thus, a higher incidence of irritant diaper dermatitis is observed in babies who have had diarrhea in the previous 48 hours.

- Once the skin is compromised, secondary infection by *Candida albicans* is common. 40–75% of diaper rashes that last >3 days are colonized with *C. albicans*.
- Bacteria may play a role in diaper dermatitis through reduction of fecal pH and resulting activation of enzymes.
- Allergy is exceedingly rare as a cause in infants.

**RISK FACTORS**

- Infrequent diaper changes
- Improper laundering (cloth diapers)
- Family history of dermatitis
- Hot, humid weather
- Recent treatment with oral antibiotics
- Diarrhea (>3 stools per day increases risk)
- Dye allergy
- Eczema may increase risk.

**GENERAL PREVENTION**

Attention to hygiene during bouts of diarrhea

**COMMONLY ASSOCIATED CONDITIONS**

- Contact (allergic or irritant) dermatitis
- Seborrheic dermatitis
- Psoriasis
- Candidiasis
- Atopic dermatitis

**DIAGNOSIS**

**HISTORY**

- Onset, duration, and change in the nature of the rash
- Presence of rashes outside the diaper area
- Associated scratching or crying
- Contact with infants with a similar rash
- Recent illness, diarrhea, or antibiotic use
- Fever
- Pustular drainage
- Lymphangitis

**PHYSICAL EXAM**
- Mild forms consist of shiny erythema ± scale.
- Margins are not always evident.
- Moderate cases have areas of papules, vesicles, and small superficial erosions.
- It can progress to well-demarcated ulcerated nodules that measure ≥1 cm in diameter.
- It is found on the prominent parts of the buttocks, medial thighs, mons pubis, and scrotum.
- Skin folds are spared or involved last.
- *Tidemark dermatitis* refers to the bandlike form of erythema of irritated diaper margins.
- Diaper dermatitis can cause an id reaction (autoeczematous) outside the diaper area.

**DIFFERENTIAL DIAGNOSIS**
- Contact dermatitis
- Seborrheic dermatitis
- Candidiasis
- Atopic dermatitis
- Scabies
- Acrodermatitis enteropathica
- Letterer-Siwe disease
- Congenital syphilis
- Child abuse
- Streptococcal infection
- Kawasaki disease
- Biotin deficiency
- Psoriasis
- HIV infection

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
Rarely needed
Follow-Up Tests & Special Considerations

- Consider a culture of lesions or a potassium hydroxide (KOH) preparation.
- The finding of anemia in association with hepatosplenomegaly and the appropriate rash may suggest a diagnosis of Langerhans cell histiocytosis or congenital syphilis.
- Finding mites, ova, or feces on a mineral oil preparation of a burrow scraping can confirm the diagnosis of scabies.

Test Interpretation

- Biopsy is rare.
- Histology may reveal acute, subacute, or chronic spongiotic dermatitis.

TREATMENT

Prevention is the key to treatment of this condition.

GENERAL MEASURES

- Expose the buttocks to air as much as possible.
- Use mild, slightly acidic cleanser with water; no rubbing and pat dry.
- Avoid impermeable waterproof pants during treatment (day or night); they keep the skin wet and subject to rash or infection.
- Change diapers frequently, even at night, if the rash is extensive.
- Superabsorbable diapers are beneficial, as they wick urine away from skin and still allow air to permeate (2)[C].
- Discontinue using baby lotion, powder, ointment, or baby oil (except zinc oxide).
- Use of appropriately formulated baby wipes (fragrance-free) is safe and as effective as water (3)[B].
- Apply zinc oxide ointment or other barrier cream to the rash at the earliest sign and BID or TID (e.g., Desitin or Balmex). Thereafter, apply to clean, thoroughly dried skin (4)[C].
- Cornstarch can reduce friction. Talc powders that do not enhance the growth of yeast can provide protection against frictional injury in diaper dermatitis, but do not form a continuous lipid barrier layer over the skin and obstruct the skin pores. These treatments are not recommended.

MEDICATION
**First Line**
- For a pure contact dermatitis, a low-potency topical steroid (hydrocortisone 0.5–1% TID for 3 to 5 days) and removal of the offending agent (urine, feces) should suffice.
- If candidiasis is suspected or diaper rash persists, use an antifungal such as miconazole nitrate 2% cream, miconazole powder, econazole (Spectazole), clotrimazole (Lotrimin), or ketoconazole (Nizoral) cream at each diaper change.
- If inflammation is prominent, consider a very low-potency steroid cream such as hydrocortisone 0.5–1% TID along with an antifungal cream ± a combination product such as clioquinol–hydrocortisone (Vioform–Hydrocortisone) cream.
- If a secondary bacterial infection is suspected, use an antistaphylococcal oral antibiotic or mupirocin (Bactroban) ointment topically.
- Precautions: Avoid high- or moderate-potency steroids often found in combination of steroid antifungal mixtures—these should never be used in the diaper area.

**Second Line**
- Sucralfate paste for resistant cases
- Recent study suggests that use of hydrocolloid dressings can speed healing of rash.

**ISSUES FOR REFERRAL**
Consider if a systemic disease such as Langerhans cell histiocytosis, acrodermatitis enteropathica, or HIV infection is suspected.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission criteria/initial stabilization
  - Febrile neonates
  - Recalcitrant rash suggestive of immunodeficiency
  - Toxic-appearing infants
- Assist first-time parents with hygiene education.

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Recheck weekly until clear, then at times of recurrence.

PATIENT EDUCATION
Patient education is vital to the treatment and prevention of recurrent cases.

PROGNOSIS
- Quick, complete clearing with appropriate treatment
- Secondary candidal infections may last a few weeks after treatment has begun.

COMPLICATIONS
- Secondary bacterial infection (Consider community-acquired methicillin-resistant Staphylococcus aureus [MRSA] in pustular dermatitis that does not respond to normal therapy.)
- Rare complication is inoculation with group A β-hemolytic Streptococcus resulting in necrotizing fasciitis.
- Secondary yeast infection

REFERENCES

ADDITIONAL READING
Algorithm: Rash

CODES

ICD10
- L22 Diaper dermatitis
- B37.2 Candidiasis of skin and nail

CLINICAL PEARLS
- Hygiene is the main preventative measure.
- Look for secondary infection in persistent cases.
DERMATITIS, SEBORRHEIC

Juan Qiu, MD, PhD

BASICS

DESCRIPTION

Chronic, superficial, recurrent inflammatory rash affecting sebum-rich, hairy regions of the body, especially the scalp, eyebrows, and face.

EPIDEMOIOLOGY

Incidence

- Predominant age: infancy, adolescence, and adulthood
- Predominant sex: male > female

Prevalence

Seborrheic dermatitis: 3–5%

ETIOLOGY AND PATHOPHYSIOLOGY

- Skin surface yeasts Malassezia may be a contributing factor (1).
- Genetic and environmental factors: Flares are common with stress/illness.
- Parallels increased sebaceous gland activity in infancy and adolescence or as a result of some acnegenic drugs.
- Seborrheic dermatitis is more common in immunosuppressed patients, suggesting that immune mechanisms are implicated in the pathogenesis of the disease, although the mechanisms are not well defined (1).

Genetics

Positive family history; no genetic marker is identified to date.

RISK FACTORS

- Parkinson disease, epilepsy, traumatic brain and spinal cord injury, Down syndrome (1)
- AIDS, lymphoma, organ transplantation (1)
- Emotional stress (1)
- Medications may flare/induce seborrheic dermatitis: buspirone, chlorpromazine, ethionamide, griseofulvin, haloperidol, interferon-α,
methyldopa, psoralen, IL-2 (1)

**GENERAL PREVENTION**
Seborrheic skin should be washed more often than usual.

**COMMONLY ASSOCIATED CONDITIONS**
- Parkinson disease
- AIDS

**DIAGNOSIS**
Diagnosis of seborrheic dermatitis usually can be made by history and physical exam.

**HISTORY**
- Intermittent active phases manifest with burning, scaling, and itching, alternating with inactive periods; activity is increased in winter and early spring, with remissions commonly occurring in summer.
- Infants
  - Cradle cap: greasy scaling of scalp, sometimes with associated mild erythema
  - Diaper and/or axillary rash
  - Age at onset typically ~1 month
  - Usually resolves by 8 to 12 months
- Adults
  - Red, greasy, scaling rash in most locations consisting of patches and plaques with indistinct margins
  - Red, smooth, glazed appearance in skin folds
  - Minimal pruritus
  - Chronic waxing and waning course
  - Bilateral and symmetric
  - Most commonly located in hairy skin areas: scalp and scalp margins, eyebrows and eyelid margins, nasolabial folds, ears and retroauricular folds, presternal area, middle to upper back, buttock crease, inguinal area, genitals, and armpits

**PHYSICAL EXAM**
- Scalp appearance varies from mild, patchy scaling to widespread, thick,
adherent crusts. Plaques are rare.

- Seborrheic dermatitis can spread onto the forehead, the posterior part of the neck, and the postauricular skin, as in psoriasis.
- Skin lesions manifest as brawny or greasy scaling over red, inflamed skin.
- Hypopigmentation is seen in African Americans.
- Infectious eczematoid dermatitis, with oozing and crusting, suggests secondary infection.
- Seborrheic blepharitis may occur independently.

DIFFERENTIAL DIAGNOSIS

- Atopic dermatitis: Distinction may be difficult in infants.
- Psoriasis
  - Usually, knees, elbows, and nails are involved.
  - Scalp psoriasis will be more sharply demarcated than seborrhea, with crusted, infiltrated plaques rather than mild scaling and erythema.
- Candida
- Tinea cruris/capitis: Suspect these when usual medications fail or hair loss occurs.
- Eczema of auricle/otitis externa
- Rosacea
- Discoid lupus erythematosus: Skin biopsy will be beneficial.
- Histiocytosis X: may appear as seborrheic-type eruption
- Dandruff: scalp only, noninflammatory

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other

Consider biopsy if

- Usual therapies fail.
- Petechiae are noted.
- Histiocytosis X is suspected.
- Fungal cultures in refractory cases or when pustules and alopecia are present

Test Interpretation

Nonspecific changes

- Hyperkeratosis, acanthosis, accentuated rete ridges, focal spongiosis, and parakeratosis are characteristic.
- Parakeratotic scale around hair follicles and mild superficial inflammatory
**TREATMENT**

**GENERAL MEASURES**

- Increase frequency of shampooing.
- Sunlight in moderate doses may be helpful.
- Cradle cap
  - Frequent shampooing with a mild, nonmedicated shampoo
  - Remove thick scale by applying warm mineral oil and then wash off 1 hour later with a mild soap and a soft-bristle toothbrush or terrycloth washcloth.
- Adults: Wash all affected areas with antiseborrheic shampoos. Start with over-the-counter products (selenium sulfide) and increase to more potent preparations (containing coal tar, sulfur, or salicylic acid) if no improvement is noted.
- For dense scalp scaling, 10% liquor carbonic detergents in Nivea oil may be used at bedtime, covering the head with a shower cap. This should be done nightly for 1 to 3 weeks.

**MEDICATION**

**First Line**

- Cradle cap: Use a coal tar shampoo or ketoconazole (Nizoral) shampoo if the nonmedicated shampoo is ineffective.
- Adults
  - Topical antifungal agents
    - Ketoconazole or miconazole 2% shampoo twice a week for clearance and then once a week or every other week for maintenance (1–3)[A]
    - Ketoconazole (Nizoral) and sertaconazole 2% cream may be used to clear scales in other areas (1–3)[A].
    - Ciclopirox 1% shampoo twice weekly (1–3)[A]
  - Topical corticosteroids
    - Begin with 1% hydrocortisone and advance to more potent (fluorinated) steroid preparations, as needed (1–3)[A].

- Avoid continuous use of the more potent steroids to reduce the risk of skin atrophy, hypopigmentation, or systemic absorption (especially in infants and children).
- Precautions: Fluorinated corticosteroids and higher concentrations of
hydrocortisone (e.g., 2.5%) may cause atrophy or striae if used on the face or on skin folds.

- Other topical agents
  - Coal tar 1% shampoo twice a week
  - Selenium sulfide 2.5% shampoo twice a week
  - Zinc pyrithione 1% shampoo twice a week
  - Lithium gluconate/succinate 8% ointment/gel twice a week (4)[A]

- Once controlled, washing with zinc soaps or selenium lotion with periodic use of steroid cream may help to maintain remission.

**Second Line**

- Calcineurin inhibitors
  - Pimecrolimus 1% cream BID (4)[A]
  - Tacrolimus 0.1% ointment (4)[A]

- Systemic antifungal therapy
  - Data are limited.
  - For moderate to severe seborrheic dermatitis
    - Ketoconazole: 200 mg/day (5)[A]
    - Itraconazole: 200 mg/day (5)[A]

- Low-molecular-weight hyaluronic acid
  - Hyaluronic acid sodium salt gel 0.2% BID (6)[B]

**Issues for Referral**

No response to first-line therapy and concerns regarding systemic illness (e.g., HIV)

**Ongoing Care**

**Follow-Up Recommendations**

**Patient Monitoring**

Every 2 to 12 weeks, as necessary, depending on disease severity and degree of patient sophistication
PATIENT EDUCATION

PROGNOSIS
- In infants, seborrheic dermatitis usually remits after 6 to 8 months.
- In adults, seborrheic dermatitis is usually chronic and unpredictable, with exacerbations and remissions. Disease is usually easily controlled with shampoos and topical steroids.

COMPLICATIONS
- Skin atrophy/striae are possible from fluorinated corticosteroids, especially if used on the face.
- Glaucoma can result from use of fluorinated steroids around the eyes.
- Photosensitivity is caused occasionally by tars.
- Herpes keratitis is a rare complication of herpes simplex: Instruct patient to stop eyelid steroids if herpes simplex develops.

REFERENCES

ADDITIONAL READING

**SEE ALSO**

Algorithm: Rash

**CODES**

**ICD10**
- L21.9 Seborrheic dermatitis, unspecified
- L21.1 Seborrheic infantile dermatitis
- L21.0 Seborrhea capitis

**CLINICAL PEARLS**
- Search for an underlying systemic disease in a patient who is unresponsive to usual therapy.
- In adults, seborrheic dermatitis is usually chronic and unpredictable, with exacerbations and remissions. Disease is usually easily controlled with shampoos and topical steroids.
DERMATITIS, STASIS

Joseph A. Florence, MD • Fereshteh Gerayli, MD, FAAFP

BASICS

DESCRIPTION

- Chronic, eczematous, erythema, scaling, and noninflammatory edema of the lower extremities accompanied by cycle of scratching, excoriations, weeping, crusting, and inflammation in patients with chronic venous insufficiency (CVI), due to impaired circulation and other factors (nutritional edema)
- Clinical skin manifestation of CVI usually appears late in the disease.
- May present as a solitary lesion; can be associated with venous leg ulcer, which is located on the medial or lateral side of the ankle
- System(s) affected: skin/exocrine
- Synonym(s): gravitational eczema; varicose eczema; venous dermatitis

EPIDEMIOLOGY

Incidence

- In the United States: common in patients age >50 years (6–7%)
- Predominant age: adult, geriatric
- Predominant sex: female > male

Geriatric Considerations

Common in this age group:

- Estimated to affect 15 to 20 million patients age >50 years in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

- Incompetence of perforating veins, superficial venous thrombosis from varicose veins, and deep vein thrombosis can each contribute to CVI leading to venous hypertension (HTN) and cutaneous inflammation. This can be a pathway to venous leg ulcer.
- Deposition of fibrin around capillaries
- Microvascular abnormalities
- Ischemia
Continuous presence of edema in ankles, usually present because of venous valve incompetency (varicose veins)
- Weakness of venous walls in lower extremities
- Trauma to edematous, eczematized skin
- Itch may be caused by inflammatory mediators (from mast cells, monocytes, macrophages, or neutrophils) liberated in the microcirculation and endothelium.
- Abnormal leukocyte–endothelium interaction is proposed to be a major factor.
- A cascade of biochemical events leads to ulceration.

**Genetics**
Familial link probable

**RISK FACTORS**
- Atopy
- Chronic edema
- Old age
- Obesity
- Previous DVT
- Previous pregnancy
- Prolonged standing
- Secondary infection
- Superimposition of itch–scratch cycle
- Trauma
- Low-protein diet
- Genetic propensity
- Tight garments that constrict the thigh
- Vein stripping
- Vein harvesting for coronary artery bypass graft surgery
- Previous cellulitis

**GENERAL PREVENTION**
- Use compression stockings to avoid recurrence of edema and to mobilize the interstitial lymphatic fluid from the region of stasis dermatitis and also following DVT.
- Topical lubricants twice a day to prevent fissuring and itching

**COMMONLY ASSOCIATED CONDITIONS**
- Varicose veins
- Venous insufficiency
- Other eczematous disease
- Hyperhomocysteinemia
- Venous HTN

**DIAGNOSIS**

**HISTORY**
- Itching, pain, and burning may precede skin signs, which are aggravated during evening hours.
- Insidious onset
- Usually bilateral
- Description may include aching/heavy legs.
- Erythema, scaling, edema of lower extremities
- Noninflammatory edema preceded the skin eruption and ulceration.
- Edema initially develops around the ankle.

**PHYSICAL EXAM**
- Evaluation of the lower extremities characteristically reveals:
  - Bilateral scaly, eczematous patches, papules, and/or plaques
  - Violaceous (sometimes brown), erythematous lesions due to deoxygenation of venous blood (postinflammatory hyperpigmentation and hemosiderin deposition within the cutaneous tissue)
- Distribution: medial aspect of ankle, with frequent extension onto the foot and lower leg, occasionally lateral side of ankle
- Brawny induration
- Stasis ulcers (frequently accompany stasis dermatitis) secondary to minor trauma
- Excoriations
- Weeping, crusting, inflammation of the skin
- Varicosities are often associated with ulcers.
- Clinical inspection reveals swelling and warmth.
- Skin changes are more common in the lower 1/3 of the extremity and medially.
- Early signs include prominent superficial veins and pitting ankle edema.
- May present as a solitary lesion mimicking a neoplasm
DIFFERENTIAL DIAGNOSIS

- Other eczematous diseases:
  - Atopic dermatitis
  - Uremic dermatitis
  - Contact dermatitis (due to topical agents used to self-treat)
  - Neurodermatitis
  - Arterial insufficiency
  - Sickle cell disease causing skin ulceration
  - Cellulitis
  - Erysipelas
- Tinea dermatophyte infection
- Pretibial myxedema
- Nummular eczema
- Lichen simplex chronicus
- Xerosis
- Asteatotic eczema
- Amyopathic dermatomyositis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Duplex ultrasound imaging is helpful in diagnosis.

Diagnostic Procedures/Other
- Rule out arterial insufficiency. Check peripheral pulses; ankle brachial pressure index (ABPI or ABI)
- Check for diabetes.

Test Interpretation
- ABPI <0.8 is suggestive of arterial insufficiency.
- ABPI can be elevated, >1.2 in diabetic patients and others with distal small vessel calcifications.
- Arterial duplex ultrasound and angiography are the gold standards.

TREATMENT

GENERAL MEASURES
Primary role of treatment is to reverse effects of venous HTN. Appropriate health care:

- **Outpatient:**
  - Reduce edema:
    - Leg elevation: legs above the level of heart for 30 minutes, 3 to 4 times daily. Avoid prolonged dependent position.
    - Compression therapy: This is the mainstay of treatment of venous stasis plus/minus ulcers. Compression bandages can be safely applied in patients with ABI of 0.8 to 1.2.
    - Elastic bandage wraps: Ace bandages or Unna paste boot (zinc gelatin) or compression stockings (compression stockings)
      - Graduated elastic compression of 30 to 40 mm Hg at the ankle improves ulcer healing rate and may prevent ulcer recurrence (1)[A].
      - Compression bandages containing both elastic and inelastic components (mixed component systems) are as effective as four-layer bandages, are easier to apply, and have less slippage and associated with favorable quality of life outcomes.
      - High compression is contraindicated in arterial insufficiency.
      - Pneumatic compression devices are beneficial, especially in nonambulatory patients and those with a component of arterial insufficiency (2)[B].
  - Improvement of lipodermatosclerosis:
    - Activity:
      - Avoid standing still.
      - Stay active and exercise regularly.
      - Elevate foot of bed unless contraindicated.
  - Inpatient, for endovascular radiofrequency ablation, vein stripping, sclerotherapy, or skin grafts:
    - Venous ulcer treatment: Treat infection: Débride the ulcer base of necrotic tissue (surgical necrotomy if possible, or enzymatic débridement with collagenase).
      - Autolytic: Modern wound dressings (hydrogel, hydrocolloids, alginate, foam bandages, plain nonadherent dressing) are better than traditional wet to dry dressing as they maintain moist wound environment, with less tissue damage on removal and less frequent changing requirement (2)[A]. However, there is no difference in healing rate of venous stasis ulcers by use of hydrocolloid dressing versus simple nonadherent dressing when used beneath compression.
      - Biologic: Topical application of granulocyte-macrophage colony-
stimulating factor promotes healing of ulcers (insufficient evidence).

- **Mechanical:** wet to dry dressings, hydrotherapy, and irrigation
- **Surgical:** modifying cause of venous HTN (by venous ligation, valvuloplasty, and endoscopic perforator vein surgery); treat ulcer by graft.

**MEDICATION**

**First Line**
- Pentoxifylline 400 mg TID is effective in treating venous leg ulcer.
- Enteric-coated aspirin (at least 300 mg) daily may improve venous ulcer healing.

In light of increasing bacterial resistance to antibiotics, current guidelines recommend the use of antibacterial preparations only for clinical infection (cellulitis, increased pain, warmth, malodorous exudate), not for bacterial colonization (3)[A].

- If secondary infection, treat with PO antibiotics for *Staphylococcus* or *Streptococcus* organisms (e.g., dicloxacillin 250 mg QID, cephalexin 500 mg BID, or levofloxacin 500 mg daily).
- If MRSA suspected, clindamycin 300 mg QID, doxycycline 100 mg BID, TMP/SMX or IV vancomycin

There is no reliable evidence in the effectiveness of topical antiseptics such as povidone-iodine, peroxide-based preparations, mupirocin, chlorhexidine (3) [A].

- Uncomplicated stasis dermatitis can be treated with short courses (about 2 weeks) of topical steroids (2)[B] (topical triamcinolone 0.1% cream/ointment BID).
- Topical antipruritic: pramoxine, camphor, menthol, and doxepin
- Topical anesthetic (lidocaine/prilocaine) may reduce pain during débridement.
- Systemic steroids for severe cases
- Silver sulfadiazine (SSD) has a positive effect in wound healing (2)[A].

**Second Line**
- Consider antibiotics on basis of culture results of exudate from infected ulcer craters.
- Lubricants when dermatitis is quiescent
- Chronic stasis dermatitis can be treated with topical emollients (e.g., white petroleum, lanolin).
- Antipruritic medications (e.g., diphenhydramine, cetirizine hydrochloride)
Hydrocolloid or a foam dressing may reduce ulcer pain; no evidence that ibuprofen dressings offer pain relief

ISSUES FOR REFERRAL
Consider referral for:
- Nonhealing ulcer
- Arterial insufficiency
- Uncertain diagnosis
- Rheumatoid arthritis
- Patch testing to evaluate for contact dermatitis
- Associated disease (e.g., symptomatic varicose veins)

ADDITIONAL THERAPIES
If the patient is on amlodipine, consider discontinuing.

SURGERY/OTHER PROCEDURES
Sclerotherapy and surgery may be required for associated disease.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- If Unna boot compression is used: Cut off and reapply boot once a week. Unna boots reduce edema by compression and prevent scratching.
- Regular use of high-compression stockings reduces chance of recurrent venous ulcer (4)[A].

DIET
Lose weight, if overweight.

PATIENT EDUCATION
- Encourage staying active to keep circulation and leg muscles in good condition. Walking is ideal.
- Keep legs elevated while sitting or lying.
- Do not wear girdles, garters, or pantyhose with tight elastic tops.
- Do not scratch.
Avoid leg injury.
Elevate foot of bed with 2- to 4-inch blocks.
Apply compression stockings prior to getting out of bed when less edema is present. Regular use of high-compression stockings may prevent recurrence of venous ulcers.

**PROGNOSIS**
- Chronic course with intermittent exacerbations and remissions
- The healing process for ulceration is often prolonged and may take months.

**COMPLICATIONS**
- Sensations of itching, pain, and burning have negative impact on the quality of life.
- Secondary bacterial infection
- DVT
- Bleeding at dermatitis sites
- Squamous cell carcinoma in edges of long-standing stasis ulcers
- Scarring, which in turn leads to further compromise to blood flow and increased likelihood of minor trauma

### SEE ALSO
- Varicose Veins
- Algorithm: Rash

### CODES

#### ICD10
- I83.10 Varicose veins of unsp lower extremity with inflammation
- I83.11 Varicose veins of right lower extremity with inflammation
- I83.12 Varicose veins of left lower extremity with inflammation

### CLINICAL PEARLS
- Treatment of edema associated with stasis dermatitis via elevation and/or compression stockings or bandages is essential for optimal results.
- Pentoxifylline and aspirin may improve venous ulcer healing.
- No difference in healing rate of venous stasis ulcers by use of hydrocolloid dressing versus simple non-adherent dressing when used beneath compression. Decision about the dressing should be based on local cost and patient or physician’s preferences.
- Mild topical corticosteroids reduce inflammation and itching; however, these may potentiate infection; high-potency topical corticosteroids should be avoided due to increased risk of atrophy and ulceration.
DIABETES MELLITUS, TYPE 1
Irfan Siddiqui, MD • Armand Krikorian, MD, FACE, FACP

BASICS
DESCRIPTION
- Type 1 diabetes mellitus (T1DM) is a chronic disease caused by pancreatic insufficiency (deficiency) of insulin production.
- Results in hyperglycemia and end-organ complications (e.g., accelerated atherosclerosis, neuropathy, nephropathy, and retinopathy)
- Features include the following:
  - Patients are insulinopenic and require insulin.
  - Polyphagia, polydipsia, and polyuria
  - Ketosis
  - Usually rapid onset
  - Body habitus: usually normal or thin physique
- System(s) affected: endocrine/metabolic

Pregnancy Considerations
- Hyperglycemia increases the incidence of congenital malformations. Tight control of blood sugar prior to conception (goal A1C <6.5%) is important (1).
- Family planning should be discussed and effective contraception offered until A1C is within goal range to reduce the risk of congenital anomalies.
- Women with microalbuminuria during the 1st trimester are at increased risk for preeclampsia and preterm delivery.
- A safe pregnancy is possible with vaginal delivery of a term baby. Close monitoring of blood sugar during labor is important.
- Many drugs used to treat diabetic complications are relatively/absolutely contraindicated in pregnancy.
- Perinatal and psychological stressors are associated with T1DM in children.

EPIDEMIOLOGY
- Age of onset peaks between 5 and 7 years of age and again around puberty; rapid decline in incidence after adolescence
- Slightly more common in males than females
Overall incidence is increasing worldwide.
More cases are diagnosed in the autumn and winter than in spring and summer.

**Incidence**
- 18/100,000 per year in the United States (0 to 60/100,000 worldwide) (2)
- Average lifetime prevalence risk of T1DM in the general population is 0.4%.
- Racial predilection for whites
- African Americans have lowest overall incidence.

**Pediatric Considerations**
- Although onset is usually before the age of 19 years, T1DM can occur for the first time in patients who are well into their 30s.
- Young children are more likely to present in diabetic ketoacidosis (DKA) due to atypical presentation and because they may not express thirst or obtain fluids as readily as older children or adults.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Genetic predisposition is thought to exist.
- Alteration in immunologic integrity, placing the $\beta$-cell at special risk for inflammatory damage
- Autoantibodies present in >90% of patients at presentation: glutamic acid decarboxylase (GAD), insulinoma-associated autoantigen 2 (IA2A), zinc transporter 8 (ZnT8A), and insulin (IAA) (2)
- Associated environmental triggers (none have been verified):
  - Vitamin D deficiency
  - Infant feeding practices (short-term breastfeeding, early exposure to complex proteins)
  - Viruses (e.g., enteroviruses, retroviruses)
  - Environmental toxins
- Various epigenetic modifications of gene expression (DNA methylation, histone modifications, and $\mu$-RNA dysregulation) have been noted, further suggesting a role between genetics and environment in the development of T1DM (3).

**Genetics**
- T1DM is a polygenic disorder with 40+ loci known to affect susceptibility to the disease (2).
Genes located on major histocompatibility complex (MHC) on chromosome 6 provide about half of the genetic susceptibility leading to T1DM risk (2). HLA class II shows the strongest association with T1DM risk, but class I MHCs also affect risk (2).

**RISK FACTORS**
- Certain human leukocyte antigen (HLA) types, MHC classes, and autoantibodies (2)
- Increased susceptibility to T1DM is inheritable (3):
  - Only 10–15% of newly diagnosed patients with T1DM have a positive family history of T1DM.
  - Among autoimmune conditions, T1DM has the highest concordance rates in monozygotic twins.
  - Average prevalence risk of T1DM in children of patients with T1DM is ~6%.
  - Relative risk for siblings of patients with T1DM is about 15%.
- See environmental triggers above (2).

**COMMONLY ASSOCIATED CONDITIONS**
- Autoimmune diseases, such as celiac disease, vitamin $B_{12}$ deficiency, and Hashimoto hypothyroidism
- T1DM can also be seen as part of autoimmune polyendocrine syndromes.

**DIAGNOSIS**

**DIFFERENTIAL DIAGNOSIS**
- Benign renal glycosuria
- Glucose intolerance
- Type 2 diabetes
- Consider monogenic diabetes if
  - Diabetes diagnosed before 6 months of age
  - Strong family history of diabetes without classic features of type 2 diabetes
  - Mild fasting hyperglycemia
  - Nonobese diabetic child with negative autoantibodies
- Secondary diabetes
  - Pancreatic disease (chronic pancreatitis, cystic fibrosis, hereditary hemochromatosis)
– Endocrine-associated diabetes: acromegaly, Cushing syndrome, pheochromocytoma, glucagonoma, neuroendocrine tumors
– Drug- or chemical-induced glucose intolerance: glucocorticosteroids, HIV protease inhibitors, atypical antipsychotics, tacrolimus, cyclosporine
• Acute poisonings (salicylate poisoning can cause hyperglycemia and glycosuria, and may mimic DKA)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Criteria for the diagnosis of diabetes (1)[C]:
  – Fasting glucose ≥126 mg/dL (7.0 mmol/L)
  – Random of ≥200 mg/dL (11.1 mmol/L) in a patient with classic symptoms of hyperglycemia
  – Oral glucose tolerance test; plasma glucose $200 mg/dL 2 hours after a glucose load of 1.75 g/kg (max dose 75 g)
  – Glycated hemoglobin (HbA1c) level ≥6.5%
  – In the absence of unequivocal hyperglycemia, results should be confirmed by repeat testing.
• Other tests to consider:
  – Serum electrolytes, especially in sicker patients who may have ketoacidosis
  – Urinalysis for glucose, ketones, and microalbuminuria
  – Pancreatic autoantibodies
    o Islet cell, IAA, GAD, IA2A, and ZnT8A
  – CBC (WBC count and hemoglobin may be elevated)
• C-peptide insulin level if needed to differentiate from type 2 diabetes. A low level or no C-peptide indicates that the pancreas is producing little or no insulin.

Test Interpretation
Inflammatory changes, lymphocytic infiltration around the islets of Langerhans, or islet cell loss

HISTORY
• Polyuria and polydipsia (4)[C]
  – Polyuria may present as nocturia, bedwetting, or incontinence in a previously continent child.
  – Polyuria may be difficult to appreciate in diaper-clad children.
• Weight loss 10–30%
– Often almost devoid of body fat at diagnosis due to hypovolemia and increased catabolism

- Prolonged or recurrent candidal infection, usually in the diaper area
- Increased fatigue, lethargy, muscle cramps
- Abdominal discomfort, nausea
- Vision changes, such as blurriness
- Altered school or work performance

**TREATMENT**

**GENERAL MEASURES**

- Overall control of carbohydrate metabolism for all pediatric age ranges (1)[C]
- Education regarding matching of mealtime insulin dose to carbohydrate intake, premeal blood glucose level and anticipated activity (1)
  - Before meals, strive for blood glucose levels in range of 90 to 1,300 mg/dL (5.0 to 7.2 mmol/L).
  - Bedtime/overnight: 90 to 150 mg/dL (5.0 to 8.3 mmol/L)
  - A1c goal: <7.5% across all pediatric age groups
  - A1c <7.0% is reasonable if achieved without excessive hypoglycemia.
- Very tight control might be dangerous in young children due to risk of repeated hypoglycemia.

<table>
<thead>
<tr>
<th>Adult A1c goal: &lt;7.0% (1)[B]</th>
</tr>
</thead>
<tbody>
<tr>
<td>– A1c &lt;6.5% reasonable in select individuals (1)[C]</td>
</tr>
<tr>
<td>– Less stringent A1c goals (such as &lt;8%) may be appropriate for elderly patients and other special populations (1)[B].</td>
</tr>
</tbody>
</table>

- Normal growth and development and overall good health (asymptomatic) (4)[C]:
  - Reach optimal height for genetic potential.
  - Appropriate and timely pubertal maturation
  - Coping psychosocial development: normal school or work attendance and performance; normal goals/career plans. Screen for depression.
- Prevent acute complications, including hypoglycemic insulin reactions and ketoacidosis, and delay or prevent chronic end-organ complications.

**MEDICATION**

- Most patients with T1DM will require insulin supplementation, either multiple-dose insulin (MDI) injections or continuous subcutaneous insulin
infusion (CSII) (1)[A].

Types of insulin (1)[C]:
- Long-acting insulin analogues: insulin glargine (Lantus/Toujeo), insulin detemir (Levemir), and insulin degludec (Tresiba). These should not be mixed with other insulins in the same syringe.
- Intermediate-acting insulin (NPH)—Humulin N or Novolin N—can be mixed with other insulins.
- Short-acting (regular) insulin: Novolin R or Humulin R
- Very rapid-acting insulin analogues: insulin lispro (Humalog), insulin aspart (Novolog), and insulin glulisine (Apidra)

First Line
- Flexible intensive insulin therapy is the gold standard.
- MDI or CSII have equal efficacy (1)[B].
- Total initial dose is 0.2 to 0.4 U/kg/day for insulin-naïve patients (will often need 0.6 to 0.7 U/kg/day).
- 40–60% of total dose given as basal insulin, with the rest as bolus insulin

MDI regimen (1)[A],(5)[C]:
- Basal, long-acting insulin once or twice a day
- Prandial, short-acting insulin based on number of carbohydrate portions (e.g., 1:10, meaning 1 U of insulin for every 10 g of carbohydrate to be eaten)
- Correctional short-acting mealtime insulin based on premeal blood glucose level (subtract target blood glucose level and divided by sensitivity factor)

CSII regimen:
- May use regular insulin or rapid-acting insulin analogues
- Insulin is infused continuously at a preset rate, and bolus doses are given with meals as above.

Second Line
- Twice-daily injections with NPH along with regular or rapid-acting insulin
- Not physiologic, but lower cost and fewer injections may improve adherence in the less-motivated patient.
- Pramlintide. Delays gastric emptying, increases satiety and weight loss; if used, adjustment of mealtime insulin dose required
- Pancreatic transplantation is usually reserved for patients with end-stage renal failure, who may receive kidney-pancreatic transplants at the same time.
- Oral hypoglycemics generally not indicated in type 1 diabetes
● Ongoing trials with tocilizumab to prevent beta cell loss in type 1 diabetes

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Newly diagnosed patients with T1DM may require hospitalization during initiation of insulin therapy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
● Normal; full participation in sports activities
● Regular aerobic exercise is recommended.

Patient Monitoring
● Blood pressure (BP) checks at every routine visit with a goal of systolic pressure of <140 mm Hg and diastolic of <90 mm Hg (1)[A]. If elevated, consider an ACE inhibitor or an angiotensin receptor blocker but not both; avoid in pregnancy (1)[B].
● Monitor height, weight, and sexual maturation (in children) (5)[C].
● Daily home blood glucose monitoring with home blood glucose meter: Blood tests should be done at least 4 to 6 times daily (more frequently in pump patients) for optimal monitoring.
● Comprehensive foot exam at least annually
● Quarterly measurement of HbA1c
● In patients with diabetes and atherosclerotic cardiovascular risk, start high intensity statin in addition to lifestyle changes (1)[A].
● Annual screenings (1)[C]:
  – Microalbuminuria for earliest signs of possible nephropathy
  – Initial dilated comprehensive eye exam within 5 years of diagnosis and then annually
  – Monofilament testing with pinprick, temperature and vibration sensation for screening of peripheral neuropathy 5 years after diagnosis and then annually
  – Annual influenza vaccine in patients ≥6 months of age
  – Pneumococcal polysaccharide vaccine to all patients ≥2 years
  – Hepatitis B vaccination to unvaccinated adults aged 19 to 59 years
DIET
- Carbohydrate counting using insulin-to-carbohydrate ratio with all meals and snacks allows patient flexibility in eating.

PROGNOSIS
- Initial remission or honeymoon phase with decreased insulin needs and easier control, usually 3 to 6 months
- Current prognosis for reduced life expectancy:
  - Increasing longevity and quality of life with careful blood glucose monitoring, improvement in insulin delivery regimens, and appropriate glycemic control

COMPLICATIONS
- Microvascular disease (retinopathy, nephropathy, neuropathy)
- Hyperlipidemia
- Macrovascular disease (coronary and cerebral artery disease)
- Chronic foot ulcers/amputations
- Hypoglycemia
- DKA
- Excessive weight gain
- Increased risk for preeclampsia and preterm delivery
- Driving mishaps
- Psychological problems of chronic disease

REFERENCES

SEE ALSO

Diabetes Mellitus, Type 2; Diabetic Ketoacidosis

CODES

**ICD10**
- E10.9 Type 1 diabetes mellitus without complications
- E10.8 Type 1 diabetes mellitus with unspecified complications
- E10.69 Type 1 diabetes mellitus with other specified complication

CLINICAL PEARLS
- Polyuria may present as nocturia, bedwetting, or incontinence in a previously continent child.
- Young children are more likely to present in DKA because they may not express thirst or obtain fluids as readily as older children or adults.
- Onset usually before the age of 19 years, but type 1 diabetes can present in patients who are well into their 30s.
- Childhood vaccines have not shown to increase the risk of T1DM (6).
DIABETES MELLITUS, TYPE 2
Swathi A.N. Rao, MD • Sathya S. Krishnasamy, MD • Jeremy Golding, MD, FAAFP

BASICS

DESCRIPTION
Diabetes mellitus (DM) type 2 is due to a progressive insulin secretory defect in the setting of insulin resistance.

Geriatric Considerations
Monitor elderly for hypoglycemia; adjust doses for renal/hepatic dysfunction and cognitive function; less aggressive glucose targets than in younger patients

Pediatric Considerations
Incidence is increasing and parallels obesity epidemic.

Pregnancy Considerations
Diet, metformin, glyburide, and insulin are all options for treatment of gestational diabetes.

EPIDEMIOLOGY

Incidence
1.5 million new cases in 2015

Prevalence
- Estimated 23.1 million Americans (7.4% of the population); 90–95% are likely type 2.
- Higher education associated with lower prevalence

ETIOLOGY AND PATHOPHYSIOLOGY
- Peripheral insulin resistance and/or defective insulin secretion with increased hepatic gluconeogenesis
- Genetic factors: monogenic (e.g., PPARγ and insulin gene mutations) and polygenic
Obesity (body mass index [BMI] ≥25 kg/m²) and visceral adiposity
- Gut microbiome changes
- Drug- or chemical-induced (e.g., glucocorticoids, highly active antiretroviral therapy [HAART], atypical antipsychotics, organ transplant immunosuppressants)

**Genetics**
- Genome-wide association studies in progress to identify associated genes; 50% concordance in monozygotic twins
- Family history is strongly predictive of risk.

**RISK FACTORS**
- Gestational diabetes or history of baby with birth weight ≥4 kg (9 lb)
- Polycystic ovary syndrome (PCOS)
- Hypertriglyceridemia or low high-density lipoprotein (HDL)—marker for insulin resistance
- Ethnicity: African American, Latino, Native American, Asian, and Pacific Islander
- Sedentary lifestyle
- Use of thiazides, antipsychotics, glucocorticoids, and statins

**GENERAL PREVENTION**
- Maintenance of normal weight, or weight loss of 7% body weight, exercise 150 min/week, and decrease in carbohydrates and overall caloric intake. Moderate-intensity exercise and resistance training are recommended.
- Higher intake of nuts, coffee, tea, and yogurt (1)[A]
- Use of metformin and thiazolidinediones (TZDs) in select patients with prediabetes (1)[A].

**COMMONLY ASSOCIATED CONDITIONS**
Hypertension, dyslipidemia, metabolic syndrome, fatty liver disease, infertility, PCOS, acanthosis nigricans, hemochromatosis

**DIAGNOSIS**
**HISTORY**
Polyuria, polydipsia, polyphagia, weight loss, weakness, fatigue, blurry vision,
neuropathy, and frequent infections

**PHYSICAL EXAM**
BMI, funduscopic exam, oral exam, cardiopulmonary exam, abdominal exam for hepatomegaly, focused neurologic exam, and diabetic foot exam

**DIFFERENTIAL DIAGNOSIS**
- Type 1 DM—low or absent insulin, pancreatic autoantibodies, ketosis
- DM is one of the features of Cushing syndrome, acromegaly, and glucagonoma.

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

Criteria for diagnosis (1)[A]
- HbA1c ≥6.5% is diagnostic.
- Hyperglycemic crisis + random plasma glucose ≥200 mg/dL (11.1 mmol/L) or
- Fasting plasma glucose (FPG) ≥126 mg/dL (7.0 mmol/L) on two occasions or
- 2-hour plasma glucose ≥200 mg/dL (11.1 mmol/L) during oral glucose tolerance test (OGTT) with 75-g glucose load
- If equivocal, repeat testing.

*Follow-Up Tests & Special Considerations*
Screen patients with history of gestational diabetes for persistent diabetes/prediabetes 6 to 12 weeks postpartum with OGTT and at least every 3 years thereafter.

**TREATMENT**

It is uncertain as to whether and to what extent tight control of Type 2 diabetes prevents long-term macro- and microvascular complications (2),(3)[A]. Individuals most likely to benefit from a more aggressive target (below) are those without preexisting complications of diabetes, with recent diagnoses of DM, and with otherwise long life expectancy. Most medications have NOT been shown to improve long-term outcomes.

- Use patient-centered approach (individualized).
- Cornerstone of therapy is lifestyle modification and control of cardiovascular
risk factors (particularly blood pressure and lipids).
- Most oral agents lower A1c 0.5–1%. Most oral agents and insulin cause weight gain.
- A1C targets—according to ADA (recommendations NOT universally accepted as not fully evidence-based) (1)[C]:
  - A1C <7.0: for those with a long life expectancy and no cardiovascular disease (CVD) who has had DM for a short duration and no history of hypoglycemia
  - A1C <8.0%: for those with a limited life expectancy, advanced micro- or macrovascular complications, extensive comorbidities, and a history of hypoglycemia or long-standing DM in whom the general goal is difficult to attain
  - ADA guidelines—preprandial glucose of 80 to 130 mg/dL and peak postprandial glucose of <180 mg/dL (1)[C]
    - Many experts recognize more liberal targets than above as appropriate for many individuals (2),(3)[A].
- ADA: FPG goal is <110 mg/dL (5.5 mmol/L) and 2-hour postprandial goal is <140 mg/dL. Use drugs from different classes to achieve adequate control and limit side effects. Use monotherapy unless A1c is ≥9% → dual therapy; if A1c ≥10%, BG 300 mg/dL, and patient is symptomatic → insulin plus additional therapy (1)[A]

GENERAL MEASURES
- Diabetic foot exam at every visit
- Nephropathy: annual urine microalbumin-to-creatinine ratio if not on ACE-inhibitor
- Retinopathy: annual diabetic eye exam
- If 40 to 75 years old, begin a statin—moderate to high intensity based on ASCVD risk.
- Low-dose aspirin in patients ≥50 years old with at least one additional CV risk factor and without risks for GI bleeding
- Hypertension: goal BP <140/80 mm Hg (tighter control may be considered on individual basis)
- Pneumococcal (PPSV-23) for all adults and pneumococcal conjugate vaccine (PCV-13) for patients >65 years (and some younger—see CDC) and annual influenza vaccine

PATIENT EDUCATION
- Diabetes self-management education and support by certified diabetes educator
- Lifestyle modifications with or without pharmacotherapy delays prediabetes progression to diabetes (1)[A].

**MEDICATION**

**First Line**

- **Biguanides**
  - Metformin: preferred first medication for most because it likely reduces risk of death and promotes weight loss and improves insulin resistance. Dosage: 500 to 2,000 mg in divided doses or ER 1,000 to 2,000 mg every evening; maximum effective dose 2,000 mg/day (1,3)[A]
  - Avoid metformin in renal insufficiency with eGFR <30, prior to radiocontrast agent use, surgery, and severe acute illnesses (e.g., liver disease, cardiogenic shock, pancreatitis, hypoxia) due to risk of lactic acidosis.
  - Caution with acute heart failure, alcohol abuse, elderly; associated with GI side effects, vitamin B12 deficiency (monitor levels yearly)
  - Can be used in CKD patients with eGFR ≥45; can use reduced dose of ≤1,000 mg with close monitoring in patients with eGFR 30 to 45 (4)[A]

- **Dipeptidyl peptidase-4 inhibitors**
  - Weight neutral with minimal risk for hypoglycemia; dose adjustments in renal function decline with exception of linagliptin.
  - Alogliptin and saxagliptin are associated with heart failure, but sitagliptin is likely not.
  - Sitagliptin (Januvia): 100 mg/day
  - Saxagliptin (Onglyza): 2.5 mg/day, maximum 5 mg/day
  - Linagliptin (Tradjenta): 5 mg/day
  - Alogliptin (Nesina) 25 mg/day; significant interactions with metformin
  - Exenatide (Byetta, Bydureon): 5 to 10 μg SC BID within 60 minutes before meals and at least 6 hours apart or exenatide (extended-release) 2 mg/week
  - Should not be used in patients with personal history/family history of medullary thyroid cancer or multiple endocrine neoplasia (MEN) type 2 (black box warning)
– Liraglutide (Victoza): 0.6 mg/day SC for 1 week and then increase to 1.2, maximum 1.8 mg/day; less expensive and better tolerated than exenatide
– Albiglutide (Tanzeum): 30 to 50 mg SC q week in a single-dose pen
– Dulaglutide (Trulicity): 0.75 to 1.50 mg weekly
– Lixisenatide (Adlyxin): uptitration to 20 mcg SC qd; available in combination drug Soliqua (insulin glargine/lixisenatide)—15 to 60 units SC qd

SGLT2 inhibitors
– Inhibit glucose reabsorption by sodium glucose cotransporter-2 inhibition and cause modest weight loss, but might increase risk of lower extremity amputation. Avoid in patients with peripheral vascular disease and foot ulcers.
– Canagliflozin (Invokana): 100 to 300 mg single dose before breakfast; adjust dose with CKD.
– Dapagliflozin (Farxiga): 5 to 10 mg daily; avoid use if eGFR <60.
– Empagliflozin (Jardiance): 10 to 25 mg daily; avoid use if eGFR <45; shown to reduce cardiovascular morbidity and death (5)[B]
– May cause hypotension, genital mycotic infections, UTI, impairment of renal function

Second Line
– Insulin: rapid (aspart, lispro, glulisine), short (regular insulin), intermediate (neutral protamine hagedorn), long-acting (glargine, detemir), ultra long-acting (degludec), concentrated (Humulin U200, U500 Kwikpen, and solution with U500-specific syringes)
  – May be used in combination with some oral agents
  – Long-acting and ultra long-acting insulins have lower risk of hypoglycemia than short-acting.
  – Insulin detemir (Levemir) or insulin glargine (Lantus, Basaglar): 10 units (or 0.1 to 0.2 U/kg) once daily in the evening or 2 divided doses; added to oral agents and then titrated. Onset of action 1 hour. No peak; duration of action 16 to 23 hours
  – A variety of concentrations available U-100, U-200, and U-300
  – Insulin degludec (Tresiba): 0.2 to 0.4 U/kg in insulin-naïve patients or 1:1 conversion in insulin-experienced patients already on basal insulin. Combination basal/bolus insulin may be used (0.5 to 2.0 U/kg/day) after failure or oral agents.
  – Degludec/aspart 70/30 (Ryzodeg) available
  – Human insulin inhalation powder (Afrezza). Given as a single inhalation
before a meal, in combination with long-acting insulin; contraindicated in chronic lung disease; can cause edema when given with TZDs
  – Consider sensor-augmented insulin pump and CGM therapy and V-Go in select patients.

- **Amylinomimetic**
  – Pramlintide (Symlin): 60 to 120 μg SC before every major meal
  – Prandial insulins (short-acting/rapid-acting) should be reduced by 50% if pramlintide is initiated, to avoid hypoglycemia.

- **α-Glucosidase inhibitors**
  – Acarbose (Precose): 25 to 100 mg TID
  – Miglitol (Glyset): 25 to 100 mg TID
  – Take at beginning of meals to decrease postprandial hyperglycemia.

- **Avoid in renal insufficiency and bowel diseases.**

- **Meglitinide:** repaglinide (Prandin): 0.5 to 4.0 mg before meals; may be useful in patients with sulfa allergy or renal impairment

- **Diphenylalanine derivatives**
  – Nateglinide (Starlix): 60 to 120 mg before meals TID

- **Bile acid sequestrants**
  – Colesevelam: 3.75 g/day or 1.875 g BID

- **Sulfonylureas**
  – Caution with renal or liver disease, sulfa allergy, creatinine clearance <50 mL/min, pregnancy; may cause weight gain
  – Glipizide (Glucotrol): 2.5 to 40.0 mg/day; dosage >10 mg/day given BID 30 minutes before meals
  – Glipizide extended-release: 5 to 20 mg/day
  – Glyburide (DiaBeta, Glynase, Micronase): 1.25 to 20.0 mg/day, Glynase: 0.75 to 12.00 mg/day
  – Glimepiride (Amaryl): 1 to 8 mg/day

- **TZDs**
  – Obtain baseline liver function tests (LFTs). Use w/caution if history of heart failure.
  – Increased risk of fractures and low bone mass
  – Rosiglitazone (Avandia): 4 to 8 mg/day
  – Pioglitazone (Actos): 15 to 45 mg/day

- **Bromocriptine** (Cycloset): 1.6 to 4.8 mg PO q AM; a dopamine agonist, mechanism of action uncertain

- **Combination therapy**
  – Ertugliflozin/metformin hydrochloride (Segluromet): SGLT2 inhibitor and biguanide: 2.5 to 7.5 mg/500 to 1,000 mg
– Canagliflozin/metformin (Invokamet): 50 to 150/500 to 1,000 mg, max dose 300/2,000 mg, XR form available
– Dapagliflozin/metformin (Xigduo): 5 to 10/500 to 1,000 mg, max dose 10/2,000 mg; XR form available
– Empagliflozin/metformin (Synjardy): 5.0 to 12.5/500 to 1,000 mg, max dose 25/2,000 mg; XR form available
– Glipizide/metformin (Metaglip): 2.5/250 mg, 2.5/500 mg, 5/500 mg; 1 to 2 tabs PO qd BID
– Glyburide/metformin (Glucovance): 1.25/250 mg, 2.5/5000 mg, 5/500 mg; 1 TO 2 tabs PO BID
– Pioglitazone/metformin (ACTOplus met) available in IR and XR forms
– Rosiglitazone/metformin (Avandamet): 2/500 mg, 2/1,000 mg, 4/500 mg, 4/1,000 mg initial therapy; 1 to 2 tabs PO BID, max 8 mg/2,000 mg/day
– Repaglinide/metformin (Prandimet): 1/500 mg, 2/500 mg, individualize dose PO BID to TID
– Alogliptin/metformin (Kazano): 12.5/500 to 1000 mg, 1 tab PO BID, max dose 25/2,000 mg
– Linagliptin/metformin (Jentadueto): 2.5/500 to 1,000 mg, 1 tab PO BID, max dose 5/2,000 mg
– Kombiglyze XR—2.5 to 5.0/500 to 1,000 mg; 1 to 2 tabs PO qd, max dose 5/2,000 mg PO daily
– Sitagliptin/metformin (Janumet): available in XR
– Empagliflozin/linagliptin (Glyxambi): 10 to 25 mg/5 mg, 1 tab q AM
– Alogliptin/pioglitazone (Oseni): 12.5 to 25/15 to 45 mg, max dose 25/45 mg daily
– Combination Duetact pioglitazone with glimepiride (Duetact): 30/2 to 4 mg, 1 tab q AM
– Insulin glargine/lixisenatide (Soliqua 100/33): 15 to 60 units SC qd
– Insulin degludec/liraglutide (Xultophy 100/3.6): 16 to 50 units SC qd

**SURGERY/OTHER PROCEDURES**

For patients with BMI >35 kg/m², consider bariatric surgery (1)[A].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

mebooksfree.com
**Patient Monitoring**
- Monitor glucose, HbA1c, BP, body weight, lipid profile, and renal and liver function q 3mo at first.
- A1c twice a year for patients with well-controlled blood glucose and quarterly for patients with hyperglycemia or recent changes in therapy

**PROGNOSIS**
Normal lifespan with attention and prevention of comorbid complications

**COMPLICATIONS**
- Emergencies: hyperosmolar coma, diabetic ketoacidosis (DKA), Charcot joints
- Atherosclerotic CVD, peripheral vascular disease, stroke
- Microvascular: peripheral neuropathy, proliferative retinopathy, erectile dysfunction, and diabetic CKD
- Ophthalmic: blindness, cataracts, glaucoma, retinopathy
- GI: nonalcoholic fatty liver disease, gastroparesis, diarrhea
- Neurologic: autonomic dysfunction, foot ulcers and soft tissue infections

**REFERENCES**
SEE ALSO
- Diabetes Mellitus, Type 1; Diabetic Ketoacidosis; Hypertension, Essential
- Algorithm: Type 2 Diabetes, Treatment

CODES

ICD10
- E11.9 Type 2 diabetes mellitus without complications
- E11.319 Type 2 diabetes mellitus with unspecified diabetic retinopathy without macular edema
- E11.21 Type 2 diabetes mellitus with nephropathy

CLINICAL PEARLS

Individualize A1c targets based on life expectancy, preexisting DM complications, comorbidities and individual patient preferences and values. Hypoglycemia is much more dangerous than hyperglycemia. Exercise, diet, BP control, and CV risk reduction with statins are the cornerstones of DM treatment.
DIABETIC KETOACIDOSIS

Melanie J. Lippmann, MD

BASICS

DESCRIPTION

- A life-threatening medical emergency in diabetics secondary to insulin deficiency and characterized by hyperglycemia, ketosis, metabolic acidosis, electrolyte disturbances, and marked dehydration
- System(s) affected: endocrine/metabolic

EPIDEMIOLOGY

Incidence

- In the United States: 46 episodes/10,000 diabetics; 2/100 patient-years of type 1 diabetes mellitus (DM) (1)
- Predominant age: 19 to 44 years (56%) and 45 to 65 years (24%); only 18% are <20 years

ETIOLOGY AND PATHOPHYSIOLOGY

A deficiency of insulin, exacerbated by an increase in counterregulatory hormones (e.g., catecholamines, cortisol, glucagon, and growth hormone) leading to a hyperglycemic crisis, osmotic diuresis, ketosis with metabolic acidosis, and frequently accompanied by electrolyte disturbances

- Noncompliance/insufficient insulin: 25%
- Infection: 30–40%
- First presentation of DM: 10–25%
- Myocardial infarction (MI): 5–7%
- No cause identified: 10–30%
- Medications (corticosteroids, sympathomimetics, atypical antipsychotics)
- Illicit drugs (cocaine)
- Trauma
- Surgery
- Emotional stress
- Pregnancy
- Cerebrovascular accident (CVA)
RISK FACTORS
- Type 1 > type 2 DM
- Younger patients at higher risk

GENERAL PREVENTION
- Close monitoring of glucose during periods of stress, infection, illness, and trauma
- Careful insulin control and regular monitoring of blood glucose levels
- “Sick day” management instructions

COMMONLY ASSOCIATED CONDITIONS
Complications of chronic (and poorly controlled) DM such as nephropathy, neuropathy, and retinopathy

DIAGNOSIS

HISTORY
- Recent illness, injury, or surgery
- Changes in diet or medications
- Missed insulin doses/ noncompliance
- Insulin pump failure
- Weight loss in patients recently diagnosed with type 1 DM
- Polyuria, nocturia, polydipsia
- Hyperphagia
- Generalized weakness
- Malaise, fatigue, lethargy
- Anorexia or increased appetite
- Nausea, vomiting
- Abdominal pain
- Decreased perspiration
- Fever

PHYSICAL EXAM
- Hypotension
- Tachycardia
- Fever or hypothermia
- Tachypnea, hyperpnea, Kussmaul respirations
● Fruity odor of ketotic breath (acetone smell)
● Decreased reflexes
● Abdominal tenderness, decreased bowel sounds
● Dry mucous membranes, poor skin turgor, dehydration
● Altered mental status
● Coma

DIFFERENTIAL DIAGNOSIS
● Hyperosmolar hyperglycemic crisis
● Alcoholic ketoacidosis
● Starvation ketosis
● Toxic ingestions (e.g., salicylates, methanol)
● Lactic acidosis
● Uremia/chronic renal failure
● Sepsis
● Acute pancreatitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

ALERT

● Diagnostic criteria (1)[C]:
  – Hyperglycemia (glucose usually 250 to 800 mg/dL) as rapidly assessed on fingerstick glucose testing, and confirmed on serum chemistry
  – Low $\text{HCO}_3^-$ (usually $\leq 18$ mEq/L)
  – Metabolic acidosis on arterial blood gases (ABGs) ($\text{pH} < 7.3$)
  – Anion gap = serum sodium $-$ (serum chloride + bicarbonate); $>10$ mmol

● Other important labs:
  – Serum ketosis: Check $\beta$-hydroxybutyrate ($\beta$-HB) instead of ketones to evaluate ketosis (2)[B]. $\beta$-HB is the predominant ketone produced and is preferred over serum ketones. $\beta$-HB $>3$ mg/dL is abnormal and should be decreased to $<1.5$ mg/dL within 12 to 24 hours (3)[B].
  – Urine ketosis (urinalysis [UA]) may only identify acetoacetate and not $\beta$-HB.
  – Increased creatinine and BUN: Markedly increased serum ketones may cross-react and cause a falsely high serum creatinine.
  – Pseudohyponatremia: Hyperglycemia or hypertriglyceridemia may cause an artificially low sodium concentration. The measured sodium is
suppressed by 1.6 mg/dL for every 100 mg/dL of glucose >100 mg/dL.
– Decreased calculated total body K⁺: Severe acidosis gives an artificially high K⁺ level.
– Increased serum osmolality (mOsm/kg) = [2 × serum Na (mEq/L) + glucose (mg/dL)/18 + BUN (mg/dL)/2.8]; if calculated osmolality <320 mOsm/kg, consider etiologies other than diabetic ketoacidosis (DKA).
– Elevated base deficit
– Hb A1c (glycosylated hemoglobin) helps assess long-term history of diabetic control.
– Glycosuria
– Hyperamylasemia, hyperlipasemia
– Hypertriglyceridemia/hypercholesterolemia

- CBC, electrolytes, BUN, creatinine
- Serum β-HB or ketones
- ABG; venous blood gases (VBGs) may also be used (VBG pH correlates with 0.03 lower than ABG pH).
- Urine and blood cultures if concern for infection
- Troponin if concern for cardiac ischemia
- Other Tests
  - ECG
    - Frequently shows sinus tachycardia (nonspecific)
    - Changes consistent with electrolyte abnormalities
    - Ischemia/MI as a precipitating factor
  - Chest x-ray to rule out possible infectious etiology
  - Consider lumbar puncture if concern for meningitis.
  - Head CT scan if suspected CVA or cerebral edema

**Diagnostic Procedures/Other**
Only if surgical disease is the underlying precipitant (e.g., appendicitis, cholecystitis)

**TREATMENT**
- Oxygen and airway management, as needed
- Establish IV access.
- Cardiac monitoring
- Start isotonic crystalloid solution (e.g., 0.9% saline, or lactated ringers bolus).
GENERAL MEASURES

- All, but mild cases require inpatient management.
- Severe DKA requires an ICU setting.
- Goals
  - Fluid resuscitation
  - Insulin therapy to normalize serum glucose
  - Resolution of anion gap acidosis and ketosis
  - Correction of electrolytes
- Identify and treat the precipitating cause (e.g., insulin noncompliance, infection, MI)
- Laboratory testing during management:
  - Serum glucose q1–2h until stable
  - Electrolytes, phosphorus, and venous pH q2–6h

MEDICATION

First Line

- Insulin (1)[C]
  - Optional initial bolus 0.1 U/kg IV and then continuous infusion at 0.1 U/kg/hr (do not use initial insulin bolus in children)
  - If without bolus, 0.14 U/kg/hr continuous infusion
  - Aim for rate of serum glucose decline of 100 mg/dL/hr
  - When glucose 200 mg/dL, reduce infusion to 0.02 to 0.05 U/kg/hr IV or give rapid-acting insulin at 0.1 U/kg SC q2h; goal glucose is 150 to 200 mg/dL.
  - Overlap and continue IV insulin infusion for 1 to 2 hours after SC insulin is initiated.
- IV fluids to correct dehydration: Start with 0.9% NaCl bolus, calculate corrected sodium; if serum Na$^+$ is high, consider 0.45% NaCl to replace free fluid loss or when adding potassium replacement.
  - When glucose is 200 mg/dL, change to 5% dextrose with 0.45% NaCl at 150 to 250 mL/hr.
- Potassium: falsely elevated due to acidosis; when K$^+$ ≤5.2 mg/dL and if urine output is adequate, start replacement with 20 to 30 mEq/L of K$^+$ in 1 L IV fluids (1).
  - Hold insulin if K$^+$ ≤3.3 mg/dL; give IV potassium 20 to 30 mEq/hr with fluids until >3.3 mg/dL to prevent cardiac arrhythmia (class III).
  - For each 0.1 unit of pH, serum K$^+$ will change by ~0.6 mEq in opposite
Phosphorus: Routine replacement may lead to hypocalcemia; if very low (<1.0), give 20 to 30 mEq/L of K-Phos in fluids.

