guidelines. If not meeting nutritional goals, dietitian, pancreatic enzyme, oral or tube supplemental feeding should be considered if indicated.

PATIENT EDUCATION
Cystic Fibrosis Foundation: www.cff.org

PROGNOSIS
- Median survival is 39.3 years.
- Progression of lung disease usually determines length of survival.

REFERENCES

ADDITIONAL READING
- Mall MA, Boucher RC. Pathophysiology of cystic fibrosis lung disease. In:

**CODES**

**ICD10**
- E84.9 Cystic fibrosis, unspecified
- E84.11 Meconium ileus in cystic fibrosis
- E84.0 Cystic fibrosis with pulmonary manifestations

**CLINICAL PEARLS**
- Meconium ileus is virtually pathognomonic for CF.
- When sweat test is equivocal, CFTR genetic testing is diagnostic.
- CF must be considered in *any* child with chronic diarrhea, especially if associated with poor growth or failure to thrive.
- All children with nasal polyps, digital clubbing, or bronchiectasis should be evaluated.
- A rapid decline in pulmonary function suggests the acquisition of resistant organisms (e.g., *B. cepacia*), CFRD, ABPA, or GERD.
DE QUERVAIN TENOSYNOVITIS
Caitlin G. Waters, MD • J. Herbert Stevenson, MD

BASICS

DESCRIPTION
- First identified in 1895 by Fritz De Quervain, de Quervain tenosynovitis is a painful condition due to stenosis of the tendon sheath in the 1st dorsal compartment of the radial aspect of the wrist.
- Caused by repetitive motion of the extensor pollicis brevis (EPB) and abductor pollicis longus (APL) over the radial styloid with resultant irritation of the surrounding tendon sheath

EPIDEMIOLOGY
- The predominant age range is 30 to 50 years.
- Women are affected more commonly than men (1).
- With new occupational and professional demands, the prevalence of this condition is increasing gradually.

Incidence
- The overall incidence of de Quervain tenosynovitis is 0.9/1,000 person-years.
- For patients age >40 years, the incidence is 1.4/1,000 person-years compared with 0.6/1,000 person-years for those <20 years.
- Women have an incidence rate ratio of 2.8/1,000 person-years compared with 0.6/1,000 person-years in men.
- The incidence ratio rate of de Quervain tenosynovitis is 1.3/1,000 person-years in blacks and 0.8/1,000 person-years in whites (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- Repetitive motions of the wrist and/or thumb result in microtrauma and thickening of the tendons (EPB, APL) and surrounding tendon sheath.
- EPB and APL movement is resisted as they glide over the radial styloid causing pain with movements of the thumb and wrist.

RISK FACTORS
- Women age 30 to 50 years
- Pregnancy (primarily 3rd trimester and postpartum)
- African American
- Systemic diseases (e.g., rheumatoid arthritis)
- Participation in activities that include repetitive motion or forceful grasping with thumb and wrist deviation such as golf, fly fishing, racquet sports, rowing, or bicycling, video gaming, and more recently text messaging
- Repetitive movements with the hand/thumb requiring forceful grasping with wrist involving ulnar/radial deviation; dental hygienists, musicians, carpenters, assembly workers, and machine operators

**GENERAL PREVENTION**
Avoid overuse or repetitive movements of the wrist and/or thumb associated with forceful grasping and ulnar/radial deviation.

**DIAGNOSIS**

**HISTORY**
- Repetitive motion activity; overuse of wrist or thumb
- Gradually worsening pain along the radial aspect of the thumb and wrist with certain movements, particularly ulnar deviation of the wrist
- Pregnancy
- Sports, leisure, and occupational history
- Trauma (rare)

**PHYSICAL EXAM**
- Pain over the radial styloid exacerbated when patients move the thumb or make a fist
- Crepitus with movement of the thumb
- Swelling over the radial styloid and base of the thumb
- Decreased range of motion of the thumb
- Pain over the 1st dorsal compartment on resisted thumb abduction or extension
- Tenderness may extend proximally or distally along the tendons with palpation or stress.
- Finkelstein test: The examiner grasps the affected thumb and deviates the hand sharply in the ulnar direction. A positive test occurs when there is pain along the distal radius.
Eickhoff test: Patient grasps a flexed thumb, and the examiner deviates the wrist in an ulnar direction.

Finkelstein test is more sensitive for determining tenosynovitis of the APL and EPB tendons (2)[A].

DIFFERENTIAL DIAGNOSIS

- Scaphoid fracture
- Scapholunate ligament tear
- Dorsal wrist ganglion
- Osteoarthritis of the 1st carpometacarpal (CMC) joint
- Flexor carpi radialis tendonitis
- Infectious tenosynovitis
- Tendonitis of the wrist extensors
- Intersection syndrome
- Trigger thumb

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Primarily a clinical diagnosis
- Radiographs of the wrist to rule out other pathology, such as CMC arthritis, if the diagnosis is in question
- MRI is the imaging test of choice to rule out coexisting soft tissue injury or wrist joint pathology.

Follow-Up Tests & Special Considerations

Ultrasound can help to detect anatomic variations in the 1st dorsal extensor compartment of the wrist and target corticosteroid injections (3,4).

Test Interpretation

Inflamed and thickened retinacular sheath of the tendon

TREATMENT

- Most cases of de Quervain syndrome are self-limited.
- Rest and NSAIDs (2)[A]
- Ice (15 to 20 minutes 5 to 6 times a day)
- Immobilization with a thumb spica splint (2)[A]
- Occupational therapy
- Corticosteroid injection (ultrasound guided)
- Consider surgery if conservative measures fail >6 months.

**GENERAL MEASURES**
- If full relief is not achieved, a corticosteroid injection of the tendon sheath can improve symptoms.
- Anatomic variation, including two tendon sheaths in the 1st compartment or the EPB tendon traveling in a separate compartment may complicate treatment. Ultrasound can distinguish these variants and improve anatomic accuracy of injections (3).
- Surgical release may be indicated after 3 to 6 months of conservative treatment if symptoms persist. Surgery is highly effective and has a relatively low rate of complications.

**MEDICATION**

*First Line*
- Splinting, rest, and NSAIDs

*Second Line*
- Corticosteroid injection of the tendon sheath has shown significant cure rates. Additional injections are sometimes required.
  - Corticosteroid injection plus immobilization is more effective than immobilization alone (5)[B].
- Percutaneous tenotomy and/or injection of platelet-rich plasma are newer techniques that show promise for treatment of de Quervain tenosynovitis.

**ISSUES FOR REFERRAL**
Referral to a hand surgeon is indicated if there is no improvement with conservative therapy.

**ADDITIONAL THERAPIES**
- Hand therapy, along with iontophoresis/phonophoresis, may help improve outcomes in persistent cases.
- Patients may use thumb-stretching exercises as part of their rehabilitation.

**SURGERY/OTHER PROCEDURES**
- Indicated for patients who have failed conservative treatment
• Endoscopic release may provide earlier relief, fewer superficial radial nerve complications, and greater patient satisfaction with resultant scar compared to open release (5)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Hospitalization for care associated with surgical treatment

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
• Additional corticosteroid injection may be performed at 4 to 6 weeks if symptoms persist. Caution with repeat steroid injections.
• Avoid repetitive motions and activities that cause pain.

DIET
As tolerated

PATIENT EDUCATION
Activity modification: Avoid repetitive movement of the wrist/thumb and forceful grasping.

PROGNOSIS
• Extremely good with conservative treatment
• Complete resolution can take up to 1 year.
• 95% success rates have been shown with conservative therapy >1 year.
• Up to 1/3 of patients will have persistent symptoms.

COMPLICATIONS
• Most complications are secondary to treatment. These include GI, renal, and hepatic injury secondary to NSAID use.
• Nerve damage may occur during surgery.
• Hypopigmentation, fat atrophy, bleeding, infection, and tendon rupture have been reported as potential adverse events from corticosteroid injection. Ultrasound guidance reduces the rate of complications.
• If not appropriately treated, thumb flexibility may be lost due to fibrosis.
REFERENCES

ADDITIONAL READING

**SEE ALSO**
Algorithm: Pain in Upper Extremity

**CODES**

**ICD10**
M65.4 Radial styloid tenosynovitis [de Quervain]

**CLINICAL PEARLS**

- Repetitive movements of the wrist and thumb, and activities that require forceful grasping are the most common causes of de Quervain tenosynovitis.
- Initial treatment is typically conservative.
- Corticosteroid injections are helpful and have lower complication rates if done under ultrasound guidance.
- Combined orthosis/corticosteroid injection approaches are more effective than either intervention alone.
- Surgery is helpful for recalcitrant cases.
DEEP VEIN THROMBOPHLEBITIS

Jaine McKenzie, MD • Patricia Martinez Quinones, MD • Keith O’Malley, MD, FACS

Basics
Description
- Development of blood clot within the deep veins, usually accompanied by inflammation of the vessel wall
- Major clinical consequences are embolization (usually to the lung), recurrent thrombosis, and postphlebitic syndrome.

Epidemiology
- Age- and gender-adjusted incidence of venous thromboembolism (VTE) is 100 times higher in the hospital than in the community. Almost half of all VTEs occur either during or soon after discharge from a hospital stay or surgery.
- Of patients with VTE, 20% complicated with pulmonary embolism (PE). The 28-day deep venous thrombosis (DVT) fatality rate is 5.4%; at 1 year, 20%; at 3 years, 29%.

Incidence
- In the United States, VTE incidence is 50.4/100,000 person per year.
- Increased incidence in Caucasian and African American populations and with aging
- Most common site: lower extremity DVT
- Incidence in pregnancy: ~0.5 to 3/1,000 (1)
- 1–5% of central venous catheters are complicated by thrombosis (2).

Prevalence
- Variable; depends on medical condition or procedure
- At time of DVT diagnosis, as many as 40% of patients also have asymptomatic PE; conversely, 30% of patients diagnosed with PE do not have demonstrable source.
- Present in 11% of patients with acquired brain injury entering neurorehabilitation
ETIOLOGY AND PATHOPHYSIOLOGY
Factors involved may include venous stasis, endothelial injury, and abnormalities of coagulation (Virchow triad).

Genetics
- Factor V Leiden, the most common thrombophilia, is found in 5% of the population and in 10–65% of all VTE events and increases VTE risk 3- to 6-fold.
- Prothrombin G20210A is found in 3% of Caucasians; increases the risk of thrombosis ~3-fold

RISK FACTORS
- Acquired: previous DVT, age, cancer, immobilization, trauma, obesity, major surgery, orthopedic surgery, medications (oral contraceptives, estrogens), antiphospholipid syndrome, cerebrovascular accident, acute infectious process, thrombocytosis, pregnancy/puerperium, central venous catheters
- Inherited: deficiencies of protein C, protein S, or antithrombin III; factor V Leiden R506Q, prothrombin G20210A, dysfibrinogenemia
- Mixed/unknown: hyperhomocysteinemia, high levels of factor VIII, high levels of thrombin activatable fibrinolysis inhibitor (TAFI), high levels of factor XI

GENERAL PREVENTION
- Mechanical thromboprophylaxis is recommended in patients with high bleeding risk and as adjunct to pharmacologic thromboprophylaxis.
- For acutely ill and for critically ill hospitalized patients at increased risk of thrombosis, low-molecular-weight heparin (LMWH), low-dose unfractionated heparin, or fondaparinux are recommended (3)[C].
- For most patients, prolonged secondary prophylaxis is not recommended.

DIAGNOSIS
- Modified Wells criteria, a validated clinical prediction rule, is useful to determine pretest probability of having a DVT.
  - Active cancer (+1 point)
  - Calf swelling >3 cm compared to other leg (+1 point)
  - Collateral superficial veins (+1 point)
– Pitting edema to symptomatic leg (+1 point)
– Previous documented DVT (+1 point)
– Swelling of entire leg (+1 point)
– Localized tenderness along deep venous system (+1 point)
– Paralysis, paresis, or recent cast immobilization of lower extremities (+1 point)
– Recently bedridden >3 days or major surgery in past 4 weeks (+1 point)
– Alternative diagnosis at least as likely (−2 points)

- Interpretation: Score of 0, DVT unlikely. Score of 1 to 2, moderate risk. Score of ≥3, DVT likely. D-dimer testing and/or ultrasound should follow based on Wells criteria score.

**HISTORY**

- Higher clinical suspicion in patient with risk factors (See “Risk Factors” section.)
- Wells criteria are used to determine pretest probability.
- DVT is classified as provoked or idiopathic based on underlying risk factors.
- Clinical assessment of bleeding risk (bleeding with previous history of anticoagulation, history of liver disease, recent surgeries, history of GI bleed) is important prior to initiating treatment.

**PHYSICAL EXAM**

- Symptoms may present as pain, swelling, or discoloration but may be nonspecific or absent.
- Resistance to dorsiflexion of the foot (Homan sign) is unreliable and nonspecific.
- Edema, due to swelling of collateral veins, is the most specific symptom.
- Uncommonly, patients may have phlegmasia alba dolens (“milk leg”) or phlegmasia cerulean dolens due to arterial occlusion secondary to extensive DVTs.

**DIFFERENTIAL DIAGNOSIS**

Cellulitis, fracture, ruptured synovial cyst (Baker cyst), lymphedema, muscle strain/tear, extrinsic compression of vein (e.g., by tumor/enlarged lymph nodes), compartment syndrome, and localized allergic reaction

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
D-dimer (sensitive but not specific; has high negative predictive value [NPV]), indicated in patients with low pretest probability of DVT or PE but not indicated high pretest probability patients; false positives in liver disease, inflammation, malignancy, trauma, pregnancy, and recent surgery

Patients with a prior DVT and those with malignancy have higher rates of VTE, which decreases the NPV of Wells criteria.

CBC, platelet count, activated partial thromboplastin time (aPTT), prothrombin time (PT)/INR

Diagnostic imaging required in patients with high pretest probability (Wells criteria)

Compression ultrasound (CUS): first-line imaging for DVT due to noninvasive nature and ease of use; sensitive and specific for popliteal and femoral thrombi if experienced user; recommended in patients with moderate or high pretest probability

In patients with suspected DVT, the diagnosis process should be guided by the assessment of the pretest probability.
- Low pretest probability: high-sensitivity D-dimer assay sufficient to exclude DVT if negative. If positive, follow with CUS.
- Moderate to high pretest probability: CUS initial test; if positive, CUS then treat DVT. If negative, DVT is excluded but consider repeat CUS in 1 week.

Contrast venography: gold standard, technically difficult, requires pedal vein cannulation, risk of morbidity

Impedance plethysmography: sensitive and specific for proximal vein thrombosis

MR venography: as accurate as contrast venography; may be useful for patients with contraindications to IV contrast

$^{125}$I-fibrinogen scan: detects only active clot formation; very good at detecting ongoing popliteal thrombi; takes 4 hours for results

**Follow-Up Tests & Special Considerations**

In young patients and/or those of concern or with idiopathic/recurrent VTE, consider thrombophilia testing (factor V Leiden mutation, prothrombin G20210A genetic assay, ATIII functional assay, protein C functional assay, protein S antigen and functional assay and free S, phospholipid-dependent tests and anticardiolipin antibodies, lupus anticoagulant [drawn before heparin]).

Risk of an underlying malignancy is more likely if recurrent VTE, risk 3.2
(95% CI 2.0–4.8). Unprovoked VTE, 4.6 times higher (vs. secondary); upper extremity DVT, not catheter associated; odds ratio (OR) 1.8, abdominal DVT; OR 2.2 (4), bilateral lower extremity DVT, OR 2.1 (4)

TREATMENT

MEDICATION

Consider starting therapy even before confirmation in patients with high pretest probability.

- Anticoagulation is mainstay of therapy. Patients with PE or proximal DVT, long-term therapy (at least 3 months) is recommended. Duration of therapy after 3 months is case-by-case basis.
- Indefinite anticoagulation is considered if there is low risk of bleeding, if index event is unprovoked PE, and/or if D-dimer is positive 1 month after stopping anticoagulation (5).
- Direct oral anticoagulants (dabigatran, rivaroxaban, apixaban, or edoxaban) recommended instead of vitamin K antagonists for the first 3 months of treatment in patients with lower extremity DVT or PE and no cancer (4)[B]
- Use and choice of anticoagulation should be considered based on patient’s history, bleeding risk, cost, and ease of compliance.

First Line

- Unfractionated heparin
  - IV drip: initial dose of 80 U/kg followed by continuous infusion of 18 U/kg/hr. Target aPTT ratio >1.5 times control. Monitor aPTT every 6 hours and adjust infusion rate accordingly until two successive values are within therapeutic range.
- LMWH
  - Enoxaparin (Lovenox): 1 mg/kg/dose SC q12h or 1.5 mg/kg daily
  - Dalteparin (Fragmin): 200 U/kg SC q24h; off-label use for treatment of DVT/PE
- Direct and indirect factor Xa inhibitors
  - Fondaparinux (Arixtra): 5 mg (body weight <50 kg), 7.5 mg (body weight = 50 to 100 kg), or 10 mg (body weight >100 kg) SC once daily
  - Rivaroxaban (Xarelto): 15 mg PO twice daily with food for the first 3 weeks then 20 mg PO qday
  - Apixaban (Eliquis): 10 mg PO twice daily for 1 week followed by 2.5 to 5.0
mg PO twice daily
- Edoxaban (Savaysa): 60 mg PO daily (>60 kg), 30 mg PO daily (≤60 kg)

- Thrombin inhibitors
  - Dabigatran (Pradaxa): 150 mg PO twice daily for creatinine clearance >30 mL/min

- Vitamin K antagonists
  - Warfarin (Coumadin): Start with 2 to 5 mg/day. Adjust to a target INR of 2 to 3; overlap with parenteral anticoagulant for minimum of 5 days until therapeutic INR sustained ≥24 hours.

- Adverse effects
  - All anticoagulants increase risk of bleeding.
  - Heparin and LMWH can also cause heparin-induced thrombocytopenia (HIT) (LMWH has lower risk) and injection site irritation.
  - Warfarin is teratogenic.
  - Dosage adjustments may be required for patients with decreased creatinine clearance.

Second Line
Heparin can be given by intermittent SC self-injection.

Pregnancy Considerations
- Warfarin (Coumadin) is a teratogen. It is contraindicated in pregnancy but is safe during breastfeeding.

LMWH are recommended over unfractionated heparin for treatment of acute DVT and PE in pregnancy (1)[B].
- Enoxaparin, dalteparin, fondaparinux, and apixaban are pregnancy Category B.
- Dabigatran, rivaroxaban, edoxaban are pregnancy Category C.

SURGERY/OTHER PROCEDURES
- In selected patients with proximal DVT (acute iliofemoral DVT <14 days, good functional status, >1 year of life expectancy), may consider catheter-directed thrombolysis/open thrombectomy (6)
- Thrombolysis (systemic or catheter directed) reduces incidence of postthrombotic syndrome (PTS) after a proximal (iliofemoral or femoral) DVT by one-third.
- Thrombectomy is recommended in patients with limb-threatening ischemia due to iliofemoral venous outflow obstruction (6).
- IVC filter
  - Not routinely inserted in patients with acute DVT
  - May be considered in patients with DVT or PE with absolute contraindication to anticoagulation, or recurrent embolism despite adequate anticoagulation
  - Special considerations can be given to patients who are chronically immobile, such as spinal cord injury patients.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Admission for respiratory distress, proximal VTE, candidate for thrombolysis, active bleeding, renal failure, phlegmasia alba dolens, phlegmasia cerulea dolens, history of HIT
- Limb elevation and multilayered compression for symptomatic relief
- In medically stable and properly anticoagulated patients, overlap of anticoagulation and warfarin monitoring may be done as an outpatient.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Resumption of normal activity with avoidance of prolonged immobility
- Compression stockings not routinely recommended for prevention of PTS after acute DVT (4)[B] but can be used for patients who already present with symptoms of PTS

**Patient Monitoring**

-Monitor platelet count while on heparin, LMWH, and fondaparinux for HIT.
- An anti-Xa activity level may help guide LMWH titration of therapy.
- Serial D-dimer measurements can be used to identify patients in whom anticoagulation can be safely discontinued.
- Investigate significant bleeding (e.g., hematuria or GI hemorrhage) because anticoagulant therapy may unmask a preexisting lesion (e.g., cancer, peptic ulcer disease, or arteriovenous [AV] malformation).

**PATIENT EDUCATION**

Dietary habits should be discussed when warfarin is initiated to ensure that intake of vitamin K–rich foods is monitored.
PROGNOSIS

- 20% of untreated proximal (iliofemoral, femoral, or popliteal) lower extremity DVTs progress to PE, and 10–20% of those are fatal. However, with anticoagulant therapy, mortality is decreased 5- to 10-fold.
- DVT confined to the infrapopliteal veins has a small risk of embolization but can propagate proximally.
- Up to 75% of patients with symptomatic DVT present with PTS after 5 to 10 years.