Sodium bicarbonate: no demonstrable benefit with a pH >7.0 (2)[B]; rehydration usually leads to resolution of acidosis although some guidelines recommend its use with pH <6.9 or in patients with life-threatening hyperkalemia; however, there is evidence that it may increase cerebral edema, especially in children (3)[A].

Magnesium: If Mg ≤1.8 mg/dL and the patient is symptomatic, consider replacement.

Precautions
- If the patient is on an insulin pump, it should be stopped.
- If glucose does not fall by 10% in first hour, give regular insulin 0.14 U/kg IV bolus and then continuous infusion at previous rate.
- If using bicarbonate, add 100 mmol or 2 ampules of sodium bicarbonate to 400 mL isotonic solution with 20 mEq KCL >200 mL/hr for 2 hours until venous pH is >7.0 and then stop infusion (1).

**Second Line**
Insulin, SC or IM: Load with 0.3 U/kg SC, followed by 0.1 U/kg/hr; space dosing to q2h once glucose <250 mg/dL; in uncomplicated DKA, may be safe and cost effective (4)[B]

**Pediatric Considerations**
- Children with moderate to severe DKA should be transferred to the nearest pediatric critical care hospital.
- Cerebral edema is a rare complication (~1%) but has a mortality of 20–50%:
  - Diagnostic criteria exist for diagnosis; CT may rule out alternative diagnoses.
  - Treat with IV bolus of mannitol 1 g/kg in 20% solution, reduce IV fluid rate, and consider hypertonic 3% saline (5).

**Geriatric Considerations**
Must be careful with impaired renal function or congestive heart failure when correcting fluid and electrolyte abnormalities

**Pregnancy Considerations**
- Pregnancy itself is diabetogenic and also results in a compensated respiratory
alkalosis (HCO₃ 19 to 20 mEq/L) with theoretically reduced buffering capacity.
- Pregnant women are more susceptible to DKA.
- Euglycemic DKA
- Increased risk of preeclampsia and fetal death
- β-Tocolytics and corticosteroids can trigger DKA
- Perinatal death: 9–35%

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- ADA admission guidelines: blood glucose >250 mg/dL; pH <7.3; HCO₃ ≤15 mEq/L; ketones in urine; ICU setting for severe DKA (6)
- IV fluids
  - 1.0 to 1.5 L over the first hour, then, if serum corrected Na is high or normal, give 0.45% NaCl at 250 to 500 mL/hr depending on hydration state.
  - Switch to 5% dextrose in 0.45% saline at maintenance rate when serum glucose <200 mg/dL; maintain blood glucose between 150 and 250 mg/dL.
  - Overly rapid correction of fluid balance may precipitate cerebral edema (2) [C]; if the blood glucose level is falling too rapidly, consider using a 10% dextrose solution instead.

Pediatric Considerations
Bolus 10 to 20 mL/kg initially; 4-hour fluid total should be <50 mL/kg to reduce chance of cerebral edema.
- Discharge criteria
  - Discharge when DKA has resolved: anion gap <12, glucose <200 mg/dL; pH >7.3; bicarbonate >18 mEq/L; additionally, patients must be tolerating PO intake and able to resume home medication regimen
  - Underlying precipitant (e.g., infection) must be identified and treated.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Monitor mental status, vital signs, and urine output q30–60min until improved, then q2–4h.
Monitor blood sugar q1h until <200 mg/dL, then q2–6h.
Monitor electrolytes, BUN, venous pH, and creatinine q2–4h.

**DIET**
- NPO initially
- Advance to preketotic diet when nausea and vomiting are controlled.
- Avoid foods with high glycemic index (e.g., soft drinks, fruit juice, white bread, added sugar, etc.).

**PROGNOSIS**
- DKA accounts for 16% of all diabetes-related fatalities
- Overall DKA mortality of 0.5–2%
- In children <10 years of age, DKA causes 70% of diabetes-related fatalities.

**COMPLICATIONS**
- Cerebral edema (most common cause of death in children with DKA)
- Pulmonary edema
- Vascular thrombosis
- Hypokalemia
- Hypophosphatemia
- Cardiac dysrhythmia (secondary to hypokalemia or acidosis)
- MI, myocardial injury
- Acute gastric dilatation
- Late hypoglycemia (secondary to treatment)
- Erosive gastritis
- Infection, mucormycosis
- Respiratory distress

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

- *Diabetes Mellitus, Type 1*
- Algorithm: *Diabetic Ketoacidosis (DKA), Treatment*

**CODES**

**ICD10**

- E10.10 Type 1 diabetes mellitus with ketoacidosis without coma
- E13.10 Oth diabetes mellitus with ketoacidosis without coma
- E10.11 Type 1 diabetes mellitus with ketoacidosis with coma

**CLINICAL PEARLS**

- Admit if blood glucose >250 mg/dL, pH <7.3, HCO₃ ≤15 mEq/L, and ketones in urine.
- Potassium is falsely elevated due to acidosis; start replacement when $K^+ ≤5.2$ mg/dL and urine output is adequate.
DIABETIC POLYNEUROPATHY
Samir Malkani, MD, MRCP—UK

BASICS

DESCRIPTION
Peripheral nerve dysfunction seen in diabetes; several patterns described (1):

- Symmetric polyneuropathy
  - Distal sensory or sensorimotor
- Mononeuropathy, radiculopathy, and polyradiculopathy
  - Cranial neuropathy
  - Focal limb or truncal neuropathy
  - Radiculoplexus neuropathy (diabetic amyotrophy)
- Acute painful small fiber neuropathy
- Autonomic neuropathies
- Chronic inflammatory demyelinating polyneuropathy (CIDP)

EPIDEMIOLOGY

Prevalence
- Generalized polyneuropathy
  - 10% at diabetes diagnosis
  - 50% at 10 years
  - Cross-sectional prevalence: 15% by symptoms; 50% by nerve conduction
- Autonomic neuropathy: 16.7% in a United Kingdom study

ETIOLOGY AND PATHOPHYSIOLOGY
- Metabolic derangement due to hyperglycemia
  - Aldose reductase converts excess glucose to sorbitol, which causes nerve damage.
  - Nonenzymatic glycation of neural proteins and lipids forms damaging advanced glycosylation end products.
  - Protein kinase C activation causes vascular endothelial changes.
  - Oxidative stress from excessive production of reactive oxygen species
  - Cyclooxygenase-2 and poly (ADP-ribose) polymerase activation
- Vasculopathy causing nerve ischemia: predominant factor in
mononeuropathies

**RISK FACTORS**
- Poor glycemic control
- Duration of diabetes
- Hypertension
- Hyperlipidemia
- Tobacco and alcohol consumption

**GENERAL PREVENTION**
- Maintenance of normal blood sugar
- Exercise and appropriate diet

**DIAGNOSIS**

**HISTORY**
- Most common form (typical): symmetric distal sensory or sensorimotor polyneuropathy
  - Distressing numbness, tingling, pain of legs/feet, usually worse at night; allodynia; hyperalgesia
  - Often silent sensory loss, patient unaware
  - Ataxia due to proprioceptive loss
  - Neuropathic foot ulcers due to analgesia and repetitive injury
  - Neuropathic degeneration of foot joints
  - Hands involved late
  - Distal muscle involvement, usually mild
- Symmetric proximal polyneuropathy
  - Proximal leg weakness and wasting
  - Muscles of shoulder girdle rarely involved
  - Pain and sensory changes less prominent
- Focal cranial or limb mononeuropathy
  - May involve 3rd, 4th, 6th, or 7th cranial nerve
  - Femoral, sciatic, or peroneal neuropathy: weakness or pain in nerve distribution
  - Any major peripheral nerve can be involved.
- Truncal neuropathies: painful radiculopathy over dermatomes
- Lumbar radiculoplexus neuropathy (diabetic amyotrophy)
– Unilateral hip, thigh pain
– Pelvic girdle and thigh weakness with atrophy
– Recovery over months

• Diabetic autonomic neuropathy
  – GI: nocturnal diarrhea, sometimes alternating with constipation;
    gastroparesis with postprandial fullness; nausea and vomiting
  – Cardiovascular: postural dizziness, exercise intolerance
  – Urogenital: urinary hesitancy, overflow incontinence; erectile dysfunction;
    vaginal dryness; sexual dysfunction
  – Sudomotor: anhidrosis or hyperhidrosis; gustatory sweating of head and
    upper body

• CIDP: progressive, severe motor loss

• Diabetic cachexia: painful small fiber neuropathy with prominent weight loss
  and depression

**PHYSICAL EXAM**

• Symmetric distal polyneuropathy
  – “Stocking-and-glove” distal sensory loss
  – Large-fiber neuropathy: loss of perception of vibration and light touch (10-
    g monofilament)
  – Small fiber involvement: loss of temperature and pinprick
  – Absent ankle reflexes
  – Wasting, weakness of small muscles in foot; changes to arch of foot or
    clawing of toes
  – With small fiber involvement, there may be lack of objective sensory deficit
    despite pain.

• Symmetric proximal polyneuropathy
  – Proximal leg, arm wasting, and weakness
  – Loss of patellar reflexes

• Focal cranial or limb mononeuropathy
  – 3rd cranial nerve palsy: painful ophthalmoplegia and ptosis; preserved
    pupillary reflexes (in contrast to compressive palsies)
  – 6th cranial nerve: lateral gaze palsy
  – Femoral neuropathy: weakness of lower leg extension, hip flexion,
    quadriceps wasting, absent patellar reflex, sensory loss in anterior thigh
  – Sciatic neuropathy: pain or sensory loss in back of thigh and leg; weakness
    of hamstrings, lower leg muscles
  – Peroneal neuropathy: foot drop

• Truncal neuropathies: sensory loss along dermatome

mebooksfree.com
Lumbar radiculoplexopathy (amyotrophy)
- Weakness and wasting pelvic girdle and thigh
- Sensory loss in L2–L3
- Absent patellar reflex

Autonomic neuropathy
- Cardiovascular: resting tachycardia; orthostatic hypotension
- Gastroparesis: postprandial distension; gastric splash

CIDP: motor weakness

DIFFERENTIAL DIAGNOSIS

- Uremic polyneuropathy
- Drug induced
  - Antineoplastic drugs: cisplatin, vincristine
  - Isoniazid
  - Amiodarone
- Toxic
  - Chronic arsenic poisoning
  - n-Hexane, methyl-n-butyl ketone
- Nutritional deficiency
  - Usually associated with alcoholism
- Paraneoplastic polyneuropathy
- Hypothyroidism

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Fasting plasma glucose, 2-hour glucose tolerance test or hemoglobin A1c for diagnosis and to assess glycemic control; may occur in “prediabetes”
- Serum B₁₂
- Thyroid function
- Creatinine and BUN
- Syphilis testing
- Serum protein electrophoresis
- Vitamin D
- In mononeuropathy/mononeuritis multiplex, test for vasculitis, paraproteinemia, and sarcoid.
- In radiculopathy or mononeuropathy, imaging studies to exclude compressive lesions
**Diagnostic Procedures/Other**

- Bedside testing of vibration perception with 128-Hz tuning fork, monofilament perception of 10-g filament
- Quantitative sensory testing for vibratory and thermal thresholds
  - Standardized measures for assessing severity and risk of foot ulceration
- Electromyogram nerve conduction velocity
  - Useful to confirm mononeuropathy and entrapment syndromes
  - Sensitive but nonspecific index of presence and severity of diabetic polyneuropathy
  - In small unmyelinated fiber painful neuropathy, test may be normal.
- Lumbar puncture
  - In CIDP, elevation of spinal fluid protein
- Skin biopsy with epidermal nerve fiber density
  - Enables direct study of small nerve fibers that are difficult to assess electrophysiologically
- Corneal confocal microscopy
  - Noninvasive approach based on examination of corneal innervation

**Test Interpretation**

- In nerve biopsy of peripheral nerve, Wallerian degeneration, focal axonal swellings containing neurofilaments, axonal atrophy, and demyelination are seen.
- Thick neural capillary basement membrane and endothelial proliferation
- Obliterative microvascular lesions and perivascular inflammation

**TREATMENT**

**GENERAL MEASURES**

- Maintain blood glucose close to normal.
- Provide appropriate footwear to prevent pressure damage to insensate feet.

**MEDICATION**

**First Line**

Management of pain and sensory neuropathy

- Calcium channel modulators: gabapentin (2),(3)[A] (off-label)
  - Binds Ca^{2+} channel–associated protein \( \alpha_2\delta \); inhibits neurotransmitter
release
– Dose range 300 to 1,200 mg TID, NNT ~4 to 8
– Reduce dose in renal insufficiency.
– Adverse effects: dizziness, fatigue, edema

**Calcium channel modulators: pregabalin (2),(3)[A]**
– Binds same calcium channel as gabapentin
– Linear pharmacokinetics and quicker onset of action compared to gabapentin
– Usual dose: 150 to 600 mg/day, NNT ~4 to 8
– Adverse effects are dizziness and edema.

**Duloxetine (2),(3)[A]**
– Selective serotonin and norepinephrine reuptake inhibitor
– Usual dose is 30 to 60 mg/day; NNT ~4 to 11
– Adverse effects are nausea and dizziness.

**Tricyclic antidepressants (TCA) (2),(3)[A] (off-label)**
– Analgesia may be related to effects on sodium channels; NNT ~2 to 5, NNH ~3 to 16
– Amitriptyline 25 to 150 mg at bedtime
– Nortriptyline (25 to 150 mg); desipramine (25 to 200 mg) less sedating than amitriptyline but limited trial data
  o Anticholinergic effects, cardiac arrhythmias may occur.

**Management of autonomic neuropathy**
– Orthostatic hypotension
  o Fludrocortisone (off-label)
  o Midodrine (off-label)
– Gastroparesis
  o Metoclopramide or domperidone
  o Erythromycin (off-label)
– Diabetic diarrhea
  o Loperamide
  o Clonidine (off-label)
  o Octreotide (off-label)
  o Antibiotics for bacterial overgrowth
– Hyperhidrosis
  o Propantheline (off-label)

**Geriatric Considerations**
Anticholinergic effects of TCAs may cause urinary retention and cardiac
arrhythmias.

**Second Line**

- **Antidepressants**
  - Venlafaxine (2),(3)[B] (75 to 225 mg daily) (off-label), NNT ~5 to 8
    - Serotonin-norepinephrine reuptake inhibitor
- **Anticonvulsants**
  - Carbamazepine (3)[C] (off-label)
    - Blocks sodium channels
    - Dose 100 to 800 mg/day
- **Topical therapies**
  - Capsaicin 0.075% cream applied TID
    - Depletes C fibers in skin of substance P
  - Lidocaine 5% (700 mg) patches applied daily to feet (off-label):
    - Causes sodium channel blockade
    - Opiate analgesia
  - Tramadol (3)[B] (off-label): 100 to 400 mg/day, NNT ~3 to 7
    - Binds opiate receptors; also inhibits reuptake of norepinephrine and serotonin; fewer opiate side effects
  - Tapentadol (3)[B]
    - Binds to μ-opiate receptor and inhibits norepinephrine uptake
- **α-Lipoic acid (3)[C]**
  - Antioxidant properties may limit free radical–mediated damage.
  - 600 mg/day PO dose; limited study data on efficacy

**ISSUES FOR REFERRAL**

If CIDP is suspected, refer to neurologist for investigation and treatment.

**ADDITIONAL THERAPIES**

- Transcutaneous electrical nerve stimulation
- Percutaneous nerve stimulation
- Electrical spinal cord stimulation
- Actovegin, dextromethorphan with quinidine
- C-peptide

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Acupuncture, Reiki, electromagnetic field treatment: no convincing trial data
SURGERY/OTHER PROCEDURES
Electrical spinal cord stimulation

ONGOING CARE

PROGNOSIS
- Generalized symmetric polyneuropathies
  - Usually slow, chronic progression
  -Insensitive but painless foot as pain lessens
- Focal neuropathies
  - Recovery over months to years

COMPLICATIONS
- Claw foot deformity
- Neurotropic ulceration
  - Painless ulcers on weight-bearing area
  - Callus formation is a precursor to ulceration.
- Neuropathic arthropathy
  - Results in complete disorganization of joint structure in foot, Charcot joint

Diabetes Mellitus, Type 1; Diabetes Mellitus, Type 2

CODES

ICD10

- E10.42 Type 1 diabetes mellitus with diabetic polyneuropathy
- E11.42 Type 2 diabetes mellitus with diabetic polyneuropathy
- E13.42 Oth diabetes mellitus with diabetic polyneuropathy

CLINICAL PEARLS

- Occasionally, when glycemic control improves dramatically, as can occur when treatment for diabetes is initiated, there may be a worsening of neuropathy symptoms (described as treatment-induced neuropathy). Symptoms usually stabilize and gradually improve as glycemic control is maintained.

- It is common to combine agents with different mechanisms of action in the management of neuropathic pain. Topical therapies can be combined with systemic therapies. There is limited evidence-based data to support combination therapy.
DIARRHEA, ACUTE

Stephen M. Testa, MD • Marie L. Borum, MD, EdD, MPH

BASICS

DESCRIPTION

- An abnormal increase in stool water content, volume, or frequency (≥3 in 24 hours) for <14 days duration
- Acute viral diarrhea (50–70%)
  - Most common cause of infectious diarrhea; noninflammatory (watery)
  - Frequently presents with associated nausea and/or vomiting
  - Symptoms usually develop after an incubation period of ~1 day and last for 1 to 3 days; typically self-limited
- Bacterial diarrhea (15–20%)
  - Most common infectious cause of inflammatory (bloody) diarrhea
  - Incubation period variable; diarrhea caused by preformed enterotoxin presents within 1 to 6 hours of contaminated food ingestion, whereas bacterial infection typically presents within 1 to 3 days.
  - Symptoms usually resolve in 1 to 7 days; antibiotic use attenuates length and/or severity of disease.
  - Suspect when concurrent illness in others who have shared potentially contaminated food.
  - Suspect Clostridium difficile in patients with recent antibiotic use or hospitalization.
- Protozoal infections (10–15%)
  - Typically cause noninflammatory (watery) diarrhea
  - Long incubation period and prolonged disease course, symptoms develop approximately 7 days after exposure and commonly last >7 days
  - Suspect when outbreaks of watery diarrhea in areas with contaminated water or food supply.
- Traveler’s diarrhea (TD) typically begins 3 to 7 days after arrival in foreign location and resolves within 5 days; rapid onset, generally self-limited

EPIDEMIOLOGY

- In developing countries, acute diarrhea is more common in children; no age
predilection in developed countries

- Acute diarrhea accounts for >128,000 U.S. hospital admissions and ~1.5 million annual deaths worldwide (1).

**Prevalence**

- Second leading cause of death in children <5 years and seventh leading cause of death among all ages worldwide
- Affects 11% of the general population
- Rotavirus and adenovirus most common in children <2 years, bacteria are more common in children >2 years
- In developing world, acute diarrhea is largely due to contaminated food and water (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**

- **Bacterial**
  - *Escherichia coli*
  - *Salmonella, Shigella, Campylobacter jejuni*
  - *Vibrio parahaemolyticus, Vibrio cholerae*
  - *Yersinia enterocolitica*
  - *C. difficile*
  - *Staphylococcus aureus*
  - *Bacillus cereus*
  - *Clostridium perfringens*
  - *Listeria monocytogenes*
- **Viral**
  - Rotavirus and norovirus (most common)
  - Adenovirus
  - Astrovirus
  - Cytomegalovirus (in immunocompromised)
- **Protozoal**
  - *Giardia lamblia*
  - *Entamoeba histolytica*
  - *Cryptosporidium*
  - *Isospora belli*
  - *Cyclospora, Microspora*
- **Pathophysiology (1)**
  - Noninflammatory: most commonly viral; increased intestinal secretions without disruption of intestinal mucosa; watery
  - Inflammatory: generally invasive or toxin-producing bacteria; disrupts
mucosal integrity with subsequent tissue invasion/damage; bloody stools

- Viral diarrhea: changes in small intestine cell morphology including villous shortening, increased number of crypt cells, and increased cellularity of the lamina propria
- Bacterial diarrhea: Bacterial invasion of colonic wall leads to mucosal hyperemia, edema, and leukocytic infiltration.

**RISK FACTORS**
- Travel to developing countries
- Failure to observe food/water precautions
- Immunocompromised host
- Antibiotic use
- Proton pump inhibitor (PPI) use
- Daycare exposure
- Fecal-oral sexual contact
- Nursing home residence
- Pregnancy (12-fold increase for listeriosis) (1)

**GENERAL PREVENTION**
- Frequent hand washing and alcohol-based hand sanitizers; hand washing promotion may reduce incidence of diarrhea by approximately 30%.
- Proper food and water precautions, particularly during foreign travel—“boil it, peel it, cook it, or forget it”
- Avoid undercooked meat, raw fish, unpasteurized milk.
- Rotavirus vaccine (for infants)
- Typhoid fever and cholera vaccine (for travel to endemic areas)

**TRAVELER’S DIARRHEA (TD) PROPHYLAXIS**
- Pretravel counseling on high-risk food/beverage
- Consider daily prophylaxis with bismuth subsalicylate (BSS) in all travelers (can reduce the risk of TD by up to 60%).
- Antibiotic prophylaxis should not be routinely used. Consider rifaximin use in patients at high risk of health-related complications of TD; fluoroquinolones no longer recommended for TD prophylaxis (2)
- Probiotics, prebiotics, and synbiotics have unclear benefit as prophylaxis.

**COMMONLY ASSOCIATED CONDITIONS**
- Inflammatory bowel disease (IBD)
- Immunocompromised (HIV, malignancy, chemotherapy)

**DIAGNOSIS**

**HISTORY**
- Duration of symptoms <14 days
- Historical clues for dehydration: orthostatic hypotension, dizziness, increased thirst, decreased urinary output, or altered mental status
- Description of stool—characteristics and output
  - Frequency
  - Quantity
  - Character: presence of mucus, blood, or fat
  - Consistency
  - Floating
  - *Giardia* associated with pale, greasy stools
- Weight loss
- Associated symptoms: change in appetite, abdominal pain or bloating, nausea/vomiting, or fever
- Recent hospitalization or antibiotic use
- Travel history
- Ingestion of raw or undercooked meat, raw seafood, unpasteurized milk
- Sick contacts
- Immunocompromised state
- Pregnancy
- Daycare exposure
- Sexual history (e.g., men who have sex with men [MSM], fecal-oral contact, HIV)
- Nursing home residence

**PHYSICAL EXAM**
- Assess degree of dehydration (1); ill-appearing, dry mucous membranes, tachycardia, orthostatic hypotension, decreased skin turgor, delayed capillary refill, altered mental status
- Fever is more suggestive of inflammatory diarrhea.
- Abdomen: Assess for tenderness, distention, rigidity.
- Rectum: blood, tenderness, stool consistency
Geriatric Considerations
Fecal impaction or obstructing neoplasm can cause overflow diarrhea with chronic constipation.

Differential Diagnosis
- IBD
- Malabsorption
- Medications (cholinergic agents, magnesium-containing antacids, chemotherapy, antibiotics)
- *C. difficile* colitis secondary to antibiotic use
- Diverticulitis, ischemic colitis
- Spastic (irritable) colon
- Fecal impaction
- Endocrinopathies: thyroid disease
- Neoplasia

Diagnostic Tests & Interpretation

Initial Tests (lab, imaging)
- Laboratory testing is reserved for patients with persistent fever, moderate-severe disease, bloody stool, immunosuppression, or symptoms lasting >7 days or in suspected outbreaks (3)[C].
- CBC
  - Leukocytosis, anemia (blood loss), eosinophilia (parasite infection), thrombocytopenia (hemolytic-uremic syndrome [HUS])
- Serum electrolytes
- BUN and creatinine may elevate with volume depletion.
- Nonanion gap metabolic acidosis
- Stool sample
  - Occult blood (IBD, bowel ischemia, and certain bacterial infections)
  - Fecal leukocytes
  - Stool ova and parasites
  - Stool culture: for bloody diarrhea, consider *Salmonella, Shigella, Campylobacter, E. coli 0157:H7, Y. enterocolitica, E. histolytica*
  - *C. difficile* toxin (especially IBD, recently hospitalized or recent antibiotic use) (4)[C]
  - *Giardia* ELISA >90% sensitive in at-risk population
  - Abdominal radiographs (flat plate and upright) if severe abdominal pain or concern for obstruction
Abdominal CT scan is preferred to evaluate intra-abdominal and intestinal disease (5)[C].

**Diagnostic Procedures/Other**
- Consider sigmoidoscopy or colonoscopy in patients with persistent diarrhea, when there is no clear diagnosis after routine blood and stool tests, and if empiric or supportive therapy is ineffective.
- Consider colonoscopy in immunocompromised patients to evaluate for CMV colitis.
- Colonoscopy helps to distinguish infectious diarrhea from IBD, ischemic colitis, cancer, or other noninfectious etiologies (5)[C].

**TREATMENT**

**GENERAL MEASURES**
- Oral rehydration and electrolyte management are key to successful treatment.
- Diet, as tolerated—“if the gut works, use it.”
- Balanced electrolyte rehydration solutions recommended in elderly and profuse, watery TD (3)[C]
- IV fluids if patient cannot tolerate oral rehydration or presents with severe dehydration

**MEDICATION**

**First Line**
- Consider empiric antibiotics (fluoroquinolones or macrolides) in patients with signs and symptoms of systemic infection, severe disease, or clear cases of TD (3)[C].
  - Fever; bloody diarrhea; fecal leukocytes
  - Immunocompromised host
  - Signs of severe volume depletion
  - Symptoms >1 week
- Tailor antibiotics to stool culture results (3)[C].
  - *Giardia*: metronidazole 250 mg PO TID for 5 to 7 days, tinidazole 2 g PO once
  - *E. histolytica*: metronidazole 500 to 750 mg PO TID for 7 to 10 days, tinidazole 2 g PO daily for 3 to 5 days
  - *Shigella*: ciprofloxacin 500 mg PO BID for 3 to 5 days or ceftriaxone 1 to 2
g IM/IV daily for 5 days
- *Campylobacter*: azithromycin 500 mg PO daily for 3 to 5 days or erythromycin 500 mg PO QID for 5 days
- *C. difficile*: metronidazole 250 to 500 mg PO/IV every 6 to 8 hours for 10 to 14 days, vancomycin 125 to 500 mg PO QID for 10 to 14 days, or fidaxomicin 200 mg PO BID for 10 days; consider fecal microbiota transplant in recurrent mild to moderate *C. difficile* infections.
- TD: ciprofloxacin 500 mg PO BID for 1 to 3 days, azithromycin 500 mg PO daily for 1 to 3 days, rifaximin 200 mg PO TID for 3 days; combined with loperamide 4 mg PO initial dose, followed by 2 mg after each episode of diarrhea for maximum of 8 mg daily; loperamide or BSS may be used alone in cases of mild TD (2)[C].

**General considerations**
- Antibiotics are not recommended in *Salmonella* infections unless caused by *Salmonella typhosa* or if the patient is febrile or immunocompromised.
- Avoid antibiotics in patients with *E. coli* 0157:H7 due to risk for HUS.
- Antibiotics are not indicated for foodborne toxigenic diarrhea.
- Avoid antimotility agents (e.g., loperamide) in patients with febrile or bloody diarrhea (especially, *E. coli* 0157:H7) or antibiotic-associated colitis.
- Antimotility agents used in combination with antibiotics may speed recovery from TD.
- Antibiotics are not recommended for the treatment of mild TD (2)[C].
- *C. difficile* infections in IBD patients: Initially treat with vancomycin or fidaxomicin; consider fecal microbiota transplant in patients with recurrent *C. difficile* infections (4)[C].

**Significant medication interactions**
- Salicylate absorption from BSS can cause toxicity in patients already taking aspirin-containing compounds and may alter anticoagulation control in patients taking warfarin.
- Avoid alcoholic beverages with metronidazole due to the possibility of a disulfiram reaction.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- BSS may help control rate of diarrhea stools (3,6)[C].
- Probiotics are recommended for prevention of antibiotic-associated diarrhea and *C. difficile* infection recurrence and to treat acute infectious diarrhea in setting of symptomatic IBS (6)[C].
Probiotic use above $10^{10}/g$ may help in patients with antibiotic-associated diarrhea (2)[A].

Probiotic strains *Lactobacillus rhamnosus GG* (LGG) and *Saccharomyces boulardii* most effective; may reduce duration by up to 1 day

Probiotics should be avoided in immunocompromised patients (2)[A].

Zinc supplementation can decrease diarrhea duration as well as associated morbidity and mortality.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Outpatient management, except for patients who are severely ill with signs of volume depletion

**ONGOING CARE**

**DIET**

- Early refeeding is encouraged. Regular diets are as effective as restricted diets.
- The traditional bananas, rice, applesauce, toast (BRAT) diet has little evidence-based support, despite heavy clinical use, and may result in suboptimal nutrition.
- During periods of active diarrhea, coffee, alcohol, dairy products, fruits, vegetables, red meats, and heavily seasoned foods may exacerbate symptoms.

**PATIENT EDUCATION**

See guidelines in “General Prevention” section.

**PROGNOSIS**

Acute diarrhea is rarely life-threatening if adequate hydration is maintained.

**COMPLICATIONS**

- Volume depletion, shock, sepsis
- Anemia
- Hemolytic uremic syndrome with *E. coli* 0157:H7
- Guillain-Barré syndrome with *C. jejuni*
- Reactive arthritis with *Salmonella, Shigella, and Yersinia*
- Functional bowel disorders (e.g., postinfectious irritable bowel syndrome [P]}

CODES

ICD10

- R19.7 Diarrhea, unspecified
- A09 Infectious gastroenteritis and colitis, unspecified
- A08.4 Viral intestinal infection, unspecified

CLINICAL PEARLS

- Viruses are the most common causes of acute diarrheal illness in the United States.
- Oral rehydration is the most important step in treating acute diarrhea.
- Routine stool culture is not recommended, unless patients present with bloody diarrhea, fever, severe dehydration, signs of inflammatory disease, persistent symptoms >7 days, or immunosuppression.
- Start empiric antibiotics in patients who are severely ill or immunocompromised.
DIARRHEA, CHRONIC

Stephen M. Testa, MD • Marie L. Borum, MD, EdD, MPH

BASICS

DESCRIPTION

- An increase in frequency of defecation, urgency, or decrease in stool consistency (typically >3 loose stools per day) for >4 weeks (1,2)
  - Abnormal form is the most important defining factor; frequent defecation with normal consistency is termed pseudo-diarrhea (2).
- Etiologies include osmotic, secretory, malabsorptive, inflammatory, infectious, and hypermotility.
- Infectious causes of chronic diarrhea are uncommon in immunocompetent patients. Parasitic etiologies are more common than bacterial.

EPIDEMIOLOGY

Prevalence

Varies by etiology, overall ~3–5% of the population in developed countries is affected (2).

ETIOLOGY AND PATHOPHYSIOLOGY

Chronic diarrhea is typically the result of disturbances in intestinal luminal water and electrolyte balance.

- Osmotic (fecal osmotic gap >75 mOsm/kg) (2)
  - Carbohydrate malabsorption
    - Disaccharides including lactose
    - Monosaccharides including fructose
    - Polyols including sorbitol, xylitol, sucralose, and saccharin (common sugar substitutes)—cannot be metabolized and create an osmotic gradient
  - Magnesium, phosphate, and sulfate overload
- Secretory (fecal osmotic gap <50 mOsm/kg) (2)
  - Stimulant laxative ingestion
  - Postcholecystectomy
Excessive intestinal bile salts cause choleretic diarrhea; often resolves in 6 to 12 months
- Ileal bile acid malabsorption
- Ileal resection of <100 cm leads to choleretic diarrhea due to excessive colonic bile salts.
- Disordered motility
  - Postvagotomy
  - Diabetic autonomic neuropathy
  - Hyperthyroidism
- Neuroendocrine tumors
  - VIPoma
  - Gastrinoma
  - Somatostatinoma
  - Carcinoid syndrome
- Metastatic medullary carcinoma of the thyroid
- Systemic mastocytosis
- Protein-losing enteropathy
- Malabsorption (2)
  - Celiac disease
  - Whipple disease
  - Giardiasis
  - Short bowel syndrome
    - Ileal resection of >100 cm leads to insufficient bile salt concentrations in the duodenum for optimal fat absorption, leading to fat and fat-soluble vitamin malabsorption.
  - Small intestinal bacterial overgrowth
  - Pancreatic exocrine insufficiency (cystic fibrosis [CF], chronic pancreatitis)
  - Inadequate bile acid production/secretion
- Inflammatory (2)
  - Ulcerative colitis
  - Crohn disease
  - Microscopic colitis (lymphocytic or collagenous)
  - Vasculitis
  - Radiation enterocolitis
  - Eosinophilic enterocolitis
- Hypermotility (normal fecal osmotic gap) (1,2)
  - Irritable bowel syndrome (IBS)
  - Functional diarrhea
- Drugs (2)
– Adverse effect of >700 drugs, most commonly: NSAIDs, PPIs, colchicine, metformin, digoxin, SSRIs
– Factitious diarrhea: excessive laxative use

• Herbal products: St. John’s wort, echinacea, garlic, saw palmetto, ginseng, cranberry extract, aloe vera

• Infectious (2)
  – Bacterial: *Clostridium difficile*, *Mycobacterium avium intracellulare*
  – Viral: cytomegalovirus
  – Parasitic: *Giardia lamblia*, *Cryptosporidium*, *Isospora*, *Entamoeba histolytica*
  – Helminthic: *Strongyloides*

• Food allergies (2)

**Genetics**

• Celiac disease is associated with HLA-DQ2 and HLA-DQ8 haplotypes on major histocompatibility complex (MHC) class II antigen-presenting cells (3).
• IBD is polygenic (4).
• CF is caused by a mutation in the CF transmembrane conductance regulator (CFTR), resulting in abnormal exocrine gland secretions.

**RISK FACTORS**

• Osmotic
  – Excessive ingestion of nonabsorbable carbohydrates
  – Lactose intolerance
  – Celiac disease

• Secretory (2)
  – Postsurgical: extensive small bowel resection/ileal surgery, vagotomy, bile acid malabsorption
  – History of neuroendocrine disease
  – History of stimulant laxative abuse
  – Dysmotility syndromes

• Malabsorptive
  – CF
  – Chronic alcohol abuse
  – Chronic pancreatitis/pancreatic insufficiency
  – Celiac disease
  – Medications (e.g., orlistat, acarbose)

• Inflammatory
  – Inflammatory bowel disease (IBD)
– NSAID use
– Thoracoabdominal radiation
– HIV/AIDS
– Antibiotic use
– Immunosuppressant therapy
• Hypermotility
  – Psychosocial stress
  – Preceding infection
• Genetic predisposition

**ALERT**
Diabetes mellitus and/or prior cholecystectomy both cause secretory and osmotic diarrhea.

**GENERAL PREVENTION**
Varies by etiology; treat the underlying cause.

**COMMONLY ASSOCIATED CONDITIONS**
• Extraintestinal manifestations of IBD include arthralgias, aphthous stomatitis, uveitis/episcleritis, erythema nodosum, pyoderma gangrenosum, perianal fistulas, rectal fissures, ankylosing spondylitis, and primary sclerosing cholangitis.
• Celiac disease is associated with dermatitis herpetiformis, type 1 diabetes, other autoimmune disorders and IgA deficiency.
• Many patients with IBS have behavioral comorbidities.
• Latex-food allergy syndrome: associated allergies to latex and banana, avocado, kiwi, and walnut (2)

**DIAGNOSIS**

**HISTORY**
• Detailed history of symptoms (1,2):
  – Onset, pattern, and frequency
  – Stool volume and quality (including presence of blood or mucus)
  – Presence of nocturnal symptoms
  – Travel history
  – Antibiotic exposure
– Dietary habits  
– Current medications  
– Family history

• Determine aggravating or alleviating factors; changes with oral intake or improvement with selective food avoidance (e.g., dairy products)

• Unintentional weight loss

• Review of systems including skin changes (rashes, hives), arthritis, ocular problems, heat intolerance, polyuria/polydipsia, headache, fever, flushing, alcohol intake

• Food allergies are rare, occurring in only 1–2% of adults. Consider in patients with hives (2).

• Flatus and bloating are predominant features of carbohydrate malabsorption (2).

• IBS or functional diarrhea by Rome IV criteria (5):
  – IBS: recurrent abdominal pain at least 1 day/week for past 3 months (symptoms >6 months); ≥2 of:
    o Related to defecation
    o Associated with change in frequency of stool
    o Associated with change in form of stool
  – Functional diarrhea: ≥25% loose or watery stools without prominent abdominal pain or bloating for >3 months (symptoms >6 months)

**PHYSICAL EXAM**

• General: Assess for volume depletion, nutritional status, recent weight loss (2).

• Skin: flushing (carcinoid), erythema nodosum (IBD), pyoderma gangrenosum (IBD), ecchymoses (vitamin K deficiency), dermatitis herpetiformis (celiac disease) (1,2)

• HEENT: iritis/uveitis (IBD)

• Neck: goiter (hyperthyroid), lymphadenopathy (Whipple disease)

• Cardiovascular: tachycardia (hyperthyroid)

• Pulmonary: wheezing (carcinoid)

• Abdomen: hyperactive bowel sounds (IBD), abdominal distension (IBD/IBS), diffuse tenderness (IBD/IBS)

• Anorectal: anorectal fistulas (IBD), anal fissures (IBD)

• Extremities: arthritis (IBD)

• Neurologic: tremor (hyperthyroid)

**DIFFERENTIAL DIAGNOSIS**
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Generally, testing is indicated in patients with alarm symptoms (bleeding, weight loss) or with persistent symptoms persist and no identifiable

- Blood: CBC with differential, electrolytes (Mg, P, Ca), total protein, albumin, thyroid-stimulating hormone (TSH), free T₄, erythrocyte sedimentation rate, iron studies (2)
- Stool: WBCs (fecal calprotectin or lactoferrin are potential surrogates), culture, ova and parasites, Giardia stool antigen, C. difficile toxin, stool electrolytes (fecal osmotic gap), fecal occult blood, qualitative fecal fat (Sudan stain) (2)
- Abdominal plain film to evaluate for obstruction, toxic megacolon, bowel ischemia (1)
- CT to evaluate for chronic pancreatitis or malignancy if abnormal pancreatic enzymes or evidence of malabsorption (1,2)
- CT or MR enterography for small bowel imaging when Crohn disease is suspected (2)

Follow-Up Tests & Special Considerations

- Celiac disease: antiendomysial antibody IgA, anti-tissue transglutaminase (TTG) IgA, antigliadin (AGA) IgA, serum IgA (10% of celiac patients have IgA deficiency—may cause false-negative results) (3)[A]
- Chronic pancreatic insufficiency: fecal elastase and chymotrypsin (2)[C]
- Protein-losing enteropathy: fecal α₁ antitrypsin (2)[C]
- Carbohydrate malabsorption: fecal pH (<7.0) and hydrogen breath test
- Small bowel overgrowth: hydrogen breath test
- Prior history of hospitalization or antibiotics: C. difficile toxin
- HIV ELISA, special stains for Isospora and Cryptosporidium (2)[C]
- Consider testing for protozoa, atypical infections, Strongyloides, and tropical sprue in travelers and migrants of endemic areas (2)[C].
- Allergy testing (2)[C]
- Neuroendocrine tumor
  - Serum: chromogranin A, VIP, gastrin (1)
  - Urine: 5-HIAA, histamine (1)
Diagnostic Procedures/Other

- Ileocolonoscopy with biopsies: IBD, microscopic colitis, CMV colitis, and colorectal neoplasia (6)[A]
- Flexible sigmoidoscopy: especially if pregnant, with comorbidities, or if left-sided symptoms predominate (tenesmus and urgency) (6)[A]
- Esophagastroduodenoscopy (EGD) with small bowel biopsies if malabsorption is suspected:
  - Celiac, *Giardia* infection, Crohn disease, eosinophilic gastroenteropathy, Whipple disease, intestinal amyloid, pancreatic insufficiency (6)[A]
- Capsule endoscopy if further evaluation of small bowel is needed (6)[C]
- Upper GI series with small bowel follow-through
- CT or magnetic resonance (MR) enterography (1,2)

Test Interpretation

- Celiac disease: Marsh classification:
  - Intraepithelial lymphocytosis, crypt hyperplasia, villous atrophy (3)
- Crohn disease: cobblestoning, linear ulcerations, skip lesions, noncaseating granulomas
- Ulcerative colitis: crypt abscesses, superficial inflammation (6)
- Lymphocytic colitis: increased intraepithelial lymphocytes, increased inflammatory cells within the lamina propria, normal mucosal architecture (6)
- Melanosis coli suggests laxative abuse (2).

TREATMENT

GENERAL MEASURES

- Volume resuscitation if necessary
- Electrolyte replacement if indicated
- If stable, treatment is generally outpatient (2)[C].

MEDICATION

First Line

- Based on underlying cause:
  - Lactose intolerance: lactose-free diet
  - Cholecystectomy or ileal resection: cholestyramine or colestipol 2 to 16 g/day PO divided BID
– Diabetes: glucose control
– Hyperthyroidism: methimazole 5 to 20 mg/day PO, propylthiouracil (PTU) 100 to 150 mg/day PO divided; thyroid ablation
– \textit{C. difficile}: vancomycin 125 mg PO q6h or metronidazole (Flagyl) 500 mg PO q8h or fidaxomicin 200 mg PO BID
– \textit{G. lamblia}: metronidazole 250 mg PO q8h, nitazoxanide 500 mg PO q12h (2)[A]
– Whipple disease: ceftriaxone 2 g IV for 14 days then Bactrim DS 160/800 mg PO BID for 1 to 2 years
– Small intestinal bacterial overgrowth: rifaximin 550 mg PO BID, fluoroquinolones 250 to 750 mg PO BID, metronidazole 500 mg PO q6–8h, penicillins
– Pancreatic insufficiency: enzyme replacement (1)[A]
– HIV/AIDS: antiretroviral therapy
– Microscopic colitis: budesonide 9 mg/day PO, mesalamine 800 mg PO TID, Pepto-Bismol 786 mg PO TID
– IBD: 5-aminosalicylic acid (5-ASA), corticosteroids (short-term only), antibiotics (short-term only), immunomodulators (6-mercaptopurine [6-MP], azathioprine, methotrexate), anti-TNF therapy (infliximab, adalimumab, certolizumab) (4)[A]
– Neuroendocrine tumor: octreotide 100 to 600 g/day SC (2)[C]
– Celiac disease: gluten-free diet (wheat/barley/rye avoidance) (3)[A]
– IBS diarrhea predominant: rifaximin 550 mg PO BID, alosetron 0.5 to 1 mg PO BID, peppermint oil, eluxadoline 100 mg PO BID (2)[C]

● **Symptom relief (2)[C]:**
  – Loperamide 4 to 8 mg/day PO divided
  – Diphenoxylate-atropine 1 to 2 tabs PO BID–QID
  – Fiber supplementation
  – Bismuth subsalicylate 525 to 1,050 mg every 0.5 to 1 hour; max dose 4,200 mg/day (2)[C]

**SURGERY/OTHER PROCEDURES**

● Resection of neuroendocrine tumors
● Intestinal resection for medically refractory IBD
● Fecal transplant for recurrent \textit{C. difficile} infection

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Many homeopathic and naturopathic formulations are available; most have not been evaluated by the FDA.

**ONGOING CARE**

**DIET**
Abstain from gluten-containing foods, nonabsorbable carbohydrates, lactose-containing products, and food allergens depending on etiology of diarrhea.
- Low FODMAP (fermentable oligosaccharides, disaccharides, monosaccharides, and polyols) diet helps relieve symptoms in up to 75% of IBS patients (2).

**PATIENT EDUCATION**
- Reassure patient of wide variation of “normal” bowel habits.
- Restrict colon stimulants.
- Specific education and dietary changes based on underlying etiology.

**PROGNOSIS**
Depends on etiology

**COMPLICATIONS**
- Fluid and electrolyte abnormalities (1)
- Malnutrition (1); anemia (1)
- Malignancy (colon cancer in IBD, small bowel cancer in celiac disease and Crohn disease, lymphoma with IBD therapies) (4)
- Infection with immunomodulator, biologic, and corticosteroid therapies for IBD (4)

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: *Diarrhea, Chronic*

**CODES**

**ICD10**

K52.9 Noninfective gastroenteritis and colitis, unspecified

**CLINICAL PEARLS**

- A comprehensive medical history guides the appropriate workup and avoids unnecessary testing.
- Consider IBS, IBD, malabsorption syndromes (e.g., lactose intolerance), celiac disease, over-the-counter medications, herbal products and chronic infections (immunocompromised) in differential diagnosis.
- Treatment is based on the underlying cause.
DIFFUSE INTERSTITIAL LUNG DISEASE

J. Andrew Woods, PharmD, BCPS • Jacqueline L. Olin, MS, PharmD, BCPS, CDE, FASHP, FCCP • Brian Hertz, MD

BASICS

DESCRIPTION

- Interstitial lung diseases (ILDs) represent a diverse group of chronic progressive lung diseases associated with alveolar inflammation and/or potentially irreversible pulmonary fibrosis.
- >200 individual diseases may present with similar characteristics, making ILD difficult to classify.
- A classification scheme proposed by the American Thoracic Society and European Respiratory Society includes these subtypes:
  - Known causes (environmental, occupational, or drug-associated disease)
  - Systemic disorders (e.g., sarcoidosis, Wegener granulomatosis, collagen vascular disease)
  - Rare lung diseases (e.g., pulmonary histiocytosis, lymphangioleiomyomatosis)
  - Idiopathic interstitial pneumonias (IIPs)
- Based on clinical, radiologic, and histologic features, IIPs are further subclassified into the following diagnoses (1):
  - Major IIPs, including idiopathic pulmonary fibrosis (IPF), nonspecific interstitial pneumonia (NSIP), respiratory bronchiolitis-associated ILD (cryptogenic organizing pneumonia [COP], etc.)
  - Rare IIPs
  - Unclassifiable IIPs
- Classification of IIPs and relationships between the subtypes are difficult to classify due to mixed patterns of injury.

Pediatric Considerations

ILD in infants and children represents a heterogeneous group of respiratory disorders. Diseases result from a variety of processes involving genetic factors and inflammatory or fibrotic responses, and processes are distinct from those
that cause ILD in adults (2). Some diseases result from developmental disorders and growth abnormalities in infancy (2). After common causes are excluded, referral of infants to a subspecialist is recommended (2).

**EPIDEMOLOGY**

**Incidence**
- Exact incidence and prevalence are difficult to determine because of differences in case definitions and procedures used in diagnosis.
- Cited incidence of IPF in the United States: 16.3 to 17.4/100,000 and pediatric ILD 1.32/1 million

**Prevalence**
Cited prevalence of IPF in the United States: 42.7 to 63 cases/100,000 in the general population and pediatric ILD of 3.6/1 million

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Alveolar inflammation may progress into irreversible fibrosis.
- Varying degrees of ventilatory dysfunction occur among the ILD subtypes.
- ILD associated with collagen vascular disease and systemic connective disorders can manifest involvement of skin, joints, muscular, and ocular systems.
- Some types of ILD are associated with specific exposures:
  - Medications (amiodarone, antibiotics [especially nitrofurantoin], chemotherapy agents, gold, illicit drugs)
  - Inorganic dusts (silicates, asbestos, talc, mica, coal dust, graphite)
  - Organic dusts (moldy hay, inhalation of fungi, bacteria, animal proteins)
  - Metals (tin, aluminum, cobalt, iron, barium)
  - Gases, fumes, vapors, aerosols

**Genetics**
Some subtypes of ILD may be associated with specific predisposing genes and environmental exposures; however, the role of genetic factors is unknown.

**RISK FACTORS**
- Environmental or occupational exposure to inorganic or organic dusts
- 66–75% of patients with ILD have a history of smoking.
- Due to diversity of diseases, age is not a reliable predictor of pathology:
  - Most patients with connective tissue disease-related pathology and inherited
subtypes present between ages 20 and 40 years.
– Median age of patients with IPF is 66 years. Studies of clinical predictors of survival including age, ethnicity, and smoking status have been inconsistent.

COMMONLY ASSOCIATED CONDITIONS
Many systemic disorders and primary diseases are associated with ILD. A partial list includes the following:

- Collagen vascular disease
- Sarcoidosis
- Amyloidosis
- Goodpasture syndrome
- Churg-Strauss syndrome
- Wegener granulomatosis

DIAGNOSIS

- Accurate diagnosis is imperative, as treatment choices and prognosis can vary with pathogenesis.
- Diagnosis of IPF requires exclusion of other known ILD causes, the presence of a UIP pattern on high-resolution computed tomography (HRCT), and/or surgical lung biopsy pattern (2).

HISTORY

- Symptoms may include progressive exertional dyspnea and nonproductive cough.
- Patients may also present with hemoptysis or fatigue.
- Obtaining a history of illness duration (acute vs. chronic), potential environmental/occupational exposures, travel, medical conditions (including systemic diseases), and medication reconciliation is important in assessing the cause of the ILD.
- Some cases of lung disease may occur weeks to years after discontinuation of an offending agent.

PHYSICAL EXAM
Physical findings are usually nonspecific. Some common features includes the following:
• Crackles (typically present on auscultation of lung bases on posterior axillary line)
• Rales
• Inspiratory “squeaks”
• Clubbing of the digits and cyanosis in advanced disease

DIFFERENTIAL DIAGNOSIS
• Acute pulmonary edema
• Diffuse hemorrhage
• Atypical pneumonia
• Diffuse bronchoalveolar cell carcinoma or lymphatic spread of tumor

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• O₂ saturation
• Peak expiratory flow rate
• CBC with differential, comprehensive metabolic profile
• CRP or sedimentation rate
• Chest x-ray (CXR): most commonly reticular pattern, less commonly nodular or mixed patterns

Follow-Up Tests & Special Considerations
HRCT of the chest is the most useful tool for distinguishing among ILD subclasses, especially if normal CXRs:
• If indicated, arterial blood gas (ABG), hypersensitivity pneumonitis panel, plasma ACE inhibitor concentration (sarcoidosis)
• If a systemic disorder is suspected, consider antinuclear antibody (ANA), rheumatoid factor (RF), erythrocyte sedimentation rate (ESR), and antineutrophil cytoplasmic antibodies (ANCA).

Diagnostic Procedures/Other
• Pulmonary function testing (PFT; spirometry, lung volumes, carbon monoxide diffusing capacity)
  – Commonly demonstrates a restrictive defect (decreased vital capacity and total lung capacity)
  – Forced vital capacity (FVC) has been shown to decline 100 to 200 mL/year in the placebo arm of IPF patients in clinical trials.
Bronchoscopy
- Bronchoalveolar lavage (BAL) cellular analysis studies may be useful in distinguishing subtypes (including sarcoidosis, hypersensitivity pneumonitis, cancer). If performed, the BAL target site should be chosen based on the HRCT finding.
- Bronchoscopic transbronchial lung biopsy may help diagnose sarcoidosis and, on occasion, is sufficiently supportive of other ILD diagnoses.

Thoracoscopic surgery for lung biopsy has the greatest diagnostic specificity for ILDs but is less frequently used given improved specificity of HRCT; may be indicated if a diagnosis cannot be determined from transbronchial biopsy or HRCT

**Test Interpretation**
- Diagnostic classifications of IIPs are based on histopathologic patterns seen on lung biopsy.
- Major histologies include an inflammation and fibrotic and granulomatous patterns.
- Characteristic changes on HRCT may help to distinguish between the following subtypes:
  - Reticulonodular, ground glass opacities, and, in later stages, honeycombing may be seen.
  - Associated hilar and mediastinal adenopathy are characteristic of stage I and II sarcoidosis.
- No specific test is the gold standard, which emphasizes the importance of a multidisciplinary consensus for diagnosis with clinical, radiologic, and pathologic findings.

**TREATMENT**
- Evidence does not support the routine use of any specific therapy for ILD in general, especially IPF (2,3).
- No survival benefit of home oxygen use in ILD
- Corticosteroids have a role in some ILD subtypes.
- Current evidence does not clearly support routine use of noncorticosteroid anti-inflammatory agents for IPF, including cyclosporine, colchicine, cyclophosphamide, cytokines, sildenafil, dual endothelin receptor antagonists (bosentan, macitentan), etanercept, methotrexate, or interferon.
- Clinical trials have indicated that anticoagulation (warfarin), ambrisentan,
imatinib, and the combination of prednisone, azathioprine, and N-acetylcysteine are ineffective, potentially harmful, and therefore not recommended in the treatment of IPF (3)[A].

- Recombinant human thrombomodulin improved 3-month survival in the setting of acute exacerbation of IPF in a small historical control study

**GENERAL MEASURES**
- Avoid/minimize offending environmental/occupational exposures/medications.
- Smoking cessation
- Supplemental oxygen, if indicated

**MEDICATION**

*First Line*
- Corticosteroids are most effective for certain ILDs, especially exacerbations of sarcoidosis, NSIP, COP, and hypersensitivity pneumonitis. However, response rates have been variable across and within subtypes. The optimal dose and duration of therapy are unknown.
- Common starting dose of prednisone is 0.5 to 1.0 mg/kg/day for 4 to 12 weeks with potential up-titration based on patient response.

*Second Line*
- Two antifibrotic agents approved for IPF exhibited modest slowing of FVC decline over 52 weeks compared to placebo. Both decreased all-cause mortality rates. It is not clear if FVC is the most conclusive meaningful efficacy variable for IPF.
  - Pirfenidone (Esbriet) decreased the rate of decline in FVC compared to placebo. Secondary trial findings include a significant improvement in progression-free survival, and pooled analysis reveals a significant reduction in all-cause death and death from IPF. The most common adverse effects are GI related (nausea, vomiting, anorexia, weight loss, GERD and dyspepsia), rash, insomnia, dizziness, fatigue, and aminotransferase elevation. Most AEs are mild to moderate in nature and do not result in pirfenidone discontinuation. Pirfenidone is not recommended for patients with severe liver impairment or ESRD (4)[A].
  - Pirfenidone is titrated over 2 weeks to 801 mg orally 3 times daily with food.
  - Nintedanib (Ofev), reduced the annual rate of decline in FVC, and fewer
Acute exacerbations occurred compared to placebo. The most common adverse effects are GI upset (nausea, vomiting, diarrhea, abdominal pain), anorexia, aminotransferase elevation, and hypertension. It is not recommended in moderate to severe liver impairment and can cause birth defects (5)[A].

- Nintedanib is given at 150 mg orally twice daily with food.
- The addition of tacrolimus to corticosteroids (with cyclosporine, cyclophosphamide, or no additional therapy) demonstrated improved event-free survival in patients with ILD complicated with polymyositis or dermatomyositis.
- Several second-line agents have been used in Wegener granulomatosis:
  - Cyclophosphamide is commonly used in treatment of Wegener granulomatosis. It is given 1.5 to 2.0 mg/kg/day PO for 3 to 6 months.
  - Methotrexate has been used in treatment of mild Wegener granulomatosis in combination with corticosteroids; a studied dosing regimen consisted of an initial dose of 0.3 mg/kg (max dose of 15 mg) once weekly, with 2.5 mg titration each week (max dose of 25 mg/week)
  - Other second-line agents that have been studied include mycophenolate, mofetil, and rituximab.

**SURGERY/OTHER PROCEDURES**
- Single- or double-lung transplantation may be a treatment of last resort. Lung transplant among selected IPF patients has demonstrated median survival of 4.5 years (6)[A]. Some ILDs associated with systemic disease may recur in the recipient lung.
- Alveolar type II cell intratracheal transplantation has been shown to be well-tolerated and potentially beneficial in patients with moderate to progressive IPF at 12 months (7).
- Clinical trials to assess the safety and efficacy of allogeneic human mesenchymal stem cell infusion in patients with mild to moderate IPF are ongoing (8).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Follow-up testing should include PFTs, cardiopulmonary stress test, pulse oximetry, and CXR.
PATIENT EDUCATION
National Heart, Lung, and Blood Institute:
http://www.nhlbi.nih.gov/health/health-topics/topics/ipf/

PROGNOSIS
IPF confers the worst prognosis (median survival of 2.5 to 3 years). A clinical prediction model to estimate the risk of death from ILD has been described (ILD-GAP model). Other subtypes, including hypersensitivity pneumonitis, NSIP, and COP, have a good prognosis.

COMPPLICATIONS
- Cor pulmonale
- Pneumothorax
- Progressive respiratory failure

REFERENCES

**CODES**

**ICD10**
- J84.9 Interstitial pulmonary disease, unspecified
- J84.10 Pulmonary fibrosis, unspecified
- J84.111 Idiopathic interstitial pneumonia, not otherwise specified

**CLINICAL PEARLS**
- ILD differs from chronic obstructive pulmonary disease (COPD); anatomically, ILD involves the lung parenchyma (i.e., alveoli), and COPD involves both airways and alveoli.
- In some cases, avoiding or minimizing offending environmental/occupational exposures, medications, and smoking may alter disease severity.
DIVERTICULAR DISEASE

Jin Sol Oh, MD • Brian P. Bateson, DO • Steven B. Holsten Jr., MD, FACS

BASICS

DESCRIPTION
Diverticulum (single) or diverticula (multiple) are outpouchings in the colonic wall. Diverticular disease is a spectrum of diseases:

- Asymptomatic diverticulosis: common incidental finding on routine colonoscopy
- Symptomatic diverticulosis: also known as symptomatic uncomplicated diverticular disease (SUDD); recurrent abdominal pain attributed to diverticulosis without colitis or diverticulitis (1)
- Acute diverticulitis: inflammation and/or infection
  - Uncomplicated diverticulitis: left lower quadrant (LLQ) pain, tenderness, leukocytosis, but no peritoneal signs or systemic toxicity
  - Complicated diverticulitis: secondary abscess formation, bowel obstruction or perforation, peritonitis, fistula, or stricture
- Diverticular bleeding
  - Accounts for >40% of lower GI bleeds and 30% of cases of hematochezia in general
  - Bleeding more common with right-sided diverticula
- System affected: entire GI tract except the rectum

EPIDEMIOLOGY

Incidence
- Diverticular disease accounts for ~300,000 hospitalizations per year in the United States.
- Diverticulitis occurs in 1–2% of the general population and in 4% of patients with diverticulosis over the course of their lifetime (1).
- Diverticular bleeding occurs in 3–5% of patients with diverticulosis.

Prevalence
- Prevalence of diverticulosis and the number of diverticula increase with age
– Diverticulosis occurs in 60% of the population >age 60 years and 70% by the age of 80 years.
– Increased from 62 to 75/100,000 persons from 1998 to 2005; large increase in incidence for patients <45 years of age, due to changes in diet
  ● Male = female overall; more common in men <65 years of age and more common in women >65 years

ETIOLOGY AND PATHOPHYSIOLOGY
A diverticulum forms where intestinal blood flow (vasa recta) penetrates the colonic mucosa. This results in decreased resistance to intraluminal pressure.

  ● Age-related degeneration of mucosal wall, increased intraluminal pressure from dense, fiber-depleted stools, and abnormal colonic motility contribute to diverticulosis.
  ● Most right-sided diverticula are true diverticula (all layers of the colonic wall).
  ● Most left-sided diverticula are pseudodiverticula (outpouchings of the mucosa and submucosa only).
  ● Diverticulitis occurs when local inflammation and infection contribute to tissue necrosis with risk for mucosal micro- or macroperforation.
  ● Diverticulitis: Microscopy reveals inflammation with lymphocytic infiltrate, ulceration, mucin depletion, necrosis, Paneth cell metaplasia, and cryptitis.
  ● Alterations in intestinal microbiota contribute to chronic inflammation (1,2).
  ● Thinning of the vasa recta over the neck of the diverticula increases susceptibility to bleeding.
  ● Diverticular disease and irritable bowel syndrome (IBS) may represent the same disease continuum.

Genetics
  ● No known genetic pattern
  ● Asian and African populations have lower overall prevalence but develop diverticular disease with adoption of a Western lifestyle.

RISK FACTORS
  ● Age >40 years
  ● Low-fiber diet
  ● Sedentary lifestyle, obesity
  ● Previous diverticulitis. Risk rises with the number of diverticula.
  ● Smoking increases the risk of perforation (1).
  ● Diverticular bleeding: increased risk with NSAIDs, steroids, and opiate
analgesics. Calcium channel blockers and statins appear to be protective against diverticular bleeding.

GENERAL PREVENTION
- High-fiber diet or nonabsorbable fiber (psyllium)
- Vigorous physical activity

COMMONLY ASSOCIATED CONDITIONS
Colon cancer, connective tissue diseases, and inflammatory bowel disease

DIAGNOSIS

HISTORY
- Diverticulosis
  - 80–85% of patients are asymptomatic. Of the 15–20% with symptoms, 1–2% will need hospitalization, and 0.5% will need surgery.
  - Abdominal pain is most common symptom: dull, colicky, primarily LLQ. Pain can be exacerbated by eating and by passing bowel movement or flatus.
  - Diarrhea or constipation
- Acute diverticulitis: uncomplicated (85%) and complicated (15%)
  - Abdominal pain: acute onset, typically in LLQ
  - Fever and/or chills
  - Anorexia, nausea (20–62%), or vomiting
  - Constipation (50%) or diarrhea (25–35%)
  - Dysuria and urinary frequency suggest bladder or ureteral irritation.
  - Pneumaturia and fecaluria with colovesical fistula
- Diverticular bleeding
  - Melena, hematochezia
  - Painless rectal bleeding
- Immunocompromised patients may not present with fever or leukocytosis but are at higher risk for perforation and abscess formation (2).

PHYSICAL EXAM
- Diverticulosis
  - Usually normal
  - May have intermittent distension or tympany
– May have heme + stools

• Acute diverticulitis
  – Abdominal tenderness (usually LLQ)
  – Abdominal distension and tympany
  – Rebound tenderness, involuntary guarding, or rigidity suggests perforation and/or peritonitis.
  – Palpable mass in LLQ (20%)
  – Bowel sounds hypoactive (could be high-pitched and intermittent if obstruction is present)
  – Rectal exam may reveal tenderness or mass.
  – Colovaginal, colovesical, and perirectal fistulae are rarely the initial presentation.

DIFFERENTIAL DIAGNOSIS
Urinary tract infection, nephrolithiasis, IBS, lactose intolerance, carcinoma, inflammatory bowel disease, fecal impaction, bowel obstruction, angiodysplasia, ischemic colitis, acute appendicitis, ectopic pregnancy

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

• Diverticulosis: no labs or imaging needed

• Acute diverticulitis
  – WBC is normal in up to 45% of cases. As diverticulitis worsens, WBC elevated with left shift.
  – Hemoglobin normal (unless bleeding)
  – ESR elevated
  – Urinalysis may show microscopic pyuria or hematuria.
  – Urine culture: usually normal; persistent infection suspicious for colovesical fistula
  – Blood cultures positive in systemic cases
  – Plain films of the abdomen (acute abdominal series—supine and upright) to assess for free air under the diaphragm (bowel perforation) and signs of bowel obstruction (dilated loops of bowel)
  – CT scan with IV, oral, and/or rectal contrast (sensitivity: 98%, specificity: 99%) to stage disease and determine treatment plan (3)[A]
  – Ultrasound and MRI (sensitivity: 94%, specificity: 92%) are useful alternatives.
  – Barium enema is not recommended due to risk of peritoneal extravasation.
Diverticular bleeding
- Decreased hemoglobin with bleeding
- Obtain coagulation panel for coagulopathy.

**Diagnostic Procedures/Other**

- Diverticular bleeding
  - Endoscopy to evaluate GI bleeding (4)
  - NG lavage to exclude upper GI bleeding (4)
  - Angiography if bleeding obscures endoscopy or when endoscopy cannot visualize a source (4)
  - 99mTc-pertechnetate–labeled RBC scan (more sensitive) with follow-up angiography to localize bleeding (not studied in a comparison trial) (4)

**TREATMENT**

**GENERAL MEASURES**

- Diverticulosis: outpatient therapy with fiber supplementation and/or bulking agents (psyllium) (>30 g/day) (3)[A]
- Uncomplicated diverticulitis: outpatient therapy with or without oral antibiotics. 1–2% of subjects require hospitalization for toxicity, septicemia, peritonitis, or failure of symptoms to resolve. Up to 30% of patients may require surgery at first episode of diverticulitis.
- Complicated diverticulitis: hospitalization, bowel rest, and IV antibiotics. Hinchey classification (severity):
  - Stage I: diverticulitis + confined paracolic abscess
  - Stage II: diverticulitis + distant abscess
  - Stage III: diverticulitis + purulent peritonitis
  - Stage IV: diverticulitis + fecal peritonitis
- Symptomatic improvement is expected within 2 to 3 days. Antibiotics should be continued for 7 to 10 days.
- Diverticular bleeding: 80% of cases resolve spontaneously (4).

**MEDICATION**

**First Line**

- Symptomatic diverticulosis: cyclical rifaximin 400 mg PO BID for 7 days every month or continuous mesalamine 800 mg PO BID (3)[C]
- Acute diverticulitis
– The routine use of antibiotics in uncomplicated diverticulitis is controversial (3,5)[C].
– Outpatient oral antibiotics: Cover for anaerobes and gram-negatives with:
  o A fluoroquinolone (ciprofloxacin 750 mg BID or levofloxacin 750 QD) plus metronidazole 500 mg TID (may use clindamycin if metronidazole intolerant) or
  o Trimethoprim/sulfamethoxazole DS BID plus metronidazole 500 mg TID
  o Treat for 7 to 10 days.
– Inpatient: Use IV antibiotics.
  o Monotherapy with a β-lactam/β-lactamase inhibitor: piperacillin/tazobactam (3,375 g IV QID) or ampicillin/subbactam 3 g IV q6h or ertapenem (1 g IV QD)
  o Penicillin-allergic patient: quinolone (levofloxacin 750 mg IV QD plus metronidazole 500 mg IV TID)
  o Unresponsive or severe disease: imipenem or meropenem
– Recurrences of acute diverticulitis may be decreased by using mesalamine ± rifaximin or probiotics.
- Diverticular bleeding
  – Consider vasopressin 0.2 to 0.3 units/min through selective intra-arterial catheter.
- Precautions
  – Avoid morphine and other opiates that may increase intraluminal pressure or promote ileus.
  – Increased fiber intake is not recommended in the acute management of diverticulitis.

**Second Line**
- Outpatient: amoxicillin/clavulanate monotherapy (875/125 mg BID) (contraindicated in patients with clearance <30 mL/min) or moxifloxacin (400 mg PO QD) plus metronidazole (500 mg PO TID)
- Severely ill inpatients: ampicillin (500 mg IV q6h) + metronidazole (500 mg IV TID) + a quinolone or ampicillin + metronidazole + an aminoglycoside

**ISSUES FOR REFERRAL**
- Acute diverticulitis patients should follow up with a gastroenterologist or surgeon after resolution of diverticulitis (6 to 8 weeks) for colonoscopy to exclude malignancy, fistula, strictures, or inflammatory bowel disease (3).
- Acute complicated diverticulitis should have appropriate surgical and critical care/infectious disease consultations.
SURGERY/OTHER PROCEDURES

- Acute diverticulitis
  - Indications for emergent surgery: peritonitis, uncontrolled sepsis, perforation, obstruction
  - Consultation to interventional radiology to drain large abscesses (>4 cm) for Hinchey I and II diverticulitis (3)
  - Generally Hinchey III or IV diverticulitis requires surgery in the same hospital admission.
  - Elective resection in recurrent diverticulitis is a case-by-case decision. It is typically advised after recovery from a bout of complicated diverticulitis which is treated nonoperatively (3).
  - Immunocompromised patients are more likely to present with acute complicated diverticulitis, fail medical management, and have complications from elective surgery.

- Diverticular bleeding
  - Endoscopy and hemostasis by epinephrine injection, electrocautery, or clipping (4)
  - Angiography can identify bleeding source and embolize the feeding artery (4).
  - Massive or recurrent bleeding requires limited or subtotal colectomy to control hemorrhage.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Probiotics such as Lactobacillus casei and Escherichia coli Nissle 1917 have been used to prevent recurrence with mixed success.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admit for systematic toxicity, sepsis, and/or peritonitis.
- Admit patients who cannot tolerate oral intake or who need IV fluids, analgesics, antibiotics, and bowel rest.

ONGOING CARE

DIET
Bowel rest with NPO during acute diverticulitis; advance diet as tolerated as bowel function returns
Patients with known diverticulosis or a history of diverticulitis should consume a high-fiber diet to prevent recurrence (5).
Avoiding nuts and popcorn is not necessary (5).

PROGNOSIS
- Good with early detection and prompt treatment
- After first episode of diverticulitis, there is a 33% chance of recurrence. After a second episode, there is a 66% chance of further recurrence.
- Most complications occur during first bout of diverticulitis.
- Younger patients are more likely to have recurrence.
- Rebleeding occurs in up to 6%.

COMPLICATIONS
Hemorrhage, perforation, peritonitis, obstruction, abscess, or colovesicular/colovaginal fistula

REFERENCES

ADDITIONAL READING
213.

**CODES**

**ICD10**

- K57.90 Diverticlos of intest, part unsp, w/o perf or abscess w/o bleed
- K57.30 Divertclos of lg int w/o perforation or abscess w/o bleeding
- K57.92 Diverticulitis of intestine, part unspecified, without perforation or abscess without bleeding

**CLINICAL PEARLS**

- Diverticulosis is common in elderly patients with a sedentary lifestyle who consume a Western diet.
- Diverticulosis patients benefit from a high-fiber diet.
- Acute uncomplicated diverticulitis can be treated with outpatient therapy with oral antibiotics.
- Acute complicated diverticulitis requires hospitalization, bowel rest, and IV antibiotics.
- The decision for surgery in diverticulitis and diverticular bleeding is made on a case-by-case basis.
- Surgical consultation is recommended in acute complicated diverticulitis.
- After an episode of diverticulitis, patients should follow up to undergo colonoscopy to rule out malignancy.
- Diverticular disease is a common cause of GI bleeding.
DOMESTIC VIOLENCE
Rhonda A. Faulkner, PhD • Luis T. Garcia, MD

BASICS
DESCRIPTION
- Domestic violence (DV) is the behavior in any relationship that is used to gain or maintain power and control over an intimate partner.
- May include physical, sexual, and/or emotional abuse; economic or psychological actions; or threats of actions that influence another person.
- Although women are at greater risk of experiencing DV, it occurs among patients of any race, age, sexual orientation, religion, gender, socioeconomic background, and education level.
- Synonym(s): intimate partner violence (IPV); spousal abuse; family violence

EPIDEMIOLOGY
Incidence
In the United States, lifetime estimates of DV are 22–39% of women, with 10–69% reporting physical assault by an intimate partner at some point in their lifetime. DV affects both sexes, but women are more likely to be victims than men and are more likely to report partner violence.

Prevalence
- DV occurs in 1 of 4 American families. Nearly 5.3 million incidents of DV occur each year among U.S. women aged ≥18 years and 3.2 million incidents among men.
- DV results in nearly 2 million injuries and up to 4,000 deaths annually in the United States.
- 14–35% of adult female patients in emergency departments report experiencing DV within the past year.
- Costs of DV are estimated to exceed $5.8 billion annually, of which $4.1 billion are for direct medical and mental health services.
- DV survivors have a 1.6- to 2.3-fold increase in health care use compared with the nonabused population.

Geriatric Considerations
4–6% of elderly are abused, with ~2 million elderly persons experiencing abuse and/or neglect each year. In 90% of cases, the perpetrator is a family member.

Elder abuse is any form of mistreatment that results in harm or loss to an older person; may include physical, sexual, emotional, financial abuse, and/or neglect

**Pediatric Considerations**

- >3 million children aged 3 to 17 years are at risk of witnessing acts of DV.
- ~1 million abused children are identified in the United States each year.
- Children living in violent homes are at increased risk of physical, sexual, and/or emotional abuse; anxiety and depression; decreased self-esteem; emotional, behavioral, social, and/or physical disturbances; and lifelong poor health.

**Pregnancy Considerations**

DV occurs during 7–20% of pregnancies. Women with unintended pregnancy are at 3 times greater risk of DV. 25% of abused women report exacerbation of abuse during pregnancy. There is a positive correlation between DV and postpartum depression.

**RISK FACTORS**

- Patient/victim risk factors
  - Substance abuse
  - Poverty/financial stressors/unemployment
  - Recent loss of social support
  - Family disruption and life cycle changes
  - History of abusive relationships or witness to abuse as child
  - Mental or physical disability in family
  - Social isolation
  - Pregnancy
  - Attempting to leave the relationship
- Perpetrator risk factors
  - Substance abuse (e.g., PCP, cocaine, amphetamines, alcohol)
  - Young age
  - Unemployment
  - Low academic achievement
  - Witnessing or experiencing violence as child
- Depression
- Personality disorders
- Threatening to self or others
- Violence to children or violence outside the home
- Owns weapons

- Relational risk factors
  - Marital conflict
  - Marital instability
  - Economic stress
  - Traditional gender role norms
  - Poor family functioning
  - Obsessive, controlling relationship

**Geriatric Considerations**
Factors associated with the abuse of older adults include increasing age, nonwhite race, low-income status, functional impairment, cognitive disability, substance use, poor emotional state, low self-esteem, cohabitation, and lack of social support.

**Pediatric Considerations**
Factors associated with child abuse or neglect include low-income status, low maternal education, nonwhite race, large family size, young maternal age, single-parent household, parental psychiatric disturbances, and presence of a stepfather.

**Prescription**
- DV is often underdiagnosed, with only 10–12% of physicians conducting routine screening.
- Although prevalence of DV in primary care settings is 7–50%, <15% are screened.
- Pregnancy increases risk.
- Barriers to screening: time constraints, discomfort with the subject, fear of offending the patient, and lack of perceived skills and resources to manage DV
- Abused patients may refuse to disclose abuse for many reasons, which include the following:
  - Not feeling emotionally ready to admit the reality of the situation
– Shame and self-blame
– Feelings of failure if abuse is admitted
– Fear of rejection by the physician
– Fear of retribution from abuser
– Belief that abuse will not happen again
– Belief that no alternatives or available resources exist

HISTORY

- Physicians should introduce the subject of DV in a general way (i.e., “I routinely ask all patients about domestic violence. Have you ever been in a relationship where you were afraid?”).

- How to screen
  - Screen patient alone, without partner or others present.
  - Ask screening questions in patient’s primary language; do not use children or other family members as interpreters.

- Partner violence screen (sensitivity 35–71%; specificity 80–94%)
  - “Have you ever been hit, kicked, punched, or otherwise, hurt by someone within the past year? If so, by whom?”
  - “Do you feel safe in your current relationship?”
  - “Is there a partner from a previous relationship who is making you feel unsafe now?”

- CDC-recommended RADAR system
  - R: Routinely screen every patient; make screening a part of everyday practice in prenatal, postnatal, routine gynecologic visits, and annual health screenings.
  - A: Ask questions directly, kindly, and be nonjudgmental.
  - D: Document findings in the patient’s chart using the patient’s own words, with details. Use body maps and photographs as necessary.
  - A: Assess the patient’s safety and see if the patient has a safety plan.
  - R: Review options for dealing with DV with the patient and provide referrals.

- SAFE questions
  - Stress/safety: “Do you feel safe in your relationship?”
  - Afraid/abused: “Have you ever been in a relationship where you were threatened, hurt, or afraid?”
  - Friends/family: “Are your friends or family aware that you have been hurt? Could you tell them, and would they be able to give you support?”
  - Emergency plan: “Do you have a safe place to go and the resources you need in an emergency?”
● HITS questions: “How often does your partner:
  – Hurt you physically?
  – Insult or talk down to you?
  – Threaten you with harm?
  – Scream or curse at you?”
● Assess pregnancy difficulties such as poor/late prenatal care, low-birth-weight babies, and perinatal deaths.
● Pelvic and abdominal pain, chronic without demonstrable pathology
● Headaches, back pain
● Gynecologic disorders
● Sexually transmitted infections (STIs) including HIV/AIDS
● Depression, suicidal ideation, anxiety, fatigue
● Substance abuse
● Eating disorders
● Overuse of health services/frequent emergency room visits
● Noncompliance

PHYSICAL EXAM
● Clinical presentation/psychological signs and symptoms
  – Delay in seeking treatment
  – Inconsistent explanation of injuries
  – Reluctance to undress
  – Signs of battered woman syndrome and/or posttraumatic stress disorder (PTSD) (flat affect/avoidance of eye contact, evasiveness, heightened startle response, sleep disturbance, traumatic flashbacks)
  – Depression, anxiety, chronic fatigue, substance abuse
  – Suspicious partner accompaniment at appointment; overly solicitous partner and/or refusal to leave exam room
● Physical signs and symptoms
  – Tympanic membrane rupture
  – Rectal or genital injury (centrally located injuries with bathing-suit pattern of distribution—concealable by clothing)
  – Head and neck injuries (site of 50% of abusive injuries)
  – Facial scrapes, loose or broken tooth, bruises, cuts, or fractures to face or body
  – Knife wounds, cigarette burns, bite marks, welts with outline of weapon (such as belt buckle)
  – Broken bones
  – Defensive posture injuries
– Injuries inconsistent with the explanation given
– Injuries in various stages of healing

## DIAGNOSTIC TESTS & INTERPRETATION

- The U.S. Preventive Services Task Force (USPSTF) in 2013 issued guidelines recommending that clinicians screen all women of childbearing age (14 to 46 years old) for DV and provide or refer women to intervention services when appropriate (1)[B].

- Other recommendations
  - American College of Physicians (ACP) recommends routine screening for DV for all women in primary care settings at periodic intervals and when women present for emergency care with traumatic injuries.
  - The American Medical Association (AMA) recommends that all patients be routinely screened for DV with inquiry into history of family violence.
  - The World Health Organization (WHO) recommends against DV screening or routine inquiry about exposure to DV; however, they recommend asking about exposure to DV when assessing conditions that may be caused or complicated by abuse (2)[B].

  - U.S. Surgeon General and American Association of Family Practitioners recommend that physicians consider the possibility of DV as a cause of illness and injury.
  - The Partner Violence Screen is a three-question screening tool with a high specificity.
  - There is no evidence of harm in screening for DV.

### Pediatric Considerations

American Academy of Pediatrics (AAP) and AMA recommend that physicians remain alert for signs and symptoms of child physical and sexual abuse in the routine exam.

### Pregnancy Considerations

American College of Obstetrics and Gynecologists (ACOG) and AMA guidelines on DV recommend that physicians routinely assess all pregnant women for DV. ACOG recommends periodic screening throughout obstetric care (at the first prenatal visit, at least once per trimester, at the postpartum checkup).

### Initial Tests (lab, imaging)

Liver function tests (LFTs), amylase, lipase if abdominal trauma is suspected
Treatment includes initial diagnosis; ongoing medical care; emotional support, counseling, and patient education regarding the DV cycle; referrals to community and supportive services as needed.

On diagnosis, use the SOS-DoC intervention:

- **S**: Offer Support and assess Safety:
  - Support: “You are not to blame. I am sorry this is happening to you. There is no excuse for DV.”
  - Remind patient of your commitment to confidential communication.
  - Safety: Listen and respond to safety issues for the patient: “Do you feel safe going home?”; “Are your children safe?”

- **O**: Discuss Options, including safety planning and follow-up:
  - Provide information about DV and help when needed. Make referrals to local resources:
    - “Do you need or want to access a safety shelter or DV service agency?”
    - “Do you want police intervention and if so, would you like me to call the police so they can make a report with you?”
    - Offer numbers to local resources and National DV Hotline: 1-800-799-SAFE (open 24/7; can provide physicians in every state with information on local resources).

- **S**: Validate patient’s Strengths:
  - “It took courage for you to talk with me today. You have shown great strength in very difficult circumstances.”

- **Do**: Document observations, assessment, and plans:
  - Use patient’s own words regarding injury and abuse.
  - Legibly document injuries: Use a body map.
  - If possible, take instant photographs of patient’s injuries if given patient consent.
  - Make patient safety plan. Prepare patient to get away in an emergency:
    - Encourage patient to keep the following items in a safe place: keys (house and car); important papers (Social Security card, birth certificates, photo ID/driver’s license, passport, green card); cash, food stamps, credit cards; medication for self and children; children’s immunization records; important phone numbers/addresses (friends, family, local shelters); personal care items (e.g., extra glasses).
    - Encourage patient to arrange a signal with someone to let that person
know when she or he needs help.

– **C: Offer Continuity:**
  – Offer a follow-up appointment and assess barriers to access.

**GENERAL MEASURES**

- Reporting child and elder abuse to protective services is mandatory in most states. Several states have laws requiring mandatory reporting of IPV.
- Contact the local DV program to find out about laws and community resources before they are needed.
- Display resource materials (National DV Hotline: 1-800-799-SAFE) in the office, all exam rooms, and restrooms.

**ADDITIONAL THERAPIES**

- National DV Hotline: 1-800-799-SAFE (7233)
- Post in all exam rooms posters in both English and Spanish; available at [http://www.thehotline.org/resources/download-materials/](http://www.thehotline.org/resources/download-materials/)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Schedule prompt follow-up appointment.
- Inquire about what has happened since last visit.
- Review medical records and ask about past episodes to convey concern for the patient and a willingness to address this health issue openly.
- DV often requires multiple interventions over time before it is resolved.

**PATIENT EDUCATION**

- Counsel patients about nonviolent ways to resolve conflict.
- Educate patients about the cycle of violence.
- Counsel parents about developmentally appropriate ways to discipline their children.
- Educate parents about the negative consequences of arguments on children and each other.
- CDC: [http://www.cdc.gov/violenceprevention/](http://www.cdc.gov/violenceprevention/)

**PROGNOSIS**
Most DV perpetrators do not voluntarily seek therapy unless pressured by partners or on legal mandate. Current evidence is insufficient on effectiveness of therapy for perpetrators.

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- T74.91XA Unspecified adult maltreatment, confirmed, initial encounter
- T74.11XA Adult physical abuse, confirmed, initial encounter
- T74.31XA Adult psychological abuse, confirmed, initial encounter

CLINICAL PEARLS

- Display resource materials in the office (e.g., posting abuse awareness posters/National DV Hotline, 1-800-799-SAFE, in both English and Spanish, in all exam rooms and restrooms).
- Given the high prevalence of DV and the lack of harm and potential benefits
of screening, routine screening is recommended.
- For those who screened positive, offer resources, reassure confidentiality, and provide close follow-up.
DOWN SYNDROME
Michele Roberts, MD, PhD • Brian G. Skotko, MD, MPP

BASICS

DESCRIPTION
- Down syndrome (DS) is a congenital condition associated with intellectual disability and an increased risk of multisystem medical problems.
- System(s) affected: neurologic (100%), cardiac (40–50%), GI (8–12%)
- Synonym(s): trisomy 21

Pediatric Considerations
Murmur may not be present at birth. Delay in recognition of heart condition may lead to irreversible pulmonary hypertension.

Geriatric Considerations
- Life expectancy has increased to ~60 years.
- Age-related health issues occur at earlier age than in the general population.
- Communication difficulties may interfere with prompt recognition of some medical issues.

Pregnancy Considerations
- American College of Obstetricians and Gynecologists (ACOG) recommends all pregnant women be offered traditional prenatal screening and diagnostic testing for DS.
  - Maternal prenatal screening may be performed in the 1st or 2nd trimester.
  - Prenatal diagnostic tests include chorionic villus sampling or amniocentesis.
- ACOG and the Society for Maternal-Fetal Medicine (SMFM) acknowledge that any women may choose noninvasive prenatal screening (NIPS), although conventional screening tests might be more appropriate. American College of Medical Genetics and Genomics (ACMG) recommends all women be offered NIPS (1,2).
- Most, but not all, men with DS are believed to be infertile.
- Most women with DS are subfertile but can conceive children with and without DS.
EPIDEMIOLOGY

Incidence
In the United States, 1 per 792 live births, ~5,300 births/year (3)

Prevalence
~206,000 persons in the United States (4)

ETIOLOGY AND PATHOPHYSIOLOGY
- Etiology: presence of all or part of an extra chromosome 21
- Trisomy 21: 95% of DS, an extra chromosome 21 is found in all cells due to nondisjunction, usually in maternal meiosis.
- Translocation DS: 3–4% of DS, extra chromosome 21q material is translocated to another chromosome (usually 13, 14, or 21); ~25% have parental origin.
- Mosaic trisomy 21: 1–2% of DS, manifestations may be milder.

Genetics
- Online Mendelian Inheritance in Man (OMIM) 190685
- Inheritance: most commonly sporadic nondisjunction resulting in trisomy 21
- Chance of having another child with DS is
  - 1% (or age risk, whichever is greater) after conceiving a pregnancy with nondisjunction trisomy 21
  - 10–15% for mothers/sisters and 3–5% for fathers/brothers who carry balanced translocation with chromosome 21
  - 100% if the parental balanced translocation is 21:21 (45,t[21:21])
  - Unclear after child with mosaic DS but ~1%

RISK FACTORS
- DS believed to occur in all races and ethnicities with equal frequency
- Chance of having an infant with DS increases with mother’s age.
- Relatively more infants with DS are born to younger mothers because younger women are more likely to become pregnant.
- Prenatal diagnosis of DS is more common in older women, and a high percentage of such pregnancies are electively terminated.

GENERAL PREVENTION
- No prevention for nondisjunction trisomy 21
Preimplantation diagnosis with in vitro fertilization (IVF), prenatal diagnosis followed by termination, and adoption are current options for expectant parents who do not wish to raise a child with DS.

COMMONLY ASSOCIATED CONDITIONS

- **Cardiac**
  - Congenital heart defects (40–50%)
- **GI/growth**
  - Feeding problems are common in infancy.
  - Structural defects (~12%)
  - Gastroesophageal reflux
  - Constipation
  - Celiac disease (~5%)
- **Pulmonary**
  - Tracheal stenosis/tracheoesophageal fistula
  - Pulmonary hypertension
  - Obstructive sleep apnea (50–75%)
- **Genitourinary**
  - Cryptorchidism, hypospadias
- **Hematologic/neoplastic**
  - Transient myeloproliferative disorder (~10%): generally resolves spontaneously; can be preleukemic (acute megakaryoblastic leukemia [AMKL]) in 20–30%
  - Leukemia (AMKL or acute lymphoblastic leukemia [ALL]) in 0.5–1%
  - Decreased risk of most solid tumors; increased risk of germ cell tumors
- **Endocrine**
  - Hypothyroidism: congenital or acquired (13–63%) (5)
  - Diabetes
- **Skeletal**
  - Atlantoaxial instability (15%): ~2% symptomatic
  - Short stature is common.
  - Scoliosis (some cases have adult onset)
  - Hip problems (1–4%)
- **Immune/rheumatologic**
  - Abnormal immune function with increased rate of respiratory infections
  - Increased risk of autoimmune disorders, including Hashimoto thyroiditis, celiac disease, and alopecia
- **Neurologic**
  - Intellectual ability ranging from mild to severe disability. Average is
moderate intellectual disability.
- Autism spectrum disorder (<18%); autism (<6%)
- Seizures (8%); typically occurring <1 year of age or >30 years of age
- Alzheimer disease: At least 40% at age 40 years develop signs of dementia; percentage increases with age.

- **Psychiatric**
  - Attention deficit hyperactivity disorder (ADHD), obsessive-compulsive disorder (OCD), oppositional-defiant disorder (ODD), and autism spectrum disorder increased frequency in children.
  - Generalized depression and anxiety with increased frequency in young adults/adults

- **Sensory**
  - Hearing loss (75%): mostly conductive due to high frequency of asymptomatic middle ear effusion; otitis media (50–70%)
  - Visual impairment (60%): mostly strabismus (refractive errors, 15%), nystagmus, cataracts (15%)

- **Dermatologic**
  - Xerosis, eczema, palmoplantar hyperkeratosis, atopic or seborrheic dermatitis, onychomycosis, syringomas, furunculosis/folliculitis

---

**DIAGNOSIS**

**HISTORY**

~85% of mothers of infants with DS learn of the diagnosis postnatally, although this is changing with the availability of NIPS.

**PHYSICAL EXAM**

- In November 2015, DS-specific growth charts were released. They describe recent growth trends in a sample of children with DS in the United States. These charts can be used as screening tools to help better assess growth and nutritional trends of children with DS, who grow differently from their typically developing peers; these charts do not represent “optimal” growth of children with DS; 50% BMI on the DS-specific growth curves corresponds to the 85% (overweight) on the standard NCHS growth curves (6).

- Infants and children
  - Brachycephaly (100%)
  - Hypotonia (80%)
– Small ears, often low set and simplified
– Upslanting palpebral fissure (90%)
– Epicanthic folds (90%)
– Brushfield spots
– Depressed nasal bridge
– Short neck, often with increased nuchal folds
– Single palmar crease, single flexion crease on 5th finger
– Increased space between toes 1 and 2, 5th finger clinodactyly, brachydactyly

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Maternal prenatal screening includes the following:
  - 1st trimester: combined screen (maternal age, $\beta$-human chorionic gonadotropin [$\beta$-hCG], pregnancy-associated plasma protein A [PAPP-A], and nuchal translucency)
  - 2nd trimester: quad screen ($\alpha$-fetoprotein, $\beta$-hCG, estriol, inhibin-A)
  - Sequential screen (combined screen in 1st trimester, if abnormal, obtain amniocentesis or await 2nd trimester quad screening)
  - Integrated screen (combined screening in 1st trimester plus quad screen in 2nd trimester)
  - NIPS with cell-free DNA (beginning at 10 weeks’ gestation) (1,2)

- Prenatal diagnosis includes the following:
  - Chorionic villus sampling: 1st trimester, ~99% accurate, ~1% miscarriage
  - Amniocentesis: 2nd trimester, ~99% accurate, ~0.25% miscarriage rate

- Postnatal diagnosis
  - Fluorescence in situ hybridization (FISH) can be performed at time of clinical suspicion, but karyotype should always be done to differentiate type of DS.
  - Parental (and adult-aged sibling) karyotype is indicated only if translocation DS found in child.

- Labs for newborns
  - Echo, with or without murmur
  - CBC with differential (to look for transient myeloproliferative disorder)
  - Thyroid-stimulating hormone (TSH)
  - Audiogram
  - Ophthalmologic exam (look for red reflex)
  - Swallowing study for those with feeding difficulties
Follow-Up Tests & Special Considerations

- After delivering a prenatal diagnosis, the physician should offer “Understanding a Down Syndrome Diagnosis” (understandingdownsyndrome.org).
- If the diagnosis is postnatal, the mother and her partner should be informed of the diagnosis promptly by a physician (preferably the obstetrician and pediatrician or family physician), on the basis of clinical observations and before the karyotype is available, but with consideration of extenuating circumstances (e.g., mother’s medical condition). The spouse/partner and infant should be present unless this would cause undue delay. The meeting should be private. Refer to the baby by name.
- In the postnatal setting, the physician should be knowledgeable on the subject of DS and should conduct a discussion with content that is current, respectful, balanced, informative, and realistic but not overly pessimistic, concentrating on what is relevant to the 1st year of life.
- Cardiac follow-up, as indicated

TREATMENT

GENERAL MEASURES
Genetic evaluation and counseling

ISSUES FOR REFERRAL
- Infant stimulation programs (early intervention)
- Lactation consultant
- Physical/occupational/speech therapy
- Educational inclusion often successful
- Pediatric cardiologist, if indicated
- DS specialty clinics can improve medical outcomes.

SURGERY/OTHER PROCEDURES
Repair of congenital anomalies is appropriate. Plastic surgery for facial features is not recommended.

COMPLEMENTARY & ALTERNATIVE MEDICINE
There is no evidence to support the use of antioxidant or folinic acid supplements in children with DS.
Craniosacral manipulation is dangerous due to potential atlantoaxial instability.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
If the social situation indicates adoption, consider the National Down Syndrome Adoption Network (NDSAN) (www.ndsan.org) national registry of families seeking to adopt a child with DS.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
The American Academy of Pediatrics recommends ongoing assessment and review, at least annually, the following surveillance:

- Vision: Assess for strabismus, cataracts, and nystagmus by ophthalmologist by 6 months, annually between ages 1 and 5 years, every 2 years ages 5 to 13 years, every 3 years ages 13 to 21 years.
- Hearing: neonatal screen with auditory brainstem response (ABR) or otoacoustic emissions (OAE), then audiogram every 6 months until age 3 years, and then annually
- Thyroid: initial newborn screen. Repeat TSH at 6 months, 12 months, and then annually (6)[C].
- Screening for celiac disease (total IgA and tissue transglutaminase [TTG]-IgA) annually, if symptomatic
- Three-view cervical spine films if patient symptomatic, beginning at 3 to 5 years of age
- Hemoglobin annually to screen for iron deficiency anemia
- Repeat echocardiogram in teens if with murmur or fatigue.

DIET
- No special diet, but caloric needs are lower in adolescents/adults with DS than their peers.
- Obesity is prevalent at all ages.
No scientific evidence supports megavitamin therapy or dietary supplements.

PATIENT EDUCATION
- National Down Syndrome Congress 800-232-NDSC: www.ndsccenter.org
- National Down Syndrome Society 800-221-4602: www.ndss.org
- The LuMind Down Syndrome Research Foundation provides information on the latest research for people with DS: www.lumindfoundation.org.
- www.lettercase.org provides peer-reviewed booklet for parents who have received a prenatal diagnosis of DS and have not yet made a decision about their pregnancy.
- downsyndromepregnancy.org provides a free downloadable book for expectant mothers who have decided to continue their pregnancies after a prenatal diagnosis of DS.
- www.downsyndromediagnosis.org provides materials to support prenatal and postnatal diagnoses.

PROGNOSIS
- Associated congenital anomalies are the immediate concern during the newborn period.
- 99% of young adults/adults with DS report being happy with their lives.
- Life expectancy ~60 years

CODES

ICD10

- Q90.9 Down syndrome, unspecified
- Q90.1 Trisomy 21, mosaicism (mitotic nondisjunction)
- Q90.0 Trisomy 21, nonmosaicism (meiotic nondisjunction)

CLINICAL PEARLS

- 99% of young adults/adults with DS report being happy with their lives.
- DS specialty clinics can improve medical outcomes.
BASICS

DESCRIPTION
- Prescription drug abuse behaviors exist on a continuum and may include:
  - Use of medication for nonmedical reasons such as to get high or enhance performance
  - Use of medication for medical reasons other than what the prescriber intended
  - Use of medication for any reason by someone other than the person for whom the medication was originally prescribed
- Commonly abused prescription medications include opioid analgesics (morphine, oxycodone, hydrocodone, oxymorphone, hydromorphone, fentanyl, methadone, buprenorphine), stimulants (amphetamine, methylphenidate), benzodiazepines (alprazolam, clonazepam, lorazepam), and barbiturates (secobarbital, amobarbital).
- *Diversion* is a term used to describe the rerouting of medications from prescriptions or other legitimate supplies for recreational use or criminal activity, such as selling prescription medication for personal profit.

EPIDEMIOLOGY
- In 2011, 1.4 million drug-related ED visits (56%) were due to abused or misused pharmaceuticals.
- Almost half of opioid overdose deaths involve a prescription opioid. In 2015, there were >15,000 overdose deaths involving prescription opioids in the United States.
- Prescription opioids are the second most common gateway to illicit drug use.

Incidence
- Predominant sex: males > females
- Predominant age: highest among adults 18 to 25 years, then adolescents and teens 12 to 17 years, followed by adults ≥26 years
- In 2011, >20% of the 3.1 million persons who were first-time substance
abusers used prescription medications nonmedically.

- 22 years is the average age for those with a first reported instance of nonmedical prescription drug use.

**Prevalence**
- The number of persons with nonmedical opioid dependence increased from 936,000 in 2002 to 1.4 million in 2011.
- Lifetime prevalence of prescription drug abuse is highest for opioids, benzodiazepines, and stimulants.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Young adults perceive prescription medications to be more socially acceptable than other illicit drugs.
- Pharmacokinetics, compound purity, government approval, extensive media advertising, and personal or family experiences with prescription medications all contribute to prescription drug misuse and dependence.

**Genetics**
Variant alleles affect the expression and function of opioid, dopamine, acetylcholine, serotonin, and GABA helping to explain susceptibility to different forms of prescription and nonprescription drugs.

**RISK FACTORS**
- Sociodemographic, psychosocial, pain-, and drug-related factors
- Genetics and environment; family history

**GENERAL PREVENTION**
- Try all available nonopioid treatments for pain before prescribing opioids for chronic pain.
  - Dose reduction of chronic opioids can decrease risks to patients and may improve pain, function and quality of life in some patients (1)[A].
- Educate and raise awareness about the dangers of misuse and abuse of prescription drugs. Focus on individuals, families, and communities.
- Educate and reinforce safe practices for prescribing medications. Office-based, peer-to-peer education and follow-up with pharmacies help identify suspected abuse behaviors.
- Develop or adopt a standard practice agreement for prescribing and monitoring controlled substances with abuse potential (2,3).
• Limit or avoid prescribing controlled medications on the first visit (until a relationship can be established).
• Take a thorough history, contact family members and past prescribers, and perform periodic urine drug screens (UDS). Stop prescription analgesics for chronic pain if they are ineffective in improving pain and function.
• Prescription monitoring programs (PMP) reduce doctor shopping but not ED visits for drug overdose and prescription drug abuse–related deaths (2).
• Avoid benzodiazepines and hypnotics in elderly patients.
• Avoid using benzodiazepines for more than 2 to 4 weeks.
• Use controlled substances cautiously if patients have a personal or family history of substance abuse or psychiatric disorders.
• Identify and treat underlying substance abuse; involve behavioral health providers when possible.

Intranasal naloxone programs in communities with >1 enrollment/100,000 people and 5 or more opioid-related overdose fatalities reduce new opioid-related overdose deaths (4)[B].
Provide education to family members/caretakers on intranasal naloxone use in the event of a suspected opioid overdose (4)[B].

COMMONLY ASSOCIATED CONDITIONS
• Opioids: respiratory depression and death with overdose, constipation, low testosterone, and sexual dysfunction with chronic use. Methadone is associated with QT prolongation, which increases risk for torsades de pointes.
• Benzodiazepines: withdrawal syndromes/delirium, psychosis, anxiety, sleep driving, blackout states, cognitive impairment, impaired driving while awake; increased fall risk and mortality in elderly patients
• Stimulants: hypertension, tachyarrhythmias, myocardial ischemia, seizures, hypothermia, psychosis, hallucinations, paranoia, anxiety

DIAGNOSIS
• Initial screening: “How many times in the past year have you used an illegal drug or used a prescription medication for nonmedical reasons?”; primary care setting sensitivity of 100% and specificity of ~75% (5)[C]
• Other screening tools:
  – Drug abuse screening test (DAST) helps determine patient’s involvement with drugs over the past year. Assess alcohol use with CAGE: Cut down, Anger at being questioned about use, Guilt about prior use, Eye-opener or
Alcohol Use Disorders Identification Test (AUDIT).

HISTORY
Consider aberrant behaviors when taking a history. Patient may ask for dose escalations and early refills ("spilled the bottle . . . ," “pharmacist shorted me . . . ,” etc.). Patients may have a strong preference for one drug, make appointments at end of day and after hours, and/or show hostile/threatening or flattering behavior.

DIAGNOSTIC TESTS & INTERPRETATION
- Despite limited evidence of reliability and accuracy, UDS are recommended to identify nonadherent patients (2)[C]. Random pill counts can also be useful in identifying patients who take more controlled substances than prescribed.
- UDS: Order an expanded panel to detect commonly used opioids (ask specifically for semisynthetics [hydrocodone, hydromorphone, oxycodone] and synthetics [methadone, fentanyl, propoxyphene, meperidine]) along with tramadol and buprenorphine.

Initial Tests (lab, imaging)
- Interpretation: Results are positive if drugs that are not prescribed are present; positive in presence of illicit drugs (i.e., marijuana, cocaine); suspect diversion if negative for prescribed drug.
- Be suspicious if patient refuses test.
- Oxycodone/OxyContin will be positive for oxycodone and oxymorphone.
- Hydrocodone will be positive for hydrocodone and hydromorphone.
- Codeine will be positive for codeine plus morphine.
- Heroin will be positive for morphine (codeine can also be seen as metabolite of common impurity found in heroin).
- If the UDS is positive for morphine, it could mean ingestion of morphine, codeine, or heroin.

TREATMENT
Addiction is a treatable chronic disease. The general approach to treatment includes inpatient, residential, or outpatient detoxification as required; counseling and intensive counseling as needed; and ongoing medication-assisted treatment with buprenorphine or injectable naltrexone.
• Begin taper to initiate discontinuation whenever there is evidence of prescription opioid abuse (2)[C]. Some situations indicate immediate discontinuation rather than taper (e.g., diversion or plan to switch to buprenorphine treatment).

• Opioid discontinuation through interdisciplinary pain care programs, buprenorphine-assisted programs, and detoxification programs have achieved opioid discontinuation rates >85% (1)[A].

• Benzodiazepines cannot be stopped abruptly for risk of seizures and death. Discontinue via slow taper or at a controlled detoxification program.

• Amphetamines can be stopped abruptly without risk of severe withdrawal or death.

GENERAL MEASURES
Alcoholics Anonymous/Narcotics Anonymous is helpful, as are Al-Anon/Alateen for family members. Nonjudgmental interactions and cognitive-behavioral therapy focused on motivational interviewing, goal setting, and brief interventions help manage anxiety, insomnia, and denial while improving willingness to change.

MEDICATION
• Opioid detoxification programs use clonidine, buprenorphine, or methadone under the direction of an addiction specialist. Buprenorphine is as effective as methadone but safer. Both buprenorphine and methadone are more effective than clonidine for detoxification.

• Buprenorphine and methadone have been found to be similarly effective when used in long-term opioid maintenance therapy. They can both also be effective in the treatment of chronic pain. Long-term therapy is preferable to short-term detoxification. Only an addiction specialist may prescribe methadone for treatment of opioid use disorder. Any provider can prescribe injectable naltrexone without special training. Any provider (MD, DO, NP or PA) may prescribe buprenorphine after completing training and obtaining an X waiver. For details, see https://www.samhsa.gov/medication-assisted-treatment/buprenorphine-waiver-management.

• Subutex (buprenorphine) lacks naloxone and is prone to diversion and abuse because patients can crush, snort, or shoot to get high. Suboxone (buprenorphine and naloxone) discourages abuse and diversion because naloxone displaces buprenorphine binding to opioid receptors when taken parenterally (naloxone is not well absorbed sublingually).
Injectable long-acting naltrexone (opioid antagonist) can reduce cravings for opioids and block pleasurable response to opioids if ingested and does not require special training to prescribe. Naltrexone should not be started until all opioids have been out of the patient’s system for at least 7 days to avoid precipitating severe withdrawal (6).

There is neither support for using or converting to long half-life benzodiazepines before beginning a slow, gradual benzodiazepine taper, although diazepam is often preferred, nor are there any benefits shown using propranolol, buspirone, progesterone, hydroxyzine, or dothiepin to manage withdrawal symptoms. Carbamazepine may be useful in patients who were dependent on ≥20 mg diazepam equivalents daily, and antidepressants may be helpful for depression and anxiety linked to benzodiazepine withdrawal.

Atomoxetine and bupropion SR can also be helpful in managing ADHD symptoms in select patients.

ISSUES FOR REFERRAL
Follow-up is often rare after abuse-related hospitalization. Enlist the help of chemical dependency groups/addiction specialists/pain management and psychiatry/psychology when patients have polysubstance abuse and to treat underlying mood and anxiety disorders, PTSD, and ADHD.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture, yoga, meditation, or martial arts may aid in anxiety management and stress reduction.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Indications for inpatient detoxification include concomitant alcohol and benzodiazepine dependence (increased risk of seizures), mental confusion/delirium, history of seizures, psychosis, active suicidal ideation, serious comorbid medical issues, or absence of social support.

ONGOING CARE
PATIENT EDUCATION
Controlled medication should be inaccessible to others (ideally in locked box/bag). Diverting medication may result in legal charges. Patients should be aware of addiction potential when starting controlled substances and about withdrawal symptoms if a medication is stopped abruptly. Respiratory depression and death are possible when opioids are mixed with benzodiazepines. Avoid alcohol and illicit drugs.

- Red flags include a need for higher doses, if prescription drugs are used to feel high or overcome stress, cravings, and preoccupation thinking about the next dose. Create a mutual plan to stop prescription medications and try something new.
- Family dynamics are often an important behavioral component.

REFERENCES

CODES

ICD10

- F19.10 Other psychoactive substance abuse, uncomplicated
• F11.10 Opioid abuse, uncomplicated
• F15.10 Other stimulant abuse, uncomplicated

CLINICAL PEARLS

• Education and PMPs help prevent prescription drug abuse.
• Standardized office practice agreements can help manage controlled substance prescriptions.
• A single effective screening question is “How many times in the past year have you used an illegal drug or prescription medication for nonmedical reasons?”
• Discontinue prescription opioid analgesics if pain or functionality does not improve or if there is evidence of abuse (i.e., positive UDS, driving while intoxicated [DWI], accidental or intentional overdose, early refills).
• Limit benzodiazepine use to 2 to 4 weeks.
• Conduct frequent UDS.
• Buprenorphine is an effective treatment for opioid use disorder that can be prescribed by any provider after completing training and obtaining an X waiver. Buprenorphine can also be used to treat chronic pain.
• Other medication-assisted treatments for opioid use disorder include naltrexone and methadone (although methadone can only be used to treat opioid use disorder by an addiction specialist).
DUCTAL CARCINOMA IN SITU

Bradley M. Turner, MD, MPH, MHA • David G. Hicks, MD

BASICS

DESCRIPTION

- Ductal carcinoma in situ (DCIS) is a heterogeneous group of lesions that have in common the presence of a clonal proliferation of neoplastic epithelial cells confined to ducts and lobules.
- Considered a premalignant lesion—the neoplastic cells are not invasive (pure DCIS)
- Classified as low, intermediate, or high grade
- Mortality from DCIS with subsequent progression to invasive breast carcinoma (IBC) is low, regardless of histologic type or type of treatment.

EPIDEMIOLOGY

Incidence

- Based on an observed average annual percentage increase of 1%, there were an estimated 61,500 new diagnoses of DCIS in 2017, and there will be an estimated 62,117 new diagnoses of DCIS in 2018.
- DCIS accounts for approximately 80–85% of in situ breast carcinomas (lobular carcinoma in situ [LCIS] accounts for approximately 15–20%).
- More stable incidence in women 50 to 69 years of age over the last several years
- Increasing incidence in women <50 years of age and >70 years of age over the last several years
- Represents ~26% of all new IBC
- Incidence rate of DCIS is comparable among women of different ethnicities.

ETIOLOGY AND PATHOPHYSIOLOGY

- A nonobligate precursor to IBC
- Presumed to be the final step prior to IBC, part of a poorly understood spectrum of polyclonal and clonal epithelial proliferative lesions
- Either low- or high-grade DCIS has the potential for subsequent invasion into
the surrounding stroma; however, the changes necessary for transition to IBC are poorly understood.

- Molecular evidence suggests that low- and high-grade DCIS are genetically distinct lesions, with high-grade DCIS associated with more aggressive disease.

**Genetics**
- Low-grade DCIS typically shows diffuse and strong expression of estrogen receptor (ER) and progesterone receptor (PR), without HER2 protein overexpression or amplification.
- High-grade DCIS not consistently ER+ or PR+; frequent HER2 protein overexpression and amplification; commonly associated with p53 gene mutations
- HER2 overexpression is even more frequent in high-grade DCIS compared to IBC.
- *BRCA1* and *BRCA2* associations observed; only screen those at high risk.

**RISK FACTORS**
- Female gender, nulliparity, late age at first birth, late age at menopause, family history of a first-degree relative with breast cancer, long-term use of postmenopausal hormone replacement therapy (combined estrogen/progestin), high breast density, history of atypical ductal hyperplasia (ADH)
- Association with age, body mass index, smoking, lactation, early menarche, increased alcohol consumption, and oral contraceptive use is less clear.

**GENERAL PREVENTION**
- Screening increases overdiagnosis with little or no reduction in the incidence of advanced cancers.
- Women with increased risk should have more aggressive screening (risk assessment tool available at [http://www.cancer.gov/bcrisktool/Default.aspx](http://www.cancer.gov/bcrisktool/Default.aspx)).
- General screening guidelines—U.S. Preventive Services Task Force (USPSTF):
  - Biennial mammography for women aged 50 to 74 years (B recommendation)
  - Mammography prior to age 50 years should be patient centered.
  - Biennial screening of ages 40 and 49 years without evidence of benefit (C recommendation)
  - Insufficient evidence to support screening mammography in women aged
75 years or older
– There is insufficient evidence to assess the benefits and harms of digital breast tomosynthesis (DBT) as a primary screening method for breast cancer (I statement).
– Insufficient evidence to support adjunctive screening for breast cancer using breast ultrasonography, magnetic resonance imaging (MRI), DBT, or other methods in women with dense breasts on an otherwise negative screening mammogram (I statement)

• General screening guidelines—National Comprehensive Cancer Network (NCCN):
  – NCCN recommends that women should be familiar with their breast; promptly report changes to their health care provider; and that periodic, consistent BSE may facilitate breast self-awareness.
  – Ages 25 to 39 years: breast awareness, CBE every 1 to 3 years
  – Age 40 years and older: breast awareness, annual CBE, annual screening mammography

• If no intervention would occur based on screening findings, patient should not undergo screening.

• Risk reduction:
  – Lifestyle modifications: Limit alcohol to <1 drink/day, exercise, maintain healthy diet, BMI <30.
  – Hormonal agents (i.e., tamoxifen) are recommended in certain high-risk women ≥35 years of age; benefits of aromatase inhibitors are less clear.
  – A recent clinical trial with anastrozole (an aromatase inhibitor) showed a significantly decreased incidence of DCIS in postmenopausal women.

**DIAGNOSIS**

**HISTORY**

• Most DCIS is now diagnosed by screening mammography (presence of microcalcifications in approximately 72%); patients may be asymptomatic with nonpalpable mass (12%) (1,2)[A].
• Advanced lesions may present with a palpable mass, nipple discharge, or Paget disease (1)[A].

**PHYSICAL EXAM**

• CBE with inspection of breasts with patient in upright and supine position;
evaluating for asymmetry, spontaneous discharge, skin changes (peau d’orange, erythema, scaling); nipple retraction/excoriation (Paget disease)

- Palpation of all breast quadrants with patient in upright and supine position, including lymph node examination (axillary, supraclavicular, and internal mammary nodes)
- Positive clinical findings: Refer for consideration of diagnostic imaging and/or surgical evaluation unless <30 years of age with a low clinical suspicion (observe 1 to 2 menstrual cycles; if positive clinical findings persist, refer for imaging).

DIFFERENTIAL DIAGNOSIS

Usual ductal hyperplasia, flat epithelial atypia, ADH, LCIS, microinvasive carcinoma (1)[A]

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Mammography Breast Imaging Reporting and Data System (BI-RADS) developed by the American College of Radiology is used for uniform reporting of mammography results.
- BI-RADS interpretation: categories (0 to 6) 0: incomplete and needs additional imaging; 1: negative; 2: benign finding; 3: probably benign finding; 4: suspicious abnormality; 5: highly suggestive of malignancy; 6: known biopsy-proven malignancy
- Similar BI-RADS interpretations for diagnostic ultrasound (US)
- Screening BI-RADS category 0: diagnostic workup with consideration for diagnostic imaging
- Screening BI-RADS categories 1 and 2: screening recommendations
- Screening BI-RADS category 3: diagnostic imaging at 6 months and then every 6 to 12 months for 2 to 3 years; consider biopsy if patient anxious or follow-up uncertain.
- Screening BI-RADS categories 4 and 5: diagnostic imaging with follow-up
- Screening BI-RADS category 6: technically not a “screening” category other than to assess a known cancer that might need additional evaluation. NCCN guidelines for breast cancer should be followed.

DCIS is commonly seen on imaging as clustered microcalcifications (2)[A].

Diagnostic imaging will result in consideration for tissue biopsy.

Follow-Up Tests & Special Considerations
US not recommended for screening

The sensitivity of breast MRI screening is higher than mammography but has lower specificity resulting in a greater number of false positives (2)[A].