COMPLICATIONS

PE (fatal in 10–20%), arterial embolism (paradoxical embolization) with AV shunting, chronic venous insufficiency, PTS, treatment-induced hemorrhage, soft tissue ischemia associated with massive clot and high venous pressures; phlegmasia cerulea dolens (rare but a surgical emergency)

ADDITIONAL READING

### SEE ALSO

Antithrombin Deficiency; Factor V Leiden; Protein C Deficiency; Protein S Deficiency; Prothrombin 20210 (Mutation); Pulmonary Embolism

### CODES

#### ICD10

- I80.209 Phlbts and thombophlb of unsp deep vessels of unsp low extrm
- I80.299 Phlebitis and thombophlb of deep vessels of unsp low extrm
- I80.10 Phlebitis and thrombophilebitis of unspecified femoral vein
CLINICAL PEARLS

- Many cases are asymptomatic.
- At time of DVT diagnosis, as many as 40% of patients also have asymptomatic PE.
- Wells criteria are useful to determine the pretest probability of a DVT, but follow-up testing and/or imaging should be done if moderate to high probability.
- Choice of anticoagulant therapy should be individualized based on patient’s history and compliance.
DEHYDRATION
Tu Dan (Kathy) Nguyen, MD

BASICS

DESCRIPTION
- A state of negative fluid balance; strictly defined as free water deficiency
- The two types of dehydration:
  - Water loss
  - Salt and water loss (combination of dehydration and hypovolemia)

EPIDEMIOLOGY
- Responsible for 10% of all pediatric hospitalizations in the United States
- Gastroenteritis, one of its leading causes, accounts to 13/1,000 children <5 years of age annually in the United States.

Incidence
- More than half a million hospital admissions annually in the United States for dehydration
- Of hospitalized older persons, 8% are dehydrated (1).
- Worldwide, ~3 to 5 billion cases of acute gastroenteritis occur each year in children <5 years of age, resulting in nearly 2 million deaths.

ETIOLOGY AND PATHOPHYSIOLOGY
- Negative fluid balance occurs when ongoing fluid losses exceed fluid intake.
- Fluid losses can be insensible (sweat, respiration), obligate (urine, stool), or abnormal (diarrhea, vomiting, osmotic diuresis in diabetic ketoacidosis).
- Negative fluid balance can lead to severe intravascular volume depletion (hypovolemia) and end-organ damage from inadequate perfusion.
- The elderly are at increased risk as kidney function, urine concentration, thirst sensation, aldosterone secretion, release of vasopressin, and renin activity are all significantly lowered with age.
- Decreased intake
- Increased output: vomiting, diarrheal illnesses, sweating, frequent urination
- “Third spacing” of fluids: effusions, ascites, capillary leaks from burns, or sepsis
Genetics
Some causes of dehydration have a genetic component (diabetes), whereas others do not (gastroenteritis).

RISK FACTORS
- Children <5 years of age at highest risk
- Elderly
- Decreased cognition
- Lack of access to water such as in critically sick intubated patients

GENERAL PREVENTION
- Patient/parent education on early signs of dehydration
- Universal precautions (including hand hygiene)

Geriatric Considerations
Systematically assessing risk factors helps with early prevention and management of dehydration in the elderly, especially those in long-term care facilities.

</table>

COMMONLY ASSOCIATED CONDITIONS
- Hypo-/hypernatremia
- Hypokalemia
Hypovolemic shock
Renal failure

DIAGNOSIS

Calculate percent dehydration = (preillness weight – illness weight)/preillness weight × 100. Supplement this along with the ongoing fluid loss.

HISTORY

- Fever
- Intake (including description and amount)
- Diarrhea (including duration, frequency, consistency, ± mucus/blood)
- Vomiting (including duration, frequency, consistency, ± bilious/nonbilious)
- Urination pattern
- Sick contacts
- Medication history (e.g., diuretics, laxatives)

PHYSICAL EXAM

- The most useful signs for identifying dehydration in children are prolonged capillary refill time, abnormal skin turgor, and abnormal respiratory pattern.
- Vitals: pulse, BP, temperature
- Orthostatic vital signs: Take BP and heart rate (HR) while supine, sitting, and standing.
  - Systolic BP decrease of 20 mm Hg, diastolic BP decrease by 10 mm Hg, or HR increase by 20 bpm suggests hypovolemia (2).
- Weight loss: <5%, 10%, or >15%
- Mental status
- Head: sunken anterior fontanelle (for infants)
- Eyes: sunken, ± tear production
- Mucous membranes: tacky, dry, or parched
- Capillary refill: ranges from brisk to >3 seconds
- Darker urine color

DIFFERENTIAL DIAGNOSIS

- Decreased intake: ineffective breastfeeding, inadequate thirst response, anorexia, malabsorption, metabolic disorder, obtunded state
- Excessive losses: gastroenteritis, diarrhea, febrile illness, diabetic ketoacidosis, hyperglycemia, hyperosmolar hyperglycemic state, diabetes
insipidus, intestinal obstruction, sepsis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- For mild dehydration: generally not necessary
- For moderate to severe dehydration
  - Electrolytes, BUN, creatinine, and glucose
  - Urinalysis (specific gravity, hematuria, glucosuria)
- Imaging does not play a role in the diagnosis of dehydration, unless the specific condition causing the dehydration requires imaging.
- In adults, inferior vena cava collapsibility is a surrogate marker for volume status.

Pediatric Considerations
Infants and the elderly may not concentrate urine maximally, making urine specific gravity less helpful.

TREATMENT

MEDICATION

First Line
- Oral rehydration is the first-line treatment in dehydrated children. If this is unsuccessful, use IV rehydration. If IV unobtainable, nasogastric (NG) or intraosseous (IO) rehydration can be considered (3).
- Oral rehydration is the first-line treatment in dehydrated adults as long as they can tolerate fluids. Have a lower threshold for IV rehydration if needed.
- If the patient is experiencing excessive vomiting, consider using an antiemetic.
- Ondansetron (PO/IV) may be effective in decreasing the rate of vomiting, improving the success rate of oral hydration, preventing the need for IV hydration, and preventing the need for hospital admission (4,5).
- Other antiemetics can be used.

Second Line
- Loperamide may reduce the duration of diarrhea compared with placebo in children with mild to moderate dehydration (two randomized controlled trials
[RCTs] yes, one RCT no).

- In children ages 3 to 12 years with mild diarrhea and minimal dehydration, loperamide decreases diarrhea duration and frequency when used with oral rehydration.

**Pediatric Considerations**

Given a higher risk for serious adverse events, loperamide is not indicated for children <3 years of age with acute diarrhea.

**ISSUES FOR REFERRAL**

- For severe dehydration, critical care referral and ICU-level care may be warranted.
- Surgical consultation for acute abdominal issues

**SURGERY/OTHER PROCEDURES**

For specific underlying causes of dehydration, such as intestinal obstruction or appendicitis

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Intractable vomiting/diarrhea
- Electrolyte abnormalities
- Hemodynamic instability
- Inability to tolerate oral rehydration therapy (ORT)
- Stabilize airway, breathing, circulation.
- If mild dehydration, try ORT.
- If excessive vomiting/severe dehydration with shock, start IV access and IV fluids immediately.
- IV fluids
  - Stage I
    - For moderate to severe dehydration in children: isotonic saline or Ringer lactate solution bolus of 10 to 20 mL/kg; may repeat up to 60 mL/kg; if still hemodynamically unstable, consider colloid replacement (blood, albumin, fresh frozen plasma) and address other causes for shock.
    - For moderate to severe hypovolemia in adults: isotonic saline or Ringer lactate 20 mL/kg/hr until normal state of consciousness returns/vital signs stabilize. Also consider colloid replacement if continued fluids required beyond 3 L.
– Stage II: Replace fluid deficit along with maintenance over 48 hours; fluid deficit = preillness weight – illness weight
– An alternative IV treatment option for moderate (10%) dehydration in children
  o Bolus with NS/LR at 20 mL/kg for 1 hour
  o Replete fluid deficit with D5 1/2 NS + 20 mEq KCl/L at 10 mL/kg for 8 hours (hours 2 to 9).
  o Replete 1.5 for maintenance fluids with D5 1/4 NS + 20 mEq/L of KCl for 16 hours (hours 10 to 24).
– An alternative to IV fluids is hypodermoclysis, the SC infusion of fluids into the body (adults).
  o Indications: hydration of patients with mild to moderate dehydration who do not tolerate oral intake because of cognitive impairment, severe dysphagia, advanced terminal illness, or intractable vomiting. It is also indicated to prevent dehydration, especially in frail elderly residents living in long-term care settings who reject the oral route for any reason; useful technique for patients with difficult IV access
  o Contraindications: severe dehydration or shock, patients with coagulopathy or receiving full anticoagulation, patients with severe generalized edema (anasarca) or congestive heart failure, and those with fluid overload (6)
  
  • Strict inputs and outputs: oral and IV input and output of urine and stool, which may include weighing wet diapers
  • Discharge criteria
    – Input > output
    – Underlying etiology treated and improving

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Activity as tolerated
  • If mild to moderate dehydration, the patient may be mobile without restrictions, although watch for orthostasis/falls.
  • If moderate to severe dehydration, bed rest

Patient Monitoring
Ongoing surveillance for recurrence
DIET
- Bland food: bananas, rice, applesauce, toast (BRAT) diet
- If diarrhea, lactose-free feeds may reduce the duration of diarrhea in children with mild to severe dehydration, compared with lactose-containing feeds.
- Small frequent sips of room temperature liquids
- Oral rehydration solutions are available commercially.
- Continue breastfeeding ad lib.

PATIENT EDUCATION
- Patients should seek medical care if they (or their child) feel faint or dizzy when rising from a sitting or lying position, becomes lethargic and/or confused, or complains of a rapid HR.
- Patients should call their physician if they are unable to keep down any fluids, vomiting has been going on >24 hours in an adult or >12 hours in a child, diarrhea has lasted >2 days in an adult/child, or an infant/child is much less active than usual or is very irritable.
- [http://www.mayoclinic.org/diseases-conditions/dehydration/basics/definition/con-20030056](http://www.mayoclinic.org/diseases-conditions/dehydration/basics/definition/con-20030056)

PROGNOSIS
Self-limited if treated early; potentially fatal if untreated and persistent

COMPlications
- Seizures
- Renal failure
- Cardiovascular arrest

REFERENCES

**SEE ALSO**

Oral Rehydration

**CODES**

**ICD10**

- E86.0 Dehydration
- E87.1 Hypo-osmolality and hyponatremia
- E86.1 Hypovolemia

**CLINICAL PEARLS**

- Dehydration is the result of a negative fluid balance and is a common cause of hospitalization in both children and the elderly.
- Begin by assessing the level of dehydration, determining the underlying cause, and calculating necessary replacement.
- Treatment is directed at restoring fluid balance via oral rehydration (first-line) therapy or IV fluids and treating underlying causes.
DELIRIUM

Whitney A. Gray, CRNP, MSN • Katrina A. Booth, MD

BASICS

DESCRIPTION

- A temporary neurologic complication of illness and/or medication(s), especially common in older patients, manifested by new confusion and impaired attention
- A medical emergency requiring immediate evaluation to decrease morbidity and mortality
- System(s) affected: neurologic
- Synonym(s): acute confusional state, altered mental status, organic brain syndrome, acute mental status change, encephalopathy

EPIDEMIOLOGY

- Predominant age: older persons
- Predominant sex: male = female

Incidence

- >50% in older ICU patients
- 11–51% in postoperative patients
- 10–40% in hospitalized older patients

Prevalence

- 8–17% in older ED patients
- 14% in older postacute care patients

ETIOLOGY AND PATHOPHYSIOLOGY

- Multifactorial: believed to result from a decline in physiologic reserves with aging, resulting in a vulnerability to new stressors
- Neuropathophysiology is not clearly defined; cholinergic deficiency, dopamine excess, and neuroinflammation are leading hypotheses.
- Often interaction between predisposing and precipitating risk factors
- With more predisposing factors (i.e., frail patients), fewer precipitating factors needed to cause delirium.
- If few predisposing factors (e.g., very robust patients), more precipitating factors needed to cause delirium.
- Multicomponent approach addressing contributing factors can reduce incidence and complications.

**RISK FACTORS**
- Predisposing risk factors
  - Advanced age, >70 years
  - Preexisting cognitive impairment
  - Functional impairment
  - Dehydration; high BUN:creatinine ratio
  - History of alcohol abuse
  - Malnutrition
  - Hearing or vision impairment
- Precipitating risk factors
  - Severe illness in any organ system(s)
  - Medical devices (urinary catheter, restraints)
  - Polypharmacy (≥5 medications)
  - Specific medications, especially benzodiazepines, opioids (meperidine), and anticholinergics (diphenhydramine), high-dose neuroleptics
  - Pain
  - Any iatrogenic event
  - Surgery
  - Sleep deprivation

**GENERAL PREVENTION**
Follow treatment approach.

**COMMONLY ASSOCIATED CONDITIONS**
Multiple but most common are the following:
- New medicine or medicine changes
- Infections (especially lung, urine, and blood stream, but consider meningitis as well)
- Toxic-metabolic (especially low sodium, elevated calcium, renal failure, and hepatic failure)
- Heart attack or stroke
- Alcohol or drug withdrawal
- Preexisting cognitive impairment increases risk
DIAGNOSIS
Diagnosis is made using a careful history, behavioral observation, and cognitive assessment.
- **DSM-5** diagnostic criteria include (1):
  - Disturbance in attention and awareness
  - Change in cognition not due to dementia
  - Onset over short (hours to days) period and fluctuates during course of day
  - Evidence from history, exam, or lab that disturbance is caused by physiologic consequence of medical condition, intoxicating substance, medication use, or more than one cause.

The Confusion Assessment Method (CAM) is the most well validated and tested clinical tool and has been adapted for ICU setting in adults (CAM-ICU) and children (pediatric CAM-ICU [pCAM-ICU]) (2)[B].

ALERT
- Key diagnostic features of the CAM
  - Acute change in mental status that fluctuates
  - Abnormal attention and either disorganized thinking or altered level of consciousness
- Several nondiagnostic symptoms may be present:
  - Short- and long-term memory problems
  - Sleep–wake cycle disturbances
  - Hallucinations and/or delusions
  - Emotional lability
  - Tremors and asterixis
- Subtypes based on level of consciousness
  - Hyperactive delirium (15%): Patients are loud, agitated, restless, and disruptive.
  - Hypoactive delirium (20%): quietly confused; sleepy; may sit and not eat, drink, or move
  - Mixed delirium (50%): features of both hyperactive and hypoactive delirium
  - Normal consciousness delirium (15%): still displays disorganized thinking, along with acute onset, inattention, and fluctuating mental status

HISTORY
- Time course of mental status changes
Recent medication changes
Symptoms of infection
New neurologic signs
Abrupt change in functional ability

PHYSICAL EXAM
- Comprehensive cardiorespiratory exam is essential.
- Focal neurologic signs are usually absent.
- Mini-Mental State Examination (MMSE) is the most well-known and studied cognitive screen, but it may not be the most appropriate in an acute care setting; shorter cognitive screens have been studied in delirious patients (i.e., short blessed test [SBT], Brief Alzheimer Screen [BAS], and Ottawa 3DY) and may be helpful if performed serially over time. Most patients will perform poorly if delirium is present; dementia cannot be diagnosed when delirium is present.
- GI/GU exam for constipation/urinary retention

DIFFERENTIAL DIAGNOSIS
- Depression (disturbance of mood, normal level of consciousness, fluctuates weeks to months)
- Dementia (insidious onset, memory problems, normal level of consciousness, fluctuates days to weeks)
- Psychosis (rarely sudden onset in older adults)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Guided by history and physical exam
  - CBC with differential
  - Comprehensive metabolic panel (CMP)
  - Urinalysis, urine culture, blood culture
  - Medication levels (digoxin, theophylline, antiepileptics where applicable)
- Chest radiograph for most
- ECG as necessary
- Others, if indicated by history and exam

Follow-Up Tests & Special Considerations
- If lab tests listed above do not indicate a precipitator of delirium, consider
  - Arterial blood gases
– Troponin
– Toxicology screen
– Ammonia
– Thyroid-stimulating hormone
– Thiamine
• Noncontrast-enhanced head CT scan if
  – Unclear diagnosis
  – Recent fall
  – Receiving anticoagulants
  – New focal neurologic signs
  – Ruling out mass before lumbar puncture

**Diagnostic Procedures/Other**

• Lumbar puncture (rarely necessary)
  – Perform if clinical suspicion of a CNS bleed, malignancy-related syndrome, or infection is high.

• EEG (rarely necessary)
  – Consider after above evaluation if cause remains unclear or suspicion of seizure activity.

**TREATMENT**

• The best treatment is prevention (3)[A].
• Addressing six risk factors (i.e., cognitive impairment, sleep deprivation, dehydration, immobility, vision impairment, and hearing impairment) in at-risk hospitalized patients can reduce the incidence of delirium by 33%.
• Principles: Maintain safety, identify causes, and manage symptoms.
• Stabilize vital signs and ensure immediate evaluation.

**GENERAL MEASURES**

• Postoperative patients should be monitored and treated for
  – Myocardial infarction/ischemia
  – Infection (i.e., pneumonia, UTI)
  – Pulmonary embolism
  – Urinary or stool retention (attempt catheter removal by postoperative day 2)
• Anesthesia route (general vs. epidural) does not affect the risk of delirium.
• ICU sedation-avoidance of benzodiazepines may reduce risk (4)[B].
• Multifactorial treatment: Identify contributing factors and provide preemptive...
care to avoid iatrogenic problems, with special attention to
- CNS oxygen delivery (attempt to attain):
  - $\text{SaO}_2 > 90\%$ with goal of $\text{SaO}_2 > 95\%$
  - Systolic BP <2/3 of baseline or >90 mm Hg
  - Hematocrit >30\%
- Fluid/electrolyte balance
  - Sodium, potassium, and glucose normal (glucose <300 mg/dL in diabetics)
  - Treat fluid overload or dehydration.
- Treat pain
  - Schedule acetaminophen (650 mg TID–QID) if constant pain; avoid if LFT elevation noted.
  - Opioids (morphine, oxycodone) may be used for breakthrough pain.

**ALERT**
- Avoid meperidine (Demerol).
- Eliminate unnecessary medications.
  - Investigate new symptoms as potential medication side effects (i.e., Beers medications).
- Regulate bowel/bladder function.
  - Bowel movement at least every 48 hours
  - Screen for urinary retention.
- Prevent major hospital-acquired problems.
  - 6-inch-thick foam mattress overlay or a pressure-reducing mattress
  - Avoid urinary catheter.
  - Incentive spirometry
  - Venous thromboembolism (VTE) prophylaxis if bedfast
  - Early mobilization
  - Environmental stimulation
    - Glasses and hearing aids
    - Clock and calendar
    - Soft lighting
    - Music and television, if desired
  - Sleep
    - Quiet environment
    - Soft music
    - Therapeutic massage
- Restraints increase risk of delirium and falls/injury.
  - Use as a last resort for patients at risk for self-injury or risk for injuring caregivers. Remove as soon as possible.
MEDICATION

- Nonpharmacologic approaches are preferred for initial treatment, but medication may be needed for agitation management, especially in the ICU setting (5)[C].
- Medications treat only the symptoms and do not address the underlying cause.
- No medication is FDA approved for delirium.
- Medications should not be used prophylactically.

First Line

- Antipsychotics
  - Monitor QTc periodically if antipsychotics are used.
  - Haloperidol (Haldol): initially, 0.25 to 0.5 mg PO/IM; reevaluate and potentially redose hourly until symptoms controlled and then use effective dose up to QID PRN. Critical care guidelines do not support use of antipsychotics for prevention of ICU delirium (4)[B].
  - Quetiapine (Seroquel) 12.5 to 25.0 mg PO BID–TID
  - Risperidone (Risperdal) 0.25 to 0.5 mg PO daily
- Benzodiazepines should generally be avoided except in alcohol withdrawal, if patient taking a benzodiazepine regularly at baseline, or antipsychotic is contraindicated. Benzodiazepines can cause delirium.
- Lorazepam (Ativan): initially, 0.25 to 0.5 mg PO/IM/IV TID–QID PRN; may need to adjust to effect (caution in impaired liver and renal function)
- Contraindications: Avoid typical antipsychotics in patients with parkinsonism or Parkinson disease.
- Precautions: Typical antipsychotics may cause extrapyramidal effects; benzodiazepines may cause delirium. Both increase fall risk. Antipsychotics may prolong the QT interval. Aripiprazole (Abilify) has minimal or no QT prolonging effect.
- Dexmedetomidine, when compared to haloperidol, has been used in the ICU setting and proven to reduce agitation in delirious ICU adults. The primary adverse effects of this medication include hypotension and bradycardia (6)[C].

Second Line

- Olanzapine (Zyprexa) 2.5 to 5.0 mg PO daily to BID
- Cholinesterase inhibitors should be avoided. Multiple trials demonstrate adverse events with cholinesterase inhibitors in the management of delirium; evidence does not support their use.
ISSUES FOR REFERRAL
Geriatric, psychiatric, or neurologic consultation is helpful if delirium is not easily explainable or resolving after full evaluation. Interprofessional team approach is best.

ADDITIONAL THERAPIES
Early mobilization critical
- Out of bed several hours daily starting on hospital day 2 (or postoperative day 1) if no contraindications

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Cognitive engagement is key.
- New delirium is a medical emergency and requires admission, except in the setting of hospice care (i.e., terminal delirium).
- IV fluids as needed for dehydration
- Monitor for the development of delirium.
- Assessment of precipitants/contributing factors (pain, constipation, urinary retention)
- Reorient; maintain day/night orientation.
- Skin care and turning regimen for immobile patients
- Maintain and encourage mobility.
- Encourage family presence and participation.
- Discharge criteria
  - Resolution of precipitating factor(s)
  - Safe discharge site if delirium is slow to resolve

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- If delirium at discharge, often needs postacute facility and ongoing assessment for resolution
- If no delirium at discharge, follow up with primary care physician in 1 to 2 weeks.

Patient Monitoring
• Evaluate and assess mental status daily.
• Continued evaluation for precipitating cause(s)

**DIET**
• Liberalize diet to increase oral intake.
• Nutritional supplements if intake poor
• Consider temporary nasogastric tube if unable to eat and bowels working.

**PROGNOSIS**
• May take weeks/months to fully resolve
• Usually improves with treatment of underlying condition(s); can lead to chronic cognitive impairment
• Delirium significantly increases a person’s 1 year mortality risk.

**COMPlications**
• Falls and functional decline
• Pressure ulcers and malnutrition
• Future cognitive dysfunction
• Higher risk for institutionalization
• Death

**REFERENCES**
nonpharmacologic approaches to the prevention and management of delirium. 

### ADDITIONAL READING

### SEE ALSO

- [Dementia](#); [Depression](#); [Substance Use Disorders](#)
- Algorithm: [Delirium](#)

### CODES

**ICD10**

- R41.0 Disorientation, unspecified
- F19.931 Oth psychoactive substance use, unsp w withdrawal delirium
- F10.231 Alcohol dependence with withdrawal delirium

### CLINICAL PEARLS

- The CAM criteria for delirium are acute onset of fluctuating mental status, inattention, and either disorganized thinking or altered level of consciousness.
- Hypoactive subtype of delirium can easily be missed.
- Addressing six risk factors (i.e., cognitive impairment, sleep deprivation, dehydration, immobility, vision impairment, and hearing impairment) in hospitalized patients can reduce the incidence of delirium by 33%.
- Delirium may not resolve as soon as the treatable contributors resolve; may take weeks or months
- Avoid diphenhydramine and benzodiazepines in older patients.
Nonpharmacologic measures are preferable over a pharmacologic sleep aid.
DEMENTIA
Umer Farooq, MD • Saeed Ahmed, MD

BASICS
DESCRIPTION

- *DSM-5* classifies dementias under neurocognitive disorders (major and mild).
- Evidence of cognitive decline from previous level of performance in one of cognitive domains (attention, executive function, learning, and memory). The cognitive deficits interfere significantly with ADLs (for major only) and do not occur exclusively in the context of delirium or any other mental disorder.
- *DSM-5* specifies the cause of neurocognitive decline secondary to the following:
  - Alzheimer dementia (AD)
    - Progressive cognitive decline; most common age >65 years
  - Vascular dementia (VaD)
    - Usually correlated with a cerebrovascular event and/or cerebrovascular disease
    - Stepwise deterioration with periods of clinical plateaus
  - Lewy body dementia
    - Fluctuating cognition associated with parkinsonism, hallucinations and delusions, gait difficulties, and falls
  - Frontotemporal dementia
    - Language difficulties, personality changes, and behavioral disturbances
  - Creutzfeldt-Jakob disease (CJD)
    - Very rare; rapid onset
  - HIV dementia
  - Substance-/medication-induced neurocognitive disorder

EPIDEMIOLOGY

Prevalence

- In patients age ≥71 years
  - AD: 5–10% up to 25% after 7th decade of life
  - VaD: 17%
  - Other: 13%
- Estimated 5.4 million Americans had AD in 2010.
- 5 million >65 years of age; 200,000 <65 years
- Prevalence expected to double by 2030.

ETIOLOGY AND PATHOPHYSIOLOGY
- AD: involves β-amyloid protein accumulation and/or neurofibrillary tangles (NFTs), synaptic dysfunction, neurodegeneration, and eventual neuronal loss
- Age, genetics, systemic disease, smoking, and other host factors may influence the β-amyloid accumulation and/or the pace of progression toward the clinical manifestations of AD.
- VaD: cerebral atherosclerosis/emboli with clinical/subclinical infarcts

Genetics
- AD: Positive family history in 50%, but 90% AD is sporadic: APOE4 increases risk but full role unclear.
- Familial/autosomal dominant AD accounts for <5% AD: amyloid precursor protein (APP), presenilin-1 (PSEN-1), and presenilin-2 (PSEN-2).

RISK FACTORS
- Age; sex: female > male
- Genetic predisposition
- Hypertension: AD; VaD
- Hypercholesterolemia: AD; VaD
- Diabetes: VaD
- Cigarette smoking: VaD
- Endocrine/metabolic abnormalities: hypothyroidism, Cushing syndrome; thiamine and vitamin B₁₂ deficiency
- Chronic alcoholism, other drugs
- Lower educational status
- Head injury early in life
- Sedentary lifestyle

GENERAL PREVENTION
- Treat reversible causes of dementia, such as drug-induced, alcohol-induced, and vitamin deficiencies.
- Treat hypertension, hypercholesterolemia, and diabetes.
- No evidence for statins (or any other specific medication) to prevent onset of dementia (1)[A]
- BP control and low-dose aspirin may prevent or lessen cognitive decline in
VaD.

COMMONLY ASSOCIATED CONDITIONS

- Anxiety and major depression
- Psychosis (delusions; delusions of persecution are common)
- Delirium
- Behavioral disturbances (agitation, aggression)
- Sleep disturbances

DIAGNOSIS

HISTORY

Probable diagnosis AD (2)[B]:

- Age between 40 and 90 years (usually >65 years)
- Progressive cognitive decline of insidious onset
- No disturbances of consciousness
- Deficits in areas of cognition
- No other explainable cause of symptoms
- Specifically rule out thyroid disease, vitamin deficiency ($B_{12}$), grief reaction, and depression.
- Supportive factors: family history of dementia

PHYSICAL EXAM

- Often normal physical
- No disturbances of consciousness
- Cognitive decline demonstrated by standardized instruments, including the following:
  - Mini-Mental State Examination
  - Montreal Cognitive Assessment (MoCA) test
  - ADAS-Cog
  - Clock draw test
- Use caution in relying solely on cognition scores, especially in those with learning difficulty, language barriers, or similar limitations.

DIFFERENTIAL DIAGNOSIS

- Major depression
- Medication side effect
- Chronic alcohol use
- Delirium
- Subdural hematoma
- Normal pressure hydrocephalus
- Brain tumor
- Thyroid disease
- Parkinson disease
- Vitamin B$_{12}$ deficiency
- Toxins (aromatic hydrocarbons, solvents, heavy metals, marijuana, opiates, sedative-hypnotics)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Used to rule out causes
  - CBC, CMP
  - Thyroid-stimulating hormone
  - Vitamin B$_{12}$ level
- Select patients
  - HIV, rapid plasma regain (RPR)
  - Erythrocyte sedimentation rate (ESR)
  - Folate
  - Heavy metal and toxicology screen
- Research studies with cerebrospinal fluid (CSF) biomarkers in patient with confirmed AD have shown decreased A beta (1 to 42) and increased tau and p-tau levels, which are specific features of AD, and CSF tau proteins are increased in CJD (3)[A].

**Neuroimaging (CT/MRI of brain): cerebral atrophy**
- Early age of onset (<65 years), rapid progression, focal neurologic deficits, cerebrovascular disease risk, or atypical symptoms: neuroimaging (MRI/CT) to rule out other causes
- Important findings
  - AD: diffuse cerebral atrophy starting in association areas, hippocampus, amygdala
  - VaD: old infarcts, including lacunar

**Diagnostic Procedures/Other**
PET scan not routinely recommended; has been approved to differentiate between Alzheimer disease and frontotemporal dementia
Test Interpretation
AD
- NFTs: abnormally phosphorylated tau protein
- Senile plaques: APP derivatives
- Microvascular amyloid

TREATMENT
GENERAL MEASURES
- Daily schedules and written directions
- Emphasis on nutrition, personal hygiene, accident-proofing the home, safety issues, sleep hygiene, and supervision
- Socialization (adult daycare)
- Sensory stimulation (display of clocks and calendars) in the early to middle stages
- Discussion with the family concerning support and advance directives

MEDICATION
- Cognitive dysfunction
- Medications for AD (4)[A] show a small improvement in some cognitive measures, but it remains unclear if the improvement is clinically significant.
- Cognitive dysfunction, mild
  - Cholinesterase inhibitors: donepezil (Aricept), 5 to 10 mg/day; rivastigmine (Exelon), 1.5 to 6 mg BID, transdermal system 4.6 mg/24 hours and 9.5 mg/24 hours; galantamine (Razadyne), 4 to 12 mg BID, extended release 8 to 24 mg/day
    - Adverse events: nausea, vomiting, diarrhea, anorexia, nightmares, bradycardia/syncope
    - Galantamine warning: associated with mortality in patients with mild cognitive impairment in clinical trial
    - It is suggested to consider cholinesterase inhibitor for patients with mild to moderate dementia (MMSE 10 to 26).
    - The patients with moderate to advanced dementia (MMSE <17), recommendations are to add memantine (10 mg twice daily) to a cholinesterase inhibitor, or using memantine alone in patients who do not tolerate or benefit from a cholinesterase inhibitor.
    - In patients with severe dementia (MMSE <10), it is suggested continuing
memantine. However, in advanced dementia, medications can be discontinued to maximize quality of life and patient comfort.

- Start drug with lowest acquisition cost; also consider adverse event profile, adherence, medical comorbidity, drug interactions, and dosing profiles.

- **Cognitive dysfunction, moderate to severe**
  - Cholinesterase inhibitors *OR*
  - Memantine (Namenda), 5 to 20 mg/day
    - Adverse events: dizziness, confusion, headache, constipation
    - *OR* combination cholinesterase inhibitor and memantine

- **Commonly associated conditions**
  - Psychosis and agitation/aggressive behavior:
    - Look for precipitating factors (infection, pain, depression, medications).
    - Nonpharmacologic therapies (behavioral interventions, music therapy, etc.) are preferred as first-line treatment.
    - Mood stabilizers (valproic acid, carbamazepine) have been used although evidence is lacking.
    - For moderate/severe symptoms; antipsychotics: Initiate low doses, risperidone 0.25 to 1 mg/day; olanzapine 1.25 to 5 mg/day; quetiapine 12.5 to 50 mg/day; aripiprazole 5 mg/day; ziprasidone 20 mg/day
    - Atypical antipsychotics associated with a better side effect profile: quetiapine and aripiprazole often first line due to decreased extrapyramidal side effect

**ALERT**

Black box warning on antipsychotics due to increased mortality in elderly with dementia

- **Depression and insomnia**
  - Depression:
    - Selective serotonin reuptake inhibitors (SSRIs): Initiate low doses, citalopram (Celexa) 10 mg/day; escitalopram (Lexapro) 5 mg/day; sertraline (Zoloft) 25 mg/day.
    - Adverse events: nausea, vomiting, agitation, parkinsonian effects, sexual dysfunction, hyponatremia
    - Venlafaxine, mirtazapine, and bupropion are also useful.
  - Sleep disturbances:
    - Low-dose antidepressants (e.g., Remeron) have significant sedative properties at 7.5 or 15 mg.
- Trazodone 25 to 100 mg is frequently used because of better side effect profile.
  - Psychosis and agitation/aggressive behavior:
    - Some data for SSRIs
    - Benzodiazepines if agitation with anxiety; in elderly, use PRN.

**Geriatric Considerations**
Initiate pharmacotherapy at low doses and titrate slowly up if necessary.
- Benzodiazepines are potentially inappropriate for older adults, yet their use persists.

**ALERT**
Benzodiazepine use is associated with increased fall risk (5)[B].
- Watch decreased renal function and hepatic metabolism.

**ISSUES FOR REFERRAL**
Neuropsychiatric evaluation particularly helpful in early stages or mild cognitive impairment

**ADDITIONAL THERAPIES**
Behavioral modification
- Socialization, such as adult daycare, to prevent isolation and depression
- Sleep hygiene program as alternative to pharmaceuticals for sleep disturbance
- Scheduled toileting to prevent incontinence

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Vitamin E is no longer recommended due to lack of evidence.
- Ginkgo biloba is not recommended due to lack of evidence.
- NSAIDs, selegiline, and estrogen lack efficacy and safety data.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Worsening physical health issues
- Psychiatry admission may be required because of safety concerns (self-harm/harm to others), self-neglect, aggressive behaviors, or other behavioral issues.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Progression of cognitive impairment by use of standardized tool (e.g., MMSE, ADAS-Cog)
- Development of behavioral problems: sleep, depression, psychosis
- Adverse events of pharmacotherapy
- Nutritional status
- Caregiver evaluation of stress

PATIENT EDUCATION

- Long-term issues: safety, management of finances, medical decision making, possible placement; legal guardianship, if necessary
- Advance directives

PROGNOSIS

- AD: usually steady progression leading to profound cognitive impairment:
  - Average survival of AD is about 8 years.
- VaD: incrementally worsening dementia, but cognitive improvement is unlikely
- Secondary dementias: Treatment of the underlying condition may lead to improvement; commonly seen with normal pressure hydrocephalus, hypothyroidism, and brain tumors

COMPLICATIONS

- Wandering
- Delirium
- Sundowner syndrome is common in older people (who are sedated) and also in people who have dementia (adverse reaction to small dose of psychoactive substances).
- Falls with injury
  - Hip fracture
  - Head trauma/hematomas
- Neglect and abuse
REFERENCES

ADDITIONAL READING

SEE ALSO

Algorithm: Dementia
CODES

ICD10
- F03 Unspecified dementia
- G30.9 Alzheimer’s disease, unspecified
- F01.50 Vascular dementia without behavioral disturbance

CLINICAL PEARLS

- Medications for AD show a small, statistically significant improvement in some cognitive measures, but it remains unclear if the improvement is clinically significant.
- Do not forget the role of adult protective services in case of elderly abuse.
- A particular concern in nursing homes relates to the use of physical restraints and antipsychotic medication, which are regulated by Omnibus Reconciliation Act of 1987.
BASICS

Vascular dementia is a heterogeneous disorder caused by the sequel of cerebrovascular disease that manifests in cognitive impairment affecting memory, thinking, language, behavior, and judgment.

DESCRIPTION

- Vascular dementia (previously known as multi-infarct dementia) was first mentioned by Thomas Willis in 1672. Later, it was further described in the late 19th century by Binswanger and Alzheimer as a separate entity from dementia paralytica caused by neurosyphilis. This concept has evolved tremendously since the advent of neuroimaging modalities.
- Synonym(s): vascular cognitive impairment (VCI); vascular cognitive disorder (VCD); arteriosclerotic dementia; poststroke dementia; senile dementia due to hardening of the arteries; Binswanger disease. Diagnostic and Statistical Manual of Mental Disorders (DSM-5) categorizes vascular dementia as mild or major VCD.

EPIDEMIOLOGY

Second most common cause of dementia after Alzheimer dementia in the elderly

Incidence

About 6 to 12 cases/1,000/person age >70 years

- Incidence of vascular dementia is declining in high-income countries in the past several decades likely due to better management of vascular risks.

Prevalence

- ~1.2–4.2% in those age >65 years
- 14–32% prevalence of dementia after a stroke

ETIOLOGY AND PATHOPHYSIOLOGY

On autopsy of those with dementia, many have significant vascular pathology
that is present, but this is not necessarily correlated clinically with vascular dementia. No set pathologic criteria exist for the diagnosis of vascular dementia such as those that exist for Alzheimer dementia. Pathology includes the following:

- **Large vessel disease**: cognitive impairment that follows a stroke
- **Small vessel disease**: includes white matter changes (leukoaraiosis), subcortical infarcts, and incomplete infarction. This is usually the most common cause of multi-infarct dementia.
- **Subcortical ischemic vascular disease**: due to small vessel involvement within cerebral white matter, brain stem, and basal ganglia. Lacunar infarcts and deep white matter changes are typically included in this category.
- **Noninfarct ischemic changes and atrophy**
- **Transient ischemic attack** (TIA)/stroke
- **Vascular, demographic, genetic factors**
  - Vascular disease (i.e., hypertension [HTN], peripheral vascular disease [PVD], atrial fibrillation, hyperlipidemia, diabetes)

**Genetics**

- Cerebral autosomal dominant arteriopathy with subcortical infarcts (CADASIL) is caused by a mutation in the **NOTCH3** gene on chromosome 19 that results in leukoencephalopathy and subcortical infarcts. This is clinically manifested in recurrent strokes, migraine with aura, and vascular dementia.
- **Apolipoprotein E** gene type: Those with ApoE4 subtypes are at higher risk of developing both vascular and Alzheimer dementia.
- **Amyloid precursor protein** (APP) gene: leads to a form of vascular dementia called heritable cerebral hemorrhage with amyloidosis

**RISK FACTORS**

- Age
- Previous stroke
- Smoking
- Diabetes (especially with frequent hypoglycemia)
- HTN
- Atrial fibrillation
- PVD
- Hyperlipidemia
- Metabolic syndrome
- Coronary atherosclerotic heart disease (1)
GENERAL PREVENTION
- Optimization and aggressive treatment of vascular risk factors, such as HTN, diabetes, and hyperlipidemia (2)[C]
- HTN is the single most modifiable risk factor and treatment for it must be optimized.
- Smoking is associated with white matter changes on imaging which may be associated with small vessel disease and vascular dementia progression (3)[B].
- Lifestyle modification: weight loss, physical activity, smoking cessation
- Medication management for vascular risk reduction: aspirin usage, statin therapy for hyperlipidemia, antihypertensive therapy (4)[B]

COMMONLY ASSOCIATED CONDITIONS
- CADASIL
- Cerebral amyloid angiopathy (CAA) causes ischemic white matter damage due to amyloid deposition in penetrating cortical vessels.

DIAGNOSIS
Differentiation between Alzheimer dementia and vascular dementia can be difficult, and significant overlap is seen in the clinical presentation of these two dementias. The diagnosis of vascular dementia is a clinical diagnosis.

HISTORY
- Gradual, stepwise progression is typical.
- Ask about onset and progression of cognitive impairment and the specific cognitive domains involved.
- Ask about vascular risk factors and previous attempts to control these risk factors.
- Ask about medication compliance.
- Ask about urinary incontinence and gait disturbances. Abnormal gait and falls are strong predictors of development of vascular dementia, particularly unsteady, frontal, and hemiparetic types of gait.
- Look for early symptoms, including difficulty performing cognitive tasks, memory, mood, and assessment of instrumental activities of daily living (IADLs).
- Past history may include TIAs, cerebrovascular accidents (CVAs), coronary
atherosclerotic heart disease, atrial fibrillation, hyperlipidemia, and/or PVD.

**PHYSICAL EXAM**
- Screen for HTN. Average daily BP and not office BP is associated with progression of cerebrovascular disease and cognitive decline in the elderly.
- Focal neurologic deficits may be present.
- Gait assessment is important, especially looking at gait initiation, gait speed, and balance (5)[C],(6)[B].
- Check for carotid bruits as well as abdominal bruits and assess for presence of PVD.
- Check body mass index and waist circumference.
- Do a thorough cardiac evaluation that includes looking for arrhythmias (i.e., atrial fibrillation).

**DIFFERENTIAL DIAGNOSIS**
- Alzheimer dementia
- Depression
- Drug intoxication
- CNS tumors
- Hypothyroidism
- Vitamin B$_{12}$ deficiency

**DIAGNOSTIC TESTS & INTERPRETATION**
- Cognitive testing, such as Saint Louis University Mental Status (SLUMS) and Montreal Cognitive Assessment (MOCA), provides more definitive information in terms of cognitive deficits, especially executive function, which may be lost earlier in vascular dementia. The Mini-Mental Status Examination is not sensitive in distinguishing Alzheimer dementia from vascular dementia because it does not have good measures of executive function.
- Neuropsychological testing may also be beneficial, especially in evaluating multiple cognitive domains and their specific involvements and deficits.

*Initial Tests (lab, imaging)*
As appropriate, consider CBC, comprehensive metabolic profile, lipid panel, thyroid function, hemoglobin A1C, and vitamin B$_{12}$.
- Imaging is used in conjunction with history and physical examination to support a clinical diagnosis of vascular dementia.
Cognitive deficits observed clinically do not always have to correlate with findings found on neuroimaging studies.

MRI is best in terms of evaluation of subtle subcortical deficits.

White matter changes and specific location of these changes can be associated with executive dysfunction and episodic memory impairment.