Screening with MRI as an adjunct to screening mammogram is only recommended in certain women: BRCA mutation (commence at age 25 to 29 years) (3)[A]; first-degree relative of BRCA carrier (commence at age 25 to 29 years) (3)[A]; ≥20% lifetime risk of breast cancer, defined by models that are largely based on family history (3)[A]; radiation to chest between the ages of 10 and 30 years (3)[C]; presence of Li-Fraumeni, PTEN, or Bannayan-Riley-Ruvalcaba syndrome in patient or first-degree relative (3)[C]; ≥20% risk of breast cancer based on gene- and/or risk-level ATM, CDH1, CHEK2, PALB2, PTEN, STK11, TP53 (3)[C].

There is insufficient evidence to recommend for or against MRI screening in the following groups: 15–20% lifetime risk of breast cancer, defined by models that are largely based on family history; heterogeneous or extremely dense breast tissue on mammography; personal history of breast cancer or DCIS.

Screening with MRI is not recommended in women with <15% lifetime risk of breast cancer (3)[C]. MRI can also complement mammography in patients with skin changes.

Although MRI and US are complementary diagnostic methods to mammography, US is less sensitive in detecting most microcalcifications and MRI does not typically detect microcalcifications at all (2)[A].

After a diagnosis of DCIS, MRI has been prospectively shown to have a sensitivity of up to 98% for high-grade DCIS (4)[A].

The NCCN Panel has included breast MRI as indicated during the initial workup of DCIS, noting that the use of MRI has not been shown to increase the likelihood of negative margins or decrease the conversion to mastectomy with DCIS.

Pathology

- Tissue is necessary for diagnosis: core needle (CN) or vacuum-assisted (VA) biopsy (mammographic/stereotactic, US, or MRI guided). Open surgical biopsy for those not amenable to CN or VA biopsy.
- Fine-needle aspiration (FNA) is not adequate for specific diagnosis of DCIS.
- Histologic classification
  - Classification is subjective; however, traditionally classified as either low, intermediate, or high grade based on architectural patterns (comedo, solid, cribriform, clinging, papillary, and micropapillary), nuclear grade
(I, II, or III), and the absence or presence of necrosis (1,2).
- Ductal intraepithelial neoplasia (DIN) is an alternative histologic classification incorporating size as a discriminating factor (2)[C].
- Grade is more important for prognosis, risk for progression, and local recurrence.
- Comedo-type necrosis (necrosis filling central portion of involved duct) is typically seen in high-grade DCIS, with varying degrees of necrosis in other types of DCIS.

- Determination of ER and PR status (1,4)[A]
- Studies show unclear or weak evidence of HER2 status as a prognostic indicator in DCIS.

TREATMENT

SURGERY/OTHER PROCEDURES

- Surgery is the primary treatment option. Options for surgery are based on risk of recurrence, anatomic location, extent of disease, and the ability to achieve “negative” margins (4)[A].
- Positive margins are considered “ink on tumor.”
- Totality of evidence does not support the routine practice of obtaining negative margin widths wider than 2 mm (4)[C],(5)[A].
- Margins <1 mm considered inadequate (1,4,5)[A]
- Margins <1 mm at the breast fibroglandular boundary (chest wall or skin) do not mandate surgical excision but may be an indication for higher boost dose radiation in patients opting for breast conservation (4)[A].
- DCIS with microinvasion, defined as no invasive focus >1 mm in size, should be considered as DCIS when considering the optimal margin width (4)[C]. When there is only minimal or focal DCIS involvement near the margin, clinical judgment can be applied to determine if reexcision might be avoided in individual cases(4)[C].
- Surgical options include the following:
  - Breast conservation (lumpectomy) without lymph node procedure, without breast radiation therapy (4)[A]
  - Breast conservation (lumpectomy) without lymph node procedure, with whole breast radiation therapy, with or without boost to tumor bed (4)[A]
  - A complete axillary lymph node dissection should not be performed in the absence of evidence of invasive cancer or proven axillary metastatic disease...
A sentinel lymph node biopsy may be considered if the lumpectomy is in an anatomic location compromising the performance of a future sentinel lymph node procedure (4)[C].

Radiation decreases recurrence rates by about 50% (2)[A].

~50% of recurrences are pure DCIS; ~50% are IBC (1,4)[A].

Drawbacks to radiation therapy include (i) the patient’s burden of daily treatment for 6 weeks and short-term side effects, such as fatigue and skin toxicity; (ii) a slightly increased risk of secondary cancers; and (iii) inability to receive radiation therapy again in the ipsilateral breast should an invasive carcinoma develop.

Recurrence generally requires mastectomy with consideration for systemic treatment (2)[C].

Patients not amenable to margin-free lumpectomy should have total mastectomy (4)[C].

Mastectomy with or without sentinel node biopsy plus optional breast reconstruction (4)[A]

Mastectomy provides maximum local control.

Rates of recurrence for DCIS and IBC are similar to lumpectomy.

Recurrence should be treated with wide local excision, chest wall radiation, and consideration for systemic treatment (4)[A].

Long-term cause-specific survival seems to be equivalent to lumpectomy with whole breast radiation (4)[A].

A sentinel lymph node biopsy may also be considered in patients with seemingly pure DCIS to be treated with mastectomy (4)[C].

Secondary chemoprevention following breast-conserving surgery for ER + DCIS:

Tamoxifen for premenopausal patients or tamoxifen or an aromatase inhibitor for postmenopausal patients for 5 years (3)[A]

There may be some advantage for aromatase inhibitor therapy in patients <60 years old or patients with concerns for thromboembolism (4)[C].

Considered in lumpectomy patients with or without whole breast radiation (4)[A]

Benefit of tamoxifen and trastuzumab in ER-negative/HER2-positive disease is unclear (1)[C].
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- History and physical exam every 6 to 12 months for the first 5 years and then annually
- Mammography every 12 months (first mammogram 6 to 12 months after breast conservation therapy) (4)[C]
- If treated with tamoxifen or an aromatase inhibitor, monitor per NCCN guidelines for breast cancer risk reduction (4)[C].

PROGNOSIS

- Good prognosis: 10-year breast cancer–specific survival rates of >95%; overall mortality after diagnosis of treated pure DCIS generally >98%
- Risk of local recurrence after mastectomy generally reported as 1–2% (higher in some studies)
- Higher risk of local recurrences after breast-conserving therapy in younger age (particularly before age 40 years), larger tumor size, high nuclear grade, comedo-type necrosis, and close/positive margin status (related to DCIS volume)
- ER+ tumors are associated with lower risk for recurrence.
- The Oncotype Dx DCIS score, a multigene assay including seven DCIS-related genes, offers hope for quantifying the risk of local recurrence of DCIS or the development of IBC in patients treated with breast-conserving therapy alone.

**ADDITIONAL READING**

**SEE ALSO**

Breast Cancer

**CODES**

**ICD10**

- D05.10 Intraductal carcinoma in situ of unspecified breast
- D05.11 Intraductal carcinoma in situ of right breast
- D05.12 Intraductal carcinoma in situ of left breast

**CLINICAL PEARLS**

- DCIS is a heterogeneous group of noninvasive neoplastic lesions from breast ductal epithelial cells.
- The incidence of DCIS has increased in women <50 and >70 years.
- The goal of DCIS treatment is to prevent recurrence and progression to IBC.
- Current standard of care: breast-conserving therapy with consideration for postoperative whole-breast radiation therapy and/or postsurgical tamoxifen or aromatase inhibitor therapy
- With appropriate therapy, the overall prognosis of pure DCIS is good.
BASICS
DESCRIPTION
- Palmar fibromatosis; caused by progressive fibrous proliferation and tightening of the fascia of the palms, resulting in flexion deformities and loss of function
- Not the same as “trigger finger,” which is caused by thickening of the distal flexor tendon
- Similar change rarely occurs in plantar fascia, usually appearing simultaneously.
- System(s) affected: musculoskeletal
- Dupuytren diathesis is an aggressive form that has ectopic involvement of knuckle pads, plantar fibromatosis (Ledderhose – 10%), and penile fibromatosis (Peyronie – 2%).
- Synonyms: morbus Dupuytren; Dupuytren disease; “Celtic hand;” Viking’s disease; palmar fascial fibromatosis, contracture of palmar fascia

EPIDEMIOLOGY
Prevalence
- Increases with age; mean prevalence in western countries: 12%, 21%, and 29% at ages 55, 65, and 75 years, respectively. Norway: 30% of males >60 years; Spain: 19% of males >60 years
- More common in Caucasians of Scandinavian or Northern European ancestry
- Mean age of onset is 60 years.

ETIOLOGY AND PATHOPHYSIOLOGY
Unknown; possibly oxidative stress, altered wound repair, and/or abnormal immune response. Occurs in three stages:
- Proliferative phase: proliferation of myofibroblasts with nodule development on palmar surface
- Involutional stage: spread along palmar fascia to fingers with cord
development
- Residual phase: spread into fingers with cord tightening and contracture formation

**Genetics**
- Autosomal dominant with incomplete penetrance:
  - Siblings with 3-fold risk
- 68% of male relatives of affected patients develop disease at some time.
- Possible association with HLA alleles

**RISK FACTORS**
- Smoking (mean 16 pack-years, odds ratio: 2.8)
- Increasing age
- Male/Caucasian; male > female (range 3.5:1 to 9:1)
- Vibration exposure and manual work—risk doubles if regular (weekly) exposure
- Diabetes mellitus (increases with duration of DM, usually mild; middle and ring finger involved)
- Epilepsy
- Chronic illness (e.g., pulmonary tuberculosis, liver disease, HIV)
- Hypercholesterolemia
- Excessive alcohol consumption
- Northern European ethnicity
- Family history
- Hand trauma
- Low body weight and BMI

**GENERAL PREVENTION**
Avoid risk factors, especially if a strong family history.

**COMMONLY ASSOCIATED CONDITIONS**
- Alcoholism
- Epilepsy (inconstant data)
- DM
- Chronic lung disease
- Occupational hand trauma (vibration)
- Hypercholesterolemia
- Carpal tunnel syndrome
• Peyronie disease
• HIV
• Cancer
• Adhesive capsulitis of shoulder

![ DIAGNOSIS ]

HISTORY
• Caucasian male aged 50 to 60 years
• Family history
• Mild pain early:
  – Begins in palm and spreads to digits
• Unilateral or bilateral (50%)
• Right hand more frequent
• Ring finger or little finger most common, but any digit can be involved
• Ulnar digits more affected than radial digits
• Flexion contracture of metacarpophalangeal (MCP) before proximal interphalangeal (PIP) joint

PHYSICAL EXAM
• Painless plaques or nodules in palmar fascia
• Cordlike band in the palmar fascia
• Skin adheres to fascia and becomes puckered.
• Palpable subcutaneous nodules
• Reduced flexibility of MCP and PIP joints
• No sign of inflammation
• Web space contractures
• Knuckle pads over PIP
  – Garrod nodes associated with severe disease
• Disease stages:
  – Early: skin pits (can also be seen in nevoid basal cell cancer and palmar keratosis)
  – Intermediate: nodules and cords. Nerves and vessels can be entwined in cords.
  – Late: contractures

DIFFERENTIAL DIAGNOSIS
Camptodactyly: early teens; tight fascial bands on ulnar side of small finger
Diabetic cheiroarthropathy: all four fingers
Volkmann ischemic contracture
Trigger finger
Ganglion cyst

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other
Diagnosis based on history and physical, testing is not routinely indicated. MRI can assess cellularity of lesions that correlate with recurrence after surgery.

Test Interpretation
- Myofibroblasts predominate.
- Nodules: Lumps fixed to skin hypercellular masses
- Cords: organized collagen type III arranged parallel and hypocellular
- First stage (proliferative): increased myofibroblasts
- Second stage (residual): dense fibroblast network
- Third stage (involutional): Myofibroblasts disappear.

TREATMENT

GENERAL MEASURES
- Physical therapy alone is ineffective:
  - Intermittent splinting is unlikely to be effective.
  - Continuous splinting may help pre- and postop.
- Follow isolated involvement of palmar fascia conservatively.
- MCP joint involvement can be followed conservatively if flexion contracture is <30 degrees.

MEDICATION

First Line
- Clostridial collagenase injections (FDA-approved 2010):
  - Degrades collagen to allow manual rupture of diseased cord
  - Best for isolated cord of MCP joint
  - 5-year recurrence rate of 47%; comparable with surgical recurrence rates (1)[B]
– More rapid recovery of hand function compared to limited fasciectomy with fewer serious adverse events (2)[B]

– Complications: injection site reaction, skin tear
– Can do two cords concurrently
– Can be effective for postsurgical recurrence

• Steroid injection:
  – Can treat acute nodules or painful knuckle pads
  – Serial triamcinolone injections improved long-term outcomes when combined with needle aponeurotomy (3)[B].
  – Steroid alone associated with 50% recurrence in 1 to 3 years

Second Line
Surgery for contracture >30%

ISSUES FOR REFERRAL
• Any involvement of PIP joints
• MCP joints contracted >30 degrees
• Impaired function
• Progressively worsening contracture
• Disabling deformity

ADDITIONAL THERAPIES
• Percutaneous and needle fasciotomy:
  – Best for MCP joint; improvement of 93% versus 57% for PIP joint
  – Recurrence common; 50%
  – Shown to be effective for recurrent disease
  – Better for MCP joints in patients with comorbid conditions; lower complication rate, but higher recurrence
  – At 3 months and 1 year, outcomes of needle fasciotomy and collagenase injections are the same (4)[B].

SURGERY/OTHER PROCEDURES
• Dermofasciectomy/limited fasciectomy/segmental aponeurectomy:
  – Greater initial correction over nonincisional treatment; higher complication rates
  – Percutaneous aponeurotomy and lipofilling (PALF) is a new, minimally invasive procedure that appears to have shorter convalescence, less long-term complications, similar operative contraction correction, and no
• Significant difference at 1 year in results versus limited fasciectomy (5)[A].

• Indications:
  – Any involvement of the PIP joints
  – MCP joints contracted at least 30 degrees
  – Positive Hueston tabletop test (Patient is unable to lay palm flat on a table.)
• May require skin grafts for wound closure with severe cutaneous shrinkage
• 80% have full range of movement with early surgery.
• Amputation of 5th digit if severe and deforming
• MCP joints respond better to surgery than PIP joints, especially if contracted >45 degrees.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Regular follow-up every 6 months to 1 year

PATIENT EDUCATION
• Avoid risk factors (alcohol, vibratory exposure, etc.), especially if strong family history.
• Mild disease: Passively stretch digits twice a day and avoid recurrent gripping of tools.

PROGNOSIS
• Unpredictable but usually slowly progressive
• 10% may regress spontaneously.
• Dupuytren diathesis predicts aggressive course. Features include ethnicity (Nordic), family history, bilateral lesions outside of palm, age <50 years—all factors with 71% risk of recurrence compared to baseline 23% without any risk factors.
• Prognosis better for MCP versus PIP joint after surgery and collagenase injection

COMPLICATIONS
• Complex regional pain syndrome
• Operative nerve injury
• Postoperative recurrence in 46–80%
• Postoperative hand edema and skin necrosis
• Digital infarction
• Limited hand function

REFERENCES

ADDITIONAL READING

• Henry M. Dupuytren’s disease: current state of the art. *Hand (N Y).*

### CODES

**ICD10**

M72.0 Palmar fascial fibromatosis [Dupuytren]

### CLINICAL PEARLS

- Dupuytren contracture is a fixed flexion deformity of (most commonly) the 4th and 5th digits due to palmar fibrosis. 90% of cases are progressive; not trigger finger, which is due to thickening of the distal flexor tendon.
- Refer patients with involvement of the PIP joints or MCP involvement with contractures of >30 degrees.
- Both surgical and enzymatic fasciotomy have high rate of recurrence.
DYSHIDROSIS

Patricia Y. Chipi, MD • George G.A. Pujalte, MD, FACSM

BASICS

DESCRIPTION

- A common chronic dermatitis often involving the palms and soles. The precise definition is frequently debated, with many terms being used interchangeably. Efforts are being made to more specifically define dyshidrosis, and literature supports the presence of several different classes within the family dyshidrosis but no general consensus.
- Dyshidrotic eczema
  - Common, chronic, or recurrent; nonerythematous; symmetric vesicular eruption primarily of the palms, soles, and interdigital areas
  - Associated with burning, itching, and pain
- Pompholyx (from Greek “bubble”)
  - Rare condition characterized by abrupt onset of large bullae
  - Often used interchangeably with dyshidrotic eczema (small vesicles); however, may be a distinct entity
- Lamellar dyshidrosis
  - Fine, spreading exfoliation of the superficial epidermis in the same distribution as described above
- System(s) affected: dermatologic, exocrine, immunologic
- Synonym(s): cheiropompholyx, keratolysis exfoliativa, vesicular palmoplantar eczema, desquamation of interdigital spaces pompholyx, acute and recurrent vesicular hand dermatitis

EPIDEMIOLOGY

Incidence

- Mean age of onset is 40 years and younger.
- Male = female
- Comprises 5–20% of hand eczema cases

Prevalence
20 cases/100,000 populations

ETIOLOGY AND PATHOPHYSIOLOGY

- Exact mechanism unknown; thought to be multifactorial
- Dermatopathology: intraepidermal spongiosis without effect on eccrine sweat glands
- Vesicles remain intact due to thickness of stratum corneum of palmar/plantar skin (1).
- Exact cause not known; although the following have been implicated: allergies, genetics, and dermatophyte infection
- Aggravating factors (debated)
  - Hyperhidrosis (in 40% of patients with the condition)
  - Detergents/solvents
  - Increased water exposure
  - Climate: hot/cold weather; humidity
  - Contact sensitivity (in 30–67% of patients with the condition) (2)
  - Nickel, cobalt, and chromate sensitivity (may include implanted orthopedic or orthodontic metals) (1)
  - Stress
  - Dermatophyte infection (present in 10% of patients with the condition) (2)
  - Prolonged wear of occlusive gloves
  - IV immunoglobulin therapy
  - Smoking
  - UVA radiation

Genetics

- Atopy: 50% of patients with dyshidrotic eczema have atopic dermatitis (1).
- Rare autosomal dominant form of pompholyx found in Chinese population maps to chromosome 18q22.1–18q22.3 (2)

RISK FACTORS

- Many risk factors are disputed in the literature, with none being consistently associated.
- Atopy
- Other dermatologic conditions
  - Atopic dermatitis (early in life)
  - Contact dermatitis (later in life)
  - Dermatophytosis
• Sensitivity to
  – Foods
  – Drugs: neomycin, quinolones, acetaminophen, and oral contraceptives
  – Contact and dietary: nickel (more common in young women), chromate (more common in men), and cobalt (1)
  – Smoking

GENERAL PREVENTION
• Control emotional stress.
• Avoid excessive sweating.
• Avoid exposure to irritants.
• Avoid diet high in metal salts (chromium, cobalt, nickel).
• Avoid smoking.

COMMONLY ASSOCIATED CONDITIONS
• Atopic dermatitis
• Allergic contact dermatitis
• Parkinson disease
• HIV (2)

DIAGNOSIS

HISTORY
• Episodes of pruritic rash
• Recent emotional stress
• Familial or personal history of atopy
• Exposure to allergens or irritants (3)
  – Occupational, dietary, or household
  – Cosmetic and personal hygiene products
  – Vesicular eruption typically occurs 24 hours after allergen challenge (1).
• Costume jewelry use
• IV immunoglobulin therapy
• HIV
• Smoking

PHYSICAL EXAM
• Transient, often recurrent, symmetrical vesicular eruptions located on volar
and plantar surfaces and lateral fingers. Lesions may not heal completely between flares (1).

- **Prodrome:** Intense pruritus may occur prior to vesicular eruption.
- **Early findings**
  - 1 to 2 mm, clear, nonerythematous, deep-seated vesicles (lasting 2 to 3 weeks)
  - Has a “tapioca” appearance
- **Late findings**
  - Unroofed vesicles with inflamed bases
  - Desquamation (terminal phase)
  - Peeling, rings of scale, or lichenification common

**DIFFERENTIAL DIAGNOSIS**

- Vesicular tinea pedis/manuum
- Vesicular id reaction
- Contact dermatitis (allergic or irritant)
- Scabies
- Chronic vesicular hand dermatitis
- Drug reaction
- Dermatophytid
- Bullous disorders: dyshidrosiform bullous pemphigoid, pemphigus, bullous impetigo, epidermolysis bullosa
- Pustular psoriasis
- Acrodermatitis continua
- Erythema multiforme
- Herpes simplex infection
- Pityriasis rubra pilaris
- Vesicular mycosis fungoides

**DIAGNOSTIC TESTS & INTERPRETATION**

**Follow-Up Tests & Special Considerations**

- Skin culture in suspected secondary infection (most commonly, *Staphylococcus aureus*) (4)
- Consider antibiotics based on culture results and severity of symptoms.

**Diagnostic Procedures/Other**

- Diagnosis is based on clinical exam.
- Potassium hydroxide (KOH) wet mount (if concerned about dermatophyte
infection)
- Patch test (if suspecting allergic cause) (4)

**Test Interpretation**
- Fine, 1- to 2-mm spongiotic, intraepidermal vesicles with little to no inflammatory change
- No eccrine glandular involvement
- Thickened stratum corneum

**TREATMENT**

**GENERAL MEASURES**
- Avoid possible causative factors: stress, direct skin contact with irritants, nickel, occlusive gloves, household cleaning products, smoking, sweating.
- Use moisturizers/emollients for symptomatic relief and to maintain effective skin barrier (4).
- Skin care
  - Wear shoes with leather rather than rubber soles (e.g., sneakers).
  - Wear socks and gloves made of cotton and change frequently.
  - Wash infrequently, carefully dry, and then apply emollient.
  - Avoid direct contact with fresh fruit (5)[C].

**MEDICATION**

**First line**
- Mild cases: topical steroids (high potency) (2)[B]
  - Considered cornerstone of therapy but limited published evidence
  - Limited use for 2 weeks due to risk of infection (4)[B]
- Moderate to severe cases
  - Ultrahigh-potency topical steroids with occlusion over treated area (4)[B]
  - Prednisone 40 to 100 mg/day tapered after blister formation ceases (2)[B]
    - Limited use due to significant side effects (4)[B]
  - Psoralens plus ultraviolet (UV)-A (PUVA) therapy, either systemic/topical or immersion in psoralens (2)[B]
- Recurrent cases (4)[B]
  - Systemic steroids at onset of itching prodrome
  - Prednisone 60 mg PO for 3 to 4 days
**Second Line**

- Topical calcineurin inhibitors (mitigate the long-term risks of topical steroid use)
  - Topical tacrolimus (6)[B]
  - Topical pimecrolimus (6)[B]
  - May not be as effective on plantar surface
- Other therapies (typically with dermatology consultation)
  - Oral cyclosporine (4)[B]; monitor for hypertension and renal injury.
  - Injections of botulinum toxin type A (BTXA) (6)[B]
    - Newer topical forms of BTXA currently being developed show promise.
    - Painful, requires nerve block
  - Systemic alitretinoin (teratogenic) (5)[B]
  - Topical bexarotene (a teratogenic retinoid X receptor agonist approved for use in cutaneous T-cell lymphoma) (6)[B]
  - Methotrexate (6)[C] (significant side effects including GI intolerance and hepatotoxicity) (4)[B]
  - Azathioprine (1)[C] (6 to 8 week onset of action; must monitor for GI side effects, liver toxicity, blood dyscrasia)
  - Disulfiram or sodium cromoglycate in nickel-allergic patients (1)[C]
- Mycophenolate mofetil (2)[C] (GI side effects; benefit: no hepatotoxicity with long-term use) (4)[B]
- Tap water iontophoresis (2)[C]

**ISSUES FOR REFERRAL**

- Allergist (if allergen testing required)
- Psychologist (if stress modification needed)

**ADDITIONAL THERAPIES**

- Other oral agents:
  - Thalidomide (do not use in pregnancy/no available studies on efficacy)
  - Dapsone 100 to 150 mg daily (also limited literature on efficacy; may be used in combination with steroids) both significant side effects; very limited use (4)[B]
- Radiation therapy (1)[C]
- UV-free phototherapy (5)[C]
- Treat underlying dermatophytosis (1).
- BTXA in those in which excessive sweating is an exacerbating factor (4)[B]
COMPLEMENTARY & ALTERNATIVE MEDICINE

- Conservative management:
  - Antihistamines: hydroxyzine, cetirizine, loratadine
  - Soaks/cold compresses of weak solutions of potassium permanganate, Burow solution (aluminum acetate), or vinegar 15 minutes, 4 times daily (4)[C]
- Exposure to sunlight as maintenance therapy, 12 minutes every other day, 10 to 15 exposures (5)[C]
- Dandelion juice (avoid in atopic patients) (6)[C]
- Cognitive relaxation techniques (4)[B]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Dyshidrotic Eczema Area and Severity Index (DASI) (1)
- Parameters used in the DASI score
  - Number of vesicles per square centimeter
  - Erythema
  - Desquamation
  - Severity of itching
  - Surface area affected
- Grading: mild (0 to 15), moderate (16 to 30), severe (31 to 60)
- Monitor BP and glucose in patients receiving systemic corticosteroids.
- Monitor for adverse effects of medications.

DIET

- Consider diet low in metal salts if there is history of nickel sensitivity (4)[B].
- Updated recommendations for low-cobalt diet are available (1).

PATIENT EDUCATION

- Instructions on self-care, complications, and avoidance of triggers/aggravating factors
PROGNOSIS

- Condition is benign.
- Usually heals without scarring
- Lesions may spontaneously resolve.
- Recurrence is common.

COMPLICATIONS

- Quality of life impact: skin tightening, pain, and decreased dexterity
- Secondary bacterial infections (S. aureus most common)
- Dystrophic nail changes
- Fissures and ulcerations
- Psychological distress
- Lymphedema

SEE ALSO
Algorithm: Rash

CODES

ICD10
L30.1 Dyshidrosis [pompholyx]

CLINICAL PEARLS

- Dyshidrosis is a transient, recurrent, vesicular eruption, most commonly of the palms, soles, and interdigital areas.
- Etiology and pathophysiology are unknown but are most likely related to a combination of genetic and environmental factors.
- Best prevention is effective skin care and limiting exposure to irritating agents.
- Treatments are based on disease severity; preferred treatments include topical
steroids, oral steroids, and calcineurin inhibitors.

- Condition, although benign and self-healing, can be chronic and debilitating with major concern for superimposed bacterial infection that may be avoided by preventative measures, early treatment, and recognition.
DYSMENORRHEA
Taiwona Elliott, DO

BASICS

DESCRIPTION

- Pelvic pain occurring at/around time of menses; a leading cause of absenteeism for women <30 years old
- Primary dysmenorrhea: pelvic pain without pathologic physical findings
- Secondary dysmenorrhea: often more severe, results from specific pelvic pathology; severity based on activity impairment
  - Mild: painful, rarely limits daily function, or requires analgesics
  - Moderate: daily activity affected, rare absenteeism, requires analgesics
  - Severe: daily activity affected, likelihood absenteeism, limited benefit from analgesics
- System affected: reproductive
- Synonym(s): menstrual cramps

EPIDEMIOLOGY

- Predominant age
  - Primary: onset 6 to 12 months after the start of menarche, teens to early 20s
  - Secondary: 20s to 30s
- Predominant sex: women only

Prevalence

- Up to 90% of menstruating females have experienced primary dysmenorrhea.
- Up to 42% lose days of school/work monthly due to dysmenorrhea.
- Up to 20% reported impairment in daily activities.

ETIOLOGY AND PATHOPHYSIOLOGY

- Primary: Elevated prostaglandin (PGF2α) production through indirect hormonal control (stimulation of production by estrogen) causes nonrhythmic hypercontractility and increased uterine muscle tone with vasoconstriction and resultant uterine ischemia. Ischemia results in hypersensitization of type C pain nerve fibers; intensity of cramps directly proportional to amount of PGF2α released
Secondary
- Endometriosis (most common cause)
- Congenital abnormalities of uterine/vaginal anatomy
- Cervical stenosis
- Pelvic inflammatory disease
- Adenomyosis
- Ovarian cysts
- Pelvic tumors, especially leiomyomata (fibroids) and uterine polyps

Genetics
Not well studied

RISK FACTORS
- Primary (1)
  - Cigarette smoking
  - Alcohol use
  - Early menarche (age <12 years)
  - Age <30 years
  - Irregular/heavy menstrual flow
  - Nonuse of oral contraceptives
  - Sexual abuse
  - Psychological symptoms (depression, anxiety, increased stress, etc.)
  - Nulliparity
- Secondary
  - Pelvic infection
  - Use of intrauterine device (IUD)
  - Structural pelvic malformations
  - Family history of endometriosis in first-degree relative

GENERAL PREVENTION
- Primary: Choose a diet low in animal fats.
- Secondary: Reduce risk of sexually transmitted infections (STIs).

Pediatric Considerations
Onset with first menses raises probability of genital tract anatomic abnormality (i.e., transverse vaginal septum, imperforate or minimally perforated hymen, uterine anomalies).
COMMONLY ASSOCIATED CONDITIONS
- Irregular/heavy menstrual periods
- Longer menstrual cycle length/duration of bleeding
- Endometriosis

DIAGNOSIS
Based on characteristic history of suprapubic/low back cramping/pain occurring at or near menstrual flow onset lasting for 8 to 72 hours (2)

HISTORY
- Primary: Onset once ovulatory cycles are established in adolescents; 6 to 12 months after menarche on average
- Patients may have associated nausea, vomiting, diarrhea, headache, fatigue, or pain radiating into the inner thighs.
- Recurrence at or just before the onset of the menstrual flow
  - Pelvic pain occurring between menstrual periods is not likely to be dysmenorrhea.
  - Present with most menstrual periods (cyclic)
- Relief associated with the following:
  - Continued bleeding for the usual duration
  - Use of analgesics, especially NSAIDs
  - Orgasm
  - Local heat application
- Response to NSAIDs helps confirm diagnosis.
- Secondary: associated with chronic pelvic pain, midcycle pain, dyspareunia, and abnormal uterine bleeding

PHYSICAL EXAM
- Primary: Physical exam typically is normal. Examine to rule out secondary dysmenorrhea. Pelvic exam is recommended if sexually active to rule out infection.
- Secondary: Evaluate for cervical discharge, uterine enlargement, tenderness, irregularity, or fixation.

DIFFERENTIAL DIAGNOSIS
- Primary: History is characteristic.
Secondary
- Pelvic/genital infection
- Complication of pregnancy
- Missed/incomplete abortion
- Ectopic pregnancy
- Uterine/ovarian neoplasm
- Endometriosis
- UTI
- Complication with IUD use

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Pregnancy test
- Urine testing for infection
- Gonorrhea/chlamydia cervical testing, especially in women age <25 years and in high-prevalence areas
- Primary: Consider pelvic ultrasound to rule out secondary abnormalities if history is not characteristic or suspected abnormality on exam.
- Secondary: Ultrasound/laparoscopy to define anatomy for severe/refractory cases. MRI may be useful as second-line noninvasive imaging if ultrasound is nondiagnostic and torsion, deep endometriosis, or adenomyosis suspected.

Follow-Up Tests & Special Considerations
Counsel regarding appropriate preventive measures for STI and pregnancy.

Diagnostic Procedures/Other
Laparoscopy is rarely needed.

Test Interpretation
- Primary: none
- Secondary: Specific anatomic abnormalities may be noted (see “Differential Diagnosis”).

Pregnancy Considerations
Consider ectopic pregnancy when pelvic pain occurs with vaginal bleeding.
TREATMENT

- Reassure the patient that treatment success is very likely with adherence to recommendations.
- Relief may require the use of several treatment modalities at the same time.

GENERAL MEASURES

- Exercise and local heat are noninvasive general measures to relieve pain.
- High-frequency transcutaneous electrical nerve stimulation (TENS) has been found to be beneficial. There is conflicting evidence for low-frequency TENS.
- Secondary dysmenorrhea: treatment of infections; suppression of endometrium if endometriosis suspected; remove IUD if contributing factor.

MEDICATION

First Line

- NSAIDs: No NSAID has been found to be superior to others. Medication should be taken on scheduled dosing 1 to 2 days prior to onset of menses and continued for 2 to 3 days (2,3)[A]. If one NSAID preparation does not work, another NSAID preparation should be tried.
  - Ibuprofen 400 mg q8h
  - Naproxen sodium 500 mg BID
  - Celecoxib 400 mg × 1 and then 200 mg q12h
  - Mefenamic acid 500 mg × 1 and then 250 mg q6h
- Hormonal contraceptives: recommended for primary dysmenorrhea in women desiring contraception (2)[B]. Directly limits endometrial growth resulting in reduced prostaglandin production and intrauterine pressure. Continuous rather than cyclic dosing may initially be more effective at reducing pain, however, may have similar benefit after 6 months (4)[B]. Estrogen-containing contraceptives are recommended first-line for secondary dysmenorrhea due to endometriosis, although progestin-only methods have also been shown to be beneficial (2)[B].
- Levonorgestrel IUDs can decrease primary dysmenorrhea (5)[B].
- Potential contraindications to NSAIDs and combined oral contraceptives (COCs)
  - Platelet disorders
  - Gastric ulceration or gastritis
  - Thromboembolic disorders
- Vascular disease
- Migraine with aura

- Precautions
  - GI irritation
  - Lactation
  - Coagulation disorders
  - Impaired renal function
  - Heart failure
  - Liver dysfunction

- Significant possible interactions
  - Coumadin-type anticoagulants
  - Aspirin with other NSAIDs

**Second Line**

- Local heat can help relieve pain and may be as effective as NSAIDs (2)[B].
- Exercise may have beneficial effects in relieving pain (6)[B].
- $\beta_2$-Adrenoceptor agonists have not definitively been shown to relieve pain in dysmenorrhea (7)[B].
- Behavioral interventions, such as relaxation exercises, may help alleviate pain in primary dysmenorrhea.

**SURGERY/OTHER PROCEDURES**

Laparoscopic uterosacral nerve ablation has been shown to relieve pain at >12 months postoperatively.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Spinal manipulation has not been shown to be effective in treating pain.
- Chinese herbal medicine shows promising evidence of decreasing pain, but more evidence is needed.
- Acupuncture treatments have been shown to decrease pain in dysmenorrhea, but further randomized, well-designed studies are needed.
- Acupoint stimulation, particularly noninvasive stimulation (acupressure), can relieve pain.
- Aromatherapy abdominal massage performed daily for 10 minutes, 7 days prior to onset of menses can decrease primary dysmenorrhea.
- Further research needed to determine benefit and safety for use of oral fennel, extracorporeal magnetic innervation, vitamin K$_1$ injection into the spleen-6
acupuncture point, use of high-frequency vibratory stimulation tampon, and vaginal sildenafil

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Both primary and secondary dysmenorrhea are usually managed in the outpatient setting.

- Primary: outpatient care
- Secondary: usually outpatient care

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Normal

DIET

- Vitamin B₁ 100 mg daily, ω-3 fatty acid, and fish oil supplementation may be beneficial.
- Magnesium has been shown to be useful, but the correct dosage has not been determined.
- Insufficient evidence to show usefulness of zinc and vitamin E at this time
- Low-fat vegetarian diet can be helpful in some patients.

PATIENT EDUCATION

Reassure the patient that primary dysmenorrhea is treatable with the use of NSAIDs, COCs, IUD, or local heat, and that it will usually abate with age and parity.

PROGNOSIS

- Primary: reduced with age and parity
- Secondary: likely to require therapy based on underlying cause

COMPLICATIONS

- Primary: anxiety and/or depression
- Secondary: infertility from underlying pathology
REFERENCES

ADDITIONAL READING

**SEE ALSO**

- Dyspareunia;
- Endometriosis;
- Menorrhagia (Heavy Menstrual Bleeding);
- Premenstrual Syndrome (PMS) and Premenstrual Dysphoric Disorder (PMDD)
Algorithm: Pelvic Pain

CODES

ICD10
- N94.6 Dysmenorrhea, unspecified
- N94.4 Primary dysmenorrhea
- N94.5 Secondary dysmenorrhea

CLINICAL PEARLS
- Dysmenorrhea is a leading cause of absenteeism for women age <30 years.
- In women who desire contraception, hormonal contraceptives are the preferred treatment.
- All NSAIDs studied have been found to be equally effective in the relief of dysmenorrhea and should be initiated 1 to 2 days prior to onset of menses with scheduled dosing.
DYSPAREUNIA
Scott T. Henderson, MD

BASICS
DESCRIPTION
- Recurrent and persistent genital pain is associated with sexual activity, which is not exclusively due to lack of lubrication or vaginismus, and is associated with distress or interpersonal difficulty.
- May be the result of organic, emotional, or psychogenic causes
  - Primary: present throughout one’s sexual history
  - Secondary: arising from some specific event or condition (e.g., menopause, drugs)
  - Superficial: pain at, or near, the introitus or vaginal barrel associated with penetration
  - Deep: pain after penetration located at the cervix or lower abdominal area
  - Complete: present under all circumstances
  - Situational: occurring selectively with specific situations
- System(s) affected: reproductive

EPIDEMIOLOGY
- Predominant age: all ages
- Predominant sex: female > male

Incidence
>50% of all sexually active women will report dyspareunia at some time.

Geriatric Considerations
Incidence increases dramatically in postmenopausal women primarily because of vaginal atrophy.

Prevalence
Most sexually active women will experience dyspareunia at some time in their lives.
- ~15% (4–40%) of adult women will have dyspareunia on a few occasions during a year.
~1–2% of women will have painful intercourse on a more-than偶尔 basis.
Male prevalence is ~1%.

ETIOLOGY AND PATHOPHYSIOLOGY

- Disorders of vaginal outlet
  - Adhesions
  - Condyloma
  - Clitoral irritation
  - Episiotomy scars
  - Fissures
  - Hymenal ring abnormalities
  - Inadequate lubrication
  - Infections
  - Lichen planus
  - Lichen sclerosus
  - Postmenopausal atrophy
  - Psoriasis
  - Trauma
  - Vulvar papillomatosis
  - Vulvar vestibulitis/vulvodynia

- Disorders of vagina
  - Abnormality of vault owing to surgery or radiation
  - Congenital malformations
  - Inadequate lubrication
  - Infections
  - Inflammatory or allergic response to foreign substance
  - Masses or tumors
  - Pelvic relaxation resulting in rectocele, uterine prolapse, or cystocele

- Disorders of pelvic structures
  - Endometriosis
  - Levator ani myalgia/spasm
  - Malignant or benign tumors of the uterus
  - Ovarian pathology
  - Pelvic adhesions
  - Pelvic inflammatory disease (PID)
  - Pelvic venous congestion
  - Prior pelvic fracture
  - Uterine fibroids
Disorders of the GI tract
- Constipation
- Crohn disease
- Diverticular disease
- Fistulas
- Hemorrhoids
- Inflammatory bowel disease

Disorders of the urinary tract
- Interstitial cystitis
- Ureteral or vesical lesions
- Urethritis

Chronic disease
- Behçet syndrome
- Diabetes
- Sjögren syndrome

Male
- Cancer of penis
- Genital muscle spasm
- Infection or irritation of penile skin
- Infection of seminal vesicles
- Lichen sclerosus
- Musculoskeletal disorders of pelvis and lower back
- Penile anatomy disorders
- Phimosis
- Prostate infections and enlargement
- Testicular disease
- Torsion of spermatic cord
- Urethritis

Psychological disorders
- Anxiety
- Conversion reactions
- Depression
- Fear
- Hostility toward partner
- Phobic reactions
- Psychological trauma

RISK FACTORS
- Fatigue
Stress
Depression
Diabetes
Estrogen deficiency
  – Menopause
  – Lactation
Previous PID
Vaginal surgery
Alcohol/marijuana consumption
Medication side effects (antihistamines, tamoxifen, bromocriptine, low-estrogen oral contraceptives, SSRIs, depo-medroxyprogesterone, desipramine)

**Pregnancy Considerations**

- Pregnancy is a potent influence on sexuality; dyspareunia is common in late pregnancy and postpartum.
  - Breastfeeding, perineal pain, fatigue, and stress can be risk factors in postpartum period.
- Episiotomies do not have a protective effect.
  - Women who experience delivery interventions including episiotomy are at greater risk than women who deliver over an intact perineum or have an unsutured tear.

**COMMONLY ASSOCIATED CONDITIONS**
Vaginismus

**DIAGNOSIS**

**HISTORY**

- Identify pain characteristics:
  - Onset
  - Duration
  - Location: entry versus deep, single versus multiple sites; positional
  - Intensity/quality: varying degrees of pelvic/genital pressure, aching, tearing, and/or burning
  - Pattern (precipitating or aggravating factors): when pain occurs (at entry, during, or after intercourse)
  - Relief measures: Avoid intercourse, change positions, and have intercourse
only at certain times of the month.

- Include menstrual, obstetric, reproductive, sexual, domestic violence, and rape histories with medical, surgical, and psychosocial history.

**PHYSICAL EXAM**

- A complete exam, including a focused pelvic exam, to identify pathology
  - Exam must include inspection and palpation of urethra, vulva, and vaginal areas; palpation of the uterine, bladder, and adnexal structures; and a rectovaginal exam.
  - Sensory mapping with a cotton-tipped applicator to identify sensitive and painful areas
- Because examination often reproduces the pain, examiner should be cautious and sensitive to patient’s anxiety.

**DIFFERENTIAL DIAGNOSIS**

Vaginismus (genito-pelvic pain penetration disorder)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

Based on history and exam findings

- Wet mount
- Gonorrhea and chlamydia cultures
- Herpes culture
- Urinalysis and urine culture
- Pap smear

**Follow-Up Tests & Special Considerations**

- Serum estradiol if vuvodynia or atrophic vaginitis
- Voiding cystourethrogram if urinary tract involvement
- GI contrast studies if GI symptoms
- Ultrasound and CT scan are of limited value; perform if clinically indicated.

**Diagnostic Procedures/Other**

Based on history and exam findings

- Colposcopy and biopsy if vaginal/vulvar lesions
- Laparoscopy if complex deep-penetration pain
- Cystoscopy if urinary tract involvement
- Endoscopy if GI involvement
**Test Interpretation**

Depends on etiology

---

**TREATMENT**

- Potential relationships exists between primary dyspareunia and vaginismus, low libido, and arousal disorders.
- Endocrine factors, such as primary amenorrhea, might reduce the biologic basis of sexual response.
- If pain prevents penetration, severe vaginismus may be present.

**GENERAL MEASURES**

- Educate the patient and partner regarding the nature of the problem. Reassure both that there are solutions to the problem.
- Initiate specific treatment when initial evaluation identifies an organic cause.
- Once organic causes are ruled out, treatment is a multidimensional and multidisciplinary approach (1)[C].
  - Individual behavioral therapy
    - Indicated to help the patient deal with intrapersonal issues and assess the role of the partner
  - Couple behavioral therapy
    - Indicated to help resolve interpersonal problems
    - May involve short-term structured intervention or sexual counseling
    - Designed to desensitize systemically uncomfortable sexual responses and intercourse through a series of interventions over a period of weeks
    - Interventions range from muscle relaxation and mutual body massage to sexual fantasies and erotic massage.

**MEDICATION**

**First Line**

Depends on the etiology

- Antibiotics, antifungals, or antivirals, as indicated, for infection
- Vaginal moisturizers and lubricants for dryness
- Analgesics and topical anesthetics for pain
- Topical estrogen for vaginal and vulvar atrophy
- Neuropathic pain associated with vulvar vestibulitis/vulvodynia may respond
to tricyclic antidepressants (amitriptyline or nortriptyline) or gabapentin.

**Second Line**
- Ospemifene for moderate to severe symptoms due to menopause-related vulvar and vaginal atrophy (2)[B]
- Intravaginal DHEA (prasterone) for moderate to severe symptoms due to menopause-related vulvar and vaginal atrophy

**ISSUES FOR REFERRAL**
Referral for long-term therapy may be necessary.

**ADDITIONAL THERAPIES**
Physical therapy for pelvic floor muscle pain

**SURGERY/OTHER PROCEDURES**
- Laparoscopic excision of endometriotic lesions has shown benefit (3)[C].
- Surgical vestibulectomy can be considered if medical measures fail with vulvar vestibulitis (4)[B].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Sitz baths may relieve painful inflammation.
- Perineal massage
- Antioxidants may improve symptoms associated with endometriosis.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
**Patient Monitoring**
- Outpatient follow-up depends on therapy.
- Every 6 to 12 months once resolved

**DIET**
A high-fiber diet may help if constipation is a contributing cause.

**PATIENT EDUCATION**
Kegel exercise information
Provide couples with information about sexual arousal techniques.

PROGNOSIS
Depends on underlying cause but most patients will respond to treatment

- Algorithms: Discharge, Vaginal; Dyspareunia
CODES

ICD10
- N94.1 Dyspareunia
- F52.6 Dyspareunia not due to a substance or known physiol cond

CLINICAL PEARLS
- Careful history to determine if patient feels pain before, during, or after intercourse will help identify cause.
  - Pain before intercourse suggests a phobic attitude toward penetration and/or the presence of vestibulitis.
  - Pain during intercourse combined with the location of the pain is most predictive of the causes of pain.
  - Introital pain after intercourse suggests vestibulitis in women of childbearing age, hypertonic pelvic floor, or vulvovaginal dystrophia.
- Potential relationship exists between primary dyspareunia and vaginismus, low libido, and arousal disorders.
- Episiotomy does not offer any benefit in the prevention of dyspareunia; an episiotomy in fact may cause more future discomfort.
DYSPEPSIA, FUNCTIONAL

Briana Lindberg, MD  •  Kristina Burgers, MD

BASICS

DESCRIPTION

• A group of epigastric symptoms classified based on presenting symptoms
• The presence of bothersome postprandial fullness, early satiety, or epigastric pain/burning in the absence of causative structural disease (to include normal upper endoscopy) for at least 1 to 3 days per week for the preceding 3 months, with initial symptom onset at least 6 months prior to diagnosis (Rome IV criteria)
• Rome IV criteria divide patients into two subtypes:
  – Postprandial distress syndrome (PDS)
  – Epigastric pain syndrome (EPS)
• System(s) affected: GI
• Synonym(s): idiopathic dyspepsia; nonulcer dyspepsia; nonorganic dyspepsia; PDS; and EPS

EPIDEMIOLOGY

Incidence
Unknown; accounts for 70% of patients with dyspepsia, and ~5% of primary care visits

Prevalence
• 10–30% prevalence worldwide
• Typically more common in Western cultures. PDS may be more common in Eastern cultures than originally recognized.
• Predominant age: adults but can be seen in children
• Predominant gender: female > male

ETIOLOGY AND PATHOPHYSIOLOGY
Unknown but proposed mechanisms or associations include gastric motility disorders, visceral pain hypersensitivity, *Helicobacter pylori* infection, alteration in upper GI microbiome, postinfectious complications, immune activation, inflammation, and gut-brain axis disorders
**Genetics**
Possible link to G-protein $\beta_3$ subunit 825 CC genotype, serotonin transport genes, and/or cholecystokinin-A-receptor gene polymorphisms

**Geriatric Considerations**
Patients ≥60 years with new-onset dyspepsia should undergo endoscopy.

**Pediatric Considerations**
Be alert for family system dysfunction.

**Pregnancy Considerations**
Pregnancy may exacerbate symptoms.

**RISK FACTORS**
- Other functional disorders: fibromyalgia, temporomandibular joint pain, chronic fatigue syndrome
- Anxiety/depression, psychosocial stressors (e.g., divorce, unemployment)
- Smoking
- Female gender

**GENERAL PREVENTION**
Avoid foods and habits known to exacerbate symptoms.

**COMMONLY ASSOCIATED CONDITIONS**
Other functional bowel disorders

**DIAGNOSIS**

**HISTORY**
- Postprandial fullness (1)[B]
- Early satiety (1)[B]
- Epigastric pain (1)[B]
- Epigastric burning (1)[B]
- Symptoms for 3 months (1)[C]
- Alarm features that may necessitate endoscopy include (2–4)[C]:
  - Unintended weight loss
– Progressive dysphagia
– Odynophagia
– Persistent vomiting
– GI bleeding
– Family history of upper GI cancer
– Age ≥60 years

PHYSICAL EXAM
● Document weight status and vital signs.
● Examine for signs of systemic illness.
  – Murphy sign for cholecystitis
  – Rebound and guarding for ulcer perforation
  – Palpation during muscle contraction for abdominal wall pain
  – Jaundice
  – Thyromegaly

DIFFERENTIAL DIAGNOSIS
● Peptic ulcer disease; gastroesophageal reflux disease
● Cholecystitis; choledocholithiasis
● Gastric or esophageal cancer; esophageal spasm
● Malabsorption syndromes; celiac disease
● Pancreatic cancer; pancreatitis
● Inflammatory bowel disease; carbohydrate malabsorption; gastroparesis
● Ischemic bowel disease
● Intestinal parasites
● Irritable bowel syndrome
● Ischemic heart disease
● Diabetes mellitus; thyroid disease
● Connective tissue disorders
● Conversion disorder
● Medication effects

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
● Functional dyspepsia is a diagnosis of exclusion. Order labs based on clinical suspicion (3)[C].
● Test for H. pylori (stool antigen or urea breath test) in areas of high H. pylori prevalence (3,4)[A].
CBC (if anemia or infection are suspected)
Liver-associated enzymes/right upper quadrant ultrasound (if hepatobiliary disease is suspected)
Pancreatic enzymes (if pancreatic disease is suspected)
Upper endoscopy for patients ≥60 to rule out malignancy (4)[C]
Upper endoscopy is unlikely to change outcomes or management (5)[C].
Self-report questionnaires can track symptoms (3)[C].

Diagnostic Procedures/Other
Esophageal manometry or gastric accommodation studies are rarely needed (3)[C].
Motility studies are unnecessary, unless gastroparesis is strongly suspected (4)[C].

Test Interpretation
None (by definition, this a functional disorder)

TREATMENT
GENERAL MEASURES
Reassurance and physician support are helpful (2,3)[C].
Treatment is based on presumed etiologies.
Discontinue offending medications (3)[C].
Routine endoscopy not recommended in dyspeptic patients <60 years even with alarm features (4)[B]

MEDICATION
First Line
Treat *H. pylori* if confirmed on testing (3,4)[A].
Trial of once daily proton pump inhibitor (PPI) medication (e.g., omeprazole 20 mg PO QD) or H2RA (e.g., ranitidine 150 mg BID) for up to 8 weeks in patients without alarm symptoms. This is most effective in EPS (3–5)[A].
Prokinetics have been proposed as first-line agents in PDS, although efficacy data for metoclopramide (only agent approved in United States) are limited (5)[C]. Prokinetics should be prescribed at the lowest effective dose to avoid potential side effects (4)[C]. Use with caution in elderly patients due to side effects of tardive dyskinesia and parkinsonian symptoms.
Second Line

- Trial of tricyclic antidepressant (TCA) medication is more helpful for EPS than PDS (e.g., amitriptyline 25 mg PO QD, can up-titrated to 50 mg PO QD), with a NNT of 6 (2,4–6)[A]. Caution in elderly. There is no benefit to SSRI/SNRI (6)[A].
- Trazodone 25 mg at bedtime is an alternative (2,5)[A]. Consider buspirone or mirtazapine if no response or if contraindications to TCA (2)[B].

ADDITIONAL THERAPIES

- Stress reduction (2,5)[C]
- Psychotherapy effective in some patients (2)[C],(3,4)[B]
- Patients should be given a positive diagnosis and reassured of benign prognosis (2)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE

Alternative medicine approaches need further study and are not currently recommended (4)[C].
- Iberogast may be helpful (2)[C].
- Probiotics have theoretical benefit but few controlled trials (2,5)[C].
- Hypnotherapy may help (3)[B].
- Transcutaneous electroacupuncture may help (3)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Provide ongoing support and reassurance.
- Upper endoscopy if persistent symptoms
- Change medications if no difference in symptoms after 4 weeks (3)[C].
- Discontinue medications once symptoms resolve (3)[C].

DIET

- Limited data to support dietary modification
- Consider limiting fatty foods (2,5)[C].
Avoid foods that exacerbate symptoms: wheat and cow milk proteins, peppers or spices, coffee, tea, and alcohol (2,5)[C].

**PATIENT EDUCATION**
Reassurance and stress reduction techniques

**PROGNOSIS**
Long-term/chronic symptoms with symptom-free periods

**COMPLICATIONS**
Iatrogenic, from evaluation to rule out serious pathology

**REFERENCES**

**ADDITIONAL READING**

- Mahadeva S, Ford AC. Clinical and epidemiological differences in functional

**SEE ALSO**

- [Irritable Bowel Syndrome](#)
- Algorithm: Dyspepsia

**CODES**

**ICD10**

K30 Functional dyspepsia

**CLINICAL PEARLS**

- Dyspepsia without underlying organic disease is functional or idiopathic.
- Consider empiric acid suppression therapy as first line for functional dyspepsia.
- Extensive diagnostic testing is not recommended unless alarm symptoms are present.
DYSPHAGIA
Felix B. Chang, MD, DABMA, FAAMA

BASICS
Difficulty transmitting the alimentary bolus from the mouth to stomach

DESCRIPTION
- Oropharyngeal dysphagia: difficulty transferring food bolus from oropharynx to proximal esophagus
- Esophageal dysphagia: difficulty moving food bolus through the body of the esophagus to the pylorus

EPIDEMIOLOGY
10% of individuals >50 years of age

Prevalence
- Common primary care complaint
- Rates of impaired swallowing in nursing home residents range from 29% to 32%

ETIOLOGY AND PATHOPHYSIOLOGY
- Oropharyngeal (transfer dysphagia):
  - Mechanical causes: pharyngeal and laryngeal cancer, acute epiglottitis, carotid body tumor, pharyngitis, tonsillitis, strep throat, lymphoid hyperplasia of lingual tonsil, lateral pharyngeal pouch, hypopharyngeal diverticulum
- Esophageal:
  - Esophageal mechanical lesions: carcinomas, esophageal diverticula, esophageal webs, Schatzki ring, structures (peptic, chemical, trauma, radiation), foreign body
  - Extrinsic mechanical lesions: peritonsillar abscess, thyroid disorders, tumors, mediastinal compression, vascular compression (enlarged left atrium, aberrant subclavus, aortic aneurysm), osteoarthritis of the cervical spine, adenopathy, esophageal duplication cyst
- Neuromuscular: achalasia, diffuse esophageal spasm, hypertonic lower esophageal sphincter, scleroderma, nutcracker esophagus, CVA, Alzheimer
disease, Huntington chorea, Parkinson disease, multiple sclerosis, skeletal muscle disease (polymyositis, dermatomyositis), neuromuscular junction disease (myasthenia gravis, Lambert-Eaton syndrome, botulism), hyper- and hypothyroidism, Guillain-Barré syndrome, systemic lupus erythematous, acute lymphoblastic leukemia, amyloidosis, diabetic neuropathy, brainstem tumors, Chagas disease

- Infection: diphtheria, chronic meningitis, tertiary syphilis, Lyme disease, rabies, poliomyelitis, CMV, esophagitis (*Candida*, herpetic)
- Globus phenomenon

**RISK FACTORS**

- **Children:** hereditary and/or congenital malformations
- **Adults:** age >50 years; elderly: GERD, stroke, COPD, chronic pain
- **Smoking,** excess alcohol intake, obesity
- **Medications:** quinine, potassium chloride, vitamin C, tetracycline, Bactrim, clindamycin, NSAIDs, procainamide, anticholinergics, bisphosphates
- **Neurologic events or diseases:** CVA, myasthenia gravis, multiple sclerosis, Parkinson disease, amyotrophic lateral sclerosis (ALS), Huntington chorea
- **HIV patients** with CD4 cell count <100 cells/mm³
- **Trauma** or irradiation of head, neck, and chest; mechanical lesions
- **Extrinsic mechanical lesions:** lung, thyroid tumors, lymphoma, metastasis
- **Iron deficiency**
- **Anterior cervical spine surgery** (up to 71% in the first 2 weeks postop; 12–14% at 1 year postop)
- **Dysphagia lusoria** (vascular abnormalities causing dysphagia): complete vascular ring, double aortic arch, right aortic arch with retroesophageal left subclavian artery and left ligamentum arteriosum, and right aortic arch with mirror-image branching and left ligamentum arteriosum

**GENERAL PREVENTION**

- Correct poorly fitting dentures.
- Educate patients to prolong chewing and drink adequate volumes of water at meals.
- Liquid and soft food diet as appropriate
- Avoid alcohol with meals.
- Prophylactic swallowing exercises in patients with head and neck cancer undergoing chemoradiation
COMMONLY ASSOCIATED CONDITIONS
Peptic structure, esophageal webs and rings, carcinoma; history of stroke, dementia, pneumonia

DIAGNOSIS

HISTORY

- Dysphagia to both solids and liquids from the onset of deglutition likely represents an esophageal motility disorder.
- Oropharyngeal dysphagia presents as difficulty initiating the swallowing process.
- Dysphagia for solids that progresses to involve liquids more likely reflects mechanical obstruction.
- Progressive dysphagia is usually caused by cancer or a peptic stricture. Intermittent dysphagia is most often related to a lower esophageal ring.
- Inquire about heartburn, weight loss, hematemesis, coffee ground emesis, anemia, regurgitation of undigested food particles, and respiratory symptoms.
- Inquire about regurgitation, aspiration, or drooling immediately after swallowing as this may represent oropharyngeal dysphagia.
- Does the food bolus feel stuck?
  - Upper sternum or back of throat may represent oropharyngeal dysphagia, whereas sensation over the lower sternum is typical of esophageal dysphagia.
- Is odynophagia present?
  - May represent inflammation, achalasia, diffuse esophageal spasm, esophagitis, pharyngitis, pill-induced esophagitis, cancer
- Globus sensation (“lump in the throat”)?
  - Potentially indicates cricopharyngeal or laryngeal disorders
- History of sour taste in the back of the throat or chronic heartburn suggests GERD.
- Inquire about alcohol and/or tobacco use.
- Are there associated symptoms such as weight loss or chest pain?
  - Double aortic arch, right aortic arch with retroesophageal left subclavian artery and left ligamentum arteriosum
  - Anticholinergics, antihistamines, and some antihypertensives can decrease salivary production.
- Halitosis: Rule out diverticulitis.
Prior history of a connective tissue disorder
Changes in speech, hoarseness, weak cough, dysphonia? Rule out neuromuscular dysfunction.