**TREATMENT**

Prevention is the real key to treatment:

- Control of risk factors, including HTN, hyperlipidemia, and diabetes
- Avoidance of tobacco and smoking cessation
- Healthy, low-cholesterol diet

**MEDICATION**

- Acetylcholinesterase inhibitors may be used but are of limited benefit in vascular dementia.
- Clinical evidence for use of memantine is limited with the clinical benefit likely modest.
- Controlling BP with any antihypertensive medications, treatment of dyslipidemia (e.g., statins), and treatment of diabetes are very important.
- Selective serotonin reuptake inhibitors (SSRIs) may be of benefit for agitation and psychosis in vascular dementia.

**ADDITIONAL THERAPIES**

- Limit alcohol drink intake to ≤1/day in women and 2/day in men.
- Heavy sustained alcohol use contributes to HTN.
- Aspirin and/or clopidogrel may be useful in some cases.

**SURGERY/OTHER PROCEDURES**

Carotid endarterectomy/stenting should be considered if evidence of significant internal carotid artery stenosis (i.e., >70–80%).

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Ginkgo biloba should be avoided due to increased risk of bleeding, especially in CAA.
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Remain sensitive to functional assessment and avoidance of pressure ulcers after CVAs.
- Avoid Foley catheter usage unless absolutely necessary due to increased risk of infection.
- Nonpharmacologic approaches to behavior management should be attempted prior to medication usage.
- Providing optimal sensory input to patients with cognitive impairment is important during hospitalizations to avoid delirium and confusion. Patients should be given frequent cues to keep them oriented to place and time. They should be informed of any changes in the daily schedule of activities and evaluations. Family and caregivers should be encouraged to be with patients with dementia as much as possible to further help them from becoming confused during hospitalization. Recreational, physical, occupational, and music therapy can be beneficial during hospitalization in avoiding delirium and preventing functional decline.
- Particular emphasis has to be placed on screening for, and optimizing, the mood of the patient. Depression is very common in older patients, especially those who have had strokes and have become hospitalized. Depression in itself can present as “pseudodementia” with worsening confusion during hospitalization and is a treatable condition.

ONGOING CARE

Vascular dementia is a condition that should be followed with multiple visits in the office setting with goals of optimizing cardiovascular risk profiles for patients. Future planning and advanced directives should be addressed early. Family and caregiver evaluation and burden should also be evaluated.

FOLLOW-UP RECOMMENDATIONS

Perform regular follow-up with a primary care provider or geriatrician for risk factor modification and education on importance of regular physical and mental exercises as tolerated.

Patient Monitoring

Appropriate evaluation and diagnosis of this condition, need for future planning,
optimizing vascular risk factors, lifestyle modification counseling, therapeutic interventions

**DIET**
- The American Heart Association diet and Dietary Approaches to Stop Hypertension (DASH) diet is recommended for optimal BP and cardiovascular risk factor control.
- Low-fat, decreased concentrated sweets and carbohydrates, especially in those with metabolic syndrome

**PATIENT EDUCATION**
- Lifestyle modification is important in vascular risk reduction (smoking cessation, exercise counseling, dietary counseling, weight-loss counseling).
- Optimizing vascular risk factors via medications (i.e., HTN, diabetes, atrial fibrillation, PVD, heart disease)
- Avoiding smoking, including secondhand smoke
- Home BP monitoring and glucometer testing of blood sugars if HTN, impaired glucose tolerance, and/or diabetes is present

**PROGNOSIS**
- Lost cognitive abilities that persist after initial recovery of deficits from stroke do not usually return. Some individuals can have intermittent periods of self-reported improvement in cognitive function.
- Risk factors for progression of cognitive and functional impairment poststroke include age, prestroke cognitive abilities, depression, polypharmacy, and decreased cerebral perfusion during acute stroke.

**COMPLICATIONS**
- Physical disability from stroke
- Severe cognitive impairment
- Death

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Alzheimer Disease; Depression; Mild Cognitive Impairment

**CODES**

**ICD10**
- F01.50 Vascular dementia without behavioral disturbance
- F01.51 Vascular dementia with behavioral disturbance

**CLINICAL PEARLS**
- Executive dysfunction and gait abnormalities are often seen early and are more pronounced in vascular dementia as opposed to Alzheimer dementia.
- Memory is relatively preserved in vascular dementia when compared with Alzheimer dementia in the early stages of this disease.
- Stepwise progression, as opposed to progressive decline in Alzheimer
dementia, is typical.
- Considerable overlap exists between vascular dementia and Alzheimer dementia in clinical practice, and classification into one of these categories is often difficult. Patients can have mixed etiologies as well.
DENTAL INFECTION
Sheila O. Stille, DMD • Hugh Silk, MD, MPH, FAAFP

BASICS

DESCRIPTION
- Pain ± swelling in the head and neck region from infection in the teeth and supporting structures; if left untreated, can lead to serious and potentially life-threatening illnesses
- Assume any head and neck infection or swelling to be odontogenic in origin until proven otherwise.
- System(s) affected: oropharynx, throat, dental, gastrointestinal
- Synonym(s): odontogenic infections, dental abscess

EPIDEMIOLOGY
- 18% of 5- to 19-year-olds have untreated dental caries (1).
- 28% of individuals age >20 years have untreated dental caries (1).
- Rates are higher in Hispanic (21.7%) and black (23%) children/teens (1)[A].
- 92% of adults 20 to 64 years have had dental caries (1).
- 25% of children 5 to 17 years account for 80% of caries in the United States.
- 17% of adults age >64 years are edentulous (1).

ETIOLOGY AND PATHOPHYSIOLOGY
Caries or trauma can lead to death of the tooth pulp, which can lead to infection and/or abscess of adjacent tissues via direct or hematogenous bacterial colonization.
- Caries (tooth decay; “cavity”) represent a contagious bacterial infection causing demineralization and destruction of the tooth tissue (enamel, dentin, and cementum).
- Streptococcus mutans is vertically transmitted to newly dentate infants from caregivers.
- Acidic secretions from S. mutans are implicated in early caries.
- Often there is polymicrobial mix of anaerobes in dental abscess (viridans streptococci and Streptococcus anginosus).
- Anaerobes, including peptostreptococci, Bacteroides, Prevotella, and Fusobacterium, have also been implicated. Lactobacilli not seen in healthy
subjects but is common in patients with extensive caries (2).

- Preventable with good oral hygiene, low cariogenic diet, access to fluoride, and professional dental care
- Fluoride has dramatically decreased dental caries.

**RISK FACTORS**

- Low socioeconomic status
- Parent and/or sibling with history of caries or existing untreated dental caries (especially in past 12 months)
- Previous dental caries
- Poor access to dental/health care; lack of dental insurance
- Fear of dentist
- Poor oral hygiene
- Poor nutrition, including diet containing high level of sugary foods and drinks
- Trauma to the teeth or jaw
- Inadequate access to and use of fluoride
- Gingival recession (increased risk of root caries)
- Physical and mental disabilities
- Decreased salivary flow (e.g., use of anticholinergic medications, immunologic diseases, radiation therapy to head and neck)

**GENERAL PREVENTION**

- Prevent caries and contagious bacterial infection (S. mutans).
- Most dental problems can be avoided through flossing/use of interdental brushes; brushing with fluoride toothpaste, systemic fluoride (fluoridated bottled water; fluoride supplements for high-risk patients and in nonfluoridated areas); fluoride varnish for moderate- to high-risk patients and all children age <6 years; regular dental cleanings (1,3).
- Prevent transmission of S. mutans from mother/caregiver to infant by improving maternal dentition, chlorhexidine gluconate rinses, and use of xylitol products for mother especially during first 2 years of a child’s life. Avoid smoking, which is linked to severe periodontal disease (2).
- Good control of systemic diseases (e.g., diabetes)
- Fluoride varnish provided by dental or medical primary care providers twice per year (2,3)

**COMMONLY ASSOCIATED CONDITIONS**

- Extensive caries, crowding, multiple missing teeth
Periapical and periodontal abscess
Soft tissue cellulitis
Periodontitis (deep inflammation ± infection of gingiva, alveolar bone support, and ligaments)

**DIAGNOSIS**

**HISTORY**
- Pain at involved tooth; can be referred to ears, jaw, cheek, neck, or sinuses; unexplained headaches
- Hot/cold sensitivity
- Pain can be unprovoked, intermittent and/or constant.
- Pain with biting or chewing
- Trismus (inability to open mouth)
- Bleeding or purulent drainage from gingival tissues
- When severe infection (systemic)
  - Fever
  - Difficulty breathing or swallowing
  - Raspy voice
  - Mental status changes
- Evaluate children <4 years with stiff neck, sore throat, and dysphagia for retropharyngeal abscess.

**PHYSICAL EXAM**
- Gingival edema and erythema
- Cheek (extraoral) or vestibular (intraoral) swelling
- Fluctuant mass at involved site
- Suppuration of gingival margin
- Submandibular or cervical lymphadenopathy
- Severe (systemic) infection may present with dysphagia, fever, and signs of airway compromise.

**DIFFERENTIAL DIAGNOSIS**
- Bacterial or viral pharyngitis
- Pericoronitis (inflammation ± infection of gum flap over mandibular last molar, typically 3rd molars)
- Otitis media or externa
- Sinusitis
- Headache/migraine
- Viral (HSV1, herpangina, hand-foot-mouth disease) or aphthous stomatitis
- Temporomandibular joint (TMJ) dysfunction (myofascial pain, ± internal derangement of TMJ)
- Parotitis
- Jaw pain can be anginal equivalent, especially in women and especially lower left side of the jaw.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- No initial labs needed, unless patient looks acutely ill.
- If acutely ill
  - Consider CBC with differential.
  - If abscess present, aspirate pus and culture for aerobes and anaerobes (4).
  - Typically polymicrobial infections with anaerobic gram-negative rods and anaerobic gram-positive cocci (4)
- Individual films of suspected teeth, including root apices; test with palpation, percussion, and cold sensitivity.
- Panoramic film or CT scan of the teeth and jaw to evaluate the extent of infection

**Follow-Up Tests & Special Considerations**
- Panoramic radiograph, particularly if trismus present
- CT scan can be helpful if facial swelling extends below inferior border of mandible or into infraorbital space. This helps to location for potential incision and drainage by oral and maxillofacial surgeon or ENT.

**TREATMENT**
- Appropriate antibiotic, if indicated. Isolated pain (no swelling or systemic signs of infection) does not warrant antibiotic use.
- If localized, consider incision and drainage.
- Appropriate pain control: Anti-inflammatory agents are first line; short-course opioids in some cases (5)[A]
- Refer to oral health provider as soon as possible for definitive treatment: root canal, extraction, gum therapy (4).
• If infection is severe (systemic symptoms), consider hospitalization with IV antibiotics until stable. May need intraoral or extraoral incision and drainage; definitive treatment (extraction or root canal therapy) necessary to prevent progression or recurrence

**GENERAL MEASURES**
• Ibuprofen 600 to 800 mg (peds: 10 mg/kg) q6h or acetaminophen 650 to 1,000 mg (peds: 10 to 15 mg/kg) q4–6h PRN for pain
• For more severe pain, consider acetaminophen with ibuprofen (synergistic effect) + short course of opioids.
• Local nerve block with long-acting anesthetic (bupivacaine); avoid penetrating infection to avoid tracking infection.

**MEDICATION**

**First Line**
• Amoxicillin: 500 mg TID for 7 to 10 days; in children, 40 to 60 mg/kg/day divided TID
• If penicillin allergic, use clindamycin 300 mg PO TID for 7 days.

**Second Line**
If long-standing infection or no response to first-line treatment
• Clindamycin: 300 mg PO TID for 7 to 10 days
• Amoxicillin/clavulanic acid (500 mg/125 mg), 1 tablet PO TID for 7 days
• If severe infection, consider IV antibiotics (ampicillin-sulbactam, cefoxitin, cefotetan).
• Consider double coverage with metronidazole 500 mg PO TID for 7 days for better bone penetration and good anaerobic coverage. Do not use metronidazole alone; will increase development of resistant strains; can be used with amoxicillin or clindamycin

**ISSUES FOR REFERRAL**
Consult an oral health provider, and ensure definitive follow-up.

**SURGERY/OTHER PROCEDURES**
• Incise and drain large, fluctuant abscesses.
• Root canal or extraction is definitive treatment.

**ADMISSION, INPATIENT, AND NURSING**
CONSIDERATIONS
Criteria for hospital admission: swelling involving deep spaces of the neck, floor of the mouth, or infraorbital region; deviation of the airway; unstable vital signs; fever (>101°F); chills; raspy voice; confusion or delirium; or evidence of invasive infection or cellulitis

- Ensure secure airway.
- IV fluid resuscitation if necessary
- Ensure good oral hygiene.
- Rinse or swab mouth with chlorhexidine gluconate BID.
- Use warm saltwater rinses several times per day, especially after incision and drainage; ice packs to decrease swelling and encourage drainage
- Discharge patient when
  - Airway not compromised
  - Abscess and sepsis eliminated
  - Able to take PO intake and ambulate

ONGOING CARE
Educate regarding proper oral hygiene, need for follow-up dental care, and potential medical complications that arise due to lack of dental care.

FOLLOW-UP RECOMMENDATIONS
- Follow-up with oral health provider within 24 hours.
- Ensure adequate PO intake, including protein.

DIET
- Maintain a healthy diet; bacteria thrive on refined sugar and starch.
- Avoid sugary foods that stick between the teeth.
- Avoid the use of sugary/carbonated drinks throughout day; water as beverage of choice between meals

Pediatric Considerations
In children, limit the frequency of sugary drinks and advise against sleeping with a bottle to decrease the chance of dental caries. Fluoride varnish twice a year (more for higher risk children) for children age <6 years (3).

PATIENT EDUCATION
• Control caries and periodontal disease.
• Biannual dental visits at a minimum
  – Limit the frequency of sugar/carbonated drinks and sugary or sticky foods.
• In young children, avoid sleeping with a bottle to decrease the chance of
dental caries.
• Brush twice daily and use floss/interdental brush daily.

PROGNOSIS
Prognosis is excellent with proper treatment.

COMPLICATIONS
• Ludwig angina
• Retropharyngeal and mediastinal infection
• Osteomyelitis
• Endocarditis/cardiac tamponade
• Submental infection
• Submandibular infection
• Can cause unstable diabetes in diabetics/worsen preexisting heart disease
• Brain abscess/death

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**
- K02.9 Dental caries, unspecified
- K04.7 Periapical abscess without sinus
- K12.2 Cellulitis and abscess of mouth

**CLINICAL PEARLS**
- Do not ignore tooth pain.
- Treat patients with facial swelling aggressively, as infections can spread quickly, leading to significant morbidity or even death.
- Prevention (oral hygiene, fluoride, dental visits) is the key to avoiding odontogenic infections.
DEPRESSION

Naureen Rafiq, MBBS ⋆ Michael G. Kavan, PhD

BASICS

DESCRIPTION

- A primary mood disorder characterized by a sustained feeling of sadness and/or decreased interest in all or most activities once enjoyed (anhedonia), which represents a change from previous functioning.
- Variants: disruptive mood dysregulation disorder, major depressive disorder (MDD), persistent depressive disorder (dysthymia), premenstrual dysphoric disorder, substance/medication-induced depressive disorder, depressive disorder due to another medical condition, other specified depressive disorder, unspecified depressive disorder.

EPIDEMIOLOGY

Incidence

In United States, 6.9% of 18 years of age or older in past year.

Prevalence

- 16.2% lifetime risk of having MDD.
- Patients can relapse; risk decreases with longer remission period but increases in patients with severe episodes, episodes at a younger age, and multiple episodes.
- Predominant age
  - Low risk before early teens but highest prevalence in teens and young adults.
- Predominant gender
  - Females > males (2:1).

ETIOLOGY AND PATHOPHYSIOLOGY

There are diverse theories on the pathophysiology of depression.

- Monoamine-deficiency hypothesis: symptoms related to decreased levels of norepinephrine (dullness and lethargy) and serotonin (irritability, hostility, and suicidal ideation) in multiple regions of the brain; other neurotransmitters.
involved include dopamine, acetylcholine, γ-aminobutyric acid (GABA), glutamate.

- **Stress/hypothalamic–pituitary–adrenal axis**: Abnormalities in cortisol response lead to depression; elevated cortisol levels can be associated with depression, but cortisol tests are not indicated for diagnosis.
- Depression as inflammatory disorder: Proinflammatory marker levels are reported to be elevated in depressed patients. Examples of these markers are C-reactive protein (CRP), interleukin (IL)-6, IL-1, and tumor necrosis factor-α (TNF-α).
- Hormones and depression: Reduction in thyroid hormone, estrogen levels, and elevation in vasopressin has been seen in people with depression.
- Other areas of research interest: abnormal circadian rhythms; impaired synthesis/metabolism of neurotransmitters
- Environmental factors and learned behavior may affect neurotransmitters and/or have an independent influence on depression.

**Genetics**

Multiple gene loci place a person at increased risk when faced with environmental stressor; twin studies suggest 37% concordance (1).

**RISK FACTORS**

- Female > male (2:1)
- Severity of first episode
- Persistent sleep disturbances
- Presence of chronic disease(s), recent myocardial infarction (MI), cardiovascular accident (CVA)
- Strong family history (depression, bipolar, suicide, substance abuse), spouse with depression
- Childhood trauma/maltreatment
- Substance abuse and dependence, domestic abuse/violence
- Losses, stressors, unemployment
- Single, divorced, or unhappily married

**COMMONLY ASSOCIATED CONDITIONS**

- Bipolar disorder, cyclothymic disorder, grief reaction, anxiety disorders, somatoform disorders, schizophrenia/schizoaffective disorders
- Medical comorbidity
- Substance abuse
DIAGNOSIS

HISTORY

DSM-5 requires all of the following criteria for MDD:

- **Criterion A:** ≥5 of the following symptoms present nearly every day during the same 2-week period, with at least 1 of the 5 being either depressed mood or loss of interest or pleasure:
  - Depressed mood most of the day by subjective report or observation from other people
  - Diminished interest or pleasure in all activities most of the day by subjective report or observation from other people
  - Decreased or increased appetite or significant weight loss without dieting or weight gain
  - Insomnia or hypersomnia
  - Fatigue or energy loss
  - Restlessness, irritability, or withdrawal observable by others
  - Worthlessness, excessive/inappropriate guilty feelings
  - Diminished thinking/concentration, poor memory, indecisiveness
  - Recurrent thoughts of death, suicidal ideations, or suicide attempt or a specific plan for committing suicide

- **Criterion B:** Symptoms cause significant social, occupational, or functional distress or impairment.

- **Criterion C:** Symptoms not attributable to substance effects or other medical conditions

*Geriatric Considerations*

- Difficult to diagnose due to medical comorbidity
- Can present with memory difficulties as chief complaint; treatment reverses memory difficulty.
- Can be the initial presentation of irreversible dementia
- Geriatric Depression Scale (GDS 15) improves rate of diagnosis in primary care setting (2,3)[A].

*Pediatric Considerations*

- Can present as irritable or angry rather than sad or dejected
- Failure to make expected weight gains can substitute weight loss symptom above.
A sudden and remarkable drop in grades can indicate difficulty concentrating.
Can present with separation anxiety

**PHYSICAL EXAM**
Complete physical with focus on endocrine, cardiac, neurologic, and psychiatric (affect, attention, cognition, memory); look for evidence of contributing medical or neurologic disorder.

**DIFFERENTIAL DIAGNOSIS**
- Psychiatric: depressed phase of bipolar disorder—inquire if prior mania, family or personal history of bipolar disorder, prior agitation, or excitement with antidepressant medication. If positive, monitor carefully for mood elevation or destabilization, adjustment disorder, and bereavement.
- Neurologic or degenerative CNS diseases, dementias
- Medical comorbidity: adrenal disease, thyroid disorders, diabetes, metabolic abnormalities (hypercalcemia), liver/renal failure, malignancy, chronic fatigue syndrome, fibromyalgia, lupus
- Nutritional: pernicious anemia, pellagra
- Medications/substances: abuse, side effects, overdose, intoxication, dependence, withdrawal

**DIAGNOSTIC TESTS & INTERPRETATION**
- A clinical diagnosis made by eliciting personal, family, social, and psychosocial factors
  - The Patient Health Questionnaire-9 (PHQ-9) is a brief screening test valid for diagnosis of MDD in primary care settings (3)[A].
  - Other validated standard rating scales include the following: Beck Depression Inventory, Zung, GDS 15, and so forth. Rating scales are also useful to track response to treatment over time (3)[A].
  - Rule out hypothyroidism, anemia, and metabolic disorders with TSH, CBC, and comprehensive metabolic panel (CMP).
  - Order urine drug screen if symptoms suggest intoxication.

**TREATMENT**
American Psychiatric Association (APA) 2010 guidelines recommend phasic approach: acute phase (first 3 months), continuation phase (4 to 9 months), and maintenance (9 months until discontinuation) (4)[A].
• Acute phase
  – Full evaluation, including risk to self and others, with selection of appropriate treatment setting (hospitalization for those at risk of harm to self or others or so incapacitated as to be unable to take care of themselves and/or who have no support system to assist with treatment)
  – Goal should be symptom remission, with intervention based on clinical picture, including patient’s preference, availability of services.
  – For mild to moderate depression, psychotherapies (individual, interpersonal, or cognitive-behavioral therapy [CBT]) and/or medication are recommended.
  – For refractory/severe depression, medication is indicated.
  – For patients not responding to medication alone, CBT should be added.
  – Continue to increase dosage q3–4wk until symptoms in remission. Full medication effect is complete in 4 to 6 weeks. Augmentation with second medication may be necessary.
  – See within 2 to 4 weeks of starting medication and q2wk until improvement and then monthly to monitor medication changes.
  – ≥6 visits recommended for monitoring (younger patients, those at high suicide risk, see within 1st week, and follow frequently)
• Continuation/maintenance phase
  – Regular visits to monitor for signs of relapse, q3–6mo if stable; depression rating scales should be used.
  – Once remission achieved, dosage should be continued for at least 6 to 9 months to reduce relapse; CBT is also effective in reducing relapse (visits typically q2wk).
  – If/when drug discontinuation is considered, medications should be tapered gradually (weeks to months).

ISSUES FOR REFERRAL
• Refer immediately for active suicidal ideation, severe self-neglect, and significant risk of self-harm.
• Failed response to medication, suspected bipolar or personality disorder.

MEDICATION
• Effectiveness of medications is comparable between/within classes; selection should be based on provider familiarity and patient characteristics/prefereces (5)[A].
• Selective serotonin reuptake inhibitors (SSRIs) and tricyclic antidepressants
(TCAs) are effective, but TCAs are second line due to side effects and lethality in overdose. Tolerability is much poorer than newer antidepressants.

- First-line SSRIs* (starting dose; usual dose)
  - Fluoxetine (Prozac): 20 mg/day; 20 to 60 mg/day; FDA-approved for teens
  - Sertraline (Zoloft): 50 mg/day; 50 to 200 mg/day
  - Paroxetine (Paxil): 10 mg/day; 20 to 50 mg/day
  - Paroxetine CR (Paxil CR): 12.5 mg/day; 25.0 to 62.5 mg/day
  - Citalopram (Celexa): 20 mg/day; 20 to 40 mg/day (higher doses not advised; ECG monitoring for doses >40 mg/day due to increased risk of QTc prolongation)
  - Escitalopram (Lexapro): 10 mg/day; 10 to 20 mg/day
  - Precautions: Abrupt discontinuation may result in withdrawal symptoms (i.e., dizziness, nausea, headache, paresthesia).
  - Fluoxetine, paroxetine may raise serum levels of other drugs; escitalopram, sertraline have minimal to no drug interactions.
  - Common side effects: sexual dysfunction (20%), nausea, GI upset, dizziness, insomnia, headache; typically resolve in the 1st week
  - Less common side effects: drowsiness, weight gain, emotional blunting, dry mouth
  - *Lower starting doses for elderly, adolescents, those with comorbid conditions, panic disorder, significant anxiety, or hepatic conditions
  - Paroxetine is Category D for pregnancy with increased risk of teratogenicity in 1st trimester.

- Others (starting dose; usual dose)
  - Venlafaxine (Effexor, Effexor XR): 37.5 mg/day; 300 mg/day
  - Bupropion XL (Wellbutrin XL): 150 mg/day; 300 to 450 mg/day (precautions: powers seizure threshold at doses >450 mg/day)
  - Duloxetine (Cymbalta): 30 mg/day; 60 to 120 mg/day
  - Desvenlafaxine (Pristiq): 50 to 100 mg/day
  - Vilazodone: (Viibryd) start 10 mg/day; usual target 40 mg/day
  - Vortioxetine: (Trintellix) start 5 mg/day; target dose 20 mg/day
  - Levomilnacipran: (Fetzima) start 20 mg/day; target dose 40 to 120 mg/day

**Second Line**

- TCAs (starting dose; usual dose)
  - Amitriptyline (Elavil): 25 to 50 mg/day; 100 to 300 mg/day
  - Nortriptyline (Pamelor): 25 mg/day; 50 to 150 mg/day
  - Doxepin (Sinequan): 25 to 50 mg/day; 100 to 300 mg/day
  - Imipramine (Tofranil, Tofranil-PM): 25 to 50 mg/day; 100 to 300 mg/day
– Desipramine (Norpramin): 25 to 50 mg/day; 100 to 300 mg/day
– Precautions: advanced age, glaucoma, benign prostate hyperplasia, hyperthyroidism, cardiovascular disease, liver disease, monoamine oxidase inhibitor (MAOI) treatment, potential for fatal overdose, arrhythmia, worsening glycemic control, SSRIs recommended for patients with diabetes (4)[A]
– Common side effects: dry mouth, blurred vision, constipation, urinary retention, tachycardia, confusion/delirium; elderly particularly susceptible
– $\alpha_2$-Antagonists (sedating, appetite stimulant) (starting dose; usual dose)
  – Mirtazapine (Remeron): 15 mg/day; 15 to 45 mg/day
– Atypical antipsychotics
  – Adjunctive treatment: aripiprazole or quetiapine
  – Treatment-resistant depression (TRD): olanzapine
– Significant side effects: dyslipidemia, hypertriglyceridemia, glucose dysregulation, diabetes mellitus, hyperprolactinemia, tardive dyskinesia, neuroleptic malignant syndrome, QTc prolongation (6)[A]
– Recommended for depression with psychotic features; consult with psychiatrist and consider carefully before starting (4)[A].

Significant potential interactions
– TCAs: amphetamines, barbiturates, clonidine, epinephrine, ethanol, norepinephrine
– All antidepressants: Allow 14-day washout period before starting MAOIs.
– MAOIs: not recommended in primary care. Significant drug and food interactions limit use.

**ALERT**

– Black box warning: increased risk of suicidality in children, adolescents, and young adults up to age 25 years who are treated with antidepressants. Although this has not been extended to adults, suicide risk assessments are warranted for all patients.
– Serotonin syndrome—a rare but potentially lethal complication from rapid increase in dose or new addition of medication with serotonergic effects
– Caution with personal or family history of bipolar disorder: Antidepressants can precipitate mania.

**Pregnancy Considerations**

SSRIs: fluoxetine, sertraline, and bupropion considered safe in pregnancy (paroxetine, Category D; other SSRIs, Category C)
ADDITIONAL THERAPIES

- CBT
  - CBT is a type of psychotherapy that focuses on how persons perceive a situation and helping them to change their unhelpful thinking and behavior, which leads to enduring improvement in their mood and functioning. It is more focused on the present, more limited in duration, and more problem-solving oriented.
- Electroconvulsive therapy (ECT) for refractory cases
- Repetitive transcranial magnetic stimulation (rTMS) may be helpful for TRD (6)[A].

COMPLEMENTARY & ALTERNATIVE MEDICINE

Used in mild depression but not regulated by FDA nor recommended by APA

- Hypericum perforatum (St. John’s wort): multiple drug interactions; not safe in pregnancy
- Data do not support S-adenosyl-l-methionine (SAMe) or acupuncture.

ONGOING CARE

PATIENT EDUCATION

- Depression is a common medical illness, not a character defect.
- Emphasize the need for long-term treatment and follow-up, which includes lifestyle changes.
- Exercise, good sleep hygiene, nutrition, and decreased use of tobacco and alcohol are recommended.

PROGNOSIS

- 70% show significant improvement.
- Of patients with a single depressive episode, 50% will relapse over their lifetime.

COMPLICATIONS

- Suicide
- Substance misuse
- Weight gain
REFERENCES

SEE ALSO

Algorithms: Depressed Mood Associated with Medical Illness; *Depressive Episode, Major*

CODES

**ICD10**

- F32.9 Major depressive disorder, single episode, unspecified
- F33.9 Major depressive disorder, recurrent, unspecified
- F34.1 Dysthymic disorder

CLINICAL PEARLS

- Therapeutic alliance is important to treatment success.
- Given the high recurrence rates, long-term treatment is often necessary.
DEPRESSION, ADOLESCENT
Joseph B. Gladwell, MD • Stephen J. Knox, MD

BASICS
DESCRIPTION
- DSM-5 depressive disorders include disruptive mood dysregulations disorder (DMDD), major depressive disorder (MDD), persistent depressive disorder, premenstrual dysphoric disorder, substance/medication-induced depressive disorder, and other nonspecific depression. This chapter focuses on MDD.
- MDD is a primary mood disorder characterized by sadness and/or irritable mood with impairment of functioning; abnormal psychological development; and a loss of self-worth, energy, and interest in typically pleasurable activities.
- DMDD is characterized by having severe, recurrent outbursts along with persistent irritability and anger.
- Persistent depressive disorder is characterized by a depressed mood for most days lasting at least 1 year in a child/adolescent.
- Adolescents with depression are likely to suffer broad functional impairment across social, academic, family, and occupational domains, along with a high incidence of relapse and a high risk for substance abuse and other psychiatric comorbidity.

EPIDEMIOLOGY
Incidence
During adolescence, the cumulative probability of depression ranges from 5% to 20% (1).

Prevalence
- MDD: 2–11% of adolescents; twice as common in females
- DMDD: 2–5%; more prominent in males

ETIOLOGY AND PATHOPHYSIOLOGY
- Unclear; low levels of neurotransmitters (serotonin, norepinephrine) may produce symptoms; decreased functioning of the dopamine system also contributes.
- External factors may affect neurotransmitters independently.
Hormonal changes during puberty likely contribute as well.

**Genetics**
- Offspring of parents with depression have 3 to 4 times increased rates of depression compared with offspring of parents without mood disorder (1).
- Family studies indicate that anxiety in childhood tends to precede adolescent depression (1).

**RISK FACTORS**
- Increased 3 to 6 times if first-degree relative has a major affective disorder; 3 to 4 times in offspring of parents with depression
- Prior depressive episodes
- History of low self-esteem, anxiety disorders, attention deficit hyperactivity disorder (ADHD), and/or learning disabilities
- Increased screen time
- Female gender
- Low socioeconomic status
- General stressors: adverse life events, difficulties with peers, loss of a loved one, academic difficulties, abuse, chronic illness, and tobacco abuse

**GENERAL PREVENTION**
Insufficient evidence for universal depression prevention programs (psychological and social)
- Some evidence indicates that child and adolescent mental health can be improved by successfully treating maternal depression (1)[A].
- Agency for Healthcare Research and Quality (AHRQ) recommends the screening of adolescents (12 to 18 years of age) for MDD when systems are in place to ensure accurate diagnosis, appropriate treatment, and follow-up.

**COMMONLY ASSOCIATED CONDITIONS**
- 2/3 of adolescents with depression have at least one comorbid psychiatric disorder.
- 20% meet the criteria for generalized anxiety disorder.
- Also associated with behavioral disorders, substance abuse, eating disorders

**DIAGNOSIS**
HISTORY

- Adolescents may present with medically unexplained somatic complaints (fatigue, irritability, headache).
- Based on DSM-5 criteria, ≥5 of the following symptoms have been present during the same 2-week period and represent a change from previous functioning: At least one of the symptoms is either depressed mood or loss of interest or pleasure:
  - Criterion A
    - Depressed mood most of the day either subjective report or observation by others (feelings of sadness, emptiness, hopelessness; in children, can be irritability)
    - Markedly diminished interest or pleasure in all activities most of the day
    - Significant weight loss when not dieting or weight gain (>5% body weight in 1 month)
    - Insomnia or hypersomnia
    - Psychomotor agitation or retardation nearly every day
    - Fatigue or loss of energy
    - Feelings of worthlessness or excessive or inappropriate feelings of guilt nearly every day
    - Diminished ability to think or concentrate, or indecisiveness, nearly every day
    - Recurrent thoughts of death, recurrent suicidal ideation, or attempt
  - Criterion B. Symptoms cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.
  - Criterion C. Episode is not attributable to substances’ effects or other medical conditions.
  - Criterion D. Episode is not better explained by a schizoaffective, schizophreniform, or delusional disorder.
  - Criterion E. There has never been a manic or hypomanic episode.

PHYSICAL EXAM

- Psychomotor retardation/agitation may be present.
- Clinicians should carefully assess patients for signs of self-injury (such as wrist lacerations) or abuse.

DIFFERENTIAL DIAGNOSIS

- Normal bereavement
- Substance-induced mood disorder
• Bipolar disorder
• Mood disorder secondary to a medical condition (thyroid, anemia, vitamin deficiency, diabetes)
• Organic CNS diseases
• Malignancy
• Infectious mononucleosis or other viral diseases
• ADHD, posttraumatic stress disorder (PTSD), eating disorders, and anxiety disorders
• Sleep disorder

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
May be used to rule out other diagnoses (i.e., CBC, TSH, glucose, mono spot, and urine drug)

**Follow-Up Tests & Special Considerations**
None with sufficient sensitivity/specificity for diagnosis

**Diagnostic Procedures/Other**

- Depression is primarily diagnosed after a formal interview, with supporting information from caregivers and teachers.
- Standardized tests are useful as screening tools and to monitor response to treatment but should not be used as the sole basis for diagnosis:
  - Beck Depression Inventory II (BDI-II): ages 13+ to 18 years (1)[A]
  - Child Depression Inventory 2 (CDI2): ages 7 to 17 years
  - Center for Epidemiologic Studies: Depression scale for Children (CES-D): ages 6 to 17 years
  - Patient Health Questionnaire-9 (PHQ-9): ages 13 to 17 years with ideal cut point of 11 or higher (instead of 10 used for adults)
- The USPSTF concludes that the current evidence is insufficient to assess the balance of benefits and harms of screening for suicide risk in adolescents in a primary care setting.

**TREATMENT**

**GENERAL MEASURES**

- Active support and monitoring with short validated scales should be used in
mild cases for 6 to 8 weeks.
- Psychotherapy and/or medication should be considered if active support and monitoring do to improve symptoms (2)[A].
- Treatment should include psychoeducation, supportive management, and family and school involvement (3)[C].
- Initial management should include treatment planning and ensuring that the patient and family is comfortable with the plan (3)[C].
- A Cochrane review showed that there was no significant difference between remission rates for adolescents treated with cognitive-behavioral therapy (CBT) versus medication or combination therapy immediately postintervention (4)[A].
- A multitreatment meta-analysis showed that combined fluoxetine/CBT had higher efficacy than monotherapies, but other selective serotonin reuptake inhibitors (SSRIs), such as sertraline and escitalopram, were better tolerated (2)[A].

### MEDICATION

#### First Line
- Fluoxetine: for depression in age >8 years. Starting dose 10 mg/day; effective dose 10 to 60 mg/day. The most studied SSRI, with the most favorable effectiveness and safety data. It has the longest half-life of the SSRIs and is not generally associated with withdrawal symptoms between doses or upon discontinuation.
- Escitalopram: for depression in age >12 years. Starting dose of 5 mg/day; effective dose of 10 to 20 mg/day
- Citalopram: for depression in age >12 years. Starting dose of 10 mg/day; effective dose of 10 to 40 mg/day (5)[A]
- Sertraline: for depression in age >12 years. Starting dose of 25 mg/day; effective dose of 50 to 200 mg/day (5)[A]
- Can titrate dose every 1 to 2 weeks if no significant adverse effects emerge (headaches, GI upset, insomnia, agitation, behavior activation, suicidal thoughts) (5)[A]
- SSRI black box warning to monitor for worsening condition, behavior changes, and suicidal thoughts (5)[A]
- Antidepressant treatment should be continued for 6 to 12 months at full therapeutic dose after the resolution of symptoms at the same dosage (3)[C].
- Given their rates of increased drug metabolism, adolescents may be at higher risk for withdrawal symptoms from SSRIs than adults; if these are present,
twice-daily dosing may be considered (2)[A].
- All other SSRIs except fluoxetine should be slowly tapered when discontinued (2)[A].

**Pediatric Considerations**
- Tricyclic antidepressants (TCAs) have not been proven to be effective in adolescents and should not be used (2)[A].
- Paroxetine (SSRI): Avoid use due to short half-life, associated withdrawal symptoms, and higher association with suicidal ideation.

**ISSUES FOR REFERRAL**
- Collaborative care interventions between mental health and primary care have a greater improvement in depressive symptoms after 12 months (5)[B].
- Primary care providers should provide initial treatment of pediatric depression. Refer to a child psychiatrist for severe, recurrent, or treatment-resistant depression or if the patient has comorbidities.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Physical exercise and light therapy may have a mild to moderate effect.
- There is some evidence that online therapies may be beneficial in treatment of adolescent depression.
- St. John’s wort, acupuncture, S-adenosylmethionine, and 5-hydroxytryptophan have not been shown to have an effect or have inadequate studies to support use in adolescent depression.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
If severely depressed, psychotic, suicidal, or homicidal, one-on-one supervision may be needed.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*
- Systematic and regular tracking of goals and outcomes from treatment should be performed, including assessment of depressive symptoms and functioning in home, school, and peer settings (5)[A].
- Diagnosis and initial treatment should be reassessed if no improvement is noted after 6 to 8 weeks of treatment (5)[A].
- The goal of treatment should be sustained symptom remission and restoration of full function.
- Educate patients and family members about the causes, symptoms, course and treatments of depression, risks of treatments, and risk of no treatment.

**PROGNOSIS**
- 60–90% of episodes remit within 1 year.
- 50–70% of remissions develop subsequent depressive episodes within 5 years.
- Depression in adolescence predicts mental health disorders in adult life, psychosocial difficulties, and ill health.
- Baseline symptom severity and comorbid anxiety may impact treatment response.
- Parental depression at baseline significantly affects intervention effects.

**COMPLICATIONS**
- Treatment-induced mania, aggression, or lack of improvement in symptoms
- School failure/refusal
- One-third of adolescents with suicidal ideation go on to make an attempt.

**REFERENCES**

5. Reeves GM, Riddle MA. A practical and effective primary care intervention

**ADDITIONAL READING**

**CODES**

**ICD10**

- F32.9 Major depressive disorder, single episode, unspecified
- F33.9 Major depressive disorder, recurrent, unspecified
- F32.8 Other recurrent depressive disorders

**CLINICAL PEARLS**

- Adolescent depression is underdiagnosed and often presents with irritability and anhedonia.
- Fluoxetine is the most studied FDA-approved for treatment of adolescent depression.
- Escitalopram, citalopram, and sertraline are also FDA-approved antidepressants.
- CBT combined with fluoxetine is efficacious for adolescents with major depression.
- Paroxetine and TCAs should not be used to treat adolescent depression.
- Referral to a child psychiatrist is appropriate for complex cases or treatment-resistant depression.
- Monitor all adolescents with depression for suicidality, especially during the first month of treatment with an antidepressant.
DEPRESSION, GERIATRIC

Fozia Akhtar Ali, MD • Nneka I. Okafor, MD, MPH

BASICS

DESCRIPTION

- Depression is a primary mood disorder characterized by a depressed mood and/or a markedly decreased interest or pleasure in normally enjoyable activities most of the day, almost every day for at least 2 weeks, and causing significant distress or impairment in daily functioning with at least four other symptoms of depression.
- Depression is not a normal result of aging.

EPIDEMIOLOGY

Prevalence rates among the elderly vary largely depending on the specific diagnostic instruments used and their current health and/or home environment:

- 2–10% of community-dwelling elderly
- 5–10% seen in primary care clinics
- 10–37% of hospitalized elderly patients
- 12–27% of nursing home residents

ETIOLOGY AND PATHOPHYSIOLOGY

- Significant gaps exist in the understanding of the underlying pathophysiology.
- Ongoing research has identified several possible mechanisms, including the following:
  - Monoamine transmission and associated transcriptional and translational activity
  - Epigenetic mechanisms and resilience factors
  - Neurotrophins, neurogenesis, neuroimmune systems, and neuroendocrine systems
  - Depression appears to be a complex interaction between heritable and environmental factors.

RISK FACTORS

- General
  - Female sex
– Lower socioeconomic status
– Widowed, divorced, or separated marital status
– Chronic physical health condition(s)
– History of mental health problems
– Family history of depression
– Death of a loved one
– Caregiving
– Social isolation
– Functional/cognitive impairment
– Lack/loss of social support
– Significant loss of independence
– Uncontrolled or chronic pain
– Insomnia/sleep disturbance

- Prevalence of depression in medical illness
  – Stroke (22–50%)
  – Cancer (18–50%)
  – Myocardial infarction (15–45%)
  – Parkinson disease (10–39%)
  – Rheumatoid arthritis (13%)
  – Diabetes mellitus (5–11%)
  – Alzheimer dementia (5–15%)

- Suicide
  – Suicide is the 11th leading cause of death in the United States for all ages.
  – Elderly account for 24% of all completed suicides.
  – Suicide rates are highest for males aged >85 years (rate 55/100,000).