PHYSICAL EXAM

General: vital signs
Skin: telangiectasia, sclerodactyly, calcinosis (r/o autoimmune disease); Raynaud phenomenon, sclerodactyly may be found in CREST syndrome or systemic scleroderma; stigmata of alcohol abuse (palmar erythema; telangiectasia)
Head, eye, ear, nose, throat (HEENT):
  – Oropharyngeal: pharyngeal erythema/edema, tonsillitis, pharyngeal ulcers or thrush, odynophagia (bacterial, viral, fungal infections); tongue fasciculations (ALS)
  – Neck: masses, lymphadenopathy, neck tenderness (thyroiditis), goiter
Neurologic:
  – Cranial nerve exam: sensory: cranial nerves V, IX, and X; motor: cranial nerves V, VII, X, XI, and XII
  – CNS, mental status exam, strength testing, Horner syndrome, ataxia, cogwheel rigidity (CVA, dementia, Parkinson disease, Alzheimer disease)
    o Eye position, extraocular motility
Informal bedside swallowing evaluation: Observe level of consciousness, postural control-upright position, oral hygiene, mobilization of oral secretions.

DIFFERENTIAL DIAGNOSIS
See “Etiology and Pathophysiology.”

DIAGNOSTIC TESTS & INTERPRETATION

Adults (1)[C]:
  ● Barium swallow
  ● Fiberoptic endoscopic examination of swallowing (FEES)
  ● Gastroesophageal endoscopy
  ● Gastroesophageal manometry
  ● Ambulatory 24-hour pH testing
  ● Esophageal manometry
  ● Videofluoroscopic swallowing study (VFSS): oropharyngeal dysphagia

Initial Tests (lab, imaging)
Guided by diagnostic considerations (2)[C]
- CBC (infection and inflammation)
- Serum protein and albumin levels for nutritional assessment
- Thyroid function studies to detect dysphagia associated with hypothyroidism or hyperthyroidism, cobalamin levels
- Antiacetylcholine antibodies (myasthenia)

Barium swallow: detects strictures or stenosis

**Follow-Up Tests & Special Considerations**
- CT scan of chest; MRI of brain and cervical spine
- VFSS (lips, tongue, palate, pharynx, larynx, proximal esophagus)
- Fiberoptic endoscopy and videofluoroscopy are similar in terms of diagnostic sensitivity (3)[C].

**Diagnostic Procedures/Other**
Endoscopy with biopsy; esophageal manometry; esophageal pH monitoring

---

**TREATMENT**

**GENERAL MEASURES**
Exclude cardiac disease. Ensure airway patency and adequate pulmonary function. Assess nutritional status. Speech therapy evaluation is helpful.

**MEDICATION**

**First Line**
- For esophageal spasms: calcium channel blockers: nifedipine 10 to 30 mg TID; imipramine 50 mg at bedtime; sildenafil 50 mg/day PRN
- For esophagitis:
  - Antacids: Tums, Mylanta, Maalox
  - H₂ blockers:
    - Cimetidine: up to 1,600 mg orally per day in 2 or 4 divided doses for 12 weeks
    - Ranitidine: initial 150 mg orally 4 times daily and maintenance 150 mg orally twice daily
    - Nizatidine: 150 mg orally twice daily for 12 weeks
    - Famotidine: 20 to 40 mg orally twice daily for 12 weeks
● Proton pump inhibitors:
  – Omeprazole: 20 mg once daily for 4 to 8 weeks
  – Lansoprazole: 30 mg once daily for up to 8 weeks
  – Rabeprazole: 20 mg orally once daily for 4 to 8 weeks
  – Esomeprazole: 20 to 40 mg orally once daily for 4 to 8 weeks
  – Pantoprazole: 40 mg orally once daily for up to 8 weeks
● Prokinetic agents: rarely used
● Precautions: may need to use liquid forms of medications because patients might have difficulty swallowing pills

ISSUES FOR REFERRAL
● Gastroenterology: endoscopy, refractory symptoms
● Surgery: dilation, esophageal myotomy, biopsy

ADDITIONAL THERAPIES
Speech therapy to assess swallowing; nutritional evaluation for dietary and positioning recommendations; physical therapy for muscle-strengthening exercise; no eating at bedtime; remaining upright after eating
● Self-expanded metal stent is safe, effective, and quicker in palliating dysphagia compared to other modalities.

SURGERY/OTHER PROCEDURES
● Esophageal dilatation (pneumatic or bougie)
● Esophageal stent; laser for cancer palliation (4)[A]
● Treat underlying problem (e.g., thyroid goiter, vascular ring, esophageal atresia).
● Nd:YAG laser incision of lower esophageal rings refractory to dilation
● Photodynamic therapy (cancer) (4)[C]
● Cricopharyngeal myotomy (oropharyngeal dysphagia)
● Surgery for Zenker diverticulum, refractory strictures, or myotomy (for achalasia)
● Percutaneous endoscopic gastrostomy (PEG) decreases risk of dysphagia when compared with nasogastric tube.

COMPLEMENTARY & ALTERNATIVE MEDICINE
● Acupuncture has been used with some success for neurogenic dysphagia.
● Electroacupuncture combined with dilating granule has been used in the
treatment of GERD.

- Insufficient evidence for routine use of botulinum toxin

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Complete or partial esophageal obstruction associated with malnutrition or dehydration
- Need for enteral feeding
- Outpatient if patient is able to maintain nutrition and has little risk of complications
- Hospitalization with total or near-total obstruction of esophageal lumen
- Hospitalization may be needed for endoscopy and/or esophageal dilatation and is generally indicated for diagnostic or therapeutic surgical procedures.
- IV fluids for dehydrated, hypovolemic patients, and patients with impaired consciousness
- Discharge when tolerating adequate diet without nausea/pain

**ONGOING CARE**

**DIET**

See “General Prevention.”

**PATIENT EDUCATION**

Dietary modification; no eating at bedtime; remaining upright after eating; smoking cessation

**PROGNOSIS**

Vary with specific diagnosis

**COMPLICATIONS**

- Oropharyngeal: pneumonia, lung abscess, aspiration, airway obstruction
- Malnutrition and dehydration

**REFERENCES**

mebooksfree.com

**ADDITIONAL READING**

**CODES**

**ICD10**

- R13.10 Dysphagia, unspecified
- R13.12 Dysphagia, oropharyngeal phase
- R13.14 Dysphagia, pharyngoesophageal phase

**CLINICAL PEARLS**

- Dysphagia is an alarm symptom that warrants prompt evaluation to define the exact cause and initiate appropriate therapy.
- Patients with oropharyngeal dysphagia usually report feeling an obstruction in the neck and point to this area when asked to identify the site of their symptoms.
ECTOPIC PREGNANCY
Jessica Johnson, MD, MPH

BASICS

DESCRIPTION
Ectopic: pregnancy implanted outside the uterine cavity. Subtypes include:
- Tubal: pregnancy implanted in any portion of the fallopian tube
- Abdominal: pregnancy implanted intra-abdominally, most commonly after tubal abortion or rupture of tubal ectopic pregnancy
- Heterotopic: pregnancy implanted intrauterine and a separate pregnancy implanted outside uterine cavity
- Ovarian: implantation of pregnancy in ovarian tissue
- Cervical: implantation of pregnancy in cervix
- Intraligamentary: implantation of pregnancy within the broad ligament

EPIDEMIOLOGY

Incidence
- 108,800 cases in 1992 in the United States, according to CDC census (most recent data available), meaning that 1.5–2.0% of all pregnancies were ectopic. The true incidence is difficult to estimate.
- In the United States, ectopic pregnancy is the leading cause of 1st trimester maternal deaths and accounts for 6% of all pregnancy-related deaths.
- Heterotopic pregnancy, although rare (1:30,000), occurs with greater frequency in women undergoing in vitro fertilization (IVF) (1/1,000).
- Increasing incidence of nontubal, and particularly cesarean scar ectopic pregnancies, due in part to more cesarean sections and more IVF

Prevalence
- ~33% recurrence rate if prior ectopic pregnancy

ETIOLOGY AND PATHOPHYSIOLOGY
- 95–97% of ectopic pregnancies occur in the fallopian tube, of which, 55–80% in the ampulla, 12–25% in the isthmus, and 5–17% in the fimbria.
- One risk factor for a tubal pregnancy is impaired movement of the fertilized
ovum to the uterine cavity due to dysfunction of the tubal cilia, scarring, or narrowing of the tubal lumen.

- Other locations are rare but may occur from reimplantation of an aborted tubal pregnancy or from uterine structural abnormalities (mainly cervical pregnancy).

**RISK FACTORS**
- History of pelvic inflammatory disease (PID), endometritis, or current gonorrhea/chlamydia infection
- Previous ectopic pregnancy
- History of tubal surgery (~33% of pregnancies after tubal ligation will be ectopic.)
- Pelvic adhesive disease (infection or prior surgery)
- Use of an intrauterine device (IUD): Overall chance of any pregnancy with an IUD is low; however, there is an increased likelihood of ectopic location if pregnancy occurs. IUDs reduce absolute risk of ectopic pregnancy.
- Use of assisted reproductive technologies
- Maternal diethylstilbestrol (DES) exposure in utero (DES was last used in 1972.)
- Tobacco use
- Patients with disorders that affect ciliary motility may be at increased risk (e.g., endometriosis, Kartagener).

**GENERAL PREVENTION**
- Reliable contraception or abstinence
- Screening for and treatment of STIs (i.e., gonorrhea, chlamydia) that can cause PID and tubal scarring

**DIAGNOSIS**

**HISTORY**
In >50% of presenting cases, patients have sudden-onset abdominal pain coupled with cessation of/or irregular menses and acute vaginal bleeding (the classic triad). Other common symptoms include nausea and/or vomiting, vaginal bleeding, and pain referred to the shoulder (from hemoperitoneum).

**PHYSICAL EXAM**
- Abdominal tenderness ± rebound tenderness
- Vaginal bleeding
- Palpable mass on pelvic exam (adnexal or cul-de-sac fullness)
- Cervical motion tenderness
- In cervical cases, an hourglass-shaped cervix might be noted.
- In cases of rupture and significant intraperitoneal bleeding, signs of shock such as pallor, tachycardia, and hypotension may be present.

**DIFFERENTIAL DIAGNOSIS**
- Missed, threatened, inevitable, or completed abortion
- Gestational trophoblastic neoplasia (“molar pregnancy”)
- Appendicitis
- Salpingitis, PID
- Ruptured corpus luteum or hemorrhagic cyst
- Ovarian tumor, benign or malignant
- Ovarian torsion
- Cervical polyp, cancer, trauma, or cervicitis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Check CBC and ABO type and antibody screen.
- Transvaginal US (TVUS) is the gold standard for diagnosis:
  - Failure to visualize a normal intrauterine gestational sac when serum human chorionic gonadotropin (hCG) is above the discriminatory level (>1,500 to 2,000 IU/L) suggests an abnormal pregnancy of unknown location (PUL).
  - An hCG level of 3,500 IU/L is associated with a 99% probability of detecting a normal intrauterine gestational sac in clinical practice (1).
  - These values are not validated for multiple gestations.
- If TVUS unavailable or inconclusive for intrauterine pregnancy (IUP), check hCG: Serial quantitative serum levels normally increase by at least 53% every 48 hours: Abnormal rise (<35%) should prompt workup for gestational abnormalities. Clinical impression of acute abdomen/intraperitoneal bleeding concurrent with a positive hCG level is indicative of ectopic pregnancy until proven otherwise.
- MRI may also be useful but costly and rarely used if TVUS is available; benefits particularly for abdominal or cesarean scar pregnancy

**Follow-Up Tests & Special Considerations**
- Serum progesterone level: >20 mg/mL associated with lower risk of ectopic pregnancy. In women with pain and/or bleeding who have an inconclusive US, serum progesterone level <3.2 ng/mL ruled out a viable pregnancy in 99.2% of women (2); may provide additional data for PUL but does not predict ectopic pregnancy (3)[B]

- Under investigation: evaluation of serum progesterone levels in conjunction with vascular endothelial growth factor, inhibin A, and activin A using an algorithm. This diagnosed patients with ectopic pregnancy with 99% accuracy.

**Diagnostic Procedures/Other**

- In the setting of an undesired pregnancy, sampling of the uterine cavity with endometrial biopsy or D&C can identify the presence/absence of intrauterine chorionic villi. When an IUP has been evacuated by curettage, hCG levels should drop by 50% within 48 hours.

- Historically, culdocentesis was performed to confirm suspected hemoperitoneum prior to surgical management. Currently, TVUS quantification of pelvic fluid is sufficient.

**Test Interpretation**

Products of conception (POC; especially chorionic villi) outside the uterine cavity

**TREATMENT**

**MEDICATION**

- Methotrexate (MTX): treatment for unruptured tubal pregnancy or for remaining POCs after laparoscopic salpingostomy. MTX inhibits DNA synthesis via folic acid antagonism by inactivating dihydrofolate reductase.

- Because TVUS often shows PUL, before treating with MTX, you should confirm suspected US findings with 2 hCG levels drawn 48 hours apart. Rise <35% is consistent with nonviable pregnancy.

- Most effective when pregnancy is <3 cm diameter, hCG <5,000 mIU/mL, and no fetal heart movement is seen. Success rate is 88% if hCG <1,000 mIU/mL, 71% if hCG 1,000 to 2,000 mIU/mL, 38% if 2,000 to 5,000 mIU/mL:
  - Three main dosage regimens exist (4):
    - Single: IM MTX 50 mg/m² of body surface area (BSA); may repeat once
(preferred method) if <15% decline in hCG between day 4 and 7. Follow hCG weekly.

- Double dose: MTX 50 mg/m² of BSA once and then repeated on day 4; if <15% decline in hCG between day 4 and 7, may repeat 3rd dose on day 7. Repeat hCG as needed on day 11 and 14 until decreases >15% in the interval, then weekly. If not dropping by day 14, refer for surgical management.

- Multidose: MTX 1 mg/kg IM/IV every other day, with leucovorin 0.1 mg/kg IM in between. Maximum 4 doses until hCG drop below 15%; course may be repeated 7 days after last dose if necessary.

  - Contraindications:
    - Hemodynamic instability or any evidence of rupture
    - Moderate to severe anemia
    - Severe hepatic or renal dysfunction
    - Immunodeficiency

  - Relative contraindications
    - Fetal heart rate seen
    - Large gestational sac (>3 cm, less effective)
    - Noncompliance or limited access to hospital or transportation
    - High hCG count >5,000 mIU/mL

- Precautions: immunologic, hematologic, renal, GI, hepatic, and pulmonary disease, or interacting medications

- Pretreatment testing: serum hCG, CBC, liver and renal function tests, blood type and screen

- Patient counseling: During therapy, refrain from use of alcohol, aspirin, NSAIDs, and folate supplements (decreases efficacy of MTX); avoid excessive sun exposure due to risk of sensitivity.
  - Adherence to scheduled follow-up appointments is critical.
  - Increased abdominal pain may occur during treatment; however, severe pain, nausea, vomiting, bleeding, dizziness, or light-headedness may indicate treatment failure and require urgent evaluation.

- Rupture of ectopic pregnancy during MTX treatment ranges from 7% to 14%.
- Side effects include stomatitis; conjunctivitis; abdominal cramping; and rarely neutropenia, pneumonitis, or alopecia (5).
- Systemic MTX may be offered in some kinds of nontubal ectopic pregnancies, but data is limited.

**ISSUES FOR REFERRAL**
Consider gynecologic consultation if not experienced in medical management.
Refer to a gynecologist for surgical care.

ADDITIONAL THERAPIES
- Physician or patient may elect for surgical treatment as primary method and then postop hCG should guide need for supplemental MTX.
- After evidence of medical failure or tubal rupture, surgery is necessary.
- Treatment of cervical, ovarian, abdominal, or other ectopic pregnancy is complicated and requires immediate specialist referral.
- Follow all patients treated medically to an hCG of 0 to ensure that there is no need for surgical intervention.
- Offer anti-D Rh prophylaxis at a dose of 50 μg to all Rh-negative women who have a surgical procedure to manage an ectopic pregnancy or if there has been significant bleeding or abdominal pain.

Expectant management of ectopic (confirmed on TVUS) should be offered to women who are clinically stable and have decreasing hCG level initially <1,500 mIU/mL (3)[B].

Expectant management to allow for spontaneous resolution of PUL is acceptable in asymptomatic patients with no evidence of rupture or hemodynamic instability coupled with an appropriately low hCG and no extraterine mass suggestive of ectopic. Ruptured tubal pregnancies may occur even with extremely low hCG levels (<100 mIU/mL) (6).

With expectant management of PUL, repeat TVUS weekly (or when hCG above discriminatory zone) until location is confirmed or clinical picture is unstable.

SURGERY/OTHER PROCEDURES
- Indications include ruptured ectopic pregnancy, inability to comply with medical follow-up, previous tubal ligation, known tubal disease, current heterotopic pregnancy, desire for permanent sterilization at time of diagnosis.
- Laparoscopy is the first-line surgical management (3)[A].
- Salpingectomy (tubal removal) is preferred and is indicated for uncontrolled bleeding, recurrent ectopic pregnancy, severely damaged tube, large gestational sac, or patient’s desire for sterilization (3)[B].
- Salpingostomy (preservation of tube) is considered in patients who wish to maintain fertility particularly if contralateral tube is damaged/absent (3)[C]:
  - No difference in recurrence rate compared to salpingectomy
  - Persistent trophoblastic tissue with salpingostomy remains in the fallopian

mebooksfree.com
tube in 4–15% of cases; will need to follow weekly hCG
- Use of US-guided intra-amniotic injection with MTX and/or potassium chloride is experimental at this time.
- Surgical treatment is first line for cesarean and cornual pregnancies.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Fails criteria for MTX management, suspicion of rupture, orthostatic, shock, and severe abdominal pain requiring IV narcotics
- Inpatient observation in the setting of an uncertain diagnosis, particularly with an unreliable patient, may be appropriate.
- Surgical emergency
  - Two IV access lines should be placed immediately if suspicion of rupture; aggressive resuscitation as needed
  - Blood product transfusion if necessary en route to OR
  - In cases of shock, pressors and cardiac support may be necessary.
- IV fluids
  - Unnecessary for a stable ectopic pregnancy being medically treated
  - Critical for a surgical patient who is bleeding
- Strict input/output, hourly vitals, orthostatics if mobile, frequent abdominal exams, serial hematocrit, pad counts if heavy vaginal bleeding
- Discharge criteria: afebrile, abdominal pain resolving or resolved, diagnosis established, surgical treatment, and recovery is complete

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

**Patient Monitoring**
- Serial serum quantitative hCG until level drops to zero:
  - After MTX administration, a strict monitoring protocol should be followed (5).
  - Following salpingostomy, weekly levels are appropriate.
  - Following salpingectomy, further follow-up may be unnecessary.
- Pelvic US for persistent or recurrent masses
- Pain control: brief course of narcotics usually necessary with medical or surgical management
Liver and renal function tests weekly following MTX administration if repeat dosing is required
- Delay of subsequent pregnancy for at least 3 months after treatment with MTX due to teratogenicity (folate deficiency) (3)[C]

**DIET**
- During treatment, avoid alcohol and foods and vitamins high in folate (leafy greens, liver, edamame) due to interaction with MTX efficacy.
- Maintain excellent hydration.

**PATIENT EDUCATION**
- Signs and symptoms of ectopic pregnancy should be reviewed.
- Patients should be encouraged to plan subsequent pregnancies and seek early medical care on discovery of future pregnancies.

**PROGNOSIS**
- Chronic ectopic pregnancies are rare and treated with surgical removal of the fallopian tube.
- Future fertility depends on fertility prior to ectopic pregnancy and degree of tubal compromise. In women with normal fertility, treatment options have no differences in future fertility rates. In women with subfertility, expectant or medical treatments confer better future fertility (3)[C].
- ~66% of women with a history of ectopic pregnancy will have a future IUP if they are able to conceive.
- If infertility persists beyond 12 months, the fallopian tubes should be evaluated.

**COMPlications**
- Hemorrhage and hypovolemic shock
- Persistent trophoblastic tissue after medical or surgical management
- Infection
- Infertility
- Blood transfusions with associated infections/transfusion reaction
- Disseminated intravascular coagulation in the setting of massive hemorrhage

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- O00.9 Ectopic pregnancy, unspecified
- O00.1 Tubal pregnancy
- O00.0 Abdominal pregnancy

**CLINICAL PEARLS**

- Ectopic pregnancy is the leading cause of 1st trimester maternal death and
accounts for 6% of U.S. pregnancy deaths.
- 97% of ectopic pregnancies occur in the fallopian tube.
- Diagnosis requires high clinical suspicion in the setting of abdominal pain and a positive pregnancy test until IUP is confirmed.
BASICS

DESCRIPTION

- Premature ejaculation (PE): inability to control ejaculatory reflex resulting in ejaculation sooner than desired; most common type of sexual dysfunction affecting all age groups:
  - Defined (ISSM 2007) as an ejaculation that always or nearly always occurs prior to or within 1 minute of penetration; an inability to ejaculate on all or nearly all penetrations and with negative personal consequences (1,2)
  - Natural biologic response is to ejaculate within 2 to 5 minutes after vaginal penetration.
  - Ejaculatory control is an acquired behavior that increases with experience.
- Delayed ejaculation (DE): prolonged time to ejaculate (>30 minutes) despite desire, stimulation, and erection
- Aspermia (lack of sperm in the ejaculate):
  - Anejaculation (AE): lack of emission or contractions of bulbospongiosus muscle
  - Retrograde ejaculation (RE): partial or complete ejaculation of semen into the bladder
  - Obstruction: ejaculatory duct obstruction or urethral obstruction
- Painful ejaculation: genital or perineal pain during or after ejaculation
- Ejaculatory anhedonia: normal ejaculation lacking orgasm or pleasure
- Hematospermia: presence of blood in the ejaculate
- Ejaculatory duct obstruction
- Synonym(s): rapid ejaculation; retarded ejaculation; inhibited orgasm in males; ejaculatory dysfunction

EPIDEMIOLOGY

Prevalence

- PE is common. Reported prevalence in U.S. males ranges from 20% to 30% depending definition.
- DE is reported in 5–8% of men age 18 to 59 years, but <3% experience the problem for >6 months.
Predominant age: all sexually mature age groups
Predominant sex: male only

ETIOLOGY AND PATHOPHYSIOLOGY

Male sexual response:

- Erection mediated by parasympathetic nervous system
- Normal ejaculation consists of three phases:
  - Emission phase: Semen is deposited into urethra by contraction of prostate, seminal vesicles, and vas deferens; under autonomic sympathetic control
  - Ejaculation phase: Semen forcibly propelled out of urethra by rhythmic contractions of bulbospongiousus and ischiocavernosus muscles. This is mediated by the somatic nervous system on the motor branches of the pudendal nerve. Bladder neck contracture induced by $\alpha$-adrenergic receptors ensures anterograde ejaculation.
  - Orgasm: the pleasurable sensation associated with ejaculation (cerebral cortex); smooth muscle contraction of accessory sexual organs; release of pressure in posterior urethra
- PE has many theoretical causes:
  - Penile hypersensitivity
  - 5-Hydroxytryptamine (5-HT) receptor sensitivity
  - Sexual inexperience
  - High level of sexual arousal and/or long interval since last ejaculation
  - Fear of sexual transmitted infections (STIs)
  - Anxiety or guilty feelings about sex
  - Lack of privacy
  - Interpersonal maladaptation (e.g., marital problems, unresponsiveness of partner)
- DE:
  - Rarely due to underlying painful disorder (e.g., prostatitis, seminal vesiculitis)
  - Psychogenic
  - Sexual performance anxiety and other psychosocial factors
  - Medications may impair ejaculation (e.g., MAOIs, SSRIs, $\alpha$- and $\beta$-blockers, thiazides, antipsychotics, tricyclic and quadcyclic antidepressants, NSAIDs, opiates, alcohol).
- Never any ejaculate:
  - Congenital structural disorder (müllerian duct cyst, wolffian abnormality)
  - Acquired (radical prostatectomy, postinfectious, posttraumatic, T10–T12
neuropathy)

- AE:
  - Retroperitoneal lymph node (LN) dissection
  - Spinal cord injury or other (traumatic) sympathetic nerve injury
  - Medications (α- and β-blockers, benzodiazepines, SSRIs, MAOIs, TCAs, antipsychotics, aminocaproic acid)
  - Diabetes mellitus (DM) (neuropathy)
  - Radical prostatectomy

- RE:
  - Transurethral resection of the prostate (25%) or other prostate resection procedures
  - Surgery on the neck of the bladder
  - Extensive pelvic surgery
  - Retroperitoneal LN dissection for testicular cancer (also may produce failure of emission)
  - Neurologic disorders (multiple sclerosis [MS], DM)
  - Medications (α-blockers, in particular tamsulosin, ganglion blockers, antipsychotics)
  - Urethral stricture (may be posttraumatic)

- Painful ejaculation:
  - Infection or inflammation (orchitis, epididymitis, prostatitis, urethritis)
  - Ejaculatory duct obstruction
  - Seminal vesicle calculi
  - Obstruction of the vas deferens
  - Psychological/functional

- Ejaculatory anhedonia:
  - Medications
  - Psychological
  - Hormonal imbalances
  - Decreased libido

- Hematospermia (often unable to find cause):
  - Inflammation/infection
  - Calculi: bladder, seminal vesicle, prostate, urethra
  - Trauma to genital area (cycling, constipation)
  - Obstruction
  - Cyst
  - Tumor (prostate cancer [1–3% present with hematospermia])
  - Arteriovenous malformations
  - Iatrogenic
– Hypertension

COMMONLY ASSOCIATED CONDITIONS
- Neurologic disorders (e.g., MS)
- DM
- Prostatitis
- Ejaculatory duct obstruction
- Urethral stricture
- Psychological disorders
- Endocrinopathies
- Relationship/interpersonal difficulties

DIAGNOSIS
- Ejaculation occurs before individual wishes (PE).
- Ejaculation does not occur following normal stimulation (including masturbation).

HISTORY
- Detailed sexual history, including:
  - Time frame of the problem
  - Quality of patient’s sexual response
  - Sense of ejaculatory control and sexual distress
  - Overall assessment of the relationship
  - Ask specific questions as patients often reluctant to discuss openly.
- Detailed history of recent and current medications
- History of past trauma or recent infections
- Past surgical history with particular attention to genitourinary (GU) surgeries
- Supplements and alternative therapies tried
- Many men do not distinguish initially between problems related to erection and ejaculation.
- Some men have unrealistic expectations of ejaculatory response and frequency.
- Include the sexual partner in the interview, especially if the patient expresses a belief that he is not meeting his partner’s needs.
- In review of systems, elicit any evidence of testosterone deficiency or prolactin excess especially if anhedonia present.
PHYSICAL EXAM
- Check vitals. Look for focal neurologic signs (MS, spinal cord injury) and psychiatric disorders.
- Thorough GU exam, including:
  - Size and texture of testes and epididymis
  - Verification of the presence of the vas deferens
  - Location and patency of urethral meatus
  - Digital rectal examination to evaluate prostate consistency and size and possible midline lesions

DIAGNOSTIC TESTS & INTERPRETATION
- Laboratory test results may be normal.
- Fasting glucose or HgbA1c to rule out diabetes
- Postorgasmic urinalysis will confirm RE. Semen fructose level, sperm count, and viscosity can be measured. Patient may complain of cloudy urine.
- AE will have fructose negative, sperm negative, nonviscous postorgasmic urinalysis.
- In painful ejaculation, urinalysis and urine culture
- If prostate cancer is considered, check prostate-specific antigen (PSA).
- In anhedonia, consider checking testosterone, prolactin, glucose, and thyroid levels.
- In hematospermia, painful ejaculation, or if ejaculatory duct obstruction is considered, transrectal ultrasound (TRUS) may be helpful.
- TRUS-guided seminal vesicle aspiration; if ejaculatory duct obstruction is present, then the aspirate will contain sperm.
- If suspicious of anatomic abnormality, can get scrotal US and/or MRI

TREATMENT

GENERAL MEASURES
- Identifying any medical cause (even if not reversible) helps patient accept condition.
- Improve partner communication.
- Psychological counseling for patient and partner
- Reduce performance pressure through reassurance.
- Use of a variety of resources may be necessary (e.g., psychiatrist, psychologist, sex therapist, vascular surgeon, urologist, endocrinologist,
neurologist).

- **PE:**
  - Use sensate focus therapy (gradual progression of nonsexual contact to sexual contact).
  - Quiet vagina: Female partner stops moving just prior to ejaculation.
  - Techniques to learn ejaculatory control (e.g., coronal squeeze technique [squeezing the glans penis until ejaculatory urge ceases] or start-and-stop technique [cessation of penile stimulation when ejaculation approaches and resumption of stimulation when ejaculatory feeling ends]) (3)[B]

- **DE:**
  - Change to antidepressant less likely to cause DE (citalopram, fluvoxamine, nefazodone)

- **AE/RE:**
  - Discontinue offending medication(s).
  - Diabetic control
  - If urethral obstruction present, refer to urology.
  - RE may be helped if intercourse occurs when bladder is full.
  - Consider penile vibratory stimulation (effective in spinal cord injuries >T10) or electroejaculation (place on monitor if lesions above T6 because autonomic dysreflexia may result) to collect sperm in AE cases.

- **Painful ejaculation:**
  - Counseling may be beneficial.
  - If seminal vesicle stones are possible, refer to urology.

- **Hematospermia:**
  - Often resolves spontaneously, without known cause
  - May try empiric antibiotic, but little evidence to support
  - If persistent or high degree of suspicion for abnormality, refer to urologist.

**MEDICATION**

- **PE:**
  - Treating underlying erectile dysfunction (if identified) with PDE5 inhibitors

- **First line:**
  - Topical anesthetic gel applied (2.5% prilocaine ±2.5% lidocaine [EMLA]) 2.5 g under a condom for 30 minutes prior to intercourse (4,5)[A]
  - Daily dosing of clomipramine 20 to 50 mg, sertraline 25 to 200 mg, fluoxetine 5 to 20 mg, or paroxetine 10 to 40 mg can delay ejaculation within 1 to 3 weeks of starting (4)[A].
  - Dapoxetine, a short-acting SSRI, used “on demand” 30 to 60 mg 1 to 2 hours prior to sex (2,4)[A]
- Tramadol 5 to 50 mg used “on demand” 2 hours before sex; effective in many studies (6)[A]
- Some other “on-demand” options include clomipramine 20 to 40 mg 4 to 24 hours before intercourse, sertraline 50 mg 4 to 8 hours before intercourse, paroxetine 20 mg 3 to 4 hours before intercourse (2)[A].
- Consider switching antidepressants to bupropion, nefazodone, mirtazapine.
- Second line: behavioral/sex therapy, pelvic floor muscle therapy (3)[B]

**DE (limited options):**
- Patients who must continue SSRIs may respond to bupropion, buspirone (1) [B], or yohimbine (1)[C] before intercourse.
- Sex therapy, self-stimulation therapies (1)[B]
- Some evidence that amantadine or cyproheptadine may be helpful (2)[B]

**AE/RE:**
- α-agonists and antihistamines can be helpful but are not approved by the FDA.
- First line:
  - Pseudoephedrine 60 mg PO daily to QID (7)[A]
  - Imipramine 25 to 75 mg PO BID (7)[A]
- Second line: For RE, can try postejaculation bladder harvest of sperm (if fertility desired); for AE, can try midodrine, penile vibratory stimulation or electroejaculation (7)[B]

**Painful ejaculation:**
- Treat underlying infection/inflammatory process.
- α-Blockers may have some benefit.

**ISSUES FOR REFERRAL**
The following conditions, when suspected, should be referred to a urologist:
- Ejaculatory duct obstruction
- Seminal vesicle or prostatic stones
- Urethral obstruction
- Vas deferens obstruction
- Calculi
- Persistent or severe hematospermia

**SURGERY/OTHER PROCEDURES**
Surgical treatment of ejaculatory duct obstruction:
- Transurethral resection of the ejaculatory ducts
ONGOING CARE

PATIENT EDUCATION
See “General Measures.”

PROGNOSIS
Often improves with therapy and counseling

COMPLICATIONS
Psychological impact on some males: signs of severe inadequacy, self-doubt, additional anxiety, and guilt

REFERENCES

ADDITIONAL READING
CODES

ICD10
- F52.4 Premature ejaculation
- N53.11 Retarded ejaculation
- N53.14 Retrograde ejaculation

CLINICAL PEARLS
- If erectile dysfunction is contributing to ejaculatory difficulty, management of erectile dysfunction should precede attempted management of ejaculatory disorders.
- Medications should always be thoroughly reviewed, as they may be the primary cause of ejaculatory disorders.
- PE and DE generally have both psychogenic and physical causes, whereas AE and RE are due to organic neurogenic/autonomic dysfunction.
- A multidisciplinary approach, including the primary care physician, urologists, psychologists, and other appropriate health care professionals, is essential to the proper treatment of ejaculatory disorders.
ELDER ABUSE

Nitin Budhwar, MD • Kimberly Kone, MD

BASICS

DESCRIPTION

- The National Center of Elder Abuse divides abuse into three categories (age >60) (1)[A]:
  - **Domestic**: abuse from someone who has a special relationship with the elderly individual (spouse, child, friend, or in-home caregiver) that occurs in the home of the elderly or caregiver
  - **Institutional**: occurs in the setting of a facility that is responsible for caring for the elderly, such as a nursing home or long-term care facility
  - **Self-neglect**: The behavior of the elderly individual leads to harm.
- Types of abuse in estimated order of occurrence:
  - Self-neglect (estimated 50%). The most common form of abuse (2)[C].
  - Financial
  - Neglect
  - Emotional
  - Physical
  - Sexual
  - Taken advantage of: misinformation and unregulated online pharmaceutical, financial companies, and so forth, that specifically target the elderly leading to deleterious outcomes (3)[C]

EPIDEMIOLOGY

Incidence

Estimate is that as many as 1:10 have been victims of abuse, placing a conservative number at 50,000 cases per year. Majority of whom are believed to be women (4)[A].

Prevalence

A recent national survey measuring prevalence of abuse in individuals of at least 60 years and older found that 11.9% of the surveyed population suffered some form of abuse:
- 5.2% encountered financial mistreatment by family members.
- 5.1% suffered potential neglect.
- 4.6% encountered emotional mistreatment, mostly by humiliation or verbal abuse.
- 1.6% encountered physical mistreatment, mostly through battery.
- 0.6% sexually mistreated, mostly through forced intercourse.

ETIOLOGY AND PATHOPHYSIOLOGY
The etiology of elder abuse is a complex biopsychosocial combination of increased dependence on the caregiver by the victim in a suboptimal environment with poor behavioral coping methods, which is compounded by increased stress.

Genetics
Not contributory

RISK FACTORS
- The victim:
  - Advanced age
  - Exploitable resources
  - Prior history of abuse in life
  - Dementia or other cognitive impairment
  - Female gender
  - Disability in caring for him/herself
  - Depression
  - Social isolation
  - Stress: health, financial, or situational
- The abuser:
  - Mental illness
  - Financial dependency
  - Substance abuse
  - History of violence
  - Other antisocial behavior (5)[C]

GENERAL PREVENTION
- Improve patient’s social contact and support.
- Identify and correct potential risk factors for elder abuse:
  - Home visit to identify for potential risks of fall hazards and barriers to
ambulation that could lead to fractures and functional decline that could leave the individual vulnerable to abuse

– Evaluate for assistive devices that help the patient independently complete his/her ADLs and prevent caregiver dependence.
– Screen for depression using validated tools like the Geriatric Depression Scale.
– Early identification and treatment of cognitive impairment

- Identify caregiver stress and burden; refer to community programs that aid with emotional assistance.
- Advance life directives planning, including identifying possible caregivers, choosing a medical power of attorney (MPOA), estate, and will planning, and so forth

COMMONLY ASSOCIATED CONDITIONS
Most common associated conditions with elder abuse are also identified as risk factors: social isolation, increased dependence for ADL/IADLs, depression, cognitive impairment, and aggressive behavior (5)[C] ,(6)[B].

DIAGNOSIS
A high index of suspicion when risk factors are present is important; types of abuse should be kept in mind as some types might not be obvious. It can be difficult to diagnose elder abuse in a single clinic visit, so it is important to get social services involved and to consider doing home visits, when abuse is suspected (5)[C].

HISTORY
It is important to take a detailed history with focus on the living arrangements, degree of functionality, who the caregivers are, and other risk factors listed above. Pay attention to clues such as withdrawal from normal activities or a sudden change in finances or abrupt changes to a will.

PHYSICAL EXAM
- It is important objectively to document positive and negative findings in your physical exam and to be very detailed because it can be admissible in court if abuse is suspected.
- Vital signs: Check weight and assess for progressive loss in weight; BP and pulse rate can be an indicator of dehydration that could be secondary to
General overall appearance:
- Wasting or cachexia
- Poor hygiene, unkempt clothing
- If the patient is bedbound, it is important to assess the integrity of the mattress and sheets. Look for excessive skin flakes, hair, or urine-soiled mattresses.

Oral exam:
- Assess for poor dentition, oral ulcers, or abscesses.

Skin exam:
- Most bruises from elder abuse are large (>5 cm) and located on the face, lateral arm, or back.
- Bite or burn marks
- It is important to check for pressure ulcers on the bony prominences of the patient: elbows, sacrum, heels, and scapula.

Mental/psychiatric:
- Withdrawn, anxious, fearful, blunted

Genital/rectal exam if sexual abuse is suspected

DIFFERENTIAL DIAGNOSIS
- Advanced dementia can present with individuals appearing withdrawn and they are often malnourished.
- Elderly with advanced dementia of Alzheimer type or Lewy body dementia can present with delusions of persecution and aggression that can be confused for elder abuse.
- Patients with Parkinson disease often fall and may exhibit fractures and bruises on a frequent basis that may mimic recurrent physical abuse.
- Coagulopathy seen in patients in advanced malignancy with bone marrow suppression or invasion, and those on chronic antiplatelet therapy can appear with bruising that can be easily confused with elder abuse.
- Wasting from malignancy, infections, chronic disease
- Thyroid disorder can present with altered mental status (AMS), depression, or anxiety.
- Chronic lung disease can present with decreased weight.
- Delirium from acute electrolyte disturbances, infectious etiology, or cardiovascular compromise can all present similar to elder abuse.
- Impaired financial status can also be confused with self-neglect.
DIAGNOSTIC TESTS & INTERPRETATION
The following workup is recommended:

- Nutritional assessment: iron, vitamin B\textsubscript{12}, folate, thiamine, albumin, prealbumin, CBC, LFTs, electrolytes
- Malignancy workup, as per current guidelines
- If bruising is noted, check for coagulopathies (e.g., platelets, bleeding times, PT/INR, and PTT).
- If cognitive impairment is observed, check thyroid-stimulating hormone, vitamin B\textsubscript{12} level; consider syphilis and HIV testing if indicated.
- Assessment of infection: may include urinalysis and culture, chest radiograph, blood count, and cultures
- Radiographic imaging of areas below soft tissue injury is indicated if there is evidence of infection (osteomyelitis) at a pressure ulcer site or bruising of a limb (fracture).
- If physical abuse is suspected and cognitive impairment present, then cranial imaging to look for hemorrhage (e.g., subdural) is indicated using CT scan or MRI.

Diagnostic Procedures/Other

- Pulse test: Check BP and pulse in presence and absence of suspected abuser. Elevation of either in the presence of the suspected abuser should raise suspicion. Useful in patients with dementia or other condition that makes history-taking difficult.
- Folstein Mini-Mental State Examination (MMSE), Montreal Cognitive Assessment (MOCA), or other validated tools to assess for cognitive impairment if suspected
- Geriatric Depression Scale if suspected
- Documentation: Practitioners may make statements of “suspected mistreatment” but should avoid making definitive diagnosis of abuse in their initial assessment, unless it is very obvious.

TREATMENT

Most states require all health care providers to report suspected elder abuse to a local agency such as the Adult Protective Services (http://www.nccafv.org/state_elder_abuse_hotlines.htm).
MEDICATION
None

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Victims of elder abuse should be admitted to the hospital if there are no safe discharge alternatives.
- Management of uncontrolled chronic conditions due to neglect (i.e., wound care from ulcers or infections)
- Cases of suspected abuse must be reported to the state’s Adult Protective Services agency or a designated alternative (e.g., if patient resides in nursing home, then report to that state’s regulatory entity). Social services may help. If physical harm has occurred, consider reporting to local law enforcement for investigation.
- Hospital security may need to be notified if restricted visitor access to a patient is required, and the patient’s name may be hidden from the public hospital census.
- If the patient is a victim of elder abuse, he/she must be relocated to a safer alternative and may need admission for sequelae caused by the abuse.
- Victims should not be discharged to a potentially abusive environment. Alternatives to discharge to the unsafe environment may include:
  - Friend or family member
  - Nursing home
  - Personal care home
  - Assisted living facility
  - Local victims’ rescue or sheltering program if available

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
 Victims of abuse should not be discharged without adequate follow-up, including:
- Primary care physician visit within 1 week
- Follow-up with Adult Protective Services or other agency; a home visit should be scheduled prior to discharge if the patient is going back home.
- Home Health Agency for assessment of safety (physical therapy)
Follow-up with appropriate mental health care

**Patient Monitoring**
The patient should have frequent visits and be followed through the appropriate agencies to reduce continuation of abuse and to identify recurring abuse.

**PATIENT EDUCATION**
- For Elder Abuse Resources in your state, you can go to the National Center of Elder Abuse at [https://ncea.acl.gov](https://ncea.acl.gov)
- Or your local representative by calling 1-800-677-1166

**PROGNOSIS**
Elder abuse and self-neglect are associated with an overall increased risk in mortality (7)[B].

**COMPLICATIONS**
Complications of elder abuse can lead to worsening depression, increased mortality, and overall poor quality of life.

**REFERENCES**
ADDITIONAL READING

CODES

ICD10

- T74.11XA Adult physical abuse, confirmed, initial encounter
- T74.21XA Adult sexual abuse, confirmed, initial encounter
- T74.01XA Adult neglect or abandonment, confirmed, initial encounter

CLINICAL PEARLS

- Elder abuse, or elder mistreatment, is a condition in which the physical, psychological, or financial well-being of an older adult is infringed upon through intentional acts or lack of action, even if harm is not intended.
- It is important to identify vulnerable individuals through proper evaluation of potential risk factors for abuse (social isolation, depression, cognitive impairment, disability requiring assistance, and financial dependence by the caregiver).
• Correction of risk factors is important to reduce the incidence of elder abuse (strengthen the patients’ social support, treat depression, provide the patient with assistive devices, screen for cognitive impairment with a trial of medication if possible, and identify caregiver burn out).

• Clearly document your physical exam with only specific objective findings.

• Contact APS or your local resources if elder abuse is suspected; it is unlawful not to report suspected elder abuse.
ENCOPRESIS

Jay Fong, MD • William T. Garrison, PhD

BASICS

DESCRIPTION

- Voluntary or involuntary fecal soilage in a (typically) previously toilet-trained child
  - Age may be chronologic or developmental.
  - No underlying organic disease
  - At least one event per month for 3 months
  - Classified into functional constipation (retentive encopresis) and functional nonretentive fecal incontinence (FNRFI); both cause fecal incontinence. There is no constipation in FNRFI. Functional constipation is more common.

- System(s) affected: GI; psychological
- Synonym(s): fecal incontinence, soiling

EPIDEMIOLOGY

Incidence

Predominant sex: male > female (4 to 6:1) Constipation accounts for 3% of general pediatric referrals; up to 84% of constipated children have fecal incontinence at some point.

Prevalence

Occurs in 1–3% of children 4 years of age

ETIOLOGY AND PATHOPHYSIOLOGY

- In 90% of cases, encopresis develops as a consequence of chronic constipation, with resulting overflow incontinence (retentive encopresis). The other 10% are caused by specific organic etiologies.
- Chronic constipation with irregular and incomplete evacuation results in progressive rectal distension and stretching of the internal/external anal sphincters.
- As a child habituates to chronic rectal distension, they may no longer sense the normal urge to defecate. Eventually, soft or liquid stool leaks around the
retained fecal mass.
- Many children voluntarily withhold stool in response to the urge to defecate for fear of pain or a preoccupation with not interrupting social activities.
- **Psychological**
  - Stool withholding, fear, anxiety
  - Difficulty with toilet training, including unusual anxiety or conflict with parent
  - Resistance to using public toilet facilities, such as school bathrooms or outdoor toilets
  - Known association with sexual abuse in boys; likely similar association in girls
  - Developmental delay
- **Anatomic**
  - Rectal distension and desensitization
  - Anal fissure or painful defecation
  - Muscle hypotonia
  - Slow intestinal motility
  - Hirschsprung disease
  - Cystic fibrosis
  - Spinal cord defects (e.g., spina bifida)
  - Congenital anorectal malformations
  - Anal stenosis
  - Anterior displacement of the anus
  - Postoperative stricture of anus or rectum
  - Pelvic mass
  - Neurofibromatosis
- **Dietary or metabolic**
  - Inadequate dietary fiber
  - Excessive protein or milk intake
  - Inadequate water intake
  - Hypothyroidism
  - Hypercalcemia
  - Hypokalemia
  - Diabetes insipidus; diabetes mellitus
  - Food allergy
  - Gluten enteropathy
- **Medication side effects**

**Genetics**
None known; although incidence may be higher in children with family history of constipation

**RISK FACTORS**
- Male gender
- Constipation
- Very low birth weight
- Painful defecation
- Difficulty with bowel training, including social pressure related to early daycare placement
- Organic/anatomic causes
- Anxiety and depression
- Insufficient fluid or fiber intake
- Refusal to use public restrooms
- Attention deficit
- History of abuse

**GENERAL PREVENTION**
Family education: toilet training when ready; optimize fluid and fiber intake.

**COMMONLY ASSOCIATED CONDITIONS**
- Constipation, Hirschsprung disease
- Cerebral palsy, cystic fibrosis
- Developmental and behavioral diagnoses, urinary incontinence

**DIAGNOSIS**

**HISTORY**
- Signs/symptoms of constipation:
  - Hard, large-caliber stools
  - <3 defecations per week
  - Pain or discomfort with stool passage
  - Withholding stool
  - Blood on stool or in diaper/toilet bowl
  - Decreased appetite
  - Abdominal pain that improves with stool passage
  - Hiding while defecating before child is toilet-trained; avoiding use of the
toilet
  – Diet low in fiber or fluids, high in dairy products
  – No stool passage in the first 48 hours of life
  – Pasty stool on underclothes
  – Recurrent UTIs
- Abrupt onset after age 5 years more likely to be associated with psychological trauma
- Overlap with attention deficit disorder (ADD) common in children >5 years
- Medication use: opiates, phenobarbital, and tricyclic antidepressants (TCAs)
- Family history of constipation

PHYSICAL EXAM
- Neurologic exam of lower extremities and perineal area, with attention to S1–S4 distribution, perineal sensation, cremasteric reflex, and anal sphincter tone
- Genital examination and digital rectal exam: Assess for anal fissures, sphincter tone, rectal distension/impaction, occult or visible blood.
- Abdominal exam: bowel sounds, percussion note (tympany), abdominal distension; palpate for stool (most common in left lower quadrant).

DIAGNOSTIC TESTS & INTERPRETATION
Most cases diagnosed by history and physical

Initial Tests (lab, imaging)
  - Only to rule out organic causes
  - UA/urine culture: UTI/glucosuria
  - Thyroid function tests: hypothyroidism
  - Electrolyte panel, including calcium: hypokalemia, hypercalcemia, or hyperglycemia
  - Abdominal plain films if impaction is suspected and not detected by abdominal or rectal exam

Follow-Up Tests & Special Considerations
  - Failure to pass meconium within 48 hours of birth, failure to thrive, bloody diarrhea, or bilious vomiting in a neonate should be promptly evaluated to exclude aganglionic megacolon.
  - Constipation and diarrhea, rash, failure to thrive, or recurrent pneumonia should prompt evaluation for cystic fibrosis. Patients with abdominal distension or ileus should be evaluated for possible obstruction.
**Diagnostic Procedures/Other**
Manometric studies may be useful in patients who have constipation that does not respond to treatment.

**TREATMENT**

**GENERAL MEASURES**
- Anticipatory toilet training advice about when children should reduce reliance on diapers or use pull-ups during the daytime hours (average age for toilet training in girls is 29 months; 31 months for boys)
- Eliminate impaction prior to maintenance therapy.
- Avoid frequent and repeated rectal exams, enemas, and suppositories, especially in infants.
- Once stools are regular in frequency, child should sit on toilet BID at the same time each day for 10 to 15 minutes and for 10 to 15 minutes after meals. Incorporate positive reinforcement for successful bowel movements.

**MEDICATION**
- Remove impaction and start maintenance treatment.
- No randomized, controlled studies have compared methods of disimpaction: can use oral agents, enemas, and rectal suppositories; oral agents are least traumatic. Glycerin suppositories are best option for infants.

**First Line**
- Disimpaction with polyethylene glycol (PEG)
  - Give 17 g (240 mL) water or juice: 1.0 to 1.5 g/kg/day for 3 days for disimpaction
  - 0.4 to 0.8 g/kg/day for maintenance
- Disimpaction with mineral oil for child >1 year; give 15 to 30 mL/year of age to max 240 mL.
  - Maintenance: 1 to 3 mL/kg/day or divided BID
  - May mix with orange juice to make palatable; avoid in infants to avoid aspiration pneumonia.
- Other maintenance regimens include the following:
  - Milk of magnesia (MOM) 400 mg (5 mL): 1 to 2 mL/kg/day BID
  - Lactulose 10 g (15 mL): 1 to 3 mL/kg/day divided BID
  - Senna syrup 8.8 g sennoside (5 mL): age 2 to 6 years: 2.5 to 7.5 mL/day
divided BID; age 6 to 12 years: 5 to 15 mL/day divided BID
– Bisacodyl suppository 10 mg: 0.5 to 1 suppository once or twice per day

ISSUES FOR REFERRAL
If symptoms do not improve after 6 months of compliance with a multifactorial treatment model, refer to pediatric gastroenterologist for further evaluation and guidance.

ADDITIONAL THERAPIES
Behavioral treatment and counseling

SURGERY/OTHER PROCEDURES
If ongoing constipation is refractory to a combination of medical and behavioral therapy, consider anorectal manometry to evaluate for internal anal sphincter achalasia (or ultrashort-segment Hirschsprung disease). If present, this condition can be treated successfully in most patients with an internal sphincter myectomy.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Children with volitional stool holding who receive behavioral treatment in addition to medications are more likely to have resolution of encopresis at 3 and 6 months than with medication alone (1)[A].
- No evidence that biofeedback training adds benefit to conventional treatment for functional fecal incontinence in children (2)[A]
- Behavioral interventions combined with laxative therapy (rather than laxative therapy alone) improve continence in children with functional fecal incontinence associated with constipation (1)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization
  – Continued soiling and recurrent impaction on outpatient medical therapy, whether from lack of medication efficacy or patient nonadherence
  – Decreased intake leading to malnutrition or dehydration
  – Recalcitrant vomiting or concern for obstruction
  – Involve appropriate agencies if concern for abuse.
  – Hospital admission and abdominal films may be necessary to ensure
complete removal of impaction. This may include direct gastric administration of balanced electrolyte–PEG solutions if the patient cannot tolerate by mouth. Serial abdominal films and observation of rectal effluent can help determine treatment adequacy.

- IV fluids if the patient is dehydrated and has difficulty tolerating oral intake
- Nursing to document stool output and character
- Discharge criteria
  - Stools that are looser in consistency and clearer in appearance are a successful inpatient end point.
  - Abdominal radiographs showing less fecal loading (compared with a pretreatment radiograph) with improving serial abdominal exams

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*

- Continue maintenance treatment for 6 months to 2 years with visits every 4 to 10 weeks for support and to ensure compliance; more frequent visits with oppositional or anxious children
- Telephone or virtual visits can be used to adjust doses and to provide ongoing encouragement.
- Treat recurrences of impaction promptly.
- Emphasize compliance with medication and self-initiation of regular bathroom visits.
- Children who do not progress using a well-designed behavior plan should be referred for more in-depth mental health evaluation and counseling.

**DIET**

Adequate fluid and fiber intake (2)[A]. Reduce cow’s milk products. Avoid excessive consumption of bananas, rice, apples, and gelatin.

**PATIENT EDUCATION**

- Demystify defecation.
- Carefully explain the treatment plan including medications and dietary changes.
- Avoid punishment for inadvertent soiling.
In children >4 years of age, explain to parents how overreliance on diapers and pull-ups (while convenient) can prolong the problem. Always attempt to use positive reinforcement for successful toilet sits and medication compliance. If positive approach is unsuccessful, consider removing desired privileges (e.g., TV, video games) for noncompliance with behavioral plan. Some children respond well to a token economy (earned privileges) to promote desired behavior.

**PROGNOSIS**
- Many children exhibit a good response and relapse due to parental noncompliance.
- From 30% to 50% of children may still have encopresis after 5 years of treatment.
- Children with psychosocial or emotional problems preceding the encopresis are more recalcitrant to treatment.

**COMPLICATIONS**
- Colitis due to excessive enema/suppository
- Perianal dermatitis
- Anal fissure

**REFERENCES**

**ADDITIONAL READING**
- Constipation Guideline Committee of the North American Society for Pediatric Gastroenterology, Hepatology and Nutrition. Evaluation and treatment of constipation in infants and children: recommendations of the...

**CODES**

**ICD10**
- R15.9 Full incontinence of feces
- R15.1 Fecal smearing
- F98.1 Encopresis not due to a substance or known physiol condition

**CLINICAL PEARLS**

- 90% of encopresis results from chronic constipation.
- Address toddler constipation early by decreasing excessive milk intake, increasing fruits/vegetables intake, and ensuring adequate fluid and fiber intake.
- Eliminate fecal impaction before initiating maintenance therapy.
ENDOCARDITIS, INFECTIVE
Lyudmila Burina Ganatra, DO, MS • Theodore B. Flaum, DO, FACOFP

BASICS
DESCRIPTION
- An infection of the valvular (primarily) and/or mural (rarely) endocardium
- System(s) affected: cardiovascular, endocrine/metabolic, hematologic/lymphatic, immunologic, pulmonary, renal/urologic, skin/exocrine, neurologic
- Synonym(s): bacterial endocarditis; subacute bacterial endocarditis (SBE); acute bacterial endocarditis (ABE)

EPIDEMIOLOGY
Incidence
- Incidence rose in the United States between 2000 and 2011 from 11 per 100,000 to 15 per 100,000
- 1.5–3% incidence 1 year after prosthetic valve replacement; 3–6% 5 years postreplacement
- Increasing incidence of cardiovascular device-related infections due to higher frequency of implantable devices, especially in the elderly

ETIOLOGY AND PATHOPHYSIOLOGY
- ABE: Staphylococcus aureus; Streptococcus groups A, B, C, G; Streptococcus pneumoniae; Staphylococcus lugdunensis; Enterococcus spp. (gram-positive); Haemophilus influenzae or parainfluenzae; Neisseria gonorrhoeae (gram-negative)
- SBE: α-hemolytic streptococci (viridans group strep), Streptococcus bovis, Enterococcus spp., S. aureus, Staphylococcus epidermidis (gram-positive); HACEK organisms: Haemophilus aphrophilus or paraphrophilus, Actinobacillus (Aggregatibacter) actinomycetemcomitans, Cardiobacterium hominis, Eikenella corrodens, Kingella kingae
- Endocarditis in IV drug abusers (tricuspid valve): S. aureus, Enterococcus spp. (gram-positive); Pseudomonas aeruginosa, Burkholderia cepacia, other
bacilli (gram-negative); Candida spp.

- Early prosthetic valve endocarditis (<60 days after valve implantation): S. aureus, S. epidermidis (gram-positive); gram-negative bacilli; fungi: Candida spp., Aspergillus spp.

- Late prosthetic valve endocarditis (>60 days after valve implantation): α-hemolytic streptococci, Enterococcus spp., S. epidermidis (gram-positive); Candida spp., Aspergillus spp.

- Culture-negative endocarditis: 10% of cases; Bartonella quintana (homeless); Brucella spp., fungi, Coxiella burnetii (Q fever), Chlamydia trachomatis, Chlamydiophila psittaci, HACEK organisms; Abiotrophia (formerly vitamin B₆-deficient streptococci); use of antibiotics prior to blood cultures

- Device-related endocarditis: coagulase-negative staphylococci or S. aureus

**RISK FACTORS**

- Injection drug use, IV catheterization, certain malignancies (colon cancer), poor dentition, chronic hemodialysis

- High-risk with:
  - Prosthetic cardiac valve, implantable devices (pacemaker, automatic implantable cardioverter defibrillator [AICD]), total parenteral nutrition
  - Previous infective endocarditis (IE)
  - Congenital heart disease (CHD): unrepaired cyanotic CHD, including palliative shunts and conduits; repaired CHD with prosthetic device during the first 6 months; repaired CHD with residual defects at or near prosthetic site; cardiac transplant with valvulopathy (1)[B]

**GENERAL PREVENTION**

- Good oral hygiene.

- Antibiotic prophylaxis is only recommended for high-risk cardiac conditions (1)[B]—prosthetic heart valve, history of endocarditis, transplant with abnormal valvular function, CHD (see “Risk Factors”).

- Procedures requiring prophylaxis
  - Oral/upper respiratory tract: any manipulation of gingival tissue or periapical region of teeth or perforation of the oral mucosa (1)[B]; invasive respiratory procedures involving incision; or biopsy of the respiratory mucosa merit prophylaxis. Amoxicillin 2 g PO (if penicillin allergic, clindamycin 600 mg PO) 30 to 60 minutes before procedure or ampicillin 2 g IV/IM are first-line prophylactic choices. For penicillin-allergic patients, use clindamycin 600 mg IV, or cephalaxin 2 g PO, or
azithromycin/clarithromycin 500 mg PO, or cefazolin/ceftriaxone 1 g IV/IM 30 minutes before procedure. Pediatric doses are amoxicillin 50 mg/kg PO (max 2 g), cephalexin 50 mg/kg PO (max 2 g), clindamycin 20 mg/kg PO (max 600 mg), and ampicillin or ceftriaxone 50 mg/kg (maximum 1 g) IM/IV.