**DIAGNOSIS**

**HISTORY**

- Depressed mood most of the day, nearly every day, and/or loss of interest/pleasure in life for at least 2 weeks
- Other common symptoms include the following:
  – Feeling hopeless, helpless, or worthless
  – Insomnia and loss of appetite/weight (alternatively, hypersomnia with increased appetite/weight in atypical depression)
  – Fatigue and loss of energy
  – Somatic symptoms (headaches, chronic pain)
- Neglect of personal responsibility or care
- Psychomotor retardation or agitation
- Diminished concentration, indecisiveness
- Thoughts of death or suicide

- Screening with “SIGECAPS”
  - Sleep: changes in sleep habits from baseline, including excessive sleep, early waking, or inability to fall asleep
  - Interest: loss of interest in previously enjoyable activities (anhedonia)
  - Guilt: excessive or inappropriate guilt that may or may not focus on a specific problem or circumstance
  - Energy: perceived lack of energy
  - Concentration: inability to concentrate on specific tasks
  - Appetite: increase/decrease in appetite
  - Psychomotor: restlessness and agitation or the perception that everyday activities are too strenuous to manage
  - Suicidality: desire to end life or hurt oneself, harmful thoughts directed internally, recurrent thoughts of death or thoughts of homicidality

**PHYSICAL EXAM**
Mental status exam, thorough neurologic exam, and general physical exam to rule out other conditions

**DIFFERENTIAL DIAGNOSIS**
Concurrent medical conditions, cognitive disorders, and medications may cause symptoms that mimic depression:

- Medical conditions: hypothyroidism, vitamin B$_{12}$ or folate deficiency, liver or renal failure, cancers, stroke, sleep disorders, electrolyte imbalances, Cushing disease, chronic fatigue syndrome
- Dementia and neurodegenerative disorders
- Delirium
- Medication-induced: interferon-α, β$_2$-blockers, isotretinoin, benzodiazepines, glucocorticoids, levodopa, clonidine, H$_2$ blockers, baclofen, varenicline, metoclopramide, reserpine
- Psychiatric disorders: adjustment disorder with depressed mood, grief reaction, bipolar disorder, dysthymic disorder, anxiety disorders, substance abuse–related mood disorders, psychotic disorders

**DIAGNOSTIC TESTS & INTERPRETATION**
**Initial Tests (lab, imaging)**

Initial laboratory evaluation is done primarily to rule out potential medical factors that could be causing symptoms.

- Thyroid-stimulating hormone (hypothyroidism)
- CBC with differential (anemia, infection)
- Vitamin B₁₂, folic acid (deficiencies)
- Urinalysis (urinary tract infection, glucosuria)
- Comprehensive metabolic panel (uremia, hypo- or hyperglycemia, hypo- or hypernatremia, hypercalcemia, liver failure)
- Urine drug screen
- 24-hour urine-free cortisol (Cushing disease)

**Follow-Up Tests & Special Considerations**

Additional testing for possible confounding medical and cognitive disorders, as warranted; may consider a sleep study for patients with decreased energy, sleep disturbances, changes in concentration, or psychomotor activity.

**Diagnostic Procedures/Other**

Validated screening tools and rating scales:

- Geriatric Depression Scale: 15- or 30-point scales
- Patient Health Questionnaire (PHQ-2 or PHQ-9)
- Hamilton Depression Rating Scale
- Beck Depression Inventory
- Cornell Scale for Depression in Dementia (1)[A]

**TREATMENT**

Although response alone, usually interpreted as a 50% reduction in symptoms, can be clinically meaningful, the goal is to treat patients to the point of remission (i.e., essentially the absence of depressive symptoms).

**GENERAL MEASURES**

- Lifestyle modifications:
  - Increase physical activity.
  - Improve nutrition.
  - Encourage social interactions.
– Exercise: may be beneficial for depression in the elderly population (2)[A]

• Psychotherapy: Studies do show some benefit in depressed elderly patients (3)[B]:
  – Cognitive-behavioral therapy
  – Problem-solving therapy
  – Interpersonal therapy
  – Psychodynamic psychotherapy

**MEDICATION**

• Typically, more conservative initial dosing and titration of antidepressants in the elderly, starting with 1/2 of the usual initiation dose and increasing within 2 to 4 weeks, as tolerated

• Continue titrating dose every 2 to 4 weeks, as appropriate, to reach an adequate treatment dose.

**First Line**

• SSRIs have been found to be effective in treating depression in the elderly and are considered first line in pharmacotherapy for depression (2)[A].

• No single SSRI clearly outperforms others in the class; choice of medication often reflects side effect profile or practitioner familiarity (4)[A]:
  – Citalopram: Start at 10 mg/day; treatment range 10 to 20 mg/day
  – Sertraline: Start at 25 to 50 mg/day; treatment range 50 to 200 mg/day
  – Escitalopram: Start at 10 mg/day; treatment range 10 to 20 mg/day
  – Fluoxetine: Start at 10 mg/day; treatment range 20 to 60 mg/day
  – Paroxetine: Start at 10 mg/day; treatment range 20 to 40 mg/day

• SSRIs should not be used concomitantly with monoamine oxidase inhibitors (MAOIs).

• Common side effects—increased risk of falls, nausea, diarrhea, sexual dysfunction

**Second Line**

Atypical antidepressants: more effective than placebo in treatment of depression in the elderly, although additional studies are needed to better delineate patient factors that determine response:

• Bupropion (sustained/twice a day and extended/once daily available): Start at 150 mg/day. Increase dose in 3 to 4 days. Treatment range 300 to 450 mg/day. Avoid in patients with elevated seizure risk, tremors, or anxiety (5)[A].

• Venlafaxine (immediate- and extended-release available): Start at 37.5 mg/day
extended release and titrate weekly. Treatment range 150 to 225 mg/day; may be associated with elevated BP at higher doses (5)[C]

- Duloxetine: Start at 20 to 30 mg/day. Treatment range 60 to 120 mg/day. Also, duloxetine may be associated with elevated BP (5)[A].
- Mirtazapine: Start at 7.5 to 15 mg nightly. Treatment range 30 to 45 mg/day; can produce problems with dry mouth, weight gain, sedation, and cognitive dysfunction (5)[A]
- Desvenlafaxine: 50 mg/day in AM; higher doses do not confer additional benefit; 50 mg every other day if CrCl <30 mL/min (5)[A]

**ISSUES FOR REFERRAL**
Depression with suicidal ideation, psychotic depression, bipolar disorder, comorbid substance abuse issues, polypharmacy, severe or refractory illness

**ADDITIONAL THERAPIES**
- For patients who have not responded to initial SSRI trial:
  - Switch to a different SSRI medication, switch to an atypical antidepressant, or augment initial antidepressant with bupropion.
- 2nd-generation antipsychotic agents (5)[C]:
  - Aripiprazole: 2 to 5 mg/day. Treatment range 5 to 15 mg/day; can produce sedation, weight gain, increased cholesterol levels
  - Should only be used for augmentation in conjunction with other antidepressant medications
- Tricyclic antidepressants (TCAs):
  - Nortriptyline: 25 to 50 mg nightly. Treatment range 75 to 150 mg nightly; can produce anticholinergic effects, weight gain, increase risk of falls (5)[C]
    - TCAs have been shown to be effective in treating depression in the elderly. However, they are difficult for elderly patients to tolerate due to side effect profile and are potentially lethal in overdose, limiting their use as initial treatment agents (6)[A].
  - MAOIs also appear more effective than placebo in the treatment of depression in the elderly. They are not used frequently in clinical practice due to potential side effects and necessary dietary restrictions (6)[A].
- Although not FDA-approved, buspirone, lithium, or triiodothyronine are sometimes used off-label to augment a primary antidepressant.
- Evidence for benefit of antidepressants in the treatment of depression in patients with dementia is equivocal. Consideration should be made for a limited trial with close monitoring for symptom improvement or side effects
and used only in patients with severe symptoms.

- Electroconvulsive therapy (ECT): has been shown to produce remission of depressive symptoms in the elderly. It should be considered as an initial option for patients with severe or psychotic depression.

### COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture: equally beneficial as counseling
- St. John’s wort may have minimal benefit and has numerous drug interactions.
- Tryptophan and hydroxytryptophan: 150 to 300 mg/day; possible efficacy, additional investigation required

### ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Inpatient care is indicated in cases of imminent safety risk (e.g., acutely suicidal patients) or for those patients unable to care adequately for themselves due to depression.

### ONGOING CARE

#### FOLLOW-UP RECOMMENDATIONS

Due to the delay of benefit following initiation of antidepressant therapy, it is necessary to ensure open communication with the patient to prevent premature discontinuation of therapy. An adequate explanation of potential side effects with instructions to call the office before discontinuing therapy is imperative.

**Patient Monitoring**

- A patient with severe depression who exhibits suicidality will require admission to an appropriate facility.
- Monitor for worsening anxiety symptoms or increase in suicidality especially in the week following initiation of antidepressants.

### DIET

No dietary restrictions are necessary, except for patients taking MAOIs, which necessitates dietary restriction of foods high in tyramine (i.e., certain cheeses and wines).
PATIENT EDUCATION

- Depression is a treatable illness.
- Medications may need to be taken for at least 2 to 4 weeks before any beneficial effect is noted and may take 6 to 8 weeks to reach maximum efficacy.
- Depression is often a recurring illness.
- National Suicide Prevention Lifeline at 1-800-273-TALK (8255) is a free, 24-hour hotline available to anyone in suicidal crisis or emotional distress. Calls will be routed to the nearest crisis center.

PROGNOSIS

- Treatment outcomes in the elderly may be worse than in the general population, possibly mediated by physical comorbidities and other factors.
- Depending on the population studied and specific clinical measures used, estimates vary for initial clinical response and remission (between 30% and 70%).

COMPLICATIONS

- Impairment in social, occupational, or interpersonal functioning
- Difficulty performing activities of daily living and self-care
- Increase in medical services utilization and increased costs of care
- Suicide

REFERENCES

SEE ALSO
Algorithms: Depressed Mood Associated with Medical Illness; Depressive Episode, Major

CODES

ICD10
- F32.9 Major depressive disorder, single episode, unspecified
- F03 Unspecified dementia
- F43.21 Adjustment disorder with depressed mood

CLINICAL PEARLS
- Depression is not a normal part of aging.
- Depression in the elderly may be difficult to diagnose precisely due to medical and cognitive comorbidities.
- Depression may present primarily with cognitive dysfunction, and this may improve with treatment of the depression.
- A multidisciplinary approach to the treatment of depression is often the most efficacious.
- SSRIs are considered first-line therapy for safety and tolerability. A full remission may take upward of 12 weeks of treatment. Long-term treatment may be needed to prevent recurrence.
DEPRESSION, POSTPARTUM

Misty Stafford, MD • Nancy Byatt, DO, MBA, FAPM

BASICS
DESCRIPTION
- Major depressive disorder (MDD) that recurs or has its onset in the postpartum period
- May also occur in mothers adopting a baby or in fathers
- Postpartum depression (PPD) is similar to nonpregnancy depression (sleep disorders, anhedonia, psychomotor changes, etc.); it most often has its onset within the first 12 weeks postpartum yet can occur within 1 year after delivery.
- Different than postpartum “blues” (sadness and emotional lability), which is experienced by 30–70% of women and has an onset and resolution within first 10 days postpartum

EPIDEMIOLOGY

Incidence
14.5% of women have a new episode of major or minor depression during postpartum period (1).

Prevalence
- >50% of women with PPD enter pregnancy depressed or have an onset during pregnancy (2).
- As many as 19.2% women suffer from depression within 3 months postpartum period (3).

ETIOLOGY AND PATHOPHYSIOLOGY
- May be related to sensitivity in hormonal fluctuations, including estrogen; progesterone; and other gonadal hormones as well as neuroactive steroids; cytokines; hypothalamic–pituitary–adrenal (HPA) axis hormones; altered fatty acid, oxytocin, and arginine vasopressin levels; and genetic and epigenetic factors
- Multifactorial including biologic–genetic predisposition in terms of neurobiologic deficit, destabilizing effects of hormone withdrawal at birth,
inflammation, and psychosocial stressors

**RISK FACTORS**
- Previous episodes of PPD
- History of MDD
- MDD during pregnancy
- Anxiety during pregnancy
- History of premenstrual dysphoria
- Family history of depression
- Unwanted pregnancy
- Socioeconomic stress
- Low self-esteem
- Young maternal age
- Alcohol abuse
- Marital conflict
- Multiple births
- African Americans and Hispanics may have higher rates of PPD.
- Postpartum pain, sleep disturbance, and fatigue
- Recent immigrant status
- Increased stressful life events
- History of childhood sexual abuse
- Decision to decrease antidepressants during pregnancy
- Intimate partner violence (4)
- Prepregnancy diabetes

**GENERAL PREVENTION**
- Universal screening during pregnancy to allow for detection and treatment
- Screen using Edinburgh Postnatal Depression Scale during pregnancy and postpartum year.
- Postnatal visits, psychotherapy, and/or psychoeducation for high-risk women
- For women with depression during pregnancy, psychotherapy or treatment with antidepressants during pregnancy may prevent PPD.
- Depression care manager who provides education, routine telephone contact, and follow-up to engage women in treatment

**COMMONLY ASSOCIATED CONDITIONS**
- Bipolar mood disorder
- Depressive disorder not otherwise specified
Dysthymic disorder
Cyclothymic disorder
MDD

DIAGNOSIS

HISTORY
- Increased/decreased sleep
- Decreased interest in formerly compelling or pleasurable activities
- Guilt, low self-esteem
- Decreased energy
- Decreased concentration
- Increased/decreased appetite
- Psychomotor agitation or retardation
- Suicidal ideation

DIFFERENTIAL DIAGNOSIS
- Baby blues: not a psychiatric disorder; mood lability resolves within days.
- Postpartum psychosis: a psychiatric emergency
- Postpartum anxiety/panic disorder
- Postpartum obsessive-compulsive disorder
- Hypothyroidism
- Postpartum thyroiditis: can occur in up to 5.7% of patients in the United States and can present as depression (5)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Thyroid-stimulating hormone (TSH), B₁₂, folate, and Vitamin D

Diagnostic Procedures/Other
- Edinburgh Postnatal Depression Scale is a validated screening tool.
- The Patient Health Questionnaire-9 (PHQ-9) is a validated commonly used screening tool.
- Edinburgh Postnatal Depression Scale (partner version): to be completed by mother’s partner to obtain his/her view of mother’s depression
TREATMENT

GENERAL MEASURES

- Outpatient individual psychotherapy in combination with pharmacotherapy
- Interpersonal psychotherapy and cognitive behavioral therapy
- Strongly consider pharmacotherapy when symptoms are moderate or severe.
- Assess suicidal ideation.
- Assess homicidal ideation and thoughts of harming baby.
- Thoughts of harming the baby require immediate hospitalization.
- Visiting nurse services can provide direct observations of the mother regarding safety concerns and mother–child bonding.

MEDICATION

First Line

- For nonbreastfeeding women, selection of antidepressants is similar to nonpostpartum patients.
- Selective serotonin reuptake inhibitors (SSRIs) are generally effective and safe:
  - Fluoxetine (Prozac): 20 to 80 mg/day PO (most activating of all SSRIs)
  - Sertraline (Zoloft): 50 to 200 mg/day PO (mildly sedating)
  - Paroxetine (Paxil): 20 to 60 mg/day PO (sedating)
  - Citalopram (Celexa): 20 to 40 mg/day PO (FDA recommendation)
  - Escitalopram (Lexapro): 10 to 20 mg/day PO
- Tricyclic antidepressants (TCAs) are effective and less expensive yet also are lethal in overdose and have unfavorable side effects:
  - Avoid TCAs in mothers with a history of suicidal ideation.
- Bupropion (Wellbutrin): 150 to 450 mg/day PO in patients with depression plus psychomotor retardation and hypersomnia and with weight gain. Bupropion is less likely to cause weight gain or sexual dysfunction and is highly activating.
- Mirtazapine (Remeron): 15 to 45 mg/day PO at bedtime; may assist with sleep restoration and weight gain; no sexual dysfunction
- Serotonin-norepinephrine reuptake inhibitors (SNRIs)
  - Venlafaxine (Effexor XR): a dual-action antidepressant that blocks the reuptake of serotonin in doses of up to 150 mg/day and then blocks the reuptake of norepinephrine in doses of 150 to 450 mg/day PO
  - Duloxetine (Cymbalta): more balanced serotonin/norepinephrine reuptake
throughout dosing; 40 to 60 mg/day PO (doses >60 mg have not been demonstrated to be more effective)

- Desvenlafaxine (Pristiq): 50 mg/day PO

- Bipolar disorder requires treatment with mood stabilizer.

- Among breastfeeding mothers
  - Breastfeeding should generally not preclude treatment with antidepressants.
  - SSRIs and some other antidepressants are considered a reasonable option during breastfeeding.
  - All antidepressants are excreted in breast milk but are generally compatible with lactation.
  - Paroxetine and sertraline have lower translactal passage.
  - SSRIs and nortriptyline have a better safety profile.
  - Translactal passage is greater with fluoxetine and citalopram (4)[B].

- Start with low doses and increase slowly. Monitor infant for adverse side effects.

- Continuing an efficacious medication is preferred over switching antidepressants to avoid exposing the mother and infant to the risks of untreated PPD (4)[B].

- Breastfeeding women need additional education and support regarding the risks and benefits of use of antidepressants during breastfeeding.

- Consider negative effects of untreated PPD on infant and child development.

- Discussions of the treatment options with the patient and her partner when possible. Take into account the patient’s personal psychiatric history and previous response to treatment, the risks of no treatment or undertreatment, available data about the safety of medications during breastfeeding, and her individual expectations and treatment preferences.

**Second Line**

Consider switching to a different antidepressant or augmentation if patient has a lack of response. Electroconvulsive therapy (ECT) is an option for depressed postpartum women who do not respond to antidepressant medications, have severe or psychotic symptoms, cannot tolerate antidepressant medications, are actively engaged in suicidal self-destructive behaviors, or have a previous history of response to ECT (5)[B].

**ISSUES FOR REFERRAL**
- Obtain psychiatric consultation for patients with psychotic symptoms.
- Strongly consider immediate hospitalization if delusions or hallucinations are present.
- Hospitalization is indicated if mother’s ability to care for self and/or infant is significantly compromised.

**ADDITIONAL THERAPIES**
- Psychoeducation, including providing reading material for the patient and family
- Psychotherapy: Interpersonal psychotherapy, cognitive behavioral therapy, and psychodynamic psychotherapy have shown to be effective.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Breastfeeding has been associated with reduced stress and improved maternal mood.
- Infant massage, infant sleep intervention, exercise, and bright light therapy may be beneficial (5)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

**ALERT**
Obtain psychiatric consultation for patients with psychotic symptoms. If delusions or hallucinations are present, strongly consider immediate hospitalization. The psychotic mother should not be left alone with the baby.

- Admission criteria/initial stabilization: presence of suicidal or homicidal ideation and/or psychotic symptoms and/or thoughts of harming baby and/or inability to care for self or infant, severe weight loss
- Discharge criteria
  - Absence of suicidal or homicidal ideation and/or psychotic symptoms and/or thoughts of harming the baby
  - Mother must be able to care for self and infant.

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Collaborative care approach, including primary care visits and case manager follow-ups
- Consultation with the infant’s doctor, particularly if the mother is breastfeeding while taking psychotropic medications

DIET

- Good nutrition and hydration, especially when breastfeeding
- Mixed evidence to support the addition of multivitamin with minerals and omega-3 fatty acids

PATIENT EDUCATION

- *This Isn’t What I Expected: Overcoming Postpartum Depression*, by Karen R. Kleiman and Valerie Davis Raskin
- *Down Came the Rain: My Journey Through Postpartum Depression*, by Brooke Shields, 2005
- *Behind the Smile: My Journey Out of Postpartum Depression*, by Marie Osmond, Marcia Wilkie, and Judith Moore, 2001
- Web resources
  - Postpartum Support International: [http://www.postpartum.net/](http://www.postpartum.net/)
  - [http://www.womensmentalhealth.org/](http://www.womensmentalhealth.org/)
  - [http://www.motherisk.org/](http://www.motherisk.org/)

PROGNOSIS

- Treatment of maternal depression to remission has been shown to have a positive impact on children’s mental health.
- Some patients, particularly those with undertreated or undiagnosed depression, may develop chronic depression requiring long-term treatment.
- Untreated maternal depression is linked to impaired mother–infant bonding and cognitive and language development delay in infants and children (6).
- Postpartum psychosis is associated with tragic outcomes such as maternal suicide and infanticide.

COMPLICATIONS
• Suicide
• Self-injurious behavior
• Psychosis
• Neglect of baby
• Harm to the baby
• Preterm and low-birth-weight baby

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**
- F53 Puerperal psychosis
- O90.6 Postpartum mood disturbance

**CLINICAL PEARLS**
- PPD is a common, debilitating medical condition that impairs a mother’s ability to function and interact with her infant and family.
- Universal screening for depression is recommended during the 1st and 3rd trimester and at regular intervals during the postpartum period.
- Early diagnosis and treatment are vital, as untreated PPD can lead to developmental difficulties for the infant and prolonged disability and suffering for the mother.
- Breastfeeding is recommended for maternal and child health. Several medication options for treating depression in mothers are safe for breastfeeding infants.
- Treatment with antidepressants should be individualized for breastfeeding mothers (4)[B].
DEPRESSION, TREATMENT RESISTANT
Michelle Magid, MD, MBA • Roger Lowell McRoberts III, MD

BASICS

DESCRIPTION
- Major depressive disorder (MDD) that has failed to respond to ≥2 adequate trials of antidepressant therapy in ≥2 different classes
- Antidepressant therapy must be given for 6 weeks at standard doses before being considered a failure.

EPIDEMIOLOGY
- Depression affects >16 million people in the United States and >350 million people worldwide.
- 16% lifetime risk of MDD
- Approximately 1/3 of patients with MDD will develop treatment-resistant depression.

ETIOLOGY AND PATHOPHYSIOLOGY
- Unclear. Low levels of neurotransmitters (serotonin, norepinephrine, dopamine) have been indicated.
- Serotonin has been linked to irritability, hostility, and suicidal ideation.
- Norepinephrine has been linked to low energy.
- Dopamine may play a role in low motivation and depression with psychotic features.
- Environmental stressors such as abuse and neglect may affect neurotransmission.
- Inflammation and oxidative stress in the brain can contribute to treatment-resistant depression.

Genetics
A genetic abnormality in the serotonin transporter gene (5-HTTLPR) may increase risk for treatment-resistant depression.

RISK FACTORS
Severity of disease
Mislabeling bipolar patients as depressed
Comorbid medical disease (including chronic pain)
Comorbid personality disorder
Comorbid anxiety disorder
Comorbid substance use disorder
Familial predisposition to poor response to antidepressants

GENERAL PREVENTION
Medication adherence in combination with psychotherapy
Maintenance electroconvulsive therapy (ECT) may prevent relapse.

COMMONLY ASSOCIATED CONDITIONS
- Suicide
- Bipolar disorder
- Substance use disorders
- Anxiety disorders
- Dysthymia
- Eating disorders
- Somatic symptom disorders

DIAGNOSIS
HISTORY
- Symptoms are the same as in MDD. However, patients do not respond to standard form of treatment. Severity and duration are extreme.
- Important to screen for suicidality in treatment-resistant depression
- Screening with SIGECAPS
  - Sleep: too much or too little
  - Interest: failure to enjoy activities
  - Guilt: excessive and uncontrollable
  - Energy: poor energy
  - Concentration: inability to focus on tasks
  - Appetite: too much or too little
  - Psychomotor changes: restlessness/agitation or slowing/lethargy
  - Suicidality: desire to end life
PHYSICAL EXAM
Mental status exam may reveal poor hygiene, poor eye contact, blunted affect, tearfulness, weight loss or gain, psychomotor retardation, or agitation.

DIFFERENTIAL DIAGNOSIS
- Bipolar disorder
- Dysthymia
- Dementia
- Early-stage Parkinson disease
- Personality disorder
- Medical illness such as malignancy, thyroid disease, HIV
- Substance use disorders

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Used to rule out medical factors that could be causing/contributing to treatment resistance
  - CBC
  - Complete metabolic profile, including liver tests, calcium, and glucose
  - Urine drug screen
  - Thyroid-stimulating hormone (TSH)
  - Vitamin D level (25-OH vitamin D)
  - Testosterone, if applicable
- CT or MRI of the brain if neurologic disease, tumor, or dementia is suspected.

Follow-Up Tests & Special Considerations
Delirium and dementia may often look like depression.

Diagnostic Procedures/Other
- Depression is a clinical diagnosis.
- Validated depression rating scales to assist
  - Beck Depression Inventory
  - Hamilton Depression Rating Scale
  - Patient Health Questionnaire 9 (PHQ-9)
**TREATMENT MEDICATION**

**First Line**
- Please see “Depression” topic. When those fail, augmentation and combination strategies are as follows:
  - Antidepressants in combination
    - Citalopram (start 20 mg/day; max dose 40 mg/day) + bupropion (start 100 mg BID; max dose 450 mg total) (1)[B]
    - Tricyclic antidepressants (TCAs) and selective serotonin reuptake inhibitors (SSRIs) may be used in combination. Proceed with caution due to risk of serotonin syndrome; citalopram (start 20 mg/day; max dose 40 mg/day) + nortriptyline (start 50 mg at bedtime; max dose 150 mg at bedtime)
  - Antidepressants + antipsychotics
    - Citalopram (start 20 mg/day; max dose 40 mg/day) + aripiprazole (2 to 5 mg/day, different mechanism of action at higher doses) OR + risperidone (start 0.5 to 1.0 mg at bedtime; max dose 6 mg/day) or + quetiapine (start 25 mg at bedtime; titrate to 100 to 300 mg at bedtime; max dose 600 mg/day) (2)[A]
  - Antidepressant + lithium
    - TCA: nortriptyline (start 50 mg at bedtime; max dose 150 mg at bedtime) + lithium (start 300 mg at bedtime; max dose 900 mg BID) (3)[A]
    - SSRI: citalopram (start 20 mg/day; max dose 40 mg QD) + lithium (start 300 mg at bedtime; max dose 900 mg BID)
  - Antidepressant + thyroid supplementation
    - Citalopram (start 20 mg/day; max dose 40 mg/day) + triiodothyronine (T3) (12.5 to 50 μg/day)

- In all above combinations, citalopram (Celexa) can be replaced with other SSRIs such as fluoxetine (Prozac) 20 to 80 mg/day, sertraline (Zoloft) 50 to 200 mg/day, and escitalopram (Lexapro) 10 to 20 mg/day or with serotonin-norepinephrine reuptake inhibitors (SNRIs) duloxetine (Cymbalta) 30 to 120 mg/day, venlafaxine XR (Effexor XR) 75 to 225 mg/day, or desvenlafaxine (Pristiq) 50 to 100 mg/day, or with a noradrenergic and specific serotonergic antidepressant (NaSSA) mirtazapine (Remeron) 15 to 45 mg at bedtime.

- Maximum doses for medication in treatment-resistant cases may be higher than in treatment-responsive cases.
Second Line

- Antidepressant in combination with therapy—in particular cognitive-behavioral therapy (CBT) (4)[B]
- Monoamine oxidase inhibitor (MAOI)
- Tranylcypromine (Parnate): start 10 mg BID, increase 10 mg/day every 1 to 3 weeks; max dose 60 mg/day
- Selegilene transdermal (Emsam patch): apply 6-mg patch daily, increase 3 mg/day; max dose 12 mg/day
- Side-effect profile (e.g., hypertensive crisis), drug–drug interactions, and dietary restrictions make MAOIs less appealing. Patch version does not require dietary restrictions at lower doses.
- High risk of serotonin syndrome, if combined with another antidepressant; 2-week washout period is advised.

ISSUES FOR REFERRAL

Treatment-resistant depression should be managed in consultation with a psychiatrist.

ADDITIONAL THERAPIES

- First line
  - ECT: safe and effective treatment for treatment-resistant and life-threatening depression, with a 60–90% success rate (5)[A]:
    - Known to rapidly relieve suicidality, psychotic depression, and catatonia
    - Controversy due to cognitive side effects during the treatment
    - Three types of lead placements
      - Bitemporal: rapid and effective; usually need 6 to 10 treatments at 1.5 times seizure threshold
      - Right unilateral: may be slightly less rapid but fewer cognitive side effects; usually need 8 to 12 treatments at 6 times seizure threshold
      - Bifrontal: newer technique that may offer similar speed to bitemporal, with slightly improved side-effect profile
- Second line
  - Deep brain stimulation (DBS): surgical implantation of intracranial electrodes, connected to an impulse generator implanted in the chest wall:
    - Reserved for those who have failed medications, psychotherapy, and ECT
    - Preliminary data are promising, showing 40–70% response rate and 35% remission rate, but further trials are warranted.
  - Transcranial magnetic stimulation (TMS): noninvasive brain stimulation
technique that is generally safe. A few case reports on efficacy in treatment-resistant depression but thus far is only FDA approved for less severe forms of the illness (3)[C].

- Vagus nerve stimulation (VNS): Surgical implantation of electrodes onto left vagus nerve. Its use in treatment-resistant depression has become limited in recent years.
- Ketamine—not FDA approved, but evidence of rapid improvement in mood and suicidal thinking, although the literature is limited. In addition, the effects of ketamine appear temporary, disappearing after days to weeks (3,6)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inpatient care is indicated for severely depressed, psychotic, catatonic, or suicidal patients.
- Discharge criteria: symptoms improving, no longer suicidal, psychosocial stressors addressed

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Frequent visits (i.e., every month)
- During follow-up, evaluate side effects, dosage, and effectiveness of medication as well as need for referral to ECT.
- Patients who have responded to ECT may need maintenance treatments (q3–12wk) to prevent relapse.
- Combination of lithium/nortriptyline after ECT appears to be as effective as maintenance ECT in reducing relapse.

DIET

Patients on MAOIs need dietary restriction.

PATIENT EDUCATION

Educate patients that depression is a medical illness, not a character defect.
- Review signs and symptoms of worsening depression and when patient needs to come in for further evaluation.
Discuss safety plan to address suicidal thoughts.

PROGNOSIS
With medication adherence, close follow-up, improved social support, and psychotherapy, prognosis improves.

COMPLICATIONS
- Suicide
- Disability
- Poor quality of life

REFERENCES

CODES

ICD10
- F32.9 Major depressive disorder, single episode, unspecified
- **F33.9 Major depressive disorder, recurrent, unspecified**

**CLINICAL PEARLS**

- Treatment-resistant depression is common, affecting 1/3 of those with MDD.
- Combination and augmentation strategies with antidepressants, antipsychotics, therapy, and mood stabilizers can be helpful.
- ECT should be considered in severe and life-threatening cases.
DERMATITIS HERPETIFORMIS

Abdul Aleem, MD • Hiral N. Shah, MD, FASGE, FACG

BASICS

DESCRIPTION

- Dermatitis herpetiformis (DH) presents as a chronic, relapsing, polymorphous, intensely pruritic, erythematous papulovesicular eruption with symmetrical distribution primarily involving extensor skin surfaces of the elbows, knees, buttocks, back, and scalp.
- DH is an autoimmune disease associated with gluten sensitivity with genetic, environmental, and immunologic influences.
- DH is distinguished from other bullous diseases by characteristic histologic and immunologic findings, as well as associated gluten-sensitive enteropathy (GSE).
- System(s) affected: skin
- Synonym(s): Duhring disease, Duhring-Brocq disease

EPIDEMIOLOGY

- Occurs most frequently in those of Northern European origin
- Rare in persons of Asian or African American origin
- Predominant age: most common in 4th and 5th decades but may present at any age
- Childhood DH is rare in most countries, although an Italian study showed 27% of patients were age of <10 years and 36% age of <20 years.
- Predominant gender: adults: male > female (1.5:1 in the United States, 2:1 worldwide); children: female > male

Incidence
1/100,000 persons per year in the United States

Prevalence
11/100,000 persons in the U.S. population; as high as 39/100,000 persons worldwide

ETIOLOGY AND PATHOPHYSIOLOGY
Evidence suggests that epidermal transglutaminase (eTG) 3, a keratinocyte enzyme involved in cell envelope formation and maintenance, is the autoantigen in DH.

eTG is highly homologous with tissue transglutaminase (tTG), which is the antigenic target in celiac disease and GSE.

The initiating event for DH is presumed to be the interaction of wheat peptides with tTGs, which results in the formation of an autoantigen with high affinity for particular class II major histocompatibility complex (MHC) molecules.

Presentation of the autoantigen leads to activation of T-cells and the humoral immune system.

IgA antibodies against tTG cross-react with eTG and result in IgA-eTG immune complexes that are deposited in the papillary dermis. Subsequent activation of complement and recruitment of neutrophils to the area result in inflammation and microabscesses.

Skin eruption may be delayed up to 5 to 6 weeks after exposure to gluten.

Gluten applied directly to the skin does not result in the eruption, whereas gluten taken by mouth or rectum does. This implies necessary processing by the GI system.

Thought to be immune complex–mediated disease

**Genetics**

- High association with human leukocyte antigen DQ2 (95%), with remaining patients being positive for DQ8, DR4, or DR3
- Strong association with combination of alleles DQA1*0501 and DQB1*0201/0202, DRB1*03 and DRB1*05/07, or DQA1*0301 and DQB1*0302

**RISK FACTORS**

- GSE: >90% of those with DH will have GSE, which may be asymptomatic.
- Family history of DH or celiac disease

**GENERAL PREVENTION**

Gluten-free diet (GFD) results in improvement of DH and reduces dependence on medical therapy. GFD also may reduce the risk of lymphomas associated with DH.

**COMMONLY ASSOCIATED CONDITIONS**
Hypothyroidism is the most common condition associated with DH.
- GSE, gluten ataxia
- Gastric atrophy, hypochlorhydria, pernicious anemia
- GI lymphoma, non-Hodgkin lymphoma
- Hyperthyroidism, thyroid nodules, thyroid cancer
- IgA nephropathy
- Autoimmune disorders, including systemic lupus erythematosus, dermatomyositis, Sjögren syndrome, rheumatoid arthritis, sarcoidosis, Raynaud phenomenon, insulin-dependent diabetes mellitus, myasthenia gravis, Addison disease, vitiligo, alopecia areata, primary biliary cirrhosis, and psoriasis

**DIAGNOSIS**

Diagnosis of DH involves a clinicopathologic correlation among clinical presentation, histologic and direct immunofluorescence (DIF) evaluation, serology, and response to therapy or dietary restriction.

**HISTORY**
- Waxing and waning, intensely pruritic eruption with papules and tiny vesicles
- Eruption may worsen with gluten intake.
- GI symptoms may be absent or may not be reported until prompted.

**PHYSICAL EXAM**
- The classic lesions of DH are described as symmetric, grouped, erythematous papules and vesicles.
- More commonly presents with erosions, excoriations, lichenification, hypopigmentation, and/or hyperpigmentation secondary to scratching and healing of old lesions
- Areas involved include extensor surfaces of elbows (90%), knees (30%), shoulders, buttocks, and sacrum. The scalp is also frequently affected. Oral lesions are rare.
- In children, purpura may be visible on digits and palmoplantar surfaces.
- Adults with associated enteropathy are most often asymptomatic, with about 20% experiencing steatorrhea and <10% with findings of bloating, diarrhea, or malabsorption.
- Children with associated enteropathy may present with abdominal pain, diarrhea, iron deficiency, and reduced growth rate.
DIFFERENTIAL DIAGNOSIS

- In adults
  - Bullous pemphigoid: linear deposition of C3 and IgG at the basement membrane zone
  - Linear IgA disease: homogeneous and linear deposition of IgA at the basement membrane zone, absence of GSE
  - Prurigo nodularis
  - Urticaria: wheals, angioedema, dermal edema
  - Erythema multiforme
- In children
  - Atopic dermatitis: face and flexural areas
  - Scabies: interdigital areas, axillae, genital region
  - Papular urticaria: dermal edema
  - Impetigo

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Serum IgA tTG antibodies: Detection of tTG antibodies was noted to be up to 95% sensitive and >90% specific for DH in patients on unrestricted diets (1,2) [A].
- Serum IgA eTG antibodies: Antibodies to eTG, the primary autoantigen in DH, were shown to be more sensitive than antibodies to tTG in the diagnosis of patients with DH on unrestricted diets (95% vs. 79%) but is not widely available in all labs (1,2)[A].
- Serum IgA endomysial antibodies (EMA): Antibodies to EMA have a sensitivity between 50% and 100% and a specificity close to 100% in patients on unrestricted diets but is more expensive, time-consuming, and operator-dependent than tTG (2).

Follow-Up Tests & Special Considerations

- Serologic assessment of anti-tTG and anti-eTG correlate with intestinal involvement of disease and in conjunction with anti-EMA may be useful in monitoring major deviations from GFD (1,2).
- Genetic testing for haplotypes HLA-DQ2 and HLA-DQ8 can also be offered to patients to determine genetic susceptibility, to screen patients with high risk of CD, or if the diagnosis is not clear (1).
**Diagnostic Procedures/Other**

- The gold standard test to establish a diagnosis DH is DIF of the perilesional skin that demonstrate characteristic granular IgA deposits in dermal papillae and/or basement membrane (1,2)[A]. It is this key diagnostic feature that differentiates this blistering skin condition from all other dermatological diseases (3).

- DIF has a sensitivity and specificity of close to 100% (1).
- In patients with high suspicion for DH with a negative DIF, another perilesional skin biopsy should be obtained from a different site (1).
- Histopathology of these lesions with routine staining reveals neutrophilic microabscesses in the tips of the dermal papillae and may show subepidermal blistering (1,2).

**TREATMENT**

**GENERAL MEASURES**

- GFD is the mainstay of treatment in DH and can lead to complete resolution of symptoms (1,2)[A].

- Typically requires 18 to 24 months of strict adherence to GFD prior to resolution of skin lesions without any additional treatment

- Lesions can recur within 12 weeks of reintroduction of gluten.

**MEDICATION**

- Despite being on GFD, the lesions of DH take several months to clear, and active lesions warrant additional treatment (3).

- Medications are useful for immediate symptom management but should only be used as an adjunct to dietary modification (2).

**First Line**

- Dapsone is approved by the FDA for use in DH and is the most widely used medication (2,4)[A].

- Initial dosing of 25 to 50 mg/day on a strict GFD typically results in improvement of symptoms within 24 to 48 hours (1,3)[C].

- It is recommended to use minimum effective dose with slow titration based on patient response and tolerability. Average maintenance dose is 1 mg/kg/day (50 to 150 mg/day) and can be increased up to 200 mg to obtain better symptom control.
Minor outbreaks on the face and scalp are common even with treatment; not ideal for long-term use in DH

Dapsone works by inhibiting neutrophil recruitment and IL-8 release, inhibiting the respiratory burst of neutrophils, and protecting cells from neutrophil-mediated injury, thereby suppressing the skin reaction. It has no role in preventing IgA deposition or mitigating the immune reaction in the gut (2,4).

Precautions
- Common side effects include nausea, vomiting, headache, dizziness, weakness, and hemolysis.
- A drop in hemoglobin of 1 to 2 g is characteristic with dapsone 100 mg/day.
- G6PD deficiency increases severity of hemolytic stress. Dapsone should be avoided, if possible, in those who are G6PD-deficient.
- Dose-related methemoglobinemia may occur with doses >100 mg/day. Cimetidine may reduce the severity of this side effect.
- Risk of distal motor neuropathy

**ALERT**
- Monitor for potentially fatal dapsone-induced sulfone syndrome: fever, jaundice and hepatic necrosis, exfoliative dermatitis, lymphadenopathy, methemoglobinemia, and hemolytic anemia.
- Can occur 48 hours or 6 months after treatment, most often 5 weeks after initiation

**Pediatric Considerations**
- <2 years: Dosing is not established.
- >2 years: 0.5 to 1.0 mg/kg/day

**Pregnancy Considerations**
- Category C: Safety during pregnancy is not established.
- Secreted in breast milk and will produce hemolytic anemia in infants
- Adherence to a strict GFD 6 to 12 months before conception should be considered with the hope of eliminating need for dapsone during pregnancy.

**Second Line**
- High-potency topical steroids can be used acutely to control symptoms until dapsone becomes effective (1)[C].
- Sulfapyridine (1 to 2 g/day) is FDA-approved for use in DH and is thought to be the active metabolite in sulfasalazine (2 to 4 g/day) (2,5)[B]. Common side
effects include nausea, vomiting, and anorexia. Enteric-coated form may reduce side effects. Other side effects include agranulocytosis, hypersensitivity reactions, hemolytic anemia, proteinuria, and crystalluria (2,5).

- Topical steroids and 3rd-generation antihistamines can be used to provide relief from symptoms of pruritus and itching.

ISSUES FOR REFERRAL
Over time, the management of DH warrants an interdisciplinary treatment that includes providing a referral to dermatologist, gastroenterologist, and registered dietitian (1,2).

ADDITIONAL THERAPIES
A single case report described topical dapsone therapy as potential alternative treatment or as an adjunct to oral dapsone to decrease systemic exposure and risk of severe side effects. However, it has not been studied extensively (6)[C].

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Every 6 to 12 months by physician and dietitian to evaluate GFD adherence and recurrence of symptoms
- Adherence to GFD can be monitored with serologic levels of anti-tTG, anti-eTG, and EMA levels (1).
- Patients on dapsone require lab monitoring weekly for the 1st month, biweekly for 2 months, and then every 3 months for the duration of medication use (1,5).