- GI/GU: Only consider coverage for Enterococcus (with penicillin, ampicillin, piperacillin, or vancomycin) for patients with an established infection undergoing procedures (1)[B].
- Cardiac valvular surgery or placement of prosthetic intracardiac/intravascular materials: perioperative cefazolin 1 to 2 g IV 30 minutes preop or vancomycin 15 mg/kg (maximum 1 g) (penicillin-allergic patients) 60 minutes preop (1)[B]
- Skin: incision and drainage of infected tissue; use agents active against skin pathogens (e.g., cefazolin 1 to 2 g IV q8h or vancomycin 15 mg/kg q12h; max 1 g) if penicillin-allergic or if methicillin-resistant S. aureus (MRSA) suspected.

**DIAGNOSIS**

- Modified Duke Criteria (1)[B] (definite: 2 major criteria, or 1 major and 3 minor criteria, or 5 minor criteria; possible: 1 major and 1 minor criteria or 3 minor criteria)
  - Major clinical criteria
    - Positive blood culture: isolation of typical microorganism for IE from two separate blood cultures or persistently positive blood culture
    - Single positive blood culture for C. burnetii or anti–phase-1 IgG antibody titer >1:800
    - Positive echocardiogram: presence of vegetation, abscess, or new partial dehiscence of prosthetic valve; must be performed rapidly if IE is suspected
    - New valvular regurgitation (change in preexisting murmur not sufficient)
  - Minor criteria
    - Predisposing heart condition or IV drug use
    - Fever ≥38.0°C (100.4°F)
    - Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysm, intracranial hemorrhage, conjunctival hemorrhage, Janeway lesions
    - Immunologic phenomena: glomerulonephritis, Osler nodes, Roth spots, rheumatoid factor (RF)
– Microbiologic evidence: positive blood culture but not a major criterion (excluding single positive cultures for coagulase-negative staphylococci and organisms that do not cause endocarditis) or serologic evidence of infection likely to cause IE

**HISTORY**

- Fever (>38°C), chills, cough, dyspnea, orthopnea; especially in subacute endocarditis: night sweats, weight loss, fatigue
- Review risk factors.
- Symptoms of transient ischemic attack, cerebrovascular accident (CVA), or myocardial infarction (MI) on presentation

**PHYSICAL EXAM**

- Most patients with IE have new murmur or change in existing murmur; signs of heart failure (rales, edema) if valve function is compromised
- Peripheral stigmata of IE: splinter hemorrhages in fingernail beds, Osler nodes on fleshy portions of extremities, “Roth spot” retinal hemorrhages, Janeway lesions (cutaneous evidence of septic emboli), palatal or conjunctival petechiae, splenomegaly, hematuria (due to emboli or glomerulonephritis)
- Neurologic findings consistent with CVA, such as visual loss, motors weakness, and aphasia

**DIFFERENTIAL DIAGNOSIS**

Fever of unknown origin, infected central venous catheter, marantic endocarditis, connective tissue diseases, intra-abdominal infections, rheumatic fever, salmonellosis, brucellosis, malignancy, tuberculosis, atrial myxoma, septic thrombophlebitis

**DIAGNOSTIC TESTS & INTERPRETATION**

- If not critically ill; three sets of blood cultures drawn >2 hours apart from different sites *before administration of antibiotics*
- If acutely ill, draw three sets of blood cultures over 1-hour *prior to empiric therapy* (1)[A]
- Leukocytosis is common in acute endocarditis.
- Anemia, decreased C3, C4, CH50, and RF in subacute endocarditis
- ESR, C-reactive protein (CRP)
- Hematuria, microscopic or macroscopic
- Consider serologies for *Chlamydia*, Q fever, *Legionella*, and *Bartonella* in
“culture-negative” endocarditis.

- Transthoracic (TTE) or transesophageal echocardiogram (TEE) (TEE preferred) should be performed as soon as IE is suspected (1)[A].
- CT scan may help locate embolic abscesses (e.g., splenic abscess).
- Vegetations are composed of platelets, fibrin, and colonies of microorganisms. Destruction of valvular endocardium, perforation of valve leaflets, rupture of chordae tendineae, abscesses of myocardium, rupture of sinus of Valsalva, and pericarditis may occur.
- Emboli, abscesses, and/or infarction of any system
- Immune-complex glomerulonephritis

**TREATMENT**

**MEDICATION**

**First Line**

- Start empiric treatment after three sets of blood cultures have been drawn. Results guide treatment.
  - Native valves: ampicillin-sulbactam 12 g/day IV divided into 4 doses with gentamicin 3 mg/kg/day IV/IM in 2 or 3 doses. If penicillin-allergic, use vancomycin 30 mg/kg/day IV in 2 doses with gentamicin 3 mg/kg/day IV/IM in 2 or 3 doses and with ciprofloxacin 1,000 mg/day PO or 800 mg/day IV, in 2 doses (2)[A].
  - Prosthetic valves: vancomycin 30 mg/kg/day IV in 2 doses with gentamicin 3 mg/kg/day IV/IM in 2 doses and rifampin 1,200 mg/day PO in 2 doses, if <12 months postsurgery. If >12 months, use native valve regimen (2)[A].
- Penicillin-susceptible viridans streptococci or S. bovis
  - Native valve: penicillin G 12 to 18 million U/day IV continuously or in 4 to 6 doses or ceftriaxone 2 g/day IV/IM in 1 dose, both for 4 weeks (1)[B]
  - Prosthetic valve: penicillin G 24 million U/day IV continuously or in 4 to 6 doses for 6 weeks or ceftriaxone 2 g/day IV/IM in 1 dose ± gentamicin 3 mg/kg IV/IM q24h for 2 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL) (1)[B]
- Penicillin-resistant viridans streptococci or S. bovis
  - Native valve: penicillin G 24 million U/day IV, either continuously or in 4 to 6 equally divided doses + gentamicin 3 mg/kg IV/IM q24h for 2 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL) (1)[B]
  - Prosthetic valve: penicillin G 24 million U/day IV, either continually or in 4
to 6 equally divided doses or ceftriaxone 2 g/day IV/IM in 1 dose for 6 weeks + gentamicin 3 mg/kg IV/IM q24h for 2 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL) (1)[B] _Staphylococcus_

- Native valve: oxacillin or nafcillin 12 g IV/day in 4 to 6 equally divided doses 6 weeks. For oxacillin-resistant strains, use vancomycin 15 mg/kg/day IV q12h for 6 weeks for goal trough of 15 to 20 μg/mL (1)[B].
- Prosthetic valve: oxacillin or nafcillin 12 g/day IV in 4 to 6 doses + rifampin 300 mg IV/PO q8h, for 6 weeks, + gentamicin 3 mg/kg/day IV for first 2 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL). For oxacillin-resistant strains, use vancomycin 15 mg/kg IV q12h, + rifampin 300 mg IV/PO q8h, both for 6 weeks, + gentamicin 3 mg/kg/day IV/IM in 2 to 3 doses for the first 2 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL) (1)[B].

- **Penicillin-sensitive Enterococcus,** native or prosthetic valve: ampicillin 2 g IV q4h or penicillin G 18 to 30 million U/day IV continuously or in 6 doses + gentamicin 3 mg/kg IV q8h for 4 to 6 weeks (peak gentamicin level 3 μg/mL and trough <1 μg/mL) (1)[B]. Consider expert consultation for penicillin-resistant enterococci.

- **HACEK** organisms: ceftriaxone 2 g IM or IV q24h for 4 weeks (1)[B] or ampicillin-sulbactam 12 g IV q4h for 4 weeks or ciprofloxacin 1 g/day PO or 800 mg/day IV in 2 equally divided doses for 4 weeks (1)[B]
  - Cardiac device–related endocarditis: device removal followed by antibiotic therapy based on organism susceptibility (3)[B]

- **Precautions:** Adjust dosage of penicillin G, gentamicin, cefazolin, ampicillin, ampicillin/sulbactam, ciprofloxacin, and vancomycin in patients with renal impairment. Rapid infusion of vancomycin <1 hour may cause “red-man syndrome” due to histamine release (not an allergic reaction). Treat with antihistamines and decrease infusion rate.

- **Interactions:** Vancomycin + gentamicin increases renal toxicity. Rifampin alters warfarin and oral hypoglycemic metabolism.

**Second Line**

For patients allergic to penicillin:

- **Penicillin-susceptible or resistant viridans group streptococci** or **S. bovis:** vancomycin 30 mg/kg/day (not to exceed 2 g/day) IV in 2 equal doses for 4 weeks (6 weeks for prosthetic valve endocarditis) for goal trough of 10 to 15 μg/mL (1)[B]

- **Enterococcus,** native or prosthetic valve: Desensitization to penicillin should
be considered. Vancomycin 15 mg/kg (usual dose, 1 g) IV q12h, + gentamicin or streptomycin (peak gentamicin level 3 μg/mL and trough <1 μg/mL) for 4 to 6 weeks (6 weeks for prosthetic valve endocarditis) (1)[B]

*Staphylococcus* of native valve: cefazolin 2 g IV q8h (not to be used in patients with immediate-type hypersensitivity to penicillin) for 6 weeks or vancomycin 30 mg/kg (usual dose, 1 g) IV q12h for a goal trough of 15 to 20 μg/mL for 6 weeks (1)[B]

**SURGERY/OTHER PROCEDURES**

Surgery is required in 50% of IE cases. Indications (2)[A]:

- Heart failure due to aortic or mitral valve disease
  - Prevention of embolism: aortic or mitral valve vegetations >10 mm with prior embolic episodes; isolated very large vegetation >15 mm; in patients with major ischemic stroke, surgery is delayed for at least 4 weeks, if possible (4)[C].
- Uncontrolled infection: persistent fever and positive cultures >7 to 10 days; infection caused by fungi or resistant organism; presence of abscess, fistula, false aneurysm, or enlarging vegetations
- Early prosthetic valve IE

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Check gentamicin peak (~3 μg/mL) and trough (<1 μg/mL) levels if used for >5 days and with renal dysfunction. Perform twice-weekly BUN and serum creatinine while on gentamicin. Consider audiometry baseline and follow-up during long-term aminoglycoside therapy.
- Check vancomycin trough (15 to 20 μg/mL) levels in all patients (typically prior to fourth dose) (2)[B].
- Baseline ECG; monitor ECG for conduction disturbances/MI in initial weeks of therapy.
- TTE at the conclusion of therapy
- Blood cultures q48h until negative

**PROGNOSIS**
Late complications contribute to poor prognosis. These include heart failure, reinfection, and cerebral emboli. 10-year survival is 60–90% (5)[A].

COMPLICATIONS

- Cerebral complications are the most frequent and severe, occurring in 15–20% of patients (1)[A].

- Emboli: arterial (e.g., MI, mesenteric, splenic, cerebral infarction), infectious (e.g., abscesses of heart, lung, brain, meninges, bone, pericardium)
  - Neurologic events are the most frequent complications in patients with IE requiring ICU admission. Ischemic stroke is the presenting symptom of IE in 20% of cases (5)[A].

- Inflammatory/immune disorders (e.g., arthritis, myositis, glomerulonephritis)

- Other complications: congestive heart failure (CHF), ruptured valve cusp, sinus of Valsalva aneurysm, arrhythmia, and mycotic aneurysms

REFERENCES

CODES

ICD10
- I33.0 Acute and subacute infective endocarditis
- I39 Endocarditis and heart valve disorder in dis classd elswhr
- A54.83 Gonococcal heart infection

CLINICAL PEARLS
- Antibiotic prophylaxis is recommended for patients with artificial heart valves, history of infective endocarditis, CHD, and cardiac transplants with valvulopathy.
- TEE/TTE and blood cultures are the mainstays for the diagnosis of IE.
- Most common organisms are viridans *Streptococcus* species and *Staphylococcus*.
ENDOMETRIAL CANCER AND UTERINE SARCOMA

Christina N. Kufel, DO, MS • Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION

- Endometrial cancer: malignancy of the endometrial lining of the uterus
  - Two types
    o Type I: estrogen-dependent, grade 1 or grade 2, better prognosis, endometrioid histology
    o Type II: estrogen-independent, higher grade, more aggressive, includes grade 3 endometrioid and nonendometrioid: serous, clear cell, mucinous, poor prognosis (1)[A]
- Cell types: adenocarcinoma, adenosquamous (malignant squamous elements), clear cell, and papillary serous
- Sarcomas: malignancy of the uterine mesenchyme and mixed tumors
  - Mixed müllerian sarcoma (carcinosarcoma): Heterologous sarcoma elements are not native to the müllerian system (e.g., cartilage or bone); homologous sarcoma elements are native to the müllerian system (40–50% prevalence of all sarcomas).
  - Leiomyosarcoma develops in the myometrium, characterized by cellular atypic mitoses and coagulative necrosis (30% prevalence of all sarcomas).
  - Endometrial stromal sarcoma develops from the stromal component of the endometrium (15% prevalence of all sarcomas).
  - Poorer prognosis (2)[C]
- Predominant age
  - Endometrial cancer: Most patients are postmenopausal:
    o Average age of diagnosis: 63 years old
  - Sarcomas: occur in both pre- and postmenopausal:
    o Average age of diagnosis: 40 to 69 years old (2)[C]
- 70% of endometrial cancer is stage I at the time of diagnosis.
- System(s) affected: reproductive
- Synonym(s): uterine cancer; endometrial cancer; corpus cancer
Pregnancy Considerations
This malignancy is not associated with pregnancy.

Epidemiology

Incidence
- Endometrial cancer is the most common gynecologic malignancy, fourth most common cancer in women, and eighth leading cause of cancer-related death in women worldwide.
- In the United States, it is estimated that endometrial cancer will account for 61,380 new cases and 10,920 deaths in 2017 according to SEER database.
- Incidence higher in Caucasian than African American, but African Americans have stage matched higher mortality (3).

Prevalence
Approximately 500,000 women in the United States

Etiology and Pathophysiology
Continuous estrogen stimulation unopposed by progesterone
- Endometrial: unopposed estrogen
  - Estrogen replacement therapy without concomitant progesterone increases the risk. Addition of progesterone decreases risk to that of general population.
- Sarcomas: etiology unknown

Genetics
- Endometrial: Lynch syndrome (hereditary nonpolyposis colorectal cancer); lifetime risk up to 30% (3); Cowden syndrome (4,5)
- Sarcoma: African American, higher incidence of leiomyosarcoma, childhood retinoblastoma survivors

Risk Factors
- Early menarche/late menopause
- Nulliparity
- Personal or family history of colon or reproductive system cancer
- Obesity
- Diabetes mellitus
- Hypertension
• Polycystic ovarian syndrome
• Increasing age
• Estrogen-secreting tumor
• Endometrial hyperplasia
• Unopposed estrogens
• Tamoxifen use

GENERAL PREVENTION
• In young women who are obese or anovulatory, the risk of endometrial cancer can be reduced by taking oral contraceptive pills, permanently losing weight, or taking cyclic progesterone to prevent unopposed estrogen’s effects on the uterus.
• Estrogen replacement therapy should always include progesterone unless the woman has had a hysterectomy.
• Cigarette smoking has been associated with a lower risk of type I endometrial cancer; however, it is not recommended secondary to its many health risks and increase risk of type II endometrial cancer.

COMMONLY ASSOCIATED CONDITIONS
• Endometrial hyperplasia: 1–25% will progress to endometrial adenocarcinoma:
  – Simple without atypia
  – Complex without atypia
  – Simple with atypia
  – Complex with atypia
    – 43% with complex hyperplasia with atypia have concurrent endometrial cancer.
• Endometrial cancer patients should be screened regularly for breast and colon cancer per routine screening guidelines.
• Patients who have breast or colon cancer are at increased risk for endometrial cancer.
• Granulosa cell tumors of the ovary produce estrogen; these patients will have an increased risk of endometrial cancer.

DIAGNOSIS

HISTORY
• Endometrial cancer
  – Postmenopausal bleeding is the most frequent sign. Any spotting or ab-
    normal discharge mandates evaluation.
  – Premenopausal patients with history of anovulation and heavy, ir-
    regular, or prolonged periods that fail multiple medical managements mandate eval-
    uation.
• Sarcoma
  – Mixed müllerian sarcoma: bleeding and prolapsing tissue, pain (2)[C]
  – Leiomyosarcoma: pelvic pain, pressure, uterine mass, abnormal bleeding

PHYSICAL EXAM
Pelvic exam: enlarged uterus, fixed

DIFFERENTIAL DIAGNOSIS
• Atypical complex hyperplasia: a premalignant lesion of the endometrium
• Cervical cancer
• Ovarian cancer invading the uterus
• Endometriosis
• Adenomyosis
• Leiomyoma

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Liver and renal function tests
• Transvaginal ultrasound usually shows increased endometrial thickness (>4
  mm in postmenopausal patients or in patients with irregular or heavy periods
  if >35 years of age, 100% NPV) (1)[A].
• Levels of cancer antigen 125 (CA-125) may be elevated when intra-
  abdominal disease is present (1)[A].
• Chest x-ray (CXR): Most common site of metastases is the lung.
• Mammogram and colonoscopy: Endometrial cancer is associated with breast
  and colon cancer.
• Routine preoperative MRI, CT, or PET scan: not recommended (3)

Follow-Up Tests & Special Considerations
• Endometrial cancer is mostly localized to the uterus; therefore, preop
  evaluation for metastasis is not needed unless metastasis is already suspected
  (2)[A].
- CT scan, PET/CT, MRI, CA-125: not part of the routine evaluation but may be needed if metastasis is suspected, patient is a poor operative candidate, or pathology returns high grade (G3 endometrioid, papillary serous, clear cell, carcinosarcoma) (2)
- MRI has been reported to show the depth of myometrial penetration accurately but is not always cost-effective (6)[A].

### Diagnostic Procedures/Other

- Office endometrial biopsy (90% accurate): If negative with high suspicion for cancer or patient continues to have bleeding, a dilation and curettage (D&C) is necessary (2)[B]. Endometrial stromal sarcoma and leiomyosarcoma rarely are diagnosed preoperatively. Any patient with history of irregular, heavy, or prolonged periods should undergo endometrial biopsy prior to endometrial ablation procedures.

- Fractional D&C is 99% accurate except in cases of sarcoma.
- If surgical approach is favored, D&C with hysteroscopic guidance is recommended over D&C alone, due to its ability to pick up discrete lesions (2)[A].

- Meta-analyses suggest hysteroscopic peritoneal dissemination of malignant cells. Unknown significance of that dispersion.

### Test Interpretation

- Federation of Gynecology and Obstetrics Staging System: revised 2009
  - Stage I (confined to corpus uteri)
    - A: No or <1/2 myometrial invasion
    - B: Invasion ≥1/2 the myometrium
  - Stage II: Tumor invades cervical stroma but does not extend beyond the uterus.
  - Stage III: Local and/or regional spread
    - A: Uterine serosal and/or adnexal invasion
    - B: Vaginal and/or parametrial involvement
    - C: Metastases to pelvic and/or para-aortic lymph nodes
    - IIIC1: +Pelvic nodes
    - IIIC2: +Para-aortic lymph nodes positive pelvic lymph nodes
  - Stage IV: Tumor invades bladder and/or bowel mucosa and/or distant metastases:
    - A: Tumor invades bladder and/or bowel mucosa.
    - B: Distant metastases, including intra-abdominal metastases and/or
inguinal lymph nodes (1)[A]

- Uterine sarcoma criteria for diagnosis: mitotic index, cellular atypia, and areas of coagulative necrosis separated from tumor (7)[C]

## TREATMENT

### GENERAL MEASURES

- Main treatment for uterine cancer is surgery.
- Radiation is used to prevent tumor recurrence at the vaginal cuff.

### MEDICATION

#### First Line

- **Endometrial**
  - Chemotherapy for advanced or recurrent disease incurable with surgery and radiation
    - Paclitaxel + carboplatin (2)[B]
    - Doxorubicin + cisplatin + paclitaxel
  - Hormonal therapy
    - Medroxyprogesterone acetate: for recurrence or metastases
    - Megestrol (Megace) 160 mg/day for at least 2 months for women with premalignant lesions, atypical complex hyperplasia, or well-differentiated endometrial cancer in patients desiring fertility. Follow with D&C to determine cancer resolution.
    - Levonorgestrel-containing intrauterine device: as mentioned earlier for patients who desire future fertility

- **Sarcoma**
  - Chemotherapy
    - Doxorubicin as single agent or in combination (7)[A]

- **Hormonal**
  - Tamoxifen or aromatase inhibitors; not fully studied, +/- progesterone
  - Progesterones

### ADDITIONAL THERAPIES

Radiation therapy

- Nonoperative candidates: radiation therapy alone
- Low risk: no adjuvant radiation therapy
● Intermediate risk: Consider adjuvant vaginal brachytherapy; reduces local recurrences but has no effect on overall survival
● Vaginal brachytherapy is equivalent to whole pelvic radiation in regards to overall survival (3).
● High risk: chemotherapy and radiation therapy in some cases (6,8)[A]

SURGERY/OTHER PROCEDURES
Surgical staging
● Extrafascial hysterectomy and bilateral salpingo-oophorectomy
● Cytologic washings
● Pelvic and para-aortic lymph node dissection
● Omental sampling, as indicated, and for papillary serous (3)
● Optimal tumor debulking (1)[A], survival advantage
● LAP2 trial: minimally invasive and laparotomy similar 5-year survival (3)

Geriatric Considerations
Older (and obese) patients may be at high risk for surgery. Alternative radiation or progesterone therapy can be considered.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
● Admission criteria/initial stabilization
  – Excessive vaginal bleeding
  – Preoperative stabilization
● Nursing: routine; ensure postoperative pain is controlled.
● Postsurgical criteria: pain controlled, tolerating diet, ambulating, and voiding

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Follow-up visit with speculum and rectovaginal exam every 3 to 6 months for 2 years, then every 6 months for 3 years, and then annually for life (2)[C]

Patient Monitoring
● Annual CXR is no longer recommended.
● CT scan or PET/CT scan of the chest, abdomen, and pelvis should be used
only to investigate suspicion of recurrent disease, not routinely.

- Control comorbid conditions.

**DIET**

As tolerated and according to comorbidities

**PATIENT EDUCATION**

After surgery:

- No intercourse for ~6 weeks
- No lifting >10 to 15 lb
- No driving until pain free
- Do not expect resumption of full activity for 6 weeks.

**PROGNOSIS**

5-year survival rates

- Uterine adenocarcinoma

(6)[A]

**COMPLICATIONS**

- Surgical: excessive bleeding, wound infection, lymphedema, deep vein thrombosis (DVT), and damage to the urinary or intestinal systems
- Radiation: diarrhea, ileus, bowel obstruction or fistula, radiation cystitis,
proctitis, vaginal stenosis, DVT

Chemotherapy: per the drug given

CODES

ICD10

- C54.1 Malignant neoplasm of endometrium
● C55 Malignant neoplasm of uterus, part unspecified
● C54.2 Malignant neoplasm of myometrium

**CLINICAL PEARLS**

● Most common presenting symptom is abnormal uterine bleeding.
● Any patient with history of irregular, heavy, or prolonged periods should undergo endometrial biopsy.
● Primary cause is unopposed estrogen.
● Endometrial thickness on transvaginal ultrasound of <5 mm makes endometrial cancer very unlikely.
● Primary treatment is with surgery, with possible chemotherapy ± radiation.
ENDOMETRIOSIS

Andrew G. Alexander, MD • Maegen Dupper, MD • Kenneth A. Ballou, MD

BASICS

DESCRIPTION

- Endometriosis is a common but potentially painful and debilitating estrogen-dependent gynecologic condition affecting women of predominately reproductive age [1][A].
- Symptoms and signs generally consist of pelvic pain and decreased fertility.
- Due to estrogen-dependent implants of endometrial tissue found outside the uterus. Although endometriomas have been recorded in liver, bowel, umbilicus, lung, and other tissue, the most common pathologic sites are:
  - Peritoneum (bladder, cul-de-sac, pelvic walls, ligaments, and fallopian tubes)
  - Ovaries
  - Rectovaginal septum
- Ectopic endometrial implants proliferate and slough with the menstrual cycle.
- Stage I (minimal) to IV (severe). Staging is useful in therapeutic planning but does not correlate with pain severity.

EPIDEMIOLOGY

Prevalence

- Female only
- Affects 11% of fertile women
- Found in 30–50% of infertile women
- Found in 50–60% of women and adolescent women with pelvic pain

Pediatric Considerations

Endometriosis may begin with puberty as endometrial implants are dependent on ovarian hormones. This can lead to debilitating pelvic pain and severe dysmenorrhea associated with missed school, social, and family activities.

Pregnancy Considerations
The presence of endometriosis decreases fecundability from 15–20% per month to 2–10% per month. 25–50% of infertile women have endometriosis. However, pelvic endometriosis generally improves during pregnancy.

**Geriatric Considerations**

Although menopause often results in a resolution of symptoms, pelvic endometriosis may extend into menopause and may be exacerbated by hormone replacement therapy (HRT).

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Not fully understood; several factors are believed to play a role, including immunologic changes and genetic predisposition in the presence of abnormal proliferating endometrial tissue implants causing chronic peritoneal inflammation.
- Theories include:
  - **Sampson theory**: Retrograde menstruation results in peritoneal implantation and disease.
  - **Halban theory**: Distant disease is probably caused by hematogenous/lymphatic dissemination or metaplastic transformation.
  - **Coelomic metaplasia**: Coelomic epithelium remains undifferentiated in the peritoneal cavity and differentiates to form functioning endometrium.
- Endometrial-associated infertility is multifactorial:
  - Pelvic inflammation
  - Anatomic disruption of pelvic structures (Involvement of the fallopian tube may cause isthmic tubal obstruction.)
  - Proliferation and activation of peritoneal macrophages (may predispose to gamete phagocytosis)
  - Alteration in eutopic endometrium

**Genetics**

Odds ratio of symptomatic endometriosis with a first-degree affected relative is 7.2. Those with affected first-degree relatives have a 26% chance of severe manifestations versus 12% if no first-degree affected relatives.

**RISK FACTORS**

- Family history
- Menstruation and ovulation
- Delayed childbirth
GENERAL PREVENTION
- Suppression of heavy menstruation and ovulation with oral contraceptives during adolescence may delay sequelae.
- Some factors are considered protective:
  - Fruits, green vegetables, n-3 long-chain fatty acids
  - Aerobic exercise may decrease pelvic pain.
- Early diagnosis and treatment might help prevent sequelae.

COMMONLY ASSOCIATED CONDITIONS
Associated with increased risks for cancer of the ovary, breast, endometrium; increased risk for cutaneous melanoma, non-Hodgkin lymphoma, autoimmune diseases, asthma, and cardiovascular disease

DIAGNOSIS
- History: dysmenorrhea (50–90% of cases) due to deep infiltrating endometrial implants
- Dyspareunia due to lesions of the cul-de-sac, uterosacral ligaments, and posterior vaginal fornix
- Dyschezia due to involvement of the rectosigmoid colon and rectovaginal regions
- Chronic pelvic pain (≥6 months) that worsens with time and begins 1 to 2 days prior to menstrual cycles
- Hematochezia
- Cyclic nausea, abdominal distention
- Infertility (late finding)
- History of pelvic pain, infertility, and hysterectomy in first- or second-degree relative

PHYSICAL EXAM
- Focal pain/tenderness on pelvic exam is associated with endometriosis in 66% of patients.
- Pelvic mass may be present.
- Immobile pelvic organs (frozen pelvis)
- Rectovaginal exam revealing uterosacral nodules, beading, or tenderness
- An exquisitely tender “barb” stabbing pain in the region of the uterosacral ligament is found in severe cases.
DIFFERENTIAL DIAGNOSIS
Differential diagnosis of pelvic pain includes all causes of acute abdomen and
- Pelvic adhesions
- Nonspecific dysmenorrhea
- Acute salpingitis/pelvic inflammatory disease
- Ruptured ovarian cyst
- Uterine leiomyomas
- Adenomyosis
- Irritable bowel syndrome
- Inflammatory bowel disease
- Pelvic malignancy
- Complications of intrauterine/ectopic pregnancy
- Cystitis
- Depression
- History of sexual abuse
- Chronic pain syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Labs are only useful to rule out other diagnoses; there are no useful labs to rule in endometriosis.
- CA-125 levels are not recommended (2)[C] due to low sensitivity.
- If history and physical exam reveal adnexal pain or tenderness with/without fullness on pelvic exam
  - Transvaginal ultrasound (US) and MRI are equally effective in detecting ovarian endometriomas: sensitivity, 80–90%; specificity, 60–98% for both
  - US is preferred (less costly).
  - Both modalities are poor in detecting peritoneal implants and adhesions.

Diagnostic Procedures/Other
Definitive diagnosis is made by the gross and microscopic characteristics of tissue visualized and biopsied during laparoscopy or laparotomy.

Test Interpretation
- Laparoscopically visualized red and blue-black lesions described as “powder-burns,” adhesions, and “chocolate cysts” on the ovarian and peritoneal surfaces
Histologically described endometrial glands and stroma on analysis of biopsied lesions

**TREATMENT**

**GENERAL MEASURES**
Management is dependent on multiple factors:

- Age and reproductive desires of the patient
- The certainty of the diagnosis
- The degree of degradation on quality of life due to pain and infertility
- The threat to other organ systems: GI tract, bladder

**MEDICATION**
Medications are used to improve the patient’s quality of life through symptom relief and to prevent progression of the disease and its potential to cause organ dysfunction. Unfortunately, few studies of medical therapy report patient-relevant outcomes. Many women gain only limited or intermittent benefit from medical therapies (3)[A].

**First Line**
Women found to have endometriomas during incidental surgery or studies may not need any treatment. Others with minimal symptoms may find sufficient relief with NSAID medications. Increased exercise, especially aerobic, may help others.

- NSAIDs initiated at the beginning or just before menses. Evidence is inconclusive on effectiveness (4)[B].
- Cyclic combined oral contraceptive pills (OCPs) suppress ovulation.

**Second Line**
- Low-dose OCPs or low-dose progestins with recommendations to switch from cyclic to continuous contraception for 3 to 6 months if symptoms persist or if there is chronic, noncyclic pelvic pain
  - Levonorgestrel intrauterine device (IUD) (Mirena) found to decrease recurrence of painful menstruation (although not FDA approved for this indication)
- Medroxyprogesterone acetate 150 mg IM 3 months. Prolonged use may lead to loss of bone mineral density of uncertain clinical significance.
Gonadotropin-releasing hormone (GnRH) agonists: inhibit pituitary gonadotropin synthesis and induce a hypoestrogenic state
- Norethindrone acetate 5 mg PO once daily plus conjugated equine estrogen 0.625 mg PO once daily

**Third Line**
If symptoms and signs continue, physicians should be experienced in the use and side effects of GnRH analogues prior to their use (symptoms return in as many as 70% of treated patients):
- Leuprolide acetate (Lupron Depot) 3.75 mg IM each month or 11.25 mg IM every 3 months (gluteal)
- Nafarelin (Synarel) intranasal one spray (200 μg) in one nostril each morning and the other nostril each evening (start between days 2 and 4 of menstrual cycle)
- Goserelin (Zoladex) implant 3.6 mg SC in upper abdominal wall every 28 days
- Danazol: also effective, with side effects similar to GnRH analogs
- Aromatase inhibitors (anastrozole and letrozole) prolong the remission induced by GnRH medications.

**ALERT**
Calcium (1,000 to 1,500 mg/day) with vitamin D 1,000 to 2,000 IU daily or low-dose estrogen with progestogen (5)[B] is recommended when using GnRH agonists to prevent calcium loss.

**ISSUES FOR REFERRAL**
- Refer early to a physician with expertise in medical and surgical treatment of endometriosis, especially if the patient desires to conceive in the future.
- Indications for referral to a properly experienced gynecologist include the following:
  - Need for definitive diagnosis
  - Failure to respond to a conservative or first-line therapy
  - Chronic pelvic pain
  - Delayed fertility

**ADDITIONAL THERAPIES**
Regular exercise and counseling for pain-management strategies. Narcotics are contraindicated for chronic pain.
SURGERY/OTHER PROCEDURES
Surgery (laparoscopy or laparotomy) is both diagnostic and therapeutic (first line or when conservative measures fail):
- Peritoneal endometriosis: laser ablation/excision/fulguration
- Ovarian endometriosis (endometriomas) >3 to 4 cm: ablation, excision, drainage
- Lysis of adhesions (LOA)
- Hysterecetomy with bilateral salpingo-oophorectomy for debilitating symptoms refractory to other medical or surgical treatments:
  - Relieves pain in 80–90%, but pain recurs in 10% within 1 to 2 years after surgery
  - Postoperative HRT should include estrogen and progestogen or progesterone.
- Interruption of nerve pathways: Laparoscopic ablations and presacral neurectomy improve dysmenorrhea.
- Fertility procedures: Ablation or excision of lesions with LOA is recommended to treat infertility in stages I and II disease:
  - Spontaneous conception should be attempted for 1 year prior to assisted reproduction techniques.
  - Disease does not endanger in vitro fertilization (IVF) pregnancies.

ALERT
Surgery for endometriomas may decrease ovarian reserve in advanced disease.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Osteopathic manipulative therapy found to improve quality of life (2)[C]
- Postsurgical use of Chinese herbal medicine has been found to be effective.
- Acupuncture may be more effective than danazol to decrease pain, irregular menstruation, and perineal swelling (6)[B].

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Routine gynecologic care
**Patient Monitoring**
Symptomatic and asymptomatic pelvic masses (http://www.acog.org/)

**PROGNOSIS**
- Excellent, especially if diagnosis and treatment plans are initiated early in disease course
- Poor for recovery of fertility if the disease has progressed to stage III/IV
- Symptoms and signs improve after bilateral oophorectomy.

**COMPLICATIONS**
Sequelae include chronic pelvic pain, reduced quality of life, repetitive surgical intervention, depression, infertility, medication side effects and costs, and infertility.

**REFERENCES**

**ADDITIONAL READING**
- de Ziegler D, Borghese B, Chapron C. Endometriosis and infertility:

**CODES**

**ICD10**

- N80.9 Endometriosis, unspecified
- N80.3 Endometriosis of pelvic peritoneum
- N80.2 Endometriosis of fallopian tube

**CLINICAL PEARLS**

- Severe dysmenorrhea and dyspareunia are never normal. Failure to respond to NSAIDs and/or OCPs warrants further investigation.
- A rectovaginal exam can be useful in patients suspected of having endometriosis.
ENDOMETRITIS AND OTHER POSTPARTUM INFECTIONS
Justin P. Lavin Jr., MD • Ayesha Hasan, MD • Cassandra Heiselman, DO, MPH

BASICS
DESCRIPTION
- Endometritis (infection of the endometrium) is the most common postpartum infection.
- Bacterial infection of genital tract, usually within the 1st week after delivery, can occur as late as 1 to 6 weeks postpartum.
- Postpartum infections of the myometrium and parametrial tissues are less common. Vaginal and cervical infections, perianal cellulitis, pelvic cellulitis, septic pelvic vein thrombophlebitis, and parametrial phlegmon are other postpartum infections of the pelvic region that are relatively rare.
- System(s) affected: reproductive
- Synonym(s): postpartum infection; endometritis; endoparametritis; endomyometritis; myometritis; endomyoparametritis; metritis; metritis with pelvic cellulitis

EPIDEMIOLOGY

Incidence
Occurs in women of childbearing years

Prevalence
- Occurs after 1–3% of all births
- Infection 10 times more likely after cesarean section
  - 2–15% of infections occur prior to labor.
  - 30–35% occur after labor in absence of appropriate antibiotic prophylaxis;
    2–15% occur after labor with appropriate prophylaxis.
  - Fifth leading cause of maternal mortality, accounting for 11% of maternal deaths
ETIOLOGY AND PATHOPHYSIOLOGY

- Endometritis is more common in labors complicated by chorioamnionitis.
- Other infections follow trauma to the perineum, vagina, cervix, and uterus.
- Postpartum infections are typically polymicrobial, involving organisms ascending from the lower genital tract:
  - Aerobic isolates (70%): *Streptococcus faecalis*, *Streptococcus agalactiae*, *Streptococcus viridans*, *Staphylococcus aureus*, *Escherichia coli*
  - Anaerobic isolates (80%): *Peptococcus* sp., *Peptostreptococcus* sp., *Clostridium* sp., *Bacteroides bivius*, *Bacteroides fragilis*, *Fusobacterium* sp.
- Other genital *Mycoplasma*
- Consider herpes simplex virus and cytomegalovirus, particularly in immunocompromised patients failing to improve on appropriate antibiotics.
- Thrombosis of any pelvic vein, including vena cava
- Phlegmon on leaves of the broad ligament

RISK FACTORS

- Cesarean delivery is the primary risk factor.
- Chorioamnionitis
- Bacterial vaginosis
- Group B streptococcal colonization of genital tract
- HIV infection
- Prolonged labor
- Prolonged rupture of membranes
- Multiple vaginal examinations
- Internal fetal monitoring during labor
- Operative vaginal delivery; manual extraction of the placenta; care in a teaching hospital
- Low socioeconomic status
- Obesity
- Anemia

GENERAL PREVENTION

- Vaginal delivery
  - Avoid unnecessary vaginal examinations.
  - Treat chorioamnionitis during labor.
  - Avoid manual placental extraction and retained placental products.
  - Consider antibiotic prophylaxis for third- and fourth-degree laceration (1) [B].
- Aseptic technique for operative vaginal delivery
- Antibiotic prophylaxis not necessary for operative vaginal delivery or manual removal of the placenta

**Cesarean delivery**
- Preoperative paint and scrub with 10% povidone-iodine scrub or an alcohol-based solution decreases puerperal infection by up to 38%.
- Prophylactic antibiotics before both emergency and scheduled cesarean deliveries prior to skin incision reduce postpartum infection (2)\[A\].
  - Administer antibiotics within 1 hour of the start of surgery (3)\[B\].
  - Appropriate administration of antibiotics results in a 40% reduction in postpartum maternal infections without any increase in neonatal infections (3)\[B\].
- Extended coverage with cephalosporin and macrolide may further decrease infection risk (4)\[A\].
- Vaginal preparation with povidone-iodine solution or alcohol-based solutions immediately before cesarean delivery reduces the risk of postoperative endometritis (5)\[A\].
- Weight-based antibiotic dosage helps ensure appropriate tissue concentrations prior to skin incision.

**COMMONLY ASSOCIATED CONDITIONS**
- Chorioamnionitis
- Wound infection

**DIAGNOSIS**

**HISTORY**
- History of cesarean delivery or chorioamnionitis
- Fever and chills
- Malaise
- Headache
- Anorexia
- Abdominal pain
- Heavy vaginal bleeding or foul smelling lochia

**PHYSICAL EXAM**
- Oral temperature >38°C (100.4°F)
- Tachycardia
- Uterine tenderness on exam
- Other localized abdominopelvic tenderness on exam
- Purulent or malodorous lochia
- Heavy vaginal bleeding
- Ileus
- Group A or B streptococcal bacteremia may have no localizing signs.

**DIFFERENTIAL DIAGNOSIS**
- “5Ws”: Wind (pneumonia); Water (UTI); Wound infection; Wow (mastitis); Wonder drug (medication-related fever)
- Viral syndrome; dehydration
- Thrombophlebitis
- Thyroid storm
- Appendicitis

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- CBC: Interpret with care. (Physiologic leukocytosis may be as high as 20,000 WBCs.)
- Two sets of blood cultures (especially with suspected sepsis)
- Diagnosis often made on clinical grounds. Potential testing includes:
  - Genital tract cultures and rapid test for group B streptococci (may be done during labor)
  - Amniotic fluid Gram stain: usually polymicrobial
  - Uterine tissue cultures: Prep the cervix with Betadine and use a shielded specimen collector or Pipelle; difficult to obtain without contamination
- If patient not responding to antibiotics in 24 to 48 hours:
  - Ultrasound for retained products of conception, pelvic abscess, or mass
  - CT or MRI looking for pelvic vein thrombophlebitis, abscess, or deep-seated wound infection

*Diagnostic Procedures/Other*
Paracentesis/culdocentesis with culture rarely necessary

*Test Interpretation*
- Superficial layer of infected necrotic tissue in microscopic sections of uterine lining
>5 neutrophils per high-power field in superficial endometrium; ≥1 plasma cell in endometrial stroma

**TREATMENT**

**MEDICATION**

**First Line**
Clindamycin 900 mg IV q8h + gentamicin 5 mg/kg IV q24h (5)[A]

- Potential side effects include nephrotoxicity, ototoxicity, pseudomembranous colitis, or diarrhea (in up to 6%).

**Second Line**
- Ampicillin/subbactam 3 g IV q6h
- Metronidazole 500 mg IV or PO q8–12h + penicillin 5,000,000 U IV q6h, or
- Ampicillin 2 g IV q6h + gentamicin 5 mg/kg IV q24h (5)[A]
- Cefoxitin 2 g IV q6h. Add ampicillin 2 g IV q6h, if clinical failure after 48 hours (5)[A].
- Cefotetan 2 g IV q12h. Add ampicillin 2 g IV q6h, if clinical failure after 48 hours (5)[A].

- Note: Base therapy on cultures, sensitivities, and clinical response.
- Contraindications
  - Drug allergy
  - Renal failure (aminoglycosides)
  - Avoid sulfa, tetracyclines, and fluoroquinolones before delivery and if breastfeeding. Metronidazole is relatively contraindicated if breastfeeding.
- Precautions:
  - Clindamycin and other antibiotics occasionally cause pseudomembranous colitis.
  - Antibiotic-associated diarrhea (*Clostridium difficile*)
- Note: Consider adding a macrolide antibiotic (for chlamydia coverage) for infections occurring after 48 hours.
- Note: Heparin typically indicated for septic pelvic vein thrombophlebitis; requires 10 days of full anticoagulation

**SURGERY/OTHER PROCEDURES**
- Curettage for retained products of conception
- Surgery or image-guided drainage to drain abscess
- Surgery to decompress the bowel
- Surgical drainage of a phlegmon is not advised unless it is suppurative. Surgical removal of other inflamed tissue is usually not required.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Inpatient care is recommended for postpartum infections.
- Many infections occur after hospital discharge.
- IV antibiotics and close observation for severe infections
- Open and drain infected wounds.
- Optimize fluid status.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Individualize according to severity.
- IV antibiotics can be stopped when the patient is afebrile for 24 to 48 hours.
- Oral antibiotics on discharge are not necessary, unless patient was bacteremic; then continue oral antibiotics to complete a 7-day course.

**DIET**
As tolerated, although may be limited by ileus

**PATIENT EDUCATION**
- Advise patient to contact physician with fever >38°C (100.4°F) postpartum, heavy vaginal bleeding, foul-smelling lochia, or other symptoms of infection.

**PROGNOSIS**
With supportive therapy and appropriate antibiotics, most patients improve quickly and recover without complication.
COMPLICATIONS

- Resistant organisms; peritonitis; pelvic abscess
- Septic pelvic thrombophlebitis
- Ovarian vein thrombosis
- Sepsis; death

REFERENCES

ADDITIONAL READING

SEE ALSO
Algorithm: Pelvic Pain

CODES

ICD10
- O86.12 Endometritis following delivery
- O86.4 Pyrexia of unknown origin following delivery
- O86.13 Vaginitis following delivery

CLINICAL PEARLS
- Postpartum endometritis follows 1–3% of all births.
- Infections are typically polymicrobial and involve organisms ascending from the lower genital tract.
- Evidence supports antibiotic prophylaxis prior to skin incision for all cesarean deliveries but not for operative vaginal deliveries.
- Clindamycin 900 mg IV q8h and gentamicin 5 mg/kg q24h are recommended as first-line therapy for endometritis. Treat until the patient is afebrile for 24 to 48 hours and stop antibiotics completely (unless there is documented bacteremia, which requires a 7-day course of therapy).
- If no improvement occurs on antibiotics, consider retained placental products, abscess, wound infection, hematoma, cellulitis, phlegmon, or septic pelvic vein thrombosis.
ENURESIS
Swati Avashia, MD, FAAP, FACP, ABIHM

BASICS
DESCRIPTION
• Classification
  – Primary nocturnal enuresis (NE): 80% of all cases; person who has never established urinary continence on consecutive nights for a period of ≥6 months
  – Secondary NE: 20% of cases; resumption of enuresis after at least 6 months of urinary continence
• NE: intermittent nocturnal incontinence after the anticipated age of bladder control (age 5 years)
  – Primary monosymptomatic NE (PMNE): bed wetting with no history of bladder dysfunction or other lower urinary tract (LUT) symptoms
  – Nonmonosymptomatic NE (NMNE): bed wetting with LUT symptoms such as frequency, urgency, daytime wetting, hesitancy, straining, weak or intermittent stream, posturination dribbling, lower abdominal or genital discomfort, or sensation of incomplete emptying

ALERT
Adult-onset NE with absent daytime incontinence is a serious symptom; complete urologic evaluation and therapy are warranted.

• System(s) affected: nervous, renal/urologic
• Synonym(s): bed wetting; sleep enuresis; nocturnal incontinence; primary NE

EPIDEMIOLOGY
Incidence
• Depends on family history
• Spontaneous resolution: 15% per year

Prevalence
• Very common; 5 to 7 million children in the United States (1)
• 10% of 7-year-olds; 3% of 11 to 12-year-olds; 0.5–1.7% at 16 to 17-year-olds
1.5 to 2 times more common in males than females
Nocturnal > day (3:1)

**Geriatric Considerations**
Often associated with daytime incontinence (formerly referred to as diurnal enuresis)

**ETIOLOGY AND PATHOPHYSIOLOGY**
- A disorder of sleep arousal, a low nocturnal bladder capacity, and nocturnal polyuria are the three factors that interrelate to cause NE.
- Both functional and organic causes (below); many theories, none absolutely confirmed
  - Detrusor instability
  - Deficiency of arginine vasopressin (AVP); decreased nocturnal AVP or decreased AVP stimulation secondary to an empty bladder (bladder distension stimulates AVP)
  - Maturational delay of CNS
  - Severe NE with some evidence of interaction between bladder overactivity and brain arousability: association with children with severe NE and frequent cortical arousals in sleep
  - Organic urologic causes in 1–4% of enuresis in children: UTI, occult spina bifida, ectopic ureter, lazy bladder syndrome, irritable bladder with wide bladder neck, posterior urethral valves, neurologic bladder dysfunction
  - Organic nonurologic causes: epilepsy, diabetes mellitus, food allergies, obstructive sleep apnea, chronic renal failure, hyperthyroidism, pinworm infection, sickle cell disease
  - NE occurs in all stages of sleep.

**Genetics**
Most commonly, NE is an autosomal-dominant inheritance pattern with high penetrance (90%).
- 1/3 of all cases are sporadic.
- 75% of children with enuresis have a first-degree relative with the condition.
- Higher rates in monozygotic versus dizygotic twins (68% vs. 36%)
- If both parents had NE, risk in child is 77%; 44% if one parent is affected. Parental age of resolution often predicts when child’s enuresis should resolve.
RISK FACTORS

- Family history
- Stressors (emotional, environmental) common in secondary enuresis (e.g., divorce, death)
- Constipation and/or encopresis
- Organic disease: 1% of monosymptomatic NE (e.g., urologic and nonurologic causes)
- Psychological disorders
  - Comorbid disorders are highest with secondary NE: depression, anxiety, social phobias, conduct disorder, hyperkinetic syndrome, internalizing disorders.
  - Association with ADHD; more pronounced in ages 9 to 12 years
- Altered mental status or impaired mobility

GENERAL PREVENTION

No known measures

COMMONLY ASSOCIATED CONDITIONS

- Obstructive sleep apnea syndrome (10–54%) (1): Atrial natriuretic factor inhibits renin-angiotensin-aldosterone pathway leading to diuresis.
- Constipation (33–75%) (1)
- Behavioral problems (specifically ADHD in 12–17%) (1)
- Overactive bladder or dysfunctional voiding (up to 41%) (1)
- Urinary tract infection (18–60%) (1)

DIAGNOSIS

HISTORY

- Age of onset, duration, severity
- LUT tract symptoms
- Daily intake patterns
- Voiding diary and stooling patterns (especially constipation)
- Psychosocial history
- Family history of enuresis
- Investigation and previous treatment history

PHYSICAL EXAM
• ENT: evaluation for adenotonsillar hypertrophy
• Abdomen: enlarged bladder, kidneys, fecal masses, or impaction
• Back: Look for dimpling or tufts of hair on sacrum.
• Genital urinary exam
  – Males: meatal stenosis, hypospadias, epispadias, phimosis
  – Females: vulvitis, vaginitis, labial adhesions, ureterocele at introitus; evidence of abuse
• Consider rectal exam: tone, fecal soiling, fecal impaction
• Neurologic exam, especially lower extremities

**DIFFERENTIAL DIAGNOSIS**

• Primary NE
  – Delayed physiologic urinary control
  – UTI (both)
  – Spina bifida occulta
  – Obstructive sleep apnea (both)
  – Idiopathic detrusor instability
  – Previously unrecognized myelopathy or neuropathy (e.g., multiple sclerosis, tethered cord, epilepsy)
  – Anatomic urinary tract abnormality (e.g., ectopic ureter)

• Secondary NE
  – Bladder outlet obstruction
  – Neurologic disease, neurogenic bladder (e.g., spinal cord injury)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

• Only obligatory test in children is urinalysis.
• Urinalysis and urine culture: UTI, pyuria, hematuria, proteinuria, glycosuria, and poor concentrating ability (low specific gravity) may suggest organic etiology, especially in adults.
• Urinary tract imaging is usually not necessary.
• If abnormal clinical findings or adult onset: renal and bladder US
• IV pyelogram, voiding cystourethrogram (VCUG), or retrograde pyelogram are rarely indicated (1).
• MRI if spinal dysraphism is suspected

**Follow-Up Tests & Special Considerations**

• Secondary enuresis: serum glucose, BUN, creatinine, thyroid-stimulating
hormone (TSH), urine culture

- In children, imaging and urodynamic studies are helpful for significant daytime symptoms, history of UTIs, suspected structural abnormalities, and in refractory cases.

**Diagnostic Procedures/Other**

Urodynamic studies may be beneficial in adults and nonmonosymptomatic NE.

**Test Interpretation**

- Dysfunctional voiding
- Detrusor instability and/or reduced bladder capacity most common findings

**TREATMENT**

**GENERAL MEASURES**

- Use nonpharmacologic approaches as first line before prescribing medications (1)[A].

  - Simple behavioral interventions (e.g., scheduled wakening, positive reinforcement, bladder training, diet changes) are effective, although less so than alarms or medications (1)[B]; found to achieve dryness in 15–20% of cases (3)
- Explain the three pathophysiologic factors.
- Encourage normal drinking patterns during daytime hours and reduction of intake 2 hours prior to sleep.
- Emphasize regular bedtime with full night’s sleep.
- Scheduled voiding before bed
- Scheduled waking for nighttime voiding
- Nightlights to light the way to the bathroom
- Reward system for dry nights
- Use pull up over regular underwear or cloth underwear with built in waterproof barrier.
- “Cleanliness training”: Child helps with changing wet bedding.

- Do not shame or punish bedwetting but have the child participate in removing and laundering soiled bedding and garments.

- Aggressive treatment of constipation, if present, with polyethylene glycol 3350 (MiraLAX); (peds: 0.8 g/kg; adults 17 g/day)

- If behavioral interventions alone have no success, combined therapy (e.g.,
enuresis alarm, bladder training, motivational therapy, and pelvic floor muscle training) is more effective than each component alone or than pharmacotherapy (1)[A].

- Enuresis alarms (bells or buzzers)
  - Considered first line; most effective treatment
  - 66–70% success rate; must be used nightly for 2 to 4 months; offers cure; significant parental involvement; disruption of sleep for entire family
  - If successful, it should be used until 14 consecutive dry nights achieved (2)[B].

- See “Patient Education” for options.

**MEDICATION**

**First Line**

- Desmopressin (DDAVP): synthetic analogue of vasopressin that decreases nocturnal urine output (2)[A]
  - Intranasal DDAVP: adults only, 20 mg (2 sprays) intranasally at bedtime
  - FDA recommends against use in children due to reports of severe hyponatremia resulting in seizures and deaths in children using intranasal formulations of desmopressin.
  - Oral DDAVP: safe in children. Begin at 0.2 mg tablet taken at bedtime on empty stomach; after 14 days of inefficient treatment can titrate to 0.4 mg (2)
    - Maximally effective in 1 hour; effect lasts 8 to 10 hours.
    - If treatment is successful, can be continued for 3 months, then stop for 2 weeks for test of dryness
    - High relapse rate after discontinuation without a structured withdrawal program. If relapse occurs, oral desmopressin can continue to be prescribed in 3-month blocks.
    - Suspend dose in children who experience acute condition affecting fluid/electrolyte balances (fever, vomiting, diarrhea, vigorous exercise).
    - 60–70% success: 30% of children have full response and 40% have partial response.

**Pediatric Considerations**

FDA recommends against using intranasal formulations of desmopressin in children due to reports of severe hyponatremia resulting in seizures and deaths (3)[A].
**Second Line**

- **Imipramine (Tofranil):** tricyclic antidepressant, anticholinergic effects; increases bladder capacity, antispasmodic properties
  - Primarily in adults; use in children is reserved for resistant cases and initiated by specialists.
  - Dose: adults, 25 to 75 mg and children >6 years, 10 to 25 mg PO at bedtime; increase by 10 to 25 mg at 1- to 2-week intervals; treat for 2 to 3 months; then taper.
  - 40% success rate but relapses after discontinuation are high (2)
  - Pretreatment ECG recommended identifying underlying rhythm disorders

- **Anticholinergics: Monotherapy is not recommended in children.**
  - **Oxybutynin (Ditropan, Ditropan XL, Oxytrol patch):** anticholinergic; smooth muscle relaxant, antispasmodic; may increase functional bladder capacity and aids in timed voiding (4)[B]
    - 30–50% success; 50% relapse after stopped
    - Ditropan: adults: 5 mg PO TID–QID; children >5 years old with overactive bladder who have failed alarm therapy and desmopressin can try 5 mg at bedtime.
    - Ditropan XL: adults: 5 mg/day PO; increase to 30 mg/day PO (5-, 10-mg tabs)
    - Oxytrol patch: 1 patch every 3 to 4 days (3.9 mg/patch) (periodic trials of the medication, that is, weekends or weeks at a time, will help determine efficacy and resolution of primary disturbance)

  - **Tolterodine (Detrol, Detrol LA):** anticholinergic; fewer side effects than Ditropan (4)[B]
    - Detrol: 1 to 2 mg PO BID in adults, 2 mg at bedtime in children >5 years old
    - Detrol LA: 2 to 4 mg/day

- **Precautions**
  - **Oxybutynin:** glaucoma, myasthenia gravis, GI or genitourinary obstruction, ulcerative colitis, constipation, megacolon; use a decreased dose in the elderly.
  - **Tolterodine:** urinary retention, gastric retention, constipation, uncontrolled narrow-angle glaucoma; significant drug interactions with CYP2D6, CYP3A3/4 substrates
  - **DDAVP:** Avoid in patients at risk for electrolyte changes or fluid retention (congestive heart failure [CHF], renal insufficiency). Stop during gastroenteritis or other acute illness with risk of dehydration.
– Imipramine: Do not use with monoamine oxidase inhibitors (MAOIs), hypotension, and arrhythmias; low-toxic therapeutic ratio

- Combination therapy with DDAVP and oxybutynin has better results than individual use (4)[B].

**ALERT**
Imipramine: cardiotoxicity and death with overdose

**ISSUES FOR REFERRAL**
- Primary NE: persistent enuresis despite nonpharmacologic and pharmacologic therapies
- Diurnal incontinence or nonmonosymptomatic enuresis with voiding dysfunction or underlying medical condition

**ADDITIONAL THERAPIES**
Individual and family psychotherapy, crisis intervention

**SURGERY/OTHER PROCEDURES**
Only for surgically correctable causes (e.g., tethered cord, ectopic ureter, benign prostatic hypertrophy, obstructive sleep apnea)

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Acupuncture has small amounts of supportive data (3)[B].

**ONGOING CARE**

**DIET**
- Limit fluid and caffeine intake 2 hours before sleep.
- Limit dairy products 4 hours before sleep (decrease osmotic diuresis) (5).

**PATIENT EDUCATION**
Web resources for hypnosis scripts, alarms, and supplies
PROGNOSIS
In children, NE is usually self-limiting; 1% will persist as adult; evaluate for organic causes.

COMPLICATIONS
UTI, perineal excoriation, psychological disturbance (especially in children)

REFERENCES

SEE ALSO
- Incontinence, Urinary Adult Female; Incontinence, Urinary Adult Male
- Algorithm: Enuresis, Secondary

CODES
**ICD10**
- N39.44 Nocturnal enuresis
- R32 Unspecified urinary incontinence
- F98.0 Enuresis not due to a substance or known physiol condition

CLINICAL PEARLS
- Initial evaluation is history, exam, and urinalysis.
- For PMNE in children, if the condition is not distressing to child and caretakers, treatment is unnecessary.
- Behavioral and lifestyle interventions are the first-line treatment for PMNE, alarms, and desmopressin are the most effective treatments.
- Dryness is possible for most children.
BASICS

DESCRIPTION

- Tendinopathy of the elbow characterized by pain and tenderness at the origins of the wrist flexors/extensors at the humeral epicondyles
- May be acute (traumatic) or chronic (overuse)
- Two types
  - Medial epicondylitis ("golfer’s elbow")
    - Involves the wrist flexors and pronators, which originate at the medial epicondyle
  - Lateral epicondylitis ("tennis elbow")
    - Involves the wrist extensors and supinators, which originate at the lateral epicondyle
- May be caused by many different athletic or occupational activities
- Common in carpenters, plumbers, gardeners, and athletes
- Usually involves the dominant arm
- Lateral epicondylitis is more common.

EPIDEMILOGY

- Predominant age: >40 years
- Predominant sex: male = female

Incidence

- Common overuse injury
- Lateral > medial
- Estimated between 1% and 3%

Prevalence

- Lateral epicondylitis: 1.3%
- Medial epicondylitis: 0.4%

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute (tendonitis)
– Inflammatory response to injury

● Chronic (tendinosis)
  – Overuse injury
  – Tendon degeneration, fibroblast proliferation, microvascular proliferation, lack of inflammatory response

● Repetitive wrist flexion or extension places strain across enthesis of flexor/extensor group.