DIET
- Grains that should be avoided: wheat (includes spelt, kamut, semolina, and triticale), rye, and barley (including malt)
- Safe grains (gluten-free): rice, amaranth, buckwheat, corn, millet, quinoa, sorghum, teff (an Ethiopian cereal grain), and oats
- Care should be taken to avoid gluten-free grains that are contaminated with sources of gluten during processing such as oats.
Sources of gluten-free starches that can be used as flour alternatives
- Cereal grains: amaranth, buckwheat, corn, millet, quinoa, sorghum, teff, rice (white, brown, wild, basmati, jasmine), and Montina
- Tubers: arrowroot, jicama, taro, potato, and tapioca
- Legumes: chickpeas, lentils, kidney beans, navy beans, pea beans, peanuts, and soybeans
- Nuts: almonds, walnuts, pistachios, chestnuts, hazelnuts, and cashews
- Seeds: sunflower, flax, and pumpkin

PATIENT EDUCATION
- Patients started on dapsone should be made aware of potential hemolytic anemia and the signs associated with methemoglobinemia.
- American Academy of Dermatology, 930 N. Meacham Road, P.O. Box 4014, Schaumberg, IL 60168-4014; (708) 330-0230
- The University of Chicago Celiac Disease Center, 5841 S. Maryland Ave., Mail Code 4069, Chicago, IL 60637; (773) 702-7593; www.celiacdisease.net or http://www.cureceliacdisease.org/
- Gluten Intolerance Group of North America, 31214-124 Ave. SE, Auburn, WA 98092; (206) 246-6652; fax (206) 246-6531; https://www.gluten.org/
- The Celiac Disease Foundation, 13251 Ventura Blvd., #1, Studio City, CA 9160; (818) 990-2354; fax (818) 990-2379

PROGNOSIS
- DH is a chronic disease with excellent prognosis, provided strict adherence to a GFD is maintained.
- 10- to 15-year survival rates do not seem to differ from general population.
- Remission in 10–15%
- Skin disease responds readily to dapsone. Occasional new lesions (2 to 3 per week) are to be expected and are not an indication for altering daily dosage.
- Strict adherence to a GFD improves clinical symptoms and decreases dapsone requirement. GFD is the only sustainable method of eliminating cutaneous and GI disease.
- Risk of lymphoma may be decreased in those who maintain a GFD.

COMPlications
- Majority of complications are associated with GSE.
- Malnutrition, weight loss, nutritional deficiencies (folate, vitamin B_{12}, iron)
- Abdominal pain, dyspepsia
Osteoporosis, dental abnormalities
Autoimmune diseases
Lymphomas

ADDITIONAL READING

Celiac Disease
Algorithm: Rash

CODES
ICD10
L13.0 Dermatitis herpetiformis

CLINICAL PEARLS

- DH is a chronic, relapsing, intensely pruritic rash that often presents with erosions, excoriations, lichenification, and pigmentary changes secondary to scratching and healing of old papulovesicular lesions.
- Strong association with GSE
- Diagnosis established with perilesional skin biopsy showing DIF demonstrating granular IgA deposits in the dermal papillae
- Serologic levels of IgA transglutaminase aid in diagnosis and monitoring of deviations from GFD.
- Mainstay of treatment is a GFD with dapsone used primarily for short-term symptom relief.
DERMATITIS, ATOPIC

Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION
- A chronic, relapsing, pruritic eczematous condition affecting characteristic sites
- Early onset cases have coexisting allergen sensitization more often than late onset.
- Clinical phenotypical presentation is highly variable, suggesting multifactorial pathophysiology.
- May have significant effect on quality of life for patient and family—similar to that of psoriasis

EPIDEMIOLOGY
- 45% of all cases begin in the first 6 months of life with 95% onset prior to age 5 years.
- 70% of affected children will have a spontaneous remission before adolescence.
- Incidence on the rise for the past 3 decades in industrialized countries; overall, affects ~15% of children at some time (United States)
- Also, may have late-onset dermatitis in adults or relapse of childhood condition—primarily hand eczema
- Asians and blacks are affected more often than whites.
- 60% if one parent is affected; rises to 80% if both parents are affected

ETIOLOGY AND PATHOPHYSIOLOGY
- Two main hypothesis: immunologic with unbalanced immune response and/or skin barrier dysfunction (1)
- Alteration in stratum corneum results in transepidermal water loss and defect in barrier function.
- Epidermal adhesion is reduced either as a result of (i) genetic mutation resulting in altered epidermal proteins or (ii) defect in immune regulation causing an altered inflammatory response.
- Interleukin-31 (IL-31) upregulation is thought to be a major factor in pruritus
mediated by cytokines and neuropeptides rather than histamine excess.

**Genetics**
- Recent discovery of association between atopic dermatitis (AD) and mutation in the filaggrin gene (*FLG*), which codes for a skin barrier protein (2)
- Both epidermal and immune coding likely involved

**RISK FACTORS**
- “Itch–scratch cycle” (stimulates histamine release)
- Skin infections
- Emotional stress
- Irritating clothes and chemicals
- Excessively hot or cold climate
- Food allergy in children (in some cases). Studies of breastfeeding conveying decreased risk versus increased risk are mixed in conclusion (3)[C].
- Exposure to tobacco smoke
- Family history of atopy
  - Asthma
  - Allergic rhinitis

**COMMONLY ASSOCIATED CONDITIONS**
- Food sensitivity/allergy in many cases
- Asthma
- Allergic rhinitis
- Hyper-IgE syndrome (Job syndrome)
  - AD
  - Elevated IgE
  - Recurrent pyodermas
  - Decreased chemotaxis of mononuclear cells

**DIAGNOSIS**

**HISTORY**
- Presence of major symptoms, including relapsing of condition, family history, typical distribution, and morphology necessary to make diagnosis of AD
- Upward of 33% report associated mood and sleep disruption.
PHYSICAL EXAM
Primarily skin manifestations

- Distribution of lesions
  - Infants: trunk, face, and flexural surfaces; diaper-sparing
  - Children: antecubital and popliteal fossae
  - Adults: hands, feet, face, neck, upper chest, and genital areas

- Morphology of lesions
  - Infants: erythema and papules; may develop oozing, crusting vesicles
  - Children and adults: Lichenification and scaling are typical with chronic eczema as a result of persistent scratching and rubbing (lichenification rare in infants).

- Associated signs
  - Facial erythema, mild to moderate
  - Perioral pallor
  - Infraorbital fold (Dennie sign/Morgan line)—atopic pleat
  - Dry skin progressing to ichthyosis
  - Increased palmar linear markings
  - Pityriasis alba (hypopigmented asymptomatic areas on face and shoulders)
  - Keratosis pilaris

DIFFERENTIAL DIAGNOSIS

- Photosensitivity rashes
- Contact dermatitis (especially if only the face is involved)
- Scabies
- Seborrheic dermatitis (especially in infants)
- Psoriasis or lichen simplex chronicus if only localized disease is present in adults
- Rare conditions of infancy
  - Histiocytosis X
  - Wiskott–Aldrich syndrome
  - Ataxia-telangiectasia syndrome
- Ichthyosis vulgaris

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- No test is diagnostic.
- Serum IgE levels are elevated in as many as 80% of affected individuals, but
test is not routinely ordered.
- Eosinophilia tends to correlate with disease severity.
- Scoring atopic dermatitis (SCORAD) is scoring system for AD comprising scores for area, intensity, and subjective symptoms.

**TREATMENT**

**GENERAL MEASURES**
- Minimize flare-ups and control the duration and intensity of flare-up.
- Avoid agents that may cause irritation (e.g., wool, perfumes).
- Minimize sweating.
- Lukewarm (not hot) bathing
- Minimize use of soap (superfatted soaps best).
- Sun exposure may be helpful.
- Humidify the house.
- Avoid excessive contact with water.
- Avoid lotions that contain alcohol.
- If very resistant to treatment, search for a coexisting contact dermatitis.

**Pediatric Considerations**
Chronic potent fluorinated corticosteroid use may cause striae, hypopigmentation, or atrophy, especially in children.

**MEDICATION**

**First Line**
- Frequent systemic lubrication with thick emollient creams (e.g., Eucerin, Vaseline) over moist skin is the mainstay of treatment before any other intervention is considered (1)[A].
- Infants and children: 0.5–1% topical hydrocortisone creams or ointments (use the “fingertip unit [FTU]” dosing) (1)[C]
- Adults: higher potency topical corticosteroids in areas other than face and skin folds
- Short-course, higher potency corticosteroids for flares; then, return to the lowest potency (creams preferred) that will control dermatitis.
- Antihistamines for pruritus (e.g., hydroxyzine 10 to 25 mg at bedtime and as needed)
**Second Line**
- Topical immunomodulators (tacrolimus or pimecrolimus) for episodic use for children >2 years. There is a black box warning from the FDA regarding potential cancer risk.
- Plastic occlusion in combination with topical medication to promote absorption
- For severe AD, consider systemic steroids for 1 to 2 weeks (e.g., prednisone 2 mg/kg/day PO [max 80 mg/day] initially, tapered over 7 to 14 days).
- Topical tricyclic doxepin, as a 5% cream, may decrease pruritus.
- Modified Goeckerman regimen (tar and ultraviolet light)
- Low-dose methotrexate was established as effective treatment in adults, and recent review suggests it is safe for children and adolescents (4)[B].
- Dupilumab, a biologic that targets mediators of inflammation (IL-22, IL-17, IFN-γ), has completed phase III trials and is awaiting approval (5).

**ISSUES FOR REFERRAL**
- Ophthalmology evaluation for persistent vernal conjunctivitis
- If using topical steroids around eyes for extended periods, ophthalmology follow-up for cataract evaluation

**ADDITIONAL THERAPIES**
- Methods to reduce house mite allergens (micropore filters on heating, ventilation, and air-conditioning systems; impermeable mattress covers)
- Behavioral relaxation therapy to reduce scratching
- Bleach baths may reduce staph colonization, but definitive evidence for benefit in the condition is lacking. Recommend 1/2 cup of standard 6% household bleach for a full tub of water and soak for 5 to 10 minutes, blotting skin dry upon leaving the bath.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Evening primrose oil (includes high content of fatty acids)
  - May decrease prostaglandin synthesis
  - May promote conversion of linoleic acid to omega-6 fatty acid
- Probiotics may reduce the severity of the condition, thus reducing medication use.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Evaluate to ensure that secondary bacterial or fungal infection does not develop as a result of disruption of the skin barrier. Most patients with AD are colonized by *Staphylococcus*. There is a little evidence for the routine use of antimicrobial interventions to reduce skin bacteria, but treatment of clinical infection with coverage for *Staphylococcus* is recommended.

DIET
- Trials of elimination may find certain “triggers” in some patients.
- Breastfeeding in conjunction with maternal hypoallergenic diets may decrease the severity in some infants (varying opinions).

PATIENT EDUCATION
- [http://www.aad.org/skin-conditions/dermatology-a-to-z/atopic-dermatitis](http://www.aad.org/skin-conditions/dermatology-a-to-z/atopic-dermatitis)
- National Eczema Association: [www.nationaleczema.org](http://www.nationaleczema.org)

PROGNOSIS
- Chronic disease
- Declines with increasing age
- 90% of patients have spontaneous resolution by puberty.
- Localized eczema (e.g., chronic hand or foot dermatitis, eyelid dermatitis, or lichen simplex chronicus) may continue in some adults.

COMPLICATIONS
- Cataracts are more common in patients with AD.
- Skin infections (usually *Staphylococcus aureus*); sometimes subclinical
- Eczema herpeticum
  - Generalized vesiculopustular eruption caused by infection with herpes simplex or vaccinia virus
  - Causes acute illness requiring hospitalization
- Atrophy and/or striae if fluorinated corticosteroids are used on face or skin folds
- Systemic absorption may occur if large areas of skin are treated, particularly if high-potency medications and occlusion are combined.

ADDITIONAL READING

SEE ALSO
Algorithm: Rash

CODES

**ICD10**
- L20.9 Atopic dermatitis, unspecified
- L20.89 Other atopic dermatitis
- L20.83 Infantile (acute) (chronic) eczema

CLINICAL PEARLS
- Institute early and proactive treatment to reduce inflammation. Use the lowest
potency topical steroid that controls symptoms.

- Monitor for secondary bacterial infection.
- Frequent systemic lubrication with thick emollient creams (e.g., Eucerin, Vaseline) over moist skin is the mainstay of treatment before any other intervention is considered.
DERMATITIS, CONTACT

Anne Walsh, ANP-BC • Konstantinos E. Deligiannidis, MD, MPH, FAAFP

BASICS

DESCRIPTION

- A cutaneous reaction to contact with an external substance
- Different mechanisms result in similar skin manifestation (1)
- Primary irritant dermatitis (ID) results from direct damage to the stratum corneum by chemicals or physical agents occurring faster than the skin is able to repair itself, leading to an inflammatory nonimmunologic cutaneous reaction. Prior sensitization is not required (2).
- Allergic contact dermatitis (ACD) affects only individuals previously sensitized to a substance. It represents a delayed hypersensitivity reaction, requiring several hours for the cascade of cellular immunity to be completed to manifest itself (2).
- System(s) affected: skin/exocrine
- Synonym(s): dermatitis venenata

EPIDEMIOLOGY

Common

Incidence

Occupational contact dermatitis: 20.5/100,000 workers/year in one Australian study

Prevalence

- Contact dermatitis represents >90% of all occupational skin disorders.
- Predominant sex: male = female
  - Variations due to differences in exposure to offending agents, as well as normal cutaneous variations between males and females (eccrine and sebaceous gland function and hair distribution)

Geriatric Considerations

Increased incidence of ID secondary to skin dryness
**Pediatric Considerations**
Increased incidence of positive patch testing due to better delayed hypersensitivity reactions (3)

**ETIOLOGY AND PATHOPHYSIOLOGY**
Hypersensitivity reaction to a substance generating cellular immunity response (4)

- **Plants**
  - Urushiol (allergen): poison ivy, poison oak, poison sumac
  - Primary contact: plant (roots/stems/leaves)
  - Secondary contact: clothes/fingernails (not blister fluid)

- **Chemicals**
  - Nickel: jewelry, zippers, hooks, and watches (5)
  - Potassium dichromate: tanning agent in leather
  - Paraphenylenediamine: hair dyes, fur dyes, and industrial chemicals
  - Turpentine: cleaning agents, polishes, and waxes
  - Soaps and detergents

- **Topical medicines**
  - Neomycin: topical antibiotics
  - Thimerosal (Merthiolate): preservative in topical medications
  - Anesthetics: benzocaine
  - Parabens: preservative in topical medications
  - Formalin: cosmetics, shampoos, and nail enamel

**Genetics**
Increased frequency of ACD in families with allergies

**RISK FACTORS**
- Occupation
- Hobbies
- Travel
- Cosmetics
- Jewelry

**GENERAL PREVENTION**
- Avoid causative agents.
- Use of protective gloves (with cotton lining) may be helpful.
DIAGNOSIS

HISTORY

- Itchy rash
- Assess for prior exposure to irritating substance.

PHYSICAL EXAM

- Acute
  - Papules, vesicles, bullae with surrounding erythema
  - Crusting and oozing
  - Pruritus
- Chronic
  - Erythematous base
  - Thickening with lichenification
  - Scaling
  - Fissuring
- Distribution
  - Where epidermis is thinner (eyelids, genitalia)
  - Areas of contact with offending agent (e.g., nail polish)
  - Palms and soles relatively more resistant, although hand dermatitis is common
  - Deeper skin folds spared
  - Linear arrays of lesions
  - Lesions with sharp borders and sharp angles are pathognomonic.
  - Well-demarcated area with a papulovesicular rash

DIFFERENTIAL DIAGNOSIS

Based on clinical impression: appearance, periodicity, and localization

- Diffuse bullous or vesicular lesions
  - Bullous pemphigoid
- Groups of vesicles
  - Herpes simplex
- Photodistribution
  - Phototoxic/allergic reaction to systemic allergen
- Eyelids
  - Seborrheic dermatitis
- Scaly eczematous lesions
  - Atopic dermatitis
– Nummular eczema
– Lichen simplex chronicus
– Stasis dermatitis
– Xerosis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Diagnostic Procedures/Other**
Consider patch tests for suspected allergic trigger (systemic corticosteroids or recent, aggressive use of topical steroids may alter results).

**Test Interpretation**

- Intercellular edema
- Bullae

**TREATMENT**

**GENERAL MEASURES**

- Remove offending agent:
  - Avoidance
  - Work modification
  - Protective clothing
  - Barrier creams, especially high-lipid content moisturizing creams (e.g., Keri lotion, petrolatum, coconut oil)
- Topical soaks with cool tap water, Burow solution (1:40 dilution), saline (1 tsp/pt water), or silver nitrate solution
- Lukewarm water baths
- Aveeno oatmeal baths
- Emollients (white petrolatum, Eucerin)

**MEDICATION**

**First Line**

- Topical medications (5)[A]
  - Lotion of zinc oxide, talc, menthol 0.15% (Gold Bond), phenol 0.5%
  - Corticosteroids for ACD as well as ID
    - High-potency steroids: fluocinonide (Lidex) 0.05% gel, cream, or ointment TID–QID
- Use high-potency steroids only for a short time and then switch to low- or medium-potency steroid cream or ointment.
- Caution regarding face/skin folds: Use lower potency steroids, and avoid prolonged usage. Switch to lower potency topical steroid once the acute phase is resolved.

- Calamine lotion for symptomatic relief
- Topical antibiotics for secondary infection (bacitracin, erythromycin)
- Systemic
  - Antihistamine
    - Hydroxyzine: 25 to 50 mg PO QID, especially useful for itching
    - Diphenhydramine: 25 to 50 mg PO QID
    - Cetirizine 10 mg PO BID–TID
- Corticosteroids
  - Prednisone: Taper starting at 60 to 80 mg/day PO, over 10 to 14 days.
  - Used for moderate to severe cases
  - May use burst dose of steroids for up to 5 days
- Antibiotics for secondary skin infections
  - Dicloxacillin: 250 to 500 mg PO QID for 7 to 10 days
  - Amoxicillin-clavulanate (Augmentin): 500 mg PO BID for 7 to 10 days
  - Erythromycin: 250 mg PO QID in penicillin-allergic patients
  - Trimethoprim-sulfamethoxazole (Bactrim DS): 160 mg/800 mg (1 tablet) PO BID for 7 to 10 days, in suspected resistant *Staphylococcus aureus*

- Precautions
  - Antihistamines may cause drowsiness.
  - Prolonged use of potent topical steroids may cause local skin effects (atrophy, stria, telangiectasia).
  - Use tapering dose of oral steroids if using >5 days.

**Second Line**
Other topical or systemic antibiotics, depending on organisms and sensitivity

**Pregnancy Considerations**
Usual caution with medications

**ISSUES FOR REFERRAL**
May need referral to a dermatologist or allergist if refractory to conventional treatment
COMPLEMENTARY & ALTERNATIVE MEDICINE
The use of complementary and alternative treatment is a supplement and not an alternative to conventional treatment.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Rarely needs hospital admission

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Stay active, but avoid overheating.

Patient Monitoring
- As necessary for recurrence
- Patch testing for etiology after resolved

DIET
No special diet

PATIENT EDUCATION
- Avoidance of irritating substance
- Cleaning of secondary sources (nails, clothes)
- Fallacy of blister fluid spreading disease

PROGNOSIS
- Self-limited
- Benign

COMPLICATIONS
- Generalized eruption secondary to autosensitization
- Secondary bacterial infection

REFERENCES

**SEE ALSO**

Algorithm: Rash

**CODES**

**ICD10**
- L25.9 Unspecified contact dermatitis, unspecified cause
- L23.9 Allergic contact dermatitis, unspecified cause
- L25.5 Unspecified contact dermatitis due to plants, except food

**CLINICAL PEARLS**
- May affect anyone exposed to irritants or allergic substances, especially in occupations that have high exposure to chemicals
- The most common allergens causing contact dermatitis are plants of the *Toxicodendron* genus (poison ivy, poison oak, poison sumac).
- Poison-ivy dermatitis typically requires 10 to 14 days of topical or oral steroid therapy to prevent recurrent eruption.
- Worldwide, nickel is the number one patch-tested allergen causing ACD (6).
- The usual treatment for contact dermatitis is avoidance of the allergen or irritating substance and temporary use of topical steroids.
- A contact dermatitis eruption presents in a nondermatomal geographic fashion due to the skin being in contact with an external source.
DERMATITIS, DIAPER

Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION

- Diaper dermatitis is a rash occurring under the covered area of a diaper. It is usually initially a contact dermatitis.
- System(s) affected: skin/exocrine
- Synonym(s): diaper rash; nappy rash; napkin dermatitis

Geriatric Considerations

Incontinence is a significant cofactor.

EPIDEMIOLOGY

Incidence

- The most common dermatitis found in infancy
- Peak incidence: 7 to 12 months of age, then decreases
- Lower incidence reported in breastfed babies due to lower pH, urease, protease, and lipase activity.

Prevalence

Prevalence has been variably reported from 4–35% in the first 2 years of life. Upward of 75% of infants will have episodes of varying duration and severity in United States.

ETIOLOGY AND PATHOPHYSIOLOGY

- Immature infant skin with histologic, biochemical, functional differences compared to mature skin (1)
- Wet skin is central in the development of diaper dermatitis, as prolonged contact with urine or feces results in susceptibility to chemical, enzymatic, and physical injury; wet skin is also penetrated more easily.
- Fecal proteases and lipases are irritants.
- Superhydrase urease enzyme found in the stratum corneum liberates ammonia from cutaneous bacteria.
- Fecal lipase and protease activity is increased by acceleration of GI transit;