● Tool/racquet gripping

● Shaking hands

● Sudden maximal muscle contraction

● Direct blow

**RISK FACTORS**

● Repetitive wrist motions
  – Flexion/pronation: medial
  – Extension/supination: lateral

● Smoking

● Obesity

● Upper extremity forceful activities

**GENERAL PREVENTION**

● Limit overuse of the wrist flexors, extensors, pronators, and supinators.

● Use proper techniques when working with hand tools or playing racquet sports.

● Use lighter tools and smaller grips.

**DIAGNOSIS**

**HISTORY**

● Pain typically localized to lateral or medial elbow

● Occupational activities

● Sports participation

● Direct trauma

● Duration and location of symptoms

● Prior treatments or medication use

● Pain with gripping

● Sensation of mild forearm weakness
PHYSICAL EXAM
- Localized pain just distal to the affected epicondyle
- Increased pain with wrist flexion/pronation (medial)
- Increased pain with wrist extension/supination (lateral)
- Medial epicondylitis
  - Tenderness at origin of wrist flexor tendons
  - Increased pain with resisted wrist flexion and pronation
  - Normal elbow range of motion
  - Increased pain with gripping
- Lateral epicondylitis
  - Tenderness at origin of wrist extensors
  - Increased pain with resisted wrist extension/supination
  - Normal elbow range of motion
  - Increased pain with gripping

DIFFERENTIAL DIAGNOSIS
- Elbow osteoarthritis
- Epicondylar fractures
- Posterior interosseous nerve entrapment (lateral)
- Ulnar neuropathy (medial)
- Synovitis
- Medial collateral ligament injury
- Referred pain from shoulder or neck

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
No imaging is required for initial evaluation and treatment of a classic overuse injury.

Follow-Up Tests & Special Considerations
- Anterior-posterior/lateral radiographs if decreased range of motion, trauma, or no improvement with initial conservative therapy. Assess for fractures or signs of arthritis.
- For recalcitrant cases
  - Musculoskeletal ultrasound (US) reveals abnormal tendon appearance (e.g., tendon thickening, partial tear at tendon origin, calcifications). US can also guide injections of steroid and/or anesthetic.
MRI can show intermediate or high T2 signal intensity within the common flexor or extensor tendon or the presence of peritendinous soft tissue edema.

**Diagnostic Procedures/Other**
Infiltration of local anesthetic with subsequent resolution of symptoms supports the diagnosis if clinically in doubt.

**TREATMENT**

**GENERAL MEASURES**
Initial treatment consists of activity modification, counterforce bracing, oral or topical NSAIDs, ice, and physical therapy:

- **Observation:** If left untreated, symptoms typically last between 6 months and 2 years. For patients with good function and minimal pain, consider conservative management using a “wait and see” approach based on patient preference.
- **Modify activity,** encourage relative rest, and correct faulty biomechanics.
- **Counterforce bracing with a forearm strap** is easy and inexpensive. Systematic reviews are inconclusive about overall efficacy, but initial bracing may improve the ability to perform daily activities in the first 6 weeks.
- **Consider nighttime wrist splinting** for repetitive daily activities if counterforce bracing fails.
- **Ice frequently after activities**
- **Physical therapy**
  - **Begin once acute pain is resolved.** Infiltration of local anesthetic can reduce pain and allow for physical therapy.
  - **Eccentric strength training and stretching program**
  - **US therapy**
  - **Corticosteroid iontophoresis**
  - **Dry needling**

**MEDICATION**

**First Line**
- **Topical NSAIDs:** Low-quality evidence suggests topical NSAIDs are significantly more effective than placebo with respect to pain and number
needed to treat to benefit (NNT = 7) in the short term (up to 4 weeks) with minimal adverse effects (1)[A].

- Oral NSAIDs: Unclear efficacy with respect to pain and function, but may offer short-term pain relief; associated with adverse GI effects (1)[A]

**Second Line**
- Corticosteroid injections: Short-term (≤8 weeks) reduction in pain. No benefits found for intermediate or long-term outcomes (2)[A].

**ISSUES FOR REFERRAL**

Failure of conservative therapy

**ADDITIONAL THERAPIES**
- Platelet-rich plasma (PRP) injections
  - Injection of concentrated autologous PRP leads to a local inflammatory response. Platelets degranulate, release growth factors, and stimulate the physiologic healing cascade.
  - PRP treatment of chronic lateral epicondylitis significantly reduces pain and increases function. The benefit exceeds that of corticosteroid injection even after a follow-up of 1 year (3)[A].
- Autologous blood injections
  - Stimulates the inflammatory cascade within the degenerated tendon by providing cellular and humoral mediators for regeneration
- US-guided percutaneous needle tenotomy
  - Injection of a local anesthetic followed by US-guided tendon fenestration, aspiration, and abrasion the underlying bone; thought to break apart scar tissue and stimulate inflammation and healing
- Prolotherapy
  - Injection of a dextrose solution into and around the tendon attachment stimulates a localized inflammatory response, leading to increased blood flow to stimulate healing.
- Glyceryl trinitrate (GTN) transdermal patch
  - Nitric oxide (NO) is a small free radical generated by NO synthases. NO is expressed by fibroblasts and is postulated to aid in collagen synthesis. Topical application of GTN theoretically improves healing by this mechanism. 1/4 of a 5-mg/24-hr GTN transdermal patch is applied once daily for up to 24 weeks.
  - Significant decreases in pain are seen at 3 weeks and 6 months compared to
Botulinum toxin A for chronic lateral epicondylitis
– Injections into the forearm extensor muscles (60 units) can be performed in the outpatient setting.

SURGERY/OTHER PROCEDURES
– Elbow surgery may be indicated in refractory cases:
  – Involves débridement and tendon release
  – Can be performed open or arthroscopically
  – Improvements in VAS, DASH scores, and grip strength seen in 5-year study (4)[B]
– Denervation of the lateral humeral epicondyle
  – Transection of the posterior cutaneous nerve of the forearm with implantation into the triceps may help with chronic symptoms and pain.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture: effective for short-term pain relief for lateral epicondyle pain

ONGOING CARE

PROGNOSIS
Good: majority resolve with conservative care

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Pain in Upper Extremity

**CODES**

**ICD10**

- M77.00 Medial epicondylitis, unspecified elbow
- M77.10 Lateral epicondylitis, unspecified elbow
- M77.01 Medial epicondylitis, right elbow

**CLINICAL PEARLS**

- Medial epicondylitis (golfer’s elbow) is characterized by pain and tenderness
at the tendinous origins of the wrist flexors at the medial epicondyle.

- Lateral epicondylitis (tennis elbow) is characterized by pain and tenderness at the tendinous origins of the wrist extensors at the lateral epicondyle.
- Left untreated, symptoms typically last between 6 months and 2 years
- Most patients improve using conservative treatment with bracing, activity modification, and physical therapy.
EPIDIDYMITIS

David B. McCabe, MD • Holly L. Baab, MD

BASICS

- Acute epididymitis: scrotal pain for <6 weeks
- Chronic epididymitis: scrotal pain for ≥3 months

DESCRIPTION

- Inflammation (infectious or noninfectious) of epididymis resulting in scrotal pain and swelling, induration of the posterior epididymis, eventual scrotal wall edema, involvement of the adjacent testicle, and hydrocele formation
- Epididymitis with involvement of testis is named epididymo-orchitis.
- Classification: infectious (bacterial, viral, fungal, parasitic) versus noninfectious (chemical, traumatic, autoimmune, idiopathic, industrial, noninfectious, vasoepididymal reflux syndrome, vasal reflux syndrome); chronic versus acute
- System(s) affected: reproductive

EPIDEMIOLOGY

- Predominant age: usually younger, sexually active men or older men with UTIs; in older men, commonly secondary to bladder outlet obstruction
- Predominant sex: male only

Pediatric Considerations

In prepubertal boys: Epididymitis is found to be the most common cause of acute scrotum—more common than testicular torsion.

Incidence

- Common (600,000 cases annually in the United States) (1)
- 1 in 1,000 adult males per year
- 1.2 in 1,000 boys age 2 to 13 years per year (2)

Prevalence

Common
ETIOLOGY AND PATHOPHYSIOLOGY

- Infectious epididymitis
  - Retrograde passage of urine or urinary bacteria from the prostate or urethra to the epididymis via the ejaculatory ducts and the vas deferens, rarely, hematogenous spread
  - Causative organism is identified in 80% of patients and varies according to patient age.
- Noninfectious epididymitis
  - Often no etiology is found; however, can be instigated by trauma, autoimmune disease, or vasculitis
  - Thought to likely be secondary to reflux of sterile urine causing a chemical inflammation rather than infectious
  - Can develop as a sequelae of strenuous exercise with a full bladder when urine is pushed through internal urethral sphincter (located at proximal end of prostatic urethra) or prolonged periods of sitting
  - Reflux of urine through orifice of ejaculatory ducts at verumontanum may occur with history of urethritis/prostatitis, as inflammation may produce rigidity in musculature surrounding orifice to ejaculatory ducts, holding them open.
  - Exposure of epididymis to foreign fluid may produce inflammatory reaction within 24 hours.
- <14 years of age
  - Cause largely unknown although likely anatomic abnormalities resulting in urine reflux such as vesicoureteral reflux, ectopic ureter, or anorectal malformation (recto-urethral fistula)
  - May also be part of postinfectious syndrome from *Mycoplasma pneumoniae*, enterovirus, or adenovirus
  - Henoch-Schönlein purpura may present as acute scrotum.
- 14 to 35 years of age
  - Usually *Chlamydia trachomatis* (serous urethral discharge) or *Neisseria gonorrhoeae* (purulent discharge) in sexually active males
  - With anal intercourse, likely *Escherichia coli* or *Haemophilus influenza*
- >35 years
  - Commonly enteric bacteria but occasionally *Staphylococcus aureus* or *Staphylococcus epidermidis*
  - In elderly men, often with distal urinary tract obstruction, benign prostatic hyperplasia (BPH), UTI, or catheterization
  - Tuberculosis (TB), if sterile pyuria, nodularity of vas deferens
(hematogenous spread), and recent infection. TB is the most common granulomatous disease affecting the epididymitis (3).

- Sterile urine reflux after transurethral prostatectomy
- Granulomatous reaction following BCG intravesical therapy for bladder cancer

- Amiodarone may cause noninfectious epididymitis; resolves with decreasing drug dosage
- Syphilis, blastomycosis, coccidioidomycosis, and cryptococcosis are rare causes, but brucellosis can be a common cause in endemic areas.

**RISK FACTORS**

- UTI
- Prostatitis
- Indwelling urethral catheter
- Urethral instrumentation or transurethral surgery
- Urethral or meatal stricture
- Transrectal prostate biopsy
- Prostate brachytherapy (seeds) for prostate cancer
- Anal intercourse
- High-risk sexual activity
- Strenuous physical activity
- Prolonged sedentary periods
- Bladder obstruction (BPH, prostate cancer)
- HIV-immunosuppressed patient
- Severe Behçet disease
- Presence of foreskin
- Constipation
- Noninfectious epididymitis
  - Increased intra-abdominal pressure (due to frequent physical strain)
    - Military recruits, especially who begin physically unprepared
    - Laborers; restaurant kitchen workers
    - Full bladder during intense physical exertion

**GENERAL PREVENTION**

- Safer sexual practices
- Mumps vaccination
- Antibiotic prophylaxis for urethral manipulation
- Early treatment of prostatitis/BPH
- Vasectomy or vasoligation during transurethral surgery
Avoid vigorous rectal exam with acute prostatitis.
Emptying the bladder prior to physical exertion
Physically conditioning the body prior to engaging in regular intense physical exertion
Treat constipation.

COMMONLY ASSOCIATED CONDITIONS
- Prostatitis/urethritis/orchitis
- Hemospermia
- Constipation
- UTI

DIAGNOSIS

HISTORY
- Gradual onset of scrotal pain, sometimes radiating to the groin region over 1 to 2 days
- Urethral discharge or symptoms of UTI, such as frequency of urination, dysuria, cloudy urine, or hematuria
- Progresses posterior-lying epididymis—body/head of epididymis
- Entire hemiscrotum becoming swollen and red; the testis becomes indistinguishable from the epididymis; the scrotal wall becomes thick and indurated; and reactive hydrocele may occur.
- Noninfectious epididymitis
  - Unilateral scrotal pain and swelling preceded by several hours of intense physical exertion. Patient may recall full bladder prior to exertion.
  - No symptoms of infection

Pediatric Considerations
- Bacteremia from *H. influenzae* infection may produce acute epididymitis.
- In adolescent males, particularly age >13 years, must rule out testicular torsion.
- History not helpful in distinguishing epididymitis from testicular torsion

Geriatric Considerations
Diabetics with sensory neuropathy may have no pain despite severe infection/abscess.
PHYSICAL EXAM

- Epididymis is markedly tender to palpation.
- The tail of the epididymis is larger in comparison with the contralateral side.
- Elevation of the testes/epididymis reduces the discomfort (Prehn sign).
- Absence of a cremasteric reflex should raise suspicion for testicular torsion.

DIFFERENTIAL DIAGNOSIS

- Testicular torsion
- Torsion of testicular appendages
- Urethritis/orchitis
- Testicular trauma
- Epididymal congestion following vasectomy
- Testicular malignancy
- Epididymal cyst
- Inguinal hernia
- Spermatocoele
- Hydrocele
- Hematocele
- Varicocele
- Epididymal adenomatoid tumor
- Epididymal rhabdomyosarcoma
- Vasculitis (Henoch-Schönlein purpura)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- All suspected cases should be evaluated for objective evidence of inflammation by one of the following:
  - Urinalysis/urine culture preferably on first-void urine to evaluate for positive leukocyte esterase and bacteriuria
  - Urine culture/Gram stain urethral discharge; ≥2 WBC per oil immersion field; evaluate for gonococcal infection.
  - Microscopic examination of sediment from a spun first-void urine with ≥10 WBC per high power field
- Urine GC/chlamydia testing by NAAT for all suspected cases (3)[A]
- CRP >24 mg/L suggestive of epididymitis (4)[C]
- Urinalysis clear and culture-negative suggest noninfectious epididymitis.
- If testicular torsion/mass cannot be excluded (especially in children), Doppler ultrasound is test of choice (2).
In adult men, Doppler ultrasound: sensitivity and specificity of 100% in evaluation of acute scrotum (5)

**Pediatric Considerations**
Further radiographic imaging in children should be done to rule out anatomic abnormalities.

**Diagnostic Procedures/Other**
This is a clinical diagnosis.

## TREATMENT

### GENERAL MEASURES
- Bed rest or restriction on activity
- Scrotal elevation, athletic scrotal supporter
- Ice pack wrapped in towel
- Avoid constipation.
- Spermatic cord block with local anesthesia in severe cases
- If noninfectious epididymitis
  - No strenuous physical activity and avoidance of any Valsalva maneuvers for several weeks
  - Empty bladder prior to strenuous exercises.

### MEDICATION

**First Line**
- Sexually active adults <35 years: doxycycline 100 mg PO BID for 10 days (C. trachomatis coverage) PLUS ceftriaxone 250 mg IM × 1 (N. gonorrhoeae coverage) (2)[C],(3)[A]
- ≥35 years, not suspecting STD etiology with suspected enteric organism (i.e., bacteriuria due to bladder outlet obstruction, prostate biopsy, urinary instrumentation, systemic disease, and/or immunosuppression)
  - Levofloxacin 500 mg/day PO for 10 days OR
  - Ofloxacin 300 mg PO BID for 10 days (2)[C],(3)[A]
  - Note: 2016 FDA Black Box warning on fluoroquinolones due to disabling and potentially permanent side effects. Consider trimethoprim sulfamethoxazole for milder infections.
Men who practice insertive anal intercourse: ceftriaxone 250 mg IM × 1 plus fluoroquinolone as above (2)[C],(3)[A]

Analgesia:
– NSAIDs (e.g., naproxen or ibuprofen) for mild to moderate pain
– Consider corticosteroid if patient cannot tolerate NSAID.
– Acetaminophen-codeine or acetaminophen-oxycodone for moderate to severe pain

Septic or toxic patient
– 3rd-generation cephalosporin or aminoglycoside

For Behçet, sarcoid, Henoch-Schönlein purpura
– Corticosteroids, such as methylprednisolone, 40 mg/day recommended

Chronic epididymitis: 2-week course of NSAIDs, scrotal icing/elevation. If no improvement, may add TCA or neuroleptic (2).

Second Line
– Trimethoprim-sulfamethoxazole (Bactrim, Septra) double-strength PO BID for 10 to 14 days; increasing bacterial resistance may limit effectiveness.
– Add rifampin (rifampicin) or vancomycin, as required.

Pediatric Considerations
– May be postinfectious inflammatory condition; treat with anti-inflammatories, analgesics.
– Antibiotic therapy can be reserved for young infants until positive urine cultures (2).

ISSUES FOR REFERRAL
– If suspicion is high for testicular torsion, then urgent referral to urologist for possible surgery (1)[C]
– Epididymitis in ages <14 years requires a urology referral due to high incidence of associated urogenital abnormalities.
– If medical management fails, should be referred to urologist to rule out anatomic abnormality or chemical epididymitis

SURGERY/OTHER PROCEDURES
– Vasostomy to drain infected material if severe or refractory case
– Scrotal exploration if unable clinically to distinguish between epididymitis and testicular torsion
– Drainage of abscesses, epididymectomy (acute suppurative), or epididymo-
orchietectomy in severe cases refractory to antibiotics
- Surgery to correct underlying anatomic abnormality or obstruction

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Intractable pain
- Sepsis
- Abscess
- Persistent vomiting
- Scheduled surgery
- Purulent drainage
- Most cases can be managed with outpatient care.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Routine follow-up in 1 week. Follow up within 72 hours if symptoms fail to improve with treatment for reevaluation of diagnosis and therapy (3)[A].
- Swelling and tenderness after antibiotic course should be evaluated for abscess, tumor, infarction, cancer, TB, and fungal epididymitis (3)[A].
- In noninfectious epididymitis, follow up in 4 weeks to assess efficacy of NSAIDs and lifestyle changes.

**DIET**
If constipation is contributing to pain or chemical epididymitis, then consider constipation prevention (high-fiber diet) and/or treatment.

**PATIENT EDUCATION**
- Stress completing course of antibiotics, even when asymptomatic.
- Early recognition and treatment of UTI or prostatitis
- Safer sexual practices
- If treated for STI, refer sexual partners for evaluation of *N. gonorrhoeae* or *C. trachomatis* if sexual contact within 60 days preceding onset of symptoms or most recent sexual partner if >60 days (3)[A].
- If noninfectious epididymitis, then educate on noninfectious etiology and
proper lifestyle changes.

**PROGNOSIS**
- Pain improves within 1 to 3 days, but induration may take several weeks/months to completely resolve.
- If bilateral involvement, sterility may result.
- In noninfectious epididymitis, symptoms usually resolve in <1 week.

**COMPLICATIONS**
- Recurrent epididymitis
- Infertility
- Oligospermia
- Testicular necrosis or atrophy
- Secondary abscess formation
- Fournier gangrene (necrotizing synergistic infection)

**REFERENCES**

**ADDITIONAL READING**
CODES

ICD10
- N45.1 Epididymitis
- N45.3 Epididymo-orchitis
- N45.4 Abscess of epididymis or testis

CLINICAL PEARLS

- With epididymitis, the pain is gradual in onset, and the tenderness is mostly posterior to the testis. With testicular torsion, the symptoms are quite rapid in onset, the testis will be higher in the scrotum and may have a transverse lie, and the cremasteric reflex will be absent. The absence of leukocytes on urine analysis and decreased blood flow on scrotal ultrasound with Doppler will suggest torsion.
- Prostatic massage is contraindicated in epididymitis because of the risk for worsening local infection. The potential for sepsis is increased with acute prostatitis.
- Noninfectious epididymitis is a clinical diagnosis of exclusion, and infectious causes are much more common but must be considered in certain occupations, such as soldiers and laborers.
Episcleritis

Daniel J. Schlegel, MD, MHA • Tamara K. Oser, MD • Sean M. Oser, MD, MPH

BASICS

- Episcleritis is irritation and inflammation of the episclera, a thin layer of tissue covering the sclera. It is not an infection.
- Episcleritis is the localized inflammation of the vascular connective tissue superficial to the sclera.
- Usually a self-limited condition, typically resolving within 3 weeks
- Most cases resolve without treatment.
- Topical lubricants and/or topical corticosteroid treatment may relieve symptoms while awaiting spontaneous resolution.

DESCRIPTION

- Edema and injection confined to the episcleral tissue
- Two types
  - Simple (diffuse scleral involvement—more common)
  - Nodular (focal area[s] of involvement—less common)

EPIDEMIOLOGY

Slight female predominance (~60–65%)

Incidence

- May occur at any age
- Peak incidence in 40s to 50s
- Community incidence not well-known (~20 to 50 cases/100,000 person-years)

Prevalence

Not historically well-known; a recent community study found a prevalence of 53 cases/100,000 persons.

ETIOLOGY AND PATHOPHYSIOLOGY

- Etiology: usually idiopathic, but other causes may be found (either nonimmune or immune)
Pathophysiology:
- Nonimmune (e.g., dry eye syndrome, with histology showing widespread vasodilation, edema, lymphocytic infiltration)
- Immune (systemic vasculitis or rheumatologic disease)

COMMONLY ASSOCIATED CONDITIONS
- Usually not associated with another condition
- Less commonly associated conditions include the following:
  - Rheumatoid arthritis
  - Vasculitis
  - Inflammatory bowel disease
  - Ankylosing spondylitis
  - Systemic lupus erythematosus
  - Gout
  - Herpes zoster
  - Hypersensitivity disorders
    - Rosacea
    - Contact dermatitis
    - Penicillin sensitivity
    - Erythema multiforme

DIAGNOSIS
Episcleritis is a clinical diagnosis (1,2)[C].

HISTORY
- History should elicit potential causative factors, recurrence, or associated systemic disease (2)[C].
- Pain is often absent; when present, it is usually mild and localized to the eye (1,2)[C].
- Mild tearing may be present (2)[C].

PHYSICAL EXAM
- Check visual acuity; decreased vision is very unusual with episcleritis, and its presence should raise suspicion for another condition such as scleritis (1,2) [C].
- The white sclera will have a pink or purplish hue.
- Focal hyperemia (2,3)[C]
- Pupils equal and reactive (2)[C]
- Superficial episcleral vascular dilation (1,2)[C]
- Episcleral edema (1,2)[C]
  - Diffuse in simple episcleritis
  - Focal in nodular episcleritis
- Tenderness over involved area may be present (2)[C] but is usually absent (3)[C].
- Superficial episcleral vascular hyperemia blanches with topical phenylephrine (1,3)[C].

**ALERT**
Recurrent episodes, difficulty confirming the diagnosis, or worsening symptoms require prompt ophthalmology referral (2)[C].

**DIFFERENTIAL DIAGNOSIS**
- Scleritis
- Bacterial conjunctivitis
- Viral conjunctivitis
- Herpes (ulcerative) keratitis
- Superficial keratitis
- Increased intraocular pressure (ocular hypertension)

**DIAGNOSTIC TESTS & INTERPRETATION**
Most patients with episcleritis do not require any further lab work or diagnostic studies (4)[C].

**TREATMENT**

**MEDICATION**
Treatment for episcleritis typically consists of symptomatic relief. The goal is to suppress the inflammation, which will, in turn, relieve the discomfort or pain. In most cases, treatment is not needed.

**First Line**
Topical lubricants such as artificial tears are typically used for initial management of symptomatic episcleritis (2)[C].
Second Line

- Topical corticosteroids are useful when discomfort is not sufficiently controlled by conservative measures (2,4,5)[C].
  - Flurometholone 0.1% drops 4 times daily; if not effective, may increase frequency
  - Prednisolone 0.5–1% eye drops
- Refractory episcleritis may be treated with oral NSAIDs (4)[C].

ISSUES FOR REFERRAL

Recurrent episodes, uncertain diagnosis, and/or worsening symptoms should prompt ophthalmology referral. Rarely, episcleritis may progress to scleritis in which case ophthalmology referral is also recommended.

ADDITIONAL THERAPIES

- Topical NSAIDs have not been shown to have a significant benefit over artificial tears (6)[B].
- When episcleritis results from viral infection, appropriate antiviral therapy is indicated (5)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Episcleritis is usually self-limited (up to 21 days) and does not typically require follow-up.

PROGNOSIS

- Most patients have no ocular complications.
- Prognosis for episcleritis is excellent, with most patients making a full recovery.

COMPLICATIONS

Associated complications are rare, even at tertiary care referral centers, where referral bias likely overestimates their community incidence. When complications do occur, they tend not to be severe.

- Anterior uveitis may occur in 4–16% of cases (1,5)[C].
- Decreased vision may occur in 0–4% of cases (1,5)[C].
Ocular hypertension has been reported in 0–3.5% of cases (1,5)[C].

REFERENCES

ADDITIONAL READING

CODES

**ICD10**
- H15.109 Unspecified episcleritis, unspecified eye
- H15.129 Nodular episcleritis, unspecified eye
- H15.102 Unspecified episcleritis, left eye

CLINICAL PEARLS

- Episcleritis typically is a benign, self-limited disorder.
- Often not painful and presents without decrease in visual acuity
- Although treatment is often not needed, when employed, the goal is
symptomatic relief while awaiting spontaneous resolution.

- Topical lubricants and/or topical corticosteroid treatment may relieve symptoms.
- Associated complications are uncommon and not severe but may include anterior uveitis, decreased vision, and ocular hypertension.
- Episcleritis can be an early presentation of scleritis, which is more severe. Accurate diagnosis of episcleritis is important.
EPISTAXIS
Rebecca Wetzel, DO • Brian E. Neubauer, MD

BASICS

DESCRIPTION
- Hemorrhage from the nose involving either the anterior or posterior mucosal surfaces
- Intractable or refractory epistaxis: recurrent or persistent despite appropriate packing or multiple episodes during a short period, each requiring medical attention
- Synonym(s): nosebleed

EPIDEMIOLOGY

Incidence
- Very common in the United States
- Estimated lifetime prevalence: ~60%
- Bimodal, with peaks in children up to 15 years and in adults >50 years, particularly ages 70 to 79 years
- Most common in males <49 years
- Rare in children age <2 years
- ~6% of patients require medical or surgical intervention; accounts for ~1 in 200 ER visits

ETIOLOGY AND PATHOPHYSIOLOGY
- Local versus systemic disease. Most nosebleeds are due to local causes.
- Anterior: 90–95% of all cases (Kiesselbach plexus)
- Posterior: 5–10% of cases (Woodruff plexus); usually branches of sphenopalatine arteries: may be asymptomatic or may present with other symptoms (hematemesis, hemoptysis)
- Idiopathic
- Local inflammation/irritation
  - Infection (viral URI, sinusitis, TB, syphilis)
  - Irritant inhalation (smoking, rhinitis)
  - Topical steroid or antihistamine use
  - Septal deviation (more air movement on one side)
– Low humidity, nasal oxygen use, CPAP
– Tumors: benign, malignant
– Vascular malformations

- Trauma
  – Epistaxis digitorum (nose picking)
  – Foreign bodies
  – Septal perforation
  – Nasal fracture
  – Nasal surgery

- Systemic
  – Thrombocytopenia
  – Congenital or acquired coagulopathies
  – Liver or renal disease
  – Chronic alcohol abuse
  – Leukemia
  – Anticoagulant drug use
  – CHF
  – Hereditary hemorrhagic telangiectasia (HHT)
  – Collagen abnormalities
  – Mitral valve stenosis
  – Multiple myeloma
  – Polycythemia vera
  – HIV

**RISK FACTORS**

- Local irritation from multiple causes
- Medications/supplements including aspirin, clopidogrel, ginseng, garlic, ginkgo biloba, sildenafil, warfarin, and other anticoagulant
- Prior septoplasty/turbinate procedures, anemia, and thrombocytopenia are risk factors for recurrent epistaxis.

**GENERAL PREVENTION**

- Humidification at night
- Cut fingernails and minimize picking.
- For topical-nasal medication users, direct spray laterally away from septum. Use opposite hand to spray (i.e., right hand to spray in left nostril).
- Petroleum jelly to prevent anterior mucosal drying
- Control hypertension (HTN) (controversial association with increased risk for recurrent epistaxis).
COMMONLY ASSOCIATED CONDITIONS

- Vascular malformation/telangiectasia (HHT)
- Neoplasm (rare; consider if persistent and unilateral)
- Systemic
  - Coagulopathy: primary or iatrogenic
  - Thrombocytopenia
  - Cirrhosis
  - Renal failure
  - Alcoholism
- No proven association with HTN but may make control of bleeding more difficult

DIAGNOSIS

HISTORY

- Assess airway patency and cardiovascular stability.
- Determine on which side bleeding began, anterior or posterior, duration.
- Define trauma (including nose picking) or other precipitating events.
- Previous episodes
- Comorbid conditions (cardiovascular compromise symptoms)
- Current medications including over-the-counter and supplements
- Nausea, hematemesis, or hemoptysis may indicate a posterior and more severe bleed.

PHYSICAL EXAM

- Blood loss through one or both nostrils in most cases is due to anterior nasal septal bleeding and can often be directly visualized.
- Focus on localizing site of bleeding to anterior versus posterior nasal cavity.
- Patient is seated, head forward, to avoid blood going down the posterior pharynx.
- Use of nasal speculum improves visualization.

DIFFERENTIAL DIAGNOSIS

- Diagnosis usually apparent; the differential for the etiology is key.
- Posterior bleeding must be included in the differential for any chronic blood loss.
DIAGNOSTIC TESTS & INTERPRETATION
Lab testing is not indicated in most uncomplicated cases in which bleeding is easily controlled.

Initial Tests (lab, imaging)
- Mild cases, responsive to pressure: no labs
- For recurrent or intractable cases
  - CBC, PT/PTT, BMP
- PT/PTT if on warfarin or other medications affecting coagulation
- Cross-match when appropriate.
- Toxicology screen when nasal use of illicit drugs is suspected
- For most cases, imaging is not indicated.

Follow-Up Tests & Special Considerations
Consider neoplasm if recurrent unilateral epistaxis, especially if not responding to treatment.

Diagnostic Procedures/Other
Nasal endoscopy

Pediatric Considerations
More likely anterior, idiopathic, and recurrent

Geriatric Considerations
More likely to be posterior bleed

TREATMENT
- Most cases are managed as outpatient (1)[B].
- Home use—Nosebleed QR: a nonprescription powder of hydrophilic polymer with potassium salt; induces scab formation
- Patient applies direct pressure by pinching the lower part of the nose (nasal ala) for 5 to 20 minutes without a break. This stops bleeding in most patients.
- Cleanse nasal cavity of blood clots by blowing nose.
- An ice pack placed over the dorsum of the nose may help with hemostasis.
- Inspect the nasal septum for the bleeding site.
GENERAL MEASURES
Resuscitation, as indicated. Use universal “airway/breathing/circulation (ABC)” approach.

MEDICATION

First Line
If general measures fail, affected naris may be sprayed with topical vasoconstrictor, such as:
- Phenylephrine: 0.5–1%
- Oxymetazoline: 0.05%
- Epinephrine: 1:1,000
- Cocaine: 4%

Second Line
- Chemical (silver nitrate) or electrical cautery
- Nasal packing: ribbon gauze, nasal tampons, nasal balloon catheter
- For intractable/refractory: Consider surgical ligation, endoscopic ligation/cautery, endovascular embolization.

ISSUES FOR REFERRAL
- Posterior bleeding frequently requires an otolaryngology consultation.
- Anterior bleeding that fails conservative measures, packing, and cauteryization
- Recurrent episodes
- HHT patients should establish care with ENT.
- Concurrent anticoagulation
  - If bleeding stops with packing, may continue same dose of warfarin if INR therapeutic; decrease dose if supratherapeutic INR.
  - If bleeding persists despite packing, stop anticoagulation and administer vitamin K 10 mg IV ×1, recheck INR in 30 minutes, if still >1.5, give PCC.
  - Novel anticoagulation may be associated with lower rates of epistaxis than warfarin. When epistaxis occurs, it may be harder to control.

ADDITIONAL THERAPIES
- Nasal packing: either with ribbon gauze or preformed nasal tampons.
  Systemic prophylactic antibiotics are unnecessary in the majority of patients with nasal packs; topical antibiotics may be as effective and cheaper (2)[B].
- FloSeal: A biodegradable hemostatic sealant (a thrombin-type gel) in one
study is more effective and better tolerated than packing (3) [B].

- Local application of tranexamic acid may reduce bleeding time as compared to anterior packing (4).
- If an actively bleeding anterior septal site is visualized, this may be treated with gentle silver nitrate cautery for ~10 seconds for definitive treatment. 75% silver nitrate is preferred. Apply in a spiral fashion, starting around the bleeding vessel, moving inward.
- Limit cautery (silver nitrate) to one side of septum, or wait 4 to 6 weeks in between treatments to reduce risk of perforation.
- Posterior: Posterior packing or tamponade with balloon devices (Foley catheter has been used). Inpatient monitoring is generally required.
- Recurrent epistaxis: Cochrane review in children shows no difference in effectiveness between antiseptic nasal cream, petroleum jelly, silver nitrate cautery, or no treatment.
  - Silver nitrate cautery followed by 4 weeks of antiseptic cream may be better than antiseptic cream alone (5).

SURGERY/OTHER PROCEDURES

- Packing
  - Layering of Vaseline ribbon gauze (1/2 inch)
    - For gauze packing, be certain that both ends of the ribbon gauze protrude from the nostril.
    - Packing is layered from the floor upward.
    - Secure packing with gauze across the outside of the nostril.
  - Nasal tampon may be used after lubricating the tip with KY Jelly or antibiotic cream or ointment.
  - Additional saline may be needed to expand the tampon if the bleeding has slowed.
  - Merocel and Rapid Rhino packs are easier to use than gauze packing and are usually well tolerated.
- Posterior bleed
  - In the emergent setting, this may be attempted utilizing a Foley catheter or a specific posterior packing balloon.
  - With both methods, the tubing is introduced through the nose similar to the passage of a nasogastric tube. Once it reaches the posterior oral pharynx, the balloon is inflated and the tubing is pulled back outward to tamponade the posterior bleeding source.
    - If using a Foley catheter (10 to 14F catheter), the balloon can be inflated with 10 mL of saline.
Traction is maintained with an umbilical cord clamp with adequate padding between the clip and the nose to avoid injury.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Consider hospitalization for elderly or for patients with posterior bleeding or coagulopathy; may also consider if significant comorbidities
- Admission criteria/initial stabilization
  - Posterior bleed
  - Hemodynamic changes
  - Clotting dysfunction
  - Universal ABC approach. Stop blood loss.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Hemodynamic monitoring if severe blood loss
- 24-Hour minimum for leaving packing in place; some recommend 3 to 5 days. Rebleed usually occurs between 24 and 48 hours. Longer durations of packing have increased risk of mucosal injury and toxic shock syndrome.

PATIENT EDUCATION

- Demonstrate proper pinching pressure techniques.
- Avoidance of trauma or irritants is key.
- Management of systemic illness and proper use of medication

PROGNOSIS

- Most are self-limited.
- Good results with proper treatment

COMPLICATIONS

- Septal perforation
- Pressure-induced tissue necrosis of the nasal mucosa
- Toxic shock syndrome with packing
- Arrhythmias triggered by packing (particularly posterior)
REFERENCES

ADDITIONAL READING

CODES

**ICD10**

R04.0 Epistaxis

CLINICAL PEARLS

- Most epistaxis is anterior and responds well to timed pressure over the anterior nares for 5 to 20 minutes.
- Most nosebleeds are idiopathic or as a result of nose picking.
- Posterior nosebleeds can be asymptomatic or present with nausea, hematemesis, or heme-positive stool.
- Consider evaluation for neoplasm in cases of recurrent unilateral epistaxis.
**ERECTILE DYSFUNCTION**

*James G. Nee, MD, FAAFP*

---

**BASICS**

**DESCRIPTION**

- Erectile dysfunction (ED): the consistent or recurrent inability to acquire or sustain an erection of sufficient rigidity and duration for sexual intercourse.
- In the past, ED was assumed to be a symptom of the aging process in men, but it is more often the result of concurrent medical conditions of the patient or from medications that patients may be taking to treat those conditions.
- Sexual problems are frequent among older men and have a detrimental effect on their quality of life but are infrequently discussed with their physicians.
- Synonym(s): impotence

---

**EPIDEMIOLOGY**

**Incidence**

It is estimated that >600,000 new cases of ED will be diagnosed annually in the United States, although this may be an underestimation of the true incidence, as ED is vastly underreported.

**Prevalence**

Overall prevalence for some degree of ED:

- 52% in men age 40 to 70 years
- Age-related increase ranging from 12.4% in men age 40 to 49 years up to 46.6% in men age 50 to 69 years

---

**ETIOLOGY AND PATHOPHYSIOLOGY**

- ED is a neurovascular event.
  - With stimulation, there is release of nitrous oxide, which increases production of cyclic guanosine 3’,5’-monophosphate (cGMP).
  - This leads to relaxation of cavernous smooth muscle, leading to increased blood flow to penis.
  - As cavernosal sinuses distend with blood, there is passive compression of subtunical veins, which decreases venous outflow, and this leads to an
erection.

- Alterations in any of these events lead to ED.
- ED may result from problems with systems required for normal penile erection.
  - Vascular: diseases that compromise blood flow
    - Peripheral vascular disease, arteriosclerosis, essential hypertension
  - Neurologic: diseases that impair nerve conduction to brain or penile vasculature
    - Spinal cord injury, stroke, diabetes
  - Endocrine: diseases associated with changes in testosterone, luteinizing hormone, prolactin levels
  - Structural: phimosis, lichen sclerosis, congenital curvature
  - Psychological: patients suffering from malaise, depression, performance anxiety
- Social habits such as smoking or excessive alcohol intake
- Medications may cause ED.
- Prostate cancer treatment
- Structural injury or trauma (bicycling accident)

**Genetics**

Rarely related to chromosomal disorders

**RISK FACTORS**

- Advancing age
- Cardiovascular disease
- Diabetes mellitus
- Metabolic syndrome
- Sedentary lifestyle
- Cigarette smoking
- Urologic surgery, radiation, trauma/injury to pelvic area or spinal cord
- Medications that induce ED
- SSRIs, β-blockers, clonidine, digoxin, spironolactone, antiandrogens, corticosteroids, H₂ blockers, anticonvulsants
- Central neurologic and endocrinologic conditions
- Substance abuse (alcohol, cocaine, opioids, marijuana)
- Psychological conditions: stress, anxiety, or depression, sexual abuse, relationship problems
GENERAL PREVENTION
The two best ways to prevent ED are by the following:
- Making healthy lifestyle choices by exercising regularly, eating well-balanced meals, limiting alcohol, and avoiding smoking
- Treating existing health problems and working with your patients to manage diabetes, heart disease, and other chronic problems

ALERT
Aging alone is not a cause.

COMMONLY ASSOCIATED CONDITIONS
- Cardiovascular disease:
  - Men with ED have a greater likelihood of having angina, myocardial infarction, stroke, transient ischemic attack, congestive heart failure, or cardiac arrhythmia compared to men without ED (1).
- Diabetes
- Neurologic conditions
- Metabolic syndrome
- Psychiatric disorders

DIAGNOSIS
Inability to achieve or maintain erection satisfactory for intercourse

HISTORY
- Identify concurrent medical illnesses or surgical procedures, history of trauma, and a list of current medications (e.g., antihypertensive meds).
- Psychosocial history: smoking, ethanol intake, recreational drug use, anxiety and depression, satisfaction with current relationship
- Presence or absence of morning erections
- Speed of onset and duration of symptoms
- Relationship of symptoms to libido
- Detailed sexual history important to rule out premature ejaculation, as this is frequently confused with ED
- Five-question International Index of Erectile Function (IIEF-5) is useful in rapid clinical assessment and measurement of effectiveness of ED treatments (1).
PHYSICAL EXAM
- Signs and symptoms of hypogonadism: gynecomastia, small testicles, decreased body hair
- Penile plaques (Peyronie disease)
- Detailed examination of the cardiovascular, neurologic, and genitourinary systems
  - Blood pressure, waist circumference, BMI
  - Check femoral and lower extremity pulses to assess vascular supply to genitals.
  - Check anal sphincter tone and genital reflexes, including cremasterics and bulbocavernosus.

DIFFERENTIAL DIAGNOSIS
- Premature ejaculation
- Decreased libido
- Anorgasmia
- Sudden versus chronic ED

DIAGNOSTIC TESTS & INTERPRETATION
Vascular and/or neurologic assessment and monitoring of nocturnal erections may be indicated in selected patients but not for routine workup (2)[C].

Initial Tests (lab, imaging)
- Depending on history, Hgb A1c, lipid panel, TSH, and morning total testosterone level (1)[C]
- Doppler, angiogram, and cavernosogram are available radiologic modalities but not recommended in routine practice for the diagnosis of ED (2)[C].

Follow-Up Tests & Special Considerations
Other hormonal tests, such as prolactin, should only be ordered when there is suspicion for a specific endocrinopathy.

Diagnostic Procedures/Other
Questionnaires can be offered to assess the severity of ED, including the International Index of Erectile Function (IEFF) and its validated and more easily administered abridged version, the Sexual Health Inventory for Men (SHIM) (2)[C].
**TREATMENT**

- Lifestyle modifications and managing medications contributing to ED is first-line therapy for ED (3)[C]. Use least invasive therapy first; reserve more invasive therapies for nonresponders.
- Cardiovascular risk stratification and risk-factor management is recommended in all men with vasculogenic ED (4).
- Current smoking is significantly associated with ED, and smoking cessation has a beneficial effect on the restoration of erectile function (1)[A].
- Phosphodiesterase type 5 (PDE-5) inhibitors are the first-line treatment for ED (1)[A].

**GENERAL MEASURES**

- Psychotherapy alone or in combination with psychoactive drugs may be helpful in men whose ED is related to depression or anxiety.
- Weight loss and increased physical activity for obese men with ED. Men with metabolic syndrome should be counseled to make lifestyle modifications to reduce the risk of cardiovascular events and ED (1)[B].

**MEDICATION**

**First Line**

PDE-5 inhibitors are effective in the treatment of ED in many men, including those with diabetes mellitus and spinal cord injury and sexual dysfunction associated with antidepressants (5). Choice should be based on patient’s preference (cost, ease of use, and adverse effects). There is insufficient evidence to support the superiority of one agent over the others (3)[A]:

- Sildenafil (Viagra): usual daily dose: 50 to 100 mg within at least 60 minutes of sexual intercourse
- Vardenafil (Levitra): usual daily dose 5 to 20 mg within at least 60 minutes of sexual intercourse
- Vardenafil (Staxyn): ODT: usual dose 10 mg within 60 minutes of sexual intercourse
- Tadalafil (Cialis): usual daily dose 5 to 20 mg within at least 30 minutes of sexual intercourse or 2.5 mg once daily without regard to sexual activity
- Avanafil (Stendra): usual daily dose: 50 to 200 mg within at least 15 to 30 minutes of sexual intercourse
  - Adverse effects of PDE-5 inhibitors: headache, facial flushing, dyspepsia,
nasal congestion, dizziness, hypotension, increased sensitivity to light (sildenafil and vardenafil), vision changes, lower back pain (tadalafil), and priapism (with excessive doses)

– Sildenafil and vardenafil should be taken on an empty stomach for maximum effectiveness.

**Geriatric Considerations**

Use doses at the lower end of the dosing range for elderly patients and evaluate exercise tolerance before prescribing.

- Sildenafil 25 mg daily
- Vardenafil 5 mg daily

**Second Line**

Intraurethral and intracavernosal injectables are second-line therapies shown to be effective and should be administered based on patient preference (1)[B]. Intracavernosal suppositories are a less invasive treatment option than intracavernosal injections; however, they are not as effective (3)[C]. Alprostadil, also known as prostaglandin E1, causes smooth muscle relaxation of the arterial blood vessels and sinusoidal tissues in the corpora:

- Intraurethral alprostadil (Muse):
  - Urethral suppository: 125-, 250-, 500-, and 1,000-μg pellets. Administer 5 to 50 minutes before intercourse. No >2 doses in 24 hours are recommended.
- Intracavernosal alprostadil (available in 2 formulations):
  - Alprostadil (Caverject): usual dose: 10 to 20 μg, with max dose of 60 μg. Injection should be made at right angles into one of the lateral surfaces of the proximal 3rd of the penis using a 0.5-inch, 27- or 30-gauge needle. Do not use >3 times a week or more than once in 24 hours.
  - Alprostadil may also be combined with papaverine (Bimix) plus phentolamine (Tri-Mix).

**ALERT**

- Initial trial dose of second-line agents should be administered under supervision of a specialist or primary care physician with expertise in these therapies.
- Patient should notify physician if erection lasts >4 hours for immediate attention.
- Vacuum pump devices are a noninvasive second-line option and are
available over the counter. Do not use vacuum devices in men with sickle cell anemia or blood dyscrasias.
- Testosterone supplementation in men with hypogonadism improves ED and libido (5)[B]. Available formulations include injectable depots, transdermal patches and gels, SC pellets, and oral therapy.
- Best practices in urology recommendation: Do not prescribe testosterone to men with ED who have normal testosterone levels (1).
- Contraindications:
  - Nitroglycerin (or other nitrates) and phosphodiesterase inhibitors: potential for severe, fatal hypotension
  - Precautions/side effects:
    - Testosterone: precautions: Exogenous testosterone reduces sperm count and thus do not use in patients wishing to keep fertility; side effects: acne, sodium retention
    - Intraurethral suppository: local penile pain, urethral bleeding, dizziness, and dysuria
    - Intracavernosal injection: penile pain, edema and hematoma, palpable nodules or plaques, and priapism
    - Sildenafil: hypotension (caution for patients on nitrates)
    - PDE-5 inhibitors: Use caution with congenital prolonged QT syndrome, class Ia or II antiarrhythmics, nitroglycerin, α-blockers (e.g., terazosin, tamsulosin), retinal disease, unstable cardiac disease, liver and renal failure.
- Significant possible interactions
  - PDE-5 inhibitor concentration is affected by CYP3A4 inhibitors (e.g., erythromycin, indinavir, ketoconazole, ritonavir, amiodarone, cimetidine, clarithromycin, delavirdine, diltiazem, fluoxetine, fluvoxamine, grapefruit juice, itraconazole, nefazodone, nevirapine, saquinavir, and verapamil). Serum concentrations and/or toxicity may be increased. Lower starting doses should be used in these patients.
  - PDE-5 inhibitor concentration may be reduced by rifampin and phenytoin.

**ADDITIONAL THERAPIES**

Men with relationship difficulties who received therapy plus sildenafil had more successful intercourse than those who received only sildenafil (6)[A].

**SURGERY/OTHER PROCEDURES**
Penile prosthesis should be reserved for patients who have failed or are ineligible first- or second-line therapies.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Trazodone, yohimbine, and herbal therapies are not recommended for the treatment of ED, as they have not proven to be efficacious.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Treatment should be assessed at baseline and after the patient has completed at least 1 to 3 weeks of a specific treatment: Monitor the quality and quantity of penile erections and monitor the level of satisfaction patient achieves.

**DIET**
Diet and exercise recommended to achieve a normal body mass index; limit alcohol.

**PROGNOSIS**
- All commercially available PDE-5 inhibitors are equally effective. In the presence of sexual stimulation, they are 55–80% effective.
  - Lower success rates with diabetes mellitus and radical prostatectomy patients who suffer from ED
- Overall effectiveness is 70–90% for intracavernosal alprostadil and 43–60% for intraurethral alprostadil (2)[B].
- Penile prostheses are associated with an 85–90% patient satisfaction rate (2)[C].

**REFERENCES**

**CODES**

**ICD10**
- N52.9 Male erectile dysfunction, unspecified
- N52.1 Erectile dysfunction due to diseases classified elsewhere
- F52.21 Male erectile disorder

**CLINICAL PEARLS**

- Nitrates should be withheld for 24 hours after sildenafil or vardenafil administration and for 48 hours after use of tadalafil. PDE-5 inhibitors are contraindicated in patients taking concurrent nitrates of any form (regular or intermittent nitrate therapy), as it can lead to severe hypotension and syncope.
- Reserve surgical treatment for patients who do not respond to drug treatment.
- The use of PDE-5 inhibitors with α-adrenergic antagonists may increase the risk of hypotension. Tamsulosin is the least likely to cause orthostatic hypotension.
- Avanafil should not be used with strong CYP3A4 inhibitors and max dose should be 50 mg with moderate CYP3A4 inhibitors.
- ED may be a marker for subclinical cardiovascular disease. Thoroughly assess patients with nonpsychogenic ED for CV risks.
ERYSIPELAS
Fozia Akhtar Ali, MD • Barbara M. Kiersz, DO

BASICS

DESCRIPTION
- Distinct form of cellulitis: notable for acute, well-demarcated, superficial bacterial skin infection with lymphatic involvement almost always caused by Streptococcus pyogenes
- Usually acute, but a chronic recurrent form can also exist (1)
- Nonpurulent
- System(s) affected: skin, exocrine

EPIDEMIOLOGY
- Predominant age: infants, children, and adults >45 years
- Greatest in elderly (>75 years)
- No gender/racial predilection

Incidence
- Erysipelas occurs in ~1/1,000 persons/year.
- Incidence on the rise since the 1980s (2)

Prevalence
Unknown

ETIOLOGY AND PATHOPHYSIOLOGY
- Group A streptococci induce inflammation and activation of the contact system, a proinflammatory pathway with antithrombotic activity, releasing proteinases and proinflammatory cytokines.
- The generation of antibacterial peptides and the release of bradykinin, a proinflammatory peptide, increase vascular permeability and induce fever and pain.
- The M proteins from the group A streptococcal cell wall interact with neutrophils, leading to the secretion of heparin-binding protein, an inflammatory mediator that also induces vascular leakage.
- This cascade of reactions leads to the symptoms seen in erysipelas: fever,
pain, erythema, and edema.

- Group A β-hemolytic streptococci primarily; commonly S. pyogenes, occasionally, other Streptococcus groups C/G
- Rarely, group B streptococci/Staphylococcus aureus may be involved.

**RISK FACTORS**

- Disruption in the skin barrier (surgical incisions, insect bites, eczematosus lesions, local trauma, abrasions, dermatophytic infections, intravenous drug user [IVDU])
- Chronic diseases (diabetes, malnutrition, nephrotic syndrome, heart failure)
- Immunocompromised (HIV)/debilitated
- Fissured skin (especially at the nose and ears)
- Toe-web intertrigo and lymphedema
- Leg ulcers/stasis dermatitis
- Venous/lymphatic insufficiency (saphenectomy, varicose veins of leg, phlebitis, radiotherapy, mastectomy, lymphadenectomy)
- Alcohol abuse
- Morbid obesity
- Recent streptococcal pharyngitis
- Varicella

**GENERAL PREVENTION**

- Good skin hygiene
- It is recommended that predisposing medical conditions, such as tinea pedis and stasis dermatitis, be appropriately managed first.
- Men who shave within 5 days of facial erysipelas are more likely to have a recurrence.
- With recurrences, search for other possible sources of streptococcal infection (e.g., tonsils, sinuses).
- Compression stockings should be encouraged for patients with lower extremity edema.
- Consider suppressive prophylactic antibiotic therapy, such as penicillin, in patients with >2 episodes in a 12-month period.

**Pediatric Considerations**

Group B Streptococcus may be a cause of erysipelas in neonates/infants.
DIAGNOSIS

Prodromal symptoms before the skin eruption of erysipelas may include:

- Moderate- to high-grade fever
- Chills
- Headache
- Malaise
- Anorexia, usually in the first 48 hours
- Vomiting
- Arthralgias

**ALERT**

It is important to differentiate erysipelas from a methicillin-resistant *S. aureus* (MRSA) infection, which usually presents with an indurated center, significant pain, and later evidence of abscess formation.

**PHYSICAL EXAM**

- Vital signs: moderate- to high-grade fever with resultant tachycardia. Hypotension may occur.
- The presence of a fever in erysipelas can be considered a differentiating factor from other skin infections.
- Headache and vomiting may be prominent.
- Acute onset of intense erythema; well-demarcated painful plaque (3)
- Peau d’orange appearance
- Milian ear sign (erythema involves skin of ear as well as face implies erysipelas)
- Vesicles and bullae may form but are not uniformly present.
- Desquamation may occur later.
- Lymphangitis
- Location
  - Lower extremity 70–80% of cases
  - Face involvement is less common (5–20%), especially nose and ears.
  - Chronic form usually recurs at site of the previous infection and may recur years after initial episode.
- Patients on systemic steroids may be more difficult to diagnose because signs and symptoms of the infection may be masked by anti-inflammatory action of the steroids.
- Systemic toxicity resolves rapidly with treatment; skin lesions desquamate on
days 5 to 10 but usually heal without scarring.
- In geriatric patients, facial involvement presents in a butterfly pattern. Pustules characteristically absent and regional lymphadenopathy with lymphangitic streaking is seen.

**Pediatric Considerations**
- Abdominal involvement is more common in infants, especially around umbilical stump.
- Face, scalp, and leg involvement are common in older children due to the excoriations when scratching in atopic dermatitis, allowing an easy port of entry.

**Geriatric Considerations**
- Fever may not be as prominent.
- 80% of cases affect the lower extremities. The rest are usually on the face.
- High-output cardiac failure may occur in debilitated patients with underlying cardiac disease.
- More susceptible to complications

**DIFFERENTIAL DIAGNOSIS**
- Cellulitis (margins are less clear and does not involve ear)
- Necrotizing fasciitis (systemic illness and more pain)
- Skin abscess (feel for area of fluctuance)
- DVT (need to rule out if clinically suspected)
- Acute gout (check patient history)
- Insect bite (check patient history)
- Dermatophytes
- Impetigo (blistered/crusted appearance; superficial)
- Ecthyma (ulcerative impetigo)
- Herpes zoster (dermatomal distribution)
- Erythema annulare centrifugum (raised pink-red ring/bull’s-eye marks)
- Contact dermatitis (no fever, pruritic, not painful)
- Giant cell urticaria (raised, wheal appearance, severe itching)
- Angioneurotic edema (no fever)
- Scarlet fever (widespread rash with indistinct borders and without edema; rash is most common early in skin folds; develops generalized “sandpaper” feeling as it progresses)
- Toxic shock syndrome (diffuse erythema with evidence of multiorgan
involvement)

- Lupus (of the face; less fever, positive antinuclear antibodies)
- Polychondritis (common site is the ear)
- Other bacterial infections to consider:
  - Meat, shellfish, fish, and poultry workers: *Erysipelothrix rhusiopathiae* (known as erysipeloid)
  - Human bite: *Eikenella corrodens*
  - Cat/dog bite: *Pasteurella multocida/Capnocytophaga canimorsus*
  - Salt water exposure: *Vibrio vulnificus*
  - Fresh/brackish water exposure: *Aeromonas hydrophila*

**DIAGNOSTIC TESTS & INTERPRETATION**

Reserve diagnostic tests for severely ill, toxic patients, or those who are immunosuppressed.

**Initial Tests (lab, imaging)**

- Leukocytosis
- Blood culture (<5% positive)
- Elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP)
- Streptococci may be cultured from exudate/noninvolved sites.

**Test Interpretation**

Biopsy is not needed; however, skin findings would show

- Dermal and epidermal edema, extending into the SC tissues
- Peau d’orange appearance caused by edema in the superficial tissue surrounding the hair follicles
- Vasodilation and enlarged lymphatics
- Mixed interstitial infiltrate mainly consisting of neutrophils and mononuclear cells
- Endothelial cell swelling
- Gram-positive cocci in lymphatics and tissue with rare invasion of local blood vessels
- Fibrotic thickening of lymphatic vessel walls with possible luminal occlusion may be seen in recurrent erysipelas.

**TREATMENT**

mebooksfree.com
GENERAL MEASURES

- Symptomatic treatment of myalgias and fever
- Adequate fluid intake
- Local treatment with cold compresses
- Elevation of affected extremity
- Appropriate therapy for any underlying predisposing condition

MEDICATION

- Antibiotics cure 50–100% of infections, but which regimen is most successful is unclear.
- Antibiotics may be as effective when given orally versus intravenously.
- A 5-day course of antibiotics may be as effective as a 10-day course at curing (4)[A].

First Line

- Adults
  - Extremities, nondiabetic
    - Primary
      - Penicillin G: 1 to 2 million U IV q6h or cefazolin 1 g IV q8h
    - Alternative (if penicillin-allergic)
      - Vancomycin 15 mg/kg IV q12h
      - When afebrile Pen VK 500 mg PO QID AC and HS
  - Total 10 days, diabetics
    - Early-mild:
      - Trimethoprim-sulfamethoxazole (TMP-SMX)-DS: 1 to 2 tabs PO BID and penicillin VK 500 mg PO QID or cephalexin 500 mg PO QID
    - Severe disease
      - IMP or MER or ERTA IV and linezolid 600 mg IV/PO BID or vancomycin IV or daptomycin 4 mg/kg IV q24h
  - Facial
    - Primary
      - Vancomycin: 15 mg/kg (actual weight) IV q8–12h with target trough 15 to 20
    - Alternative
      - Daptomycin 4 mg/kg IV q24h or linezolid 600 mg IV q12h
- Children
  - Penicillin G
    - 0 to 7 days, <2,000 g = 50,000 U/kg q12h
8 to 28 days, <2,000 g = 75,000 U/kg q8h
0 to 7 days, >2,000 g = 50,000 U/kg q8h
8 to 28 days, >2,000 g = 50,000 U/kg q6h
>28 days = 50,000 U/kg/day

- Cefazolin
  0 to 7 days, <2,000 g = 25 mg/kg q12h
  8 to 28 days, <2,000 g = 25 mg/kg q12h
  0 to 7 days, >2,000 g = 25 mg/kg q12h
  8 to 28 days, >2,000 g = 25 mg/kg q8h
  >28 days = 25 mg/kg q8h

- No reported group A streptococci resistance to β-lactam antibiotics
- In chronic recurrent infections, prophylactic treatment after the acute infection resolves:
  - Penicillin G benzathine: 1.2 million U IM q4wk or penicillin VK 500 mg PO BID or azithromycin 250 mg PO QD
- If staphylococcal infection is suspected or if patient is acutely ill, consider a β-lactamase-stable antibiotic.
- Consider community-acquired MRSA, and depending on regional sensitivity, may treat MRSA with TMP-SMX DS 1 tab PO BID or vancomycin 1 g IV q12h or doxycycline 100 mg PO BID.

ISSUES FOR REFERRAL
Recurrent infection, treatment failure

ADDITIONAL THERAPIES
Some patients may notice a deepening of erythema after initiating antimicrobial therapy. This may be due to the destruction of pathogens that release enzymes, increasing local inflammation. In this case, treatment with corticosteroids, in addition to antimicrobials, can mildly reduce healing time and antibiotic duration in patients with erysipelas. Consider prednisolone 30 mg/day with taper over 8 days.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization
  - Patient with systemic toxicity
  - Patient with high-risk factors (e.g., elderly, lymphedema, postsplenectomy, diabetes)
– Failed outpatient care
- IV therapy if systemic toxicity/unable to tolerate PO
- Discharge criteria: no evidence of systemic toxicity with resolution of erythema and swelling

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Bed rest with elevation of extremity during acute infection, then activity as tolerated

**Patient Monitoring**

Patients should be treated until all symptoms and skin manifestations have resolved.

**PATIENT EDUCATION**

Stress importance of completing prescribed medication regimen.

**PROGNOSIS**

- Patients should recover fully if adequately treated.
- May experience deepening of erythema after initiation of antibiotics
- Most respond to therapy after 24 to 48 hours.
- Mortality is <1% in patients receiving appropriate treatment.
- Bullae formation suggests longer disease course and often indicates a concomitant *S. aureus* infection that may require antibiotic coverage for MRSA.
- Chronic edema/scarring may result from chronic recurrent cases.
- Rarely, obstructive lymphadenitis may result from chronic recurrent cases.

**COMPLICATIONS**

- Recurrent infection
- Abscess (suggests staphylococcal infection)
- Necrotizing fasciitis
- Lymphedema (most prominent risk factor for recurrence) *(5)*
- Bacteremia, which may lead to sepsis
- Pneumonia (due to sepsis/toxin-producing organism)
- Meningitis (due to sepsis/toxin-producing organism)
- Embolism
- Gangrene
- Bursitis, septic arthritis, tendinitis, or osteitis

REFERENCES

ADDITIONAL READING

CODES

ICD10
A46 Erysipelas

CLINICAL PEARLS

- Athlete’s foot is the most common portal of entry.
- Erysipelas is distinguished from cellulitis by its sharp, shiny, fiery-red, raised border.
- In recurrent cases, search for other possible source of streptococcal infection (e.g., tonsils, sinuses, intertrigo).
- Most erysipelas infections now occur on the legs, rather than the face.
ERYTHEMA MULTIFORME
Losika Sivaganeshan, MD, MPH • Pradeepa P. Vimalachandran, MD, MPH

BASICS

- Erythema multiforme (EM) is relatively common, acute, recurrent, self-limiting inflammatory disease.
  - Mostly (~90% of cases) triggered by infectious agents (up to 50% by herpes simplex virus [HSV]-1 or -2), or less commonly, by drugs and vaccinations (1,2).
  - Skin lesions include acrally distributed, distinct targetoid lesions with concentric color variation, sometimes accompanied by oral, genital, or ocular mucosal lesions (1,3).
  - Flat, atypical lesions and macules with or without blisters are more suggestive of Stevens-Johnson syndrome (SJS) or toxic epidermal necrolysis (TEN) (4,5).
- There are no universal diagnostic criteria, but clinical history, clinical examination, skin biopsy, laboratory studies, and special consideration of persistent EM are all included in making a diagnosis.

DESCRIPTION

- Two subtypes, erythema multiforme minor (EMm) and erythema multiforme major (EMM), with the former involving none or one mucous membrane, and the latter involving at least two mucous membrane sites. EMM is now separate from SJS and TEN.
- Recurrent EM is defined as >3 attacks but has a mean number of 6 attacks (range 2 to 24) per year and a mean duration of 6 to 9.5 years (range 2 to 36) (1).

EPIDEMIOLOGY

Incidence
Annual U.S. incidence is estimated at <1% (1).

Prevalence
- Peak incidence in 20s and 40s; rare <3 years and >50 years of age.
Slight male predominance is observed.

ETIOLOGY AND PATHOPHYSIOLOGY

- The exact pathophysiology of EM is incompletely understood but appears to be the result of a TH1-mediated immune response to an inciting event such as infection or drug exposure.
- Genetic susceptibility can be a predisposing factor in some patients with EM. Different HLA alleles have been found to be consistent in patients with EM.
- HSV containing a certain HSV pol, a polymerase associated with the HSV-triggered EM seems to involve autoimmune activation (1).
- With electron microscopy, there is evidence of lichenoid inflammatory infiltrate and epidermal necrosis including circulating immune complexes, deposition of C3, IgM, and fibrin around the upper dermal blood vessels.
- SJS and TEN have an increased granulysin and perforin expression within T cells than in EM (4,5).
- Previous viral infections, particularly; also Epstein-Barr, coxsackie, echovirus, varicella, mumps, poliovirus, hepatitis C, cytomegalovirus, HIV, molluscum contagiosum virus (1).
- Bacterial infections, particularly Mycoplasma pneumoniae; other reported bacterial infections include Treponema pallidum, Mycobacterium tuberculosis and Gardnerella vaginalis (1).
- Medications, including NSAIDs, antibiotics, penicillin, sulfonamides, and antiepileptics (1,3).
- Vaccines: stronger association with HPV, MMR, and small pox vaccines, but also associated with hepatitis B, meningococcal, pneumococcal, varicella, influenza, diphtheria-pertussis-tetanus, and H. influenzae (2).
- Occupational exposures: herbicides (alachlor and butachlor), iodoacetonitrile.
- Radiation therapy.
- Premenstrual hormone changes (3).
- Malignancy (3).

Genetics

Strong association with HLA-DQB10301, particularly in herpes-related cases (1); possible association in recurrent cases with HLA-B35, -B62, -DR53.

RISK FACTORS

Previous history of EM.
GENERAL PREVENTION
- Known or suspected etiologic agents should be avoided.
- Acyclovir or valacyclovir may help prevent herpes-related recurrent EM.

COMMONLY ASSOCIATED CONDITIONS
See “Etiology and Pathophysiology” earlier.

DIAGNOSIS

Clinical

HISTORY
- Absent or mild prodromal symptoms
- Acute, self-limiting, episodic course
- History of new medication
- Preceding HSV infection 10 to 15 days before the skin eruptions
- Rash involving the skin and sometimes the mucous membrane, most commonly the mouth.
- Symptoms of any of the infections associated with EM, most commonly HSV and M. pneumonieae

PHYSICAL EXAM
- Acral extremities
- Symmetric cutaneous eruptions composed of targetoid lesions with concentric color variation
- Mucosal involvement
  - Oral involvement manifests as erythema, erosions, bullae, and ulcerations on both nonkeratinized and keratinized mucosal surfaces and on the vermillion of the lips; minimal involvement in EMM, if present, most commonly involves the mouth
  - Can include any mucosal tissue including genital, ocular, oral, and so forth
  - At least two mucosal sites involved in EMM, including eyes (conjunctivitis, keratitis); mouth (stomatitis, cheilitis, characteristic blood-stained crusted erosions on lips); and probable trachea, bronchi, GI tract, or genital tract (balanitis and vulvitis) (5)

DIFFERENTIAL DIAGNOSIS
- **SJS**
  - Generalized distribution of lesions; concentrated on the trunk
  - Macular atypical targetoid lesions
  - Flat target lesions or macules with coalescence of lesions
  - Blisters and skin detachment <10% of the total body surface area (5)
  - 1–5% mortality
  - Presence of constitutional symptoms with presence of high fever (>38.5°C) more likely with SJS than EM
  - More likely to have mucosal involvement at ≥2 sites, lymphadenopathy, high C-reactive protein levels (>10 mg/dL), and hepatic dysfunction, and >90% have severe mucosal involvement at least at one site (1)

- **TEN**
  - Similar to SJS but has full-thickness skin necrosis and skin detachment >30% of the total body surface area (5,6)
  - 34–40% mortality rate

- Urticaria
- Fixed drug eruption
- Bullous pemphigoid
- Paraneoplastic pemphigoid
- Sweet syndrome
- Rowell syndrome
- Polymorphous light eruption
- Cutaneous small-vessel vasculitis
- Mucocutaneous lymph node syndrome
- Erythema annulare centrifugum
- Acute hemorrhagic edema of infancy
- Subacute cutaneous lupus erythematosus
- Contact dermatitis
- Pityriasis rosea
- HSV
- Secondary syphilis
- Tinea corporis
- Dermatitis herpetiformis
- Herpes gestationis
- Septicemia
- Serum sickness
- Viral exanthem
- Rocky Mountain spotted fever
- Meningococcemia
Lichen planus
Behçet syndrome
Recurrent aphthous ulcers
Herpetic gingivostomatitis
Granuloma annulare

**DIAGNOSTIC TESTS & INTERPRETATION**

- No lab test is indicated to make the diagnosis of EM (1).
- Skin biopsy of lesional and perilesional tissue in equivocal conditions
- Direct and indirect immunofluorescence (DIF and IIF) to differentiate EM from other vesiculobullous diseases. DIF is detected on a biopsy of perilesional skin, and IIF is detected from a blood sample (1).
- HSV tests in recurrent EM (serologic tests, swab culture, or tests using skin biopsy sample to check HSV antigens or DNA in keratinocytes by DIF or direct fluorescent antibody [DFA] or polymerase chain reaction [PCR])
- Antibody staining to IFN-γ and TNF-α to differentiate HSV from drug-associated EM
- As the second most common cause of EM, *M. pneumoniae* should be worked up with CXR, swabs, and serologic test.
- In persistent EM, check complement levels (1).

**Initial Tests (lab, imaging)**

No imaging studies are indicated in most cases unless there is suspicion for *M. pneumoniae*.

**Follow-Up Tests & Special Considerations**

Chest x-ray may be necessary if an underlying pulmonary infection (*M. pneumoniae*) is suspected.

**Test Interpretation**

- Vacuolar interface dermatitis with CD4+ T lymphocytes and histiocytes in papillary dermis and the dermal–epidermal junction
- Superficial perivascular lymphocytic inflammation
- Satellite cell necrosis
- Necrotic keratinocytes mainly in the basal layer
- Papillary dermal edema
TREATMENT

GENERAL MEASURES

- Step 1: Discontinue or treat inciting factor (1).
- Wound care for severe cases with epidermal detachment
- Oral lesions should be addressed to insure maintenance of PO intake. This can include oral anesthetic solutions and antiseptic rinses.

MEDICATION

- Acute EM
  - Discontinuation of inciting factors and treatment of underlying disease (1) [B]
  - Symptomatic treatment with oral antihistamines and topical (1)[B]
  - HSV-induced EM: Most recent sources report no proven effect on the course of EM using antivirals with acute mild EM (1)[B].
  - M. pneumoniae-associated EM may require antibiotics.
- Mucosal membrane EM
  - Consider high-potency topical corticosteroid gel, oral antiseptic, and oral anesthetic solutions if mild.
  - If more severe, consider prednisone 40 to 60 mg/day with dosage tapered over 2 to 4 weeks (1)[B].
  - Ophthalmology consultation is imperative for ocular involvement.
- Recurrent EM
  - First-line treatment with HSV-associated and idiopathic recurrent EM is antiviral prophylaxis; 12 to 24 months of prophylaxis is most effective (1) [B].
  - Therapy includes acyclovir 400 mg BID, valacyclovir 500 mg BID, famciclovir 250 mg BID (1)[B].
  - Second-line therapy includes dapsone (100 to 150 mg/day), azathioprine (Imuran, 100 to 150 mg/day), thalidomide (100 to 200 mg/day), tacrolimus (0.1% ointment daily), mycophenolate mofetil (CellCept, 1,000 to 1,500 mg BID), hydroxychloroquine (400 mg/day) (1)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Care at home
- Hospitalization needed for fluid and electrolyte management in patient with
severe mucous membrane involvement, impaired oral intake, and dehydration

- IV antibiotics if secondary infection develops

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*

- The disease is self-limiting.
- Complications are rare, with no mortality.

**DIET**

As tolerated, with increased fluid intake

**PATIENT EDUCATION**

- The disease is self-limiting. However, the recurrence risk may be 30%.
- Avoid any identified etiologic agents.

**PROGNOSIS**

- Rash evolves over 1 to 2 weeks and subsequently resolves within 2 to 6 weeks, generally without scarring or sequelae.
- Following resolution, there may be some postinflammatory hyper- or hypopigmentation.

**COMPLICATIONS**

Secondary infection

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Cutaneous Drug Reactions; Dermatitis Herpetiformis; Pemphigoid Gestationis; Stevens-Johnson Syndrome; Toxic Epidermal Necrolysis; *Urticaria*

**CODES**

**ICD10**

- L51.9 Erythema multiforme, unspecified
- L51.8 Other erythema multiforme
- L51.0 Nonbullous erythema multiforme

**CLINICAL PEARLS**

- EM is diagnosed clinically by careful review of the history, thorough detailed physical exam, and by excluding other similar disorders. No lab tests are required for the diagnosis.
- Typical lesions are characteristic targetoid or “iris” lesions but can include raised targetoids.
- Lesions are symmetrically distributed on palms, soles, dorsum of the hands,
and extensor surfaces of extremities and face. The oral mucosa is the most affected mucosal region in EM.

- Management of EM involves determining the etiology when possible. The first step is to treat the suspected infection or discontinue the causative drug.
- Complications are rare. Most cases are self-limited. However, the recurrence risk may be as high as 30%.
- Recurrent cases often are secondary to HSV infection. Antiviral therapy may be beneficial.
ERYTHEMA NODOSUM

Lolwa Al-Obaid, MD • Faruq Pradhan, MBBCh • Fredric D. Gordon, MD, AGAF

BASICS

DESCRIPTION

- A delayed-type hypersensitivity reaction to various antigens, or an autoimmune reaction presenting as a panniculitis (1) that affects subcutaneous fat
- Clinical pattern of multiple, bilateral, erythematous, tender nodules in a typically pretibial distribution that undergo a characteristic pattern of color changes, similar to that seen in bruises. Unlike erythema induratum, the lesions of erythema nodosum (EN) do not typically ulcerate.
- Occurs most commonly on the shins; less commonly on the thighs, forearms, trunk, head, or neck
- Often associated with nonspecific prodrome including fever, weight loss, and arthralgia
- Often idiopathic but may be associated with a number of clinical entities
- Usually remits spontaneously in weeks to months without scarring, atrophy, or ulceration
- Uncommon to have recurrences after initial presentation

Pregnancy Considerations

May have repeat outbreaks during pregnancy

Pediatric Considerations

Rare pediatric variant has lesions only on palms or soles, often unilateral; typically has a shorter duration in children than adults

EPIDEMIOLOGY

Incidence

- 1 to 5/100,000/year
- Predominant age: 20 to 30 years
- Predominant sex: female > male (6:1) in adults
Prevalence
- Varies geographically depending on the prevalence of disorders associated with EN
- Reported 1 to 5/100,000

ETIOLOGY AND PATHOPHYSIOLOGY
- Idiopathic: up to 55%
- Infectious: 44%. Streptococcal pharyngitis (most common), mycobacteria, mycoplasma, chlamydia, mycoplasma, coccidioidomycosis, rarely can be caused by Campylobacter spp., rickettsiae, Salmonella spp., psittacosis, syphilis
- Sarcoidosis: 11–25%
- Drugs: 3–10%; sulfonamides amoxicillin, oral contraceptives, bromides, azathioprine, vemurafenib
- Pregnancy: 2–5%
- Enteropathies: 1–4%; ulcerative colitis, Crohn disease, Behçet disease, celiac disease, diverticulitis
- Rare causes: <1% (2)
  - Fungal: dermatophytes, coccidioidomycosis, histoplasmosis, blastomycosis
  - Viral/chlamydial: infectious mononucleosis, lymphogranuloma venereum, paravaccinia, HIV
  - Malignancies: lymphoma/leukemia, sarcoma, myelodysplastic syndrome
  - Sweet syndrome

RISK FACTORS
See “Etiology and Pathophysiology.”

COMMONLY ASSOCIATED CONDITIONS
See “Etiology and Pathophysiology.”

DIAGNOSIS

HISTORY
- Often a prodrome 1 to 3 weeks prior to onset of lesions; can consist of malaise, fever, weight loss, cough, and arthralgia
- Increasingly tender nodules on the legs, usually over the shins
- Fever, malaise, chills, fatigue
Headache
Can precede systemic process by weeks

**PHYSICAL EXAM**
- Lesions initially present as warm, tender, erythematous firm nodules and become fluctuant, gradually fading to resemble a bruise over 1 to 2 months (erythema contusiformis).
- Typically pretibial, although can extend proximally to involve thighs or trunk (atypically can involve extensor surface of forearms)
- Diameter varies from 1 to 10 cm with poor demarcation.

**DIFFERENTIAL DIAGNOSIS**
- Nodular vasculitis or erythema induratum (warm ulcerating calf nodules)
- Superficial thrombophlebitis
- Cellulitis
- Weber-Christian disease (violaceous, scarring nodules)
- Lupus panniculitis
- Cutaneous polyarteritis nodosa
- Sarcoideal granulomas
- Cutaneous T-cell lymphoma
- EN leprosum (clinically similar to EN but shows vasculitis on histopathology)
- Subcutaneous infection (including staphylococcus, Sporothrix schenckii, Nocardia brasiliensis, Mycobacterium marinum, Leishmania braziliensis)

**DIAGNOSTIC TESTS & INTERPRETATION**
Diagnosis is made clinically, with support of testing.
- ESR or C-reactive protein (CRP): often elevated, but can be normal in up to 40% [3][C]
- CBC: mild leukocytosis [3][C]
- Urine pregnancy test [3][C]
- Throat culture, antistreptolysin O titer [3][C]
- Blood and/or stool culture, stool ova and parasites (O&P)
- Tuberculin skin testing [3][C]
- Seronegative rheumatoid factor

**Initial Tests (lab, imaging)**
CXR for hilar adenopathy or infiltrates related to sarcoidosis or tuberculosis [3][C]
**Diagnostic Procedures/Other**
Deep-incisional or excisional skin biopsy including subcutaneous tissue; rarely necessary except in atypical cases with ulceration, duration >12 weeks, or absence of nodules overlying lower limbs (4)[C]

**Test Interpretation**
- Septal panniculitis without vasculitis
- Neutrophilic infiltrate in septa of fat tissue early in course
- Actinic radial (Miescher) granulomas, consisting of collections of histiocytes around a central stellate cleft, may be seen.
- Fibrosis, paraseptal granulation tissue, lymphocytes, and multinucleated giant cells predominate late in course (5).

**TREATMENT**
- Condition usually self-limited within 1 to 2 months
- All medications listed as treatment for EN are off-label uses of the medications. There are no specific FDA-approved medications.

**GENERAL MEASURES**
- Mild compression bandages and leg elevation may reduce pain. (Wet dressings, hot soaks, and topical medications are not useful.)
- Discontinue potentially causative drugs.
- If specific cause is identified, treatment of the condition typically leads to resolution of EN.
- Indication for treatment is poorly defined in literature; hence, therapy specifically for EN is directed toward symptom management.

**MEDICATION**

**First Line**
- NSAIDs:
  - Ibuprofen 400 mg PO q4–6h (not to exceed 3,200 mg/day)
  - Indomethacin 25 to 50 mg PO TID
  - Naproxen 250 to 500 mg PO BID
- Precautions
  - GI upset/bleeding (avoid in Crohn or ulcerative colitis)
  - Fluid retention
– Renal insufficiency
– Dose reduction in elderly, especially those with renal disease, diabetes, or heart failure
– May mask fever
– NSAIDs can increase cardiovascular (CV) risk.

• Significant possible interactions
  – May blunt antihypertensive effects of diuretics and β-blockers
  – NSAIDs can elevate plasma lithium levels.
  – NSAIDs can cause significant elevation and prolongation of methotrexate levels.

Second Line

• Potassium iodide 400 to 900 mg/day divided BID or TID × 3 to 4 weeks (for persistent lesions); need to monitor for hyperthyroidism with prolonged use; pregnancy class D (6)[B]

• Corticosteroids for severe, refractory, or recurrent cases in which an infectious workup is negative. Prednisone 1 mg/kg/day for 1 to 2 weeks is the recommended dose/duration. Potential side effects include hyperglycemia, hypertension, weight gain, worsening gastroesophageal reflux disease, mood changes, bone loss, osteonecrosis, and proximal myopathy (2).

• For EN related to Behçet disease, one can also consider colchicine 0.6 to 1.2 mg BID. Potential side effects include GI upset and diarrhea (7)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Occasionally, admission may be needed for the antecedent illness (e.g., tuberculosis).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

• Keep legs elevated.
• Elastic wraps or support stockings may be helpful when patients are ambulating.

Patient Monitoring
Monthly follow-up or as dictated by underlying disorder

**DIET**
No restrictions

**PATIENT EDUCATION**
- Lesions will resolve over a few weeks to months.
- Scarring is unlikely.
- Joint aches and pains may persist.
- <20% recur.

**PROGNOSIS**
- Individual lesions resolve generally within 2 weeks.
- Total time course of 6 to 12 weeks but may vary with underlying disease
- Joint aches and pains may persist for years.
- Lesions do not scar.
- Recurrences: occurs over variable periods, averaging several years; seen most often in sarcoid, streptococcal infection, pregnancy, and oral contraceptive use. If medication induced, avoid recurrent exposure.

**COMPLICATIONS**
- Vary according to underlying disease
- None expected from lesions of EN

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- L52 Erythema nodosum
- A18.4 Tuberculosis of skin and subcutaneous tissue

**CLINICAL PEARLS**

- Lesions of EN appear to be erythematous patches, but when palpated, their underlying nodularity is appreciated.
- Evaluation for a concerning underlying etiology is necessary in EN, but most cases are idiopathic.
- EN in the setting of hilar adenopathy may be seen with multiple etiologies and does not exclusively indicate sarcoidosis.
- In patients with a history of Hodgkin lymphoma, EN may be an early sign of recurrence.
ESOPHAGEAL VARICES

Maximos Attia, MD, FAAFP • Marcelle Meseheha, MD

BASICS

DESCRIPTION

- Dilated submucosal distal esophageal veins connecting the portal and systemic circulations
- Results from portal hypertension (most commonly a result of cirrhosis), resistance to portal blood flow, and increased portal venous blood inflow
- Variceal rupture: most common fatal complication of cirrhosis; severity of liver disease correlates with presence of varices and risk of bleeding.

EPIDEMIOLOGY

Incidence

- 30% of cirrhotic patients have varices at the time of diagnosis. This increases to 90% at 10 years.
- 1-year rate of first variceal bleeding is 5% for small varices, 15% for large varices.

Pediatric Considerations

Portal hypertension is common in chronic liver disease (CLD) in children. No clear guidelines for screening; pharmacologic or endoscopic treatment is equivalent.

Prevalence

- 50% of patients with esophageal varices experience bleeding at some point.
- Variceal bleeding: 10–20% mortality in the 6 weeks following the episode
- Gender: male > female

ETIOLOGY AND PATHOPHYSIOLOGY

- Portal hypertension causes the formation of portacaval anastomoses which decompress the portal circulation. This leads to a congested submucosal venous plexus with tortuous dilated veins in the distal esophagus. Variceal rupture results in hemorrhage.
- Pathophysiology of portal hypertension:
Increased resistance to portal flow at the level of hepatic sinusoids caused by
  - Intrahepatic vasoconstriction due to decreased nitric oxide production and increased release of endothelin-1 (ET-1), angiotensinogen, and eicosanoids
  - Sinusoidal remodeling causes disruption of blood flow.

- Increased portal flow caused by hyperdynamic circulation due to splanchnic arterial vasodilation through mediators such as nitric oxide, prostacyclin, and TNF

Causes of portal hypertension:
- Prehepatic:
  - Extrahepatic portal vein obstruction (EHPVO) or
  - Massive splenomegaly with increased splenic vein blood flow
- Posthepatic:
  - Severe right-sided heart failure, constrictive pericarditis, and hepatic vein obstruction (Budd-Chiari syndrome)
- Intrahepatic:
  - Cirrhosis (accounts for most cases of portal hypertension)
  - Less frequent causes are schistosomiasis, massive fatty change, diseases affecting portal microcirculation as nodular regenerative hyperplasia, and diffuse fibrosing granulomatous disease as sarcoidosis.

Genetics
Cirrhosis is rarely hereditary.

RISK FACTORS
- Cirrhosis
- In cirrhotic patients, thrombocytopenia and splenomegaly are independent predictors of esophageal varices.
- Noncirrhotic portal hypertension
- Increased bleeding risk for known varices is associated with varix size; endoscopic signs (red wale marks, cherry-red spots); vessel wall thickness; abrupt increase in variceal pressure (i.e., Valsalva maneuver)
- MELD/Child-Pugh score; presence of portal vein thrombosis; high hepatic venous pressure gradient (HVPG)

GENERAL PREVENTION
Prevent underlying causes: Prevent alcohol abuse, administer hepatitis B
vaccine, needle hygiene, IV drug use (needle exchange programs to reduce risk of hepatitis C); specific screening and therapy for hepatitis B and C, hemochromatosis

COMMUNITY ASSOCIATED CONDITIONS
- Portal hypertensive gastropathy; varices in stomach, duodenum, colon, rectum (causes massive bleeding, unlike hemorrhoids); rarely at umbilicus (caput medusa) or ostomy sites
- Isolated gastric varices can occur due to splenic vein thrombosis/stenosis from hypercoagulability/contiguous inflammation (most commonly, chronic pancreatitis).
- Other complications of cirrhosis: hepatic encephalopathy, ascites, hepatorenal syndrome, spontaneous bacterial peritonitis, hepatocellular carcinoma

DIAGNOSIS
- First indication of varices is often GI bleeding: hematemesis, hematochezia, and/or melena.
- Occult bleeding (anemia): uncommon

HISTORY
- Underlying history of cirrhosis/liver disease. Variceal bleed can be initial presentation of previously undiagnosed cirrhosis.
- Alcohol abuse, exposure to blood-borne viruses through intravenous drug use or sexual practices
- Hematemesis, melena, or hematochezia
- Rapid upper GI bleed can present as rectal bleeding.

PHYSICAL EXAM
- Assess hemodynamic stability: hypotension, tachycardia (active bleeding).
- Abdominal exam—liver palpation/percussion (often small and firm with cirrhosis)
- Splenomegaly, ascites (shifting dullness; puddle splash)
- Visible abdominal periumbilical collateral circulation (caput medusae)
- Peripheral stigmata of alcohol abuse: spider angiomata on chest/back, palmar erythema, testicular atrophy, gynecomastia
- Anal varices
- Hepatic encephalopathy; asterixis
Blood on rectal exam

DIFFERENTIAL DIAGNOSIS

- Upper GI bleeding: 10–30% are due to varices.
  - In patients with known varices, as many as 50% bleed from nonvariceal sources.
  - Peptic ulcer; gastritis
  - Gastric/esophageal malignancy
  - Congestive gastropathy of portal hypertension
  - Arteriovenous malformation
  - Mallory-Weiss tears
  - Aortoenteric fistula
  - Hemoptyisis; nosebleed

- Lower GI bleeding
  - Rectal varices; hemorrhoids
  - Colonic neoplasia
  - Diverticulosis/arteriovenous malformation
  - Rapidly bleeding upper GI site

- Continued/recurrent bleeding risk: actively bleeding/large varix, high Childs-Pugh severity score, infection, renal failure

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Anemia: Hemoglobin may be normal in active bleeding; may require 6 to 24 hours to equilibrate; other causes of anemia are common in cirrhotics.
- Thrombocytopenia: most sensitive and specific parameter, correlates with portal hypertension, large esophageal varices
- Abnormal aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, bilirubin; prolonged PT, low albumin suggest cirrhosis.
- BUN, creatinine (BUN often elevated in GI bleed)
- Sodium level; may drop in patients treated with terlipressin (1)[A]
- Esophagogastroduodenoscopy (1)[A]
  - Can identify actively bleeding varices as well as large varices and stigmata of recent bleeding
  - Can be used to treat bleeding with esophageal band ligation (preferred to sclerotherapy); prevent rebleeding; detect gastric varices, portal hypertensive gastropathy; diagnose alternative bleeding sites
  - Can identify and treat nonbleeding varices (protruding submucosal veins in
the distal third of the esophagus)

**Diagnostic Procedures/Other**

- Transient elastography (TE) for identifying CLD patients at risk of developing clinically significant portal hypertension (CSPH) (1)[A]
- HVPG >10 mm Hg: gold standard to diagnose CSPH (normal: 1 to 5 mm Hg) (1)[A]
- HVPG response of ≥10% or to ≤12 mm Hg to intravenous propranolol identifies responders to nonselective β-blocker (NSBB) and is linked to a decreased risk of variceal bleeding (1,2)[A].
- Video capsule endoscopy screening as an alternative to traditional endoscopy
- Doppler sonography (second line): demonstrates patency, diameter, and flow in portal and splenic veins, and collaterals; sensitive for gastric varices; documents patency after ligation or transjugular intrahepatic portosystemic shunt (TIPS)
- CT- or MRI-angiography (second line, not routine): demonstrates large vascular channels in abdomen, mediastinum; demonstrates patency of intrahepatic portal and splenic vein
  - Venous-phase celiac arteriography: demonstrates portal vein and collaterals; hepatic vein occlusion
  - Portal pressure measurement using retrograde catheter in hepatic vein

**TREATMENT**

**GENERAL MEASURES**

- Treat underlying cirrhotic comorbidities.
- Variceal bleeding is often complicated by hepatic encephalopathy and infection.
- **Active bleeding (3)[A]**
  - IV access, hemodynamic resuscitation
  - Type and crossmatch packed RBCs. Overtransfusion increases portal pressure and increases rebleeding risk.
  - Treat coagulopathy as necessary. Fresh frozen plasma may increase blood volume and increase rebleeding risk.
  - Avoid sedation, monitor mental status, avoid nephrotoxic drugs and β-blockers acutely.
  - IV octreotide to lower portal venous pressure as adjuvant to endoscopic
management; IV bolus of 50 \( \mu g \) followed by drip of 50 \( \mu g/hr \)
- Terlipressin (alternative): 2 mg q4h IV for 24 to 48 hours and then 1 mg q4h
- Erythromycin 250 mg IV 30 to 120 minutes before endoscopy (1)[A]
- Urgent upper GI endoscopy for diagnosis and treatment
  - Variceal band ligation preferred to sclerotherapy for bleeding varices; also for nonbleeding medium-to-large varices to decrease bleeding risk
  - Ligation: lower rates of rebleeding, fewer complications, more rapid cessation of bleeding, higher rate of variceal eradication
  - Repeat ligation/sclerosant for rebleeding.
- If endoscopic treatment fails, consider self-expanding esophageal metal stents or per oral placement of Sengstaken-Blakemore-type tube up to 24 hours to stabilize patient for TIPS (1)[C].
- As many as 2/3 of patients with variceal bleeding develop an infection, most commonly spontaneous bacterial peritonitis, UTI, or pneumonia; antibiotic prophylaxis with oral norfloxacin 400 mg or IV ceftriaxone 1 g q24h for up to a week
- In active bleeding, avoid \( \beta \)-blockers, which decrease BP and blunt the physiologic increase in heart rate during acute hemorrhage.
- Prevent recurrence of acute bleeding.
  - Vasoconstrictors: terlipressin, octreotide (reduce portal pressure)
  - Endoscopic band ligation (EBL): if bleeding recurs/portal pressure measurement shows portal pressure remains >12 mm Hg
  - TIPS: second-line therapy if above methods fail; TIPS decreases portal pressure by creating communication between hepatic vein and an intrahepatic portal vein branch.

**MEDICATION**

Primary prevention of variceal bleeding (4)[A]
- Endoscopy: assesses variceal size, presence of red wale sign (longitudinal variceal reddish streak that suggests either a recent bleed or a pending bleed) to determine risk stratification
  - Endoscopy every 2 to 3 years if cirrhosis but no varices; every 1 to 2 years if small varices and not receiving \( \beta \)-blockers (2)[A]

**First Line**
- (Not actively bleeding). NSBB reduce portal pressure and decrease risk of first bleed from 25% to 15% when used as primary prophylaxis; beneficial in
cirrhosis with small varices and increased hemorrhage risk as well as cirrhosis + medium-to-large varices (2,4)[A]

- Carvedilol: 6.25 mg daily (2)[A] is more effective than NSBB in dropping HVPG (1)[A].
  - Propranolol: 20 mg BID increase until heart rate decreased by 25% from baseline
  - Nadolol 80 mg daily; increase as above
  - Contraindications: severe asthma

- Chronic prevention of rebleeding (secondary prevention): NSBBs and EBL reduce rate of rebleeding to a similar extent, but β-blockers reduce mortality, whereas ligation does not (5)[A].

**Second Line**
Obliterate varices with esophageal banding for not tolerant of medication prophylaxis.

- During ligation: proton pump inhibitors, such as lansoprazole 30 mg/day, until varices obliterated
- Management of Budd-Chiari syndrome: anticoagulation, angioplasty/thrombolysis, TIPS, and orthotopic liver transplantation (1)[C]
- Management of EHPVO: anticoagulation (1)[B]; mesenteric-left portal vein bypass (Meso-Rex procedure) (1)[C]

**ISSUES FOR REFERRAL**
Refer for endoscopy, liver transplant, and interventional radiology for TIPS.

**ADDITIONAL THERAPIES**
Pneumococcal and hepatitis A/B (HAV/HBV) vaccine

**SURGERY/OTHER PROCEDURES**
- Esophageal transection: in rare cases of uncontrollable, exsanguinating bleeding
- Liver transplantation

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Inpatient to stabilize acute bleeding and hemodynamic status, therapeutic endoscopy. ICU is typically the most appropriate initial setting.
- Discharge criteria: bleeding cessation; hemodynamic stability and appropriate
plan for treating comorbidities

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Close monitoring of vital signs
- Endoscopic variceal ligation, every 1 to 4 weeks, until varices eradicated
- If TIPS, repeat endoscopy to assess rebleeding.
- Endoscopic screening in patients with known cirrhosis every 2 to 3 years; yearly in patients with decompensated cirrhosis (1)[C]
- Patients with a liver stiffness <20 kPa and with platelets >150,000 can avoid endoscopic screening (1)[A] and may follow up by annual TE and platelet count (1)[C].

PATIENT EDUCATION
National Digestive Diseases Information Clearinghouse (http://www.niddk.nih.gov/health-information/health-topics/digestive-diseases/Pages/default.aspx) or American Liver Foundation (http://www.liverfoundation.org/)

PROGNOSIS
- Depends on underlying comorbidities
- In cirrhosis, 1-year survival is 50% for those who survive at least 2 weeks following a variceal bleed.
- In-hospital mortality remains high and is related to severity of underlying cirrhosis, ranging from 0% in Child-Pugh class A disease to 32% in Child-Pugh class C disease (3).
- Prognosis in noncirrhotic portal fibrosis is better than for cirrhotics.

COMPLICATIONS
- Formation of gastric varices after eradication of esophageal varices
- Esophageal varices can recur.
- Hepatic encephalopathy, renal dysfunction, hepatorenal syndrome
- Infections after banding/ligation of varices
REFERENCES

ADDITIONAL READING

SEE ALSO

*Cirrhosis of the Liver; Portal Hypertension*

CODES

**ICD10**

- 185.00 Esophageal varices without bleeding
- 185.01 Esophageal varices with bleeding
- 185.10 Secondary esophageal varices without bleeding
CLINICAL PEARLS

- Thrombocytopenia is the most sensitive marker of increased portal pressure and large esophageal varices.
- In acute bleeding, avoid $\beta$-blockers.
- In acute bleeding, overtransfusion can elevate portal pressure and increase bleeding risk.
BASICS

DESCRIPTION

- A postural (occurring with voluntary maintenance of a position against gravity) or kinetic (occurring during voluntary movement) flexion–extension tremor that is slow and rhythmic and primarily affects the hands and forearms, head, or voice with a frequency of 4 to 12 Hz
- Older patients tend to have lower frequency tremors, whereas younger patients exhibit frequencies in the higher range.
- May be familial, sporadic, or associated with other movement disorders
- Incidence and prevalence increase with age, but symptom onset can occur at any age.
- The tremor can be intermittent and exacerbated by emotional or physical stressors, fatigue, and caffeine.
- System(s) affected include neurologic, musculoskeletal, ear/nose/throat (ENT) (voice)

EPIDEMIOLOGY

Essential tremor is the most common pathologic tremor in humans.

Incidence

- Can occur at any age but bimodal peaks exist in the 2nd and 6th decades
- Incidence rises significantly after age 49 years.

Prevalence

The overall prevalence for essential tremor has been estimated between 0.4% and 0.9% but is increased in older patients with an estimated 4.6% at age 65 years and up to 22% at age 95 years.

ETIOLOGY AND PATHOPHYSIOLOGY

- Suspected to originate from an abnormal oscillation within thalamocortical and cerebello-olivary loops, as lesions in these areas tend to reduce essential tremor
- Essential tremor is not a homogenous disorder; many patients have other motor manifestations and nonmotor features, including cognitive and psychiatric symptoms.

**Genetics**
- Positive family history in 50–70% of patients; autosomal dominant inheritance is demonstrated in many families with poor penetrance. Twin studies suggest that environmental factors are also involved.
- A link to genetic loci exists on chromosomes 2p22–2p25, 3q13, and 6p23. In addition, a Ser9Gly variant in the dopamine D₃ receptor gene on 3q13 has been suggested as a risk factor.

**COMMONLY ASSOCIATED CONDITIONS**
- Can be present in 10% of patients with Parkinson disease (PD); characteristics of PD that distinguish it from essential tremor include 3- to 5-Hz resting tremor; accompanying rigidity, bradykinesia, or postural instability; and no change with alcohol consumption
- Patients with essential tremor have a 4% risk of developing PD.
- Resting tremor, typically of the arm, may be seen in up to 20–30% of patients with essential tremor. Although action tremor is the hallmark feature of essential tremor, it is commonly found in patients with PD as well.

**DIAGNOSIS**

**HISTORY**
- Core criteria for diagnosis
  - Bilateral (less likely unilateral) action (postural or kinetic) tremor of the hands and forearms that is most commonly asymmetric
  - Absence of other neurologic signs, with the exception of cogwheel phenomenon
  - May have isolated head tremor with no signs of dystonia
- Secondary criteria include long duration (>3 years), positive family history, and beneficial response to alcohol.

**PHYSICAL EXAM**
- Tremor can affect upper limbs (~95% of patients).
- Less commonly, the tremor affects head (~34%), lower limbs (~30%), voice
(~12%), tongue (~7%), face (~5%), and trunk (~5%).

DIFFERENTIAL DIAGNOSIS

- PD
- Wilson disease
- Hyperthyroidism
- Multiple sclerosis
- Dystonic tremor
- Cerebellar tremor
- Asterixis
- Psychogenic tremor
- Orthostatic tremor
- Drug-induced or enhanced physiologic tremor (amiodarone, cimetidine, lamotrigine, itraconazole, valproic acid, SSRIs, steroids, lithium, cyclosporine, β-adrenergic agonists, ephedrine, theophylline, tricyclic antidepressants [TCAs], antipsychotics)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- No specific biologic marker or diagnostic test is available.
- Ceruloplasmin and serum copper to rule out Wilson disease
- Thyroid-stimulating hormone to rule out thyroid dysfunction
- Serum electrolytes, BUN, creatinine
- Brain MRI usually is not necessary or indicated unless Wilson disease is found or exam findings imply central lesion.

Diagnostic Procedures/Other

- Accelerometry evaluates tremor frequency and amplitude; >95% of PD cases exhibit frequencies in the 4- to 6-Hz range, and 95% of essential tremor cases exhibit frequencies in the 5- to 8-Hz range.
- Surface electromyography is less helpful in distinguishing essential tremor from PD.

Test Interpretation

Posture-related tremor seen on exam
**TREATMENT**

**MEDICATION**

Pharmacologic treatment should be considered when tremor interferes with activities of daily living (ADLs) or causes psychological distress.

**First Line**

- Propranolol 60 to 320 mg/day in divided doses or in long-acting formulation reduces limb tremor magnitude by ~50%, and almost 70% of patients experience improvement in clinical rating scales. There is insufficient evidence to recommend propranolol for vocal tremor. Single doses of propranolol, taken before social situations that are likely to exacerbate tremor, are useful for some patients.

- Primidone 25 mg at bedtime, gradually titrated to 150 to 300 mg at bedtime, improves tremor amplitude by 40–50%. Maximum dose is 750 mg/day, with doses >250 mg/day typically divided to BID or TID. Low-dose therapy (<250 mg/day) is just as effective as high-dose (750 mg/day) therapy.

- Propranolol and primidone have similar efficacy when used as initial therapy for limb tremor; both carry a level A recommendation (1)[A].

- 30–50% of patients will not respond to either propranolol or primidone.

**Second Line**

- Topiramate at a mean dose of 292 mg/day demonstrated significantly greater reduction in Tremor Rating Scale (TRS) compared with placebo (7.70 vs. 0.08; \( p < .005 \); baseline TRS = 37.0) in a small study combining results of three double-blind, randomized, controlled trials following a common protocol. Use is limited by dropout rates as high as 40% due to appetite suppression, weight loss, paresthesias, and concentration difficulties (2)[B].

- Gabapentin up to 400 mg TID (3)[B]

- Sotalol, nadolol, and atenolol are alternative \( \beta \)-blockers; each has less evidence than propranolol to support use.

- Clonazepam and alprazolam should be used with caution because of potential abuse.

- Clozapine has shown efficacy at doses of 6 to 75 mg/day but is recommended only for refractory cases of limb tremor because of a 1% risk of agranulocytosis. The American Academy of Neurology (AAN) indicates that insufficient evidence exists to support or refute the efficacy of clozapine for chronic use (1)[A].
Memantine, in a pilot study using doses up to 40 mg/day, showed significant benefit in a small subset of the study group. Adverse events at this dose included dizziness, somnolence, and poor energy (4)[B].

Pramipexole, at a dose of 2.1 mg/day, demonstrated moderate efficacy in reducing severity of tremor in a pilot study of 29 patients. Immediate- and extended-release formulations were equally effective (5)[B].

Levetiracetam and 3,4-diaminopyridine are probably ineffective at reducing limb tremor and should not be considered according to the AAN (1)[A].

Other medications that have been evaluated for treatment of essential tremor, with limited data to support their use, include acetazolamide, clonidine, flunarizine, methazolamide, nimodipine, olanzapine, phenobarbital, pregabalin, quetiapine, sodium oxybate, and zonisamide (1)[A].

Alcohol may provide transient improvement in symptoms, but its brief duration of action, subsequent rebound, and associated risk of developing alcohol addiction make it a less attractive option for longer term treatment. Alcohol may be an appropriate option for short-term, situation-specific improvement in symptoms.

Botulinum toxin A injections should be offered as a treatment option for cervical dystonia (level A recommendation from AAN) and may be offered for blepharospasm, focal upper extremity dystonia, adductor laryngeal dystonia, and upper extremity essential tremor. Limited data support its use for head and vocal tremor (6)[B].

**ISSUES FOR REFERRAL**
Referral to a neurologist can help to differentiate those with dystonia, neuropathic tremor, PD, or drug-induced tremor.

**SURGERY/OTHER PROCEDURES**
- Deep brain stimulation provides a magnitude of benefit that is superior to all available medications and may be used to treat medically refractory limb tremor; it has fewer adverse effects than thalamotomy.
- Bilateral thalamic stimulation is effective in reducing tremor and functional disability; however, dysarthria is a possible complication.
- Unilateral thalamotomy may be used to treat limb tremor that is refractory to medical management.
- Bilateral thalamotomy is not recommended because of adverse side effects.
ONGOING CARE

DIET
Avoid caffeine.

PATIENT EDUCATION
Although essential tremor can cause significant impairment in daily functioning, it does not decrease life expectancy.

PROGNOSIS
Tremor tends to worsen with age, increasing in amplitude.

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**

G25.0 Essential tremor

**CLINICAL PEARLS**

- Core criteria for diagnosis of essential tremor include bilateral action or postural tremor of the hands, forearm, and/or head without a resting component.
- Beneficial response to alcohol and positive family history help to differentiate essential tremor from PD (PD is characterized by tremor at rest, bradykinesia, and rigidity, and it does not improve with alcohol use.).
- 10% of patients with PD will have both resting tremors of PD and essential tremor.
- Wilson disease, thyroid disease, and medication effect should be ruled out.
- Brain MRI is usually not necessary or indicated.
First-line treatments include propranolol and primidone. 30–50% of patients will not benefit from these first-line treatments.
EUSTACHIAN TUBE DYSFUNCTION

Adam W. Kowalski, MD • Vernon Wheeler, MD, FAAFP

BASICS

DESCRIPTION

- A spectrum of disorders involving impairment of the functional valve of the eustachian tube (ET)
- ETD can be classified as *patulous dysfunction*, in which the ET is excessively open, or *dilatory dysfunction*, in which there is failure of the tubes to dilate (i.e., open) appropriately.
- Pathophysiology related to pressure dysregulation, impaired protection secondary to reflux of irritating material into the middle ear, or impaired clearance by the mucociliary system
- May occur in the setting of pressure changes (e.g., scuba diving or air travel) or acute upper airway inflammation (e.g., allergic or infectious rhinosinusitis, acute otitis media [OM])
- Chronic ETD may lead to a retracted tympanic membrane, recurrent serous effusion, recurrent OM, adhesive OM, chronic mastoiditis, or cholesteatoma.
- System(s) affected: auditory
- Synonym(s): auditory tube dysfunction; ET disorder; blocked ET; patulous ET

ALERT

- Sudden sensorineural hearing loss (SSNHL) can be misdiagnosed as ETD.
- A simple 512-Hz tuning fork test lateralizes to the opposite ear in SSNHL and to the affected ear in ETD with conductive hearing loss.
- Any SSNHL is a medical emergency and should be referred to an otolaryngologist immediately.

EPIDEMIOLOGY

- Most common in children <5 years of age, thought to be related to anatomical differences (see “Etiology and Pathophysiology” section)
- Usually decreases with age

Incidence

70% of children by age 7 years have experienced ETD.
Prevalence
- 1% of the adult population
- Males > females
- Highest prevalence among Native Americans, Inuits, Australian Aborigines, Hispanics, Africans

ETIOLOGY AND PATHOPHYSIOLOGY
- Under normal circumstances, the ET is closed, opening to release a small amount of air to equilibrate middle ear pressure with surrounding atmospheric pressure.
- ETD is failure of the ET, palate, nasal cavities, and nasopharynx to regulate middle ear and mastoid pressure.
- ET functions
  - Ventilation/regulation of middle ear pressure
  - Protection from nasopharyngeal secretions
  - Drainage of middle ear fluid
  - ET is closed at rest and opens with yawning, swallowing, and chewing.
- Cycle of dysfunction: structural or functional obstruction of the ET:
  - Negative pressure develops in middle ear.
  - Serous exudate is drawn to the middle ear by negative pressure or refluxed into the middle ear if the ET opens momentarily.
  - Infection of static fluid causes edema and release of inflammatory mediators, exacerbating the cycle of inflammation and obstruction.
- In children, a horizontal and shorter ET predisposes to difficulties with ventilation and drainage.
- Adenoid hypertrophy can block the torus tubarius (proximal opening of the ET).
- In adults, paradoxical closing of the ET with swallowing occurs in a majority of affected patients.
- Tumors that impair/occlude the ET or that invade the tensor veli palatini to impair normal swallow regulation, can also lead to dysfunction.

Genetics
Twin studies show a genetic component. Specific genetic cause is undefined.

RISK FACTORS
Adult and pediatric
- Allergic rhinitis, tobacco exposure, GERD, chronic sinusitis, adenoid
hypertrophy or nasopharyngeal mass, neuromuscular disease, altered immunity

● Prematurity and low birth weight, young age, daycare, crowded living conditions, low socioeconomic status, prone sleeping position, prolonged bottle use, craniofacial abnormalities (e.g., cleft palate, Down syndrome)

**Pregnancy Considerations**
ETD may be exacerbated by rhinitis of pregnancy; symptoms resolve postpartum.

**GENERAL PREVENTION**
● Control of upper airway inflammation: allergies, infectious rhinosinusitis, GERD
● Autoinsufflation of middle ear (i.e., blow gently against pinched nostril and closed mouth)
● Avoid atmospheric pressure changes (e.g., plane flight, scuba diving) in the setting of acute allergy exacerbation or URI.
● Avoid exposure to environmental irritants: tobacco smoke and pollutants.

**COMMONLY ASSOCIATED CONDITIONS**
● Hearing loss
● OM: acute, chronic, and serous
● Chronic mastoiditis
● Cholesteatoma
● Allergic rhinitis
● Chronic sinusitis/URI
● Adenoid hypertrophy
● GERD
● Cleft palate
● Down syndrome
● Obesity
● Nasopharyngeal carcinoma or other tumor

**DIAGNOSIS**

**HISTORY**
● Symptoms of ear pain, fullness, “plugging,” hearing loss, tinnitus, popping or
snapping noises, and vertigo
– Unilateral or bilateral. Evaluate adults with persistent unilateral symptoms for nasopharyngeal tumor.
– History of previous ear infections, surgeries, head trauma, recent flying or diving
– Voice change (hypo- or hypernasal voice, consider NP mass or palatal dysfunction)
– Differentiate patulous dysfunction, in which patient’s own voice and breath sounds are amplified (autophony), from dilatory dysfunction, in which patient complains more of ear pain, “plugged” ear, hearing loss, and tinnitus.

ETDQ-7 is a questionnaire that attempts to quantify ETD in adult patients. Based on presence and intensity of symptoms in past 1 month, severity is rated on 1 to 7 scale. A total score >14.5 categorizes patient as having ETD (1,2)[B].
– Pressure in ears in past 1 month?
– Pain in ears in past 1 month?
– A feeling that ears are clogged or “under water”?
– Ear symptoms when you have cold or sinusitis?
– Crackling or popping sounds in the ears?
– Ringing in ears?
– A feeling that your hearing is muffled?

PHYSICAL EXAM
● Pneumatic otoscopy: retracted tympanic membrane, effusion, decreased drum movement
● Toynbee maneuver: View changes of the drum while patient autoinsufflates against closed lips and pinched nostrils; may show various degrees of retraction
  – Entire drum may be retracted and “lateralize” with insufflation.
  – Posterosuperior quadrant (pars flaccida) may form a retraction pocket.
● Tuning fork tests: 512-Hz fork placed on the forehead lateralizes to affected ear (Weber test); the fork will be louder behind the ear on the mastoid than in front of the ear (bone conduction > air conduction, Rinne test) in conductive hearing loss.
● Nasopharyngoscopy: adenoid hypertrophy or nasopharyngeal mass
● Anterior rhinoscopy: deviated nasal septum, polyps, mucosal hypertrophy, turbinate hypertrophy
DIFFERENTIAL DIAGNOSIS

- SSNHL (a medical emergency)
- Tympanic membrane perforation
- Barotrauma
- Temporomandibular joint disorder
- Ménière disease
- Superior semicircular canal dehiscence

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- No routine radiologic studies needed if clinical signs/symptoms suggest ETD
- CT scan (not necessary) may show changes related to OM or middle ear/mastoid opacification.
- Functional MRI might determine cause of ETD (in recalcitrant cases), as the ET opening can be visualized during Valsalva.

Diagnostic Procedures/Other

- Audiogram may show conductive hearing loss.
- Tympanometry: Type B or C tympanograms indicate fluid or retraction, respectively; negative middle ear peak pressures seen even with normal (type A) tympanograms

TREATMENT

- Due to limited high-quality evidence, it is difficult to recommend any one treatment option/intervention as superior (3)[C].
- Use of a “nasal balloon” shown effective for clearing OM with effusion; unclear of benefit for ETD
- General principle is to remove or fix the underlying cause (e.g., infection, tumor, perforation of TM, restore tensor palatini muscle) and reduce or eliminate the cycle of infection/inflammation.
- Although no evidence exists, some consider antibiotics for AOM; decongestants, nasal steroids, antihistamines (if allergic rhinitis is present), and surgery/procedures for recalcitrant cases
- Tympanostomy tubes ± adenoidectomy when indicated for recurrent ear infections or severe progressive retractions
**MEDICATION**

- Antibiotics only if infection is suspected as cause of ETD (4)[A]
- Few data support pharmacologic treatments such as decongestants, nasal steroids, or antihistamines for ETD.
- Medications treat comorbid conditions.
- Decongestants, topical, oral
  - Avoid prolonged use (>3 days); can cause rhinitis medicamentosa
  - Decongestants are most useful for acute ETD related to a resolving URI.
  - Decongestants are not typically used for relief of chronic ETD in children.
    - Phenylephrine: adults and children ≥12 years of age, 1 tablet (10 mg) q4h PRN; children 6 to 11 years of age, 5 mg q4h PRN; children 4 to 5 years of age, 2.5 mg q4h PRN
    - Pseudoephedrine: adults, 60 mg q4–6h PRN; children 6 to 12 years of age, 30 mg q4–6h PRN; children 4 to 5 years of age, 15 mg q4–6h PRN
    - Oxymetazoline: adults and children ≥6 years of age, 1 to 2 sprays each nostril q12h PRN. Limit use to ≤3 days.
      - Phenylephrine: adults, 1 to 2 sprays each nostril q4h PRN. Limit use to ≤3 days.
- Nasal steroids (may be beneficial for those with allergic rhinitis) (5)[A]
  - Beclomethasone (Beconase, Vancenase): adults and children ≥12 years of age, 1 to 2 sprays each nostril BID; children 6 to 11 years of age, 1 spray each nostril BID; not recommended for children <6 years of age
  - Budesonide (Rhinocort): adults and children ≥6 years of age, 1 spray each nostril daily
  - Ciclesonide (Omnaris) (a prodrug activated on nasal mucosa): adults and children ≥6 years of age, 2 sprays each nostril daily
  - Flunisolide (Nasarel, Nasalide): adults and children ≥6 years of age, 2 sprays each nostril BID
  - Fluticasone furoate (Veramyst): adults and children ≥12 years of age, 2 sprays each nostril daily; children 2 to 11 years of age, 1 spray each nostril daily
  - Fluticasone propionate (Flonase): adults 1 to 2 sprays each nostril daily; children ≥4 years of age, 1 spray each nostril daily
  - Mometasone (Nasonex): adults and children ≥12 years of age, 2 sprays each nostril daily; children 2 to 12 years of age, 1 spray each nostril daily
  - Triamcinolone (Nasacort): adults and children ≥6 years of age, 1 to 2 sprays each nostril daily; children 2 to 5 years of age, 1 spray each nostril daily
- 2nd-generation H₁ antihistamines (may be beneficial for those with ETD and
chronic rhinitis)
– Cetirizine (Zyrtec) (tablets, chewable tablets, liquid): adults and children ≥6 years of age, 5 to 10 mg/day PO; children 12 months to 5 years of age: 2.5 mg/day PO, may increase to BID; children 6 to <12 months of age: 2.5 mg/day PO
– Desloratadine (Clarinex) (tablets, RediTabs, liquid): adults and children ≥12 years of age, 5 mg/day PO; children 6 to 11 years of age, 2.5 mg/day PO; children 12 months to 5 years of age, 1.25 mg/day PO; children 6 to 11 months of age, 1 mg/day PO
– Fexofenadine (Allegra) (tablets, RediTabs, liquid): adults and children ≥12 years of age, 60 mg PO BID or 180 mg/day PO; children 2 to 11 years of age, 30 mg PO BID
– Levocetirizine (Xyzal) (tablets, liquid): adults and children ≥12 years of age, 2.5 to 5.0 mg PO every evening; children 6 to 11 years of age, 2.5 mg PO every evening; children 6 months to 5 years of age, 1.25 mg PO every evening

Antihistamine nasal sprays (may be beneficial for those with ETD and chronic rhinitis)
– Azelastine (Astepro or Astelin): adults and children ≥12 years of age, 1 to 2 sprays each nostril BID; children 6 to 11 years of age, 1 spray each nostril BID
– Olopatadine (Patanase): adults and children ≥12 years of age, 2 sprays each nostril BID; children 6 to 11 years of age, 1 spray each nostril BID

SURGERY/OTHER PROCEDURES
– Myringotomy and pressure equalization tube placement to ventilate middle ear, relieve pressure, and prevent sequelae of chronically retracted drum
– Patients with ETD during pressure changes may benefit from minimally invasive laser eustachian tuboplasty.

Balloon tuboplasty (limited data in terms of efficacy, safety, and long-term outcomes) (6)[B]

Adenoidectomy if hypertrophied tissue is present
– In children, first set of tubes are typically placed alone. Adenoidectomy is performed with second set of tubes if problems recur.
– Some advocate adenoidectomy even in absence of excess tissue; reduces frequency and number of subsequent tubes
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Monitor pressure equalization tubes every 6 to 8 months in children and every 6 to 12 months in adults.
- Monitor tympanic membrane retraction pocket for progression every 6 to 12 months to allow for early intervention for progression in hearing loss, obvious ossicular erosion, or cholesteatoma.

DIET

Breastfeeding is associated with lower incidence of ETD and OM.

PROGNOSIS

If symptoms of ETD persist beyond age 7 years, patient is more likely to have long-term problems and require regular monitoring.

COMPLICATIONS

Morbidity related to hearing compromise or associated sequela of chronic ear infections

REFERENCES

### ADDITIONAL READING

### SEE ALSO

Algorithm: Ear Pain/Otalgia

### CODES

**ICD10**

- H69.90 Unspecified Eustachian tube disorder, unspecified ear
- H69.00 Patulous Eustachian tube, unspecified ear
- H68.109 Unspecified obstruction of Eustachian tube, unspecified ear

### CLINICAL PEARLS

- ETD can be acute or chronic. Treatment is based on the underlying etiology.
- Rule out SSNHL (medical emergency) which can be misdiagnosed as ETD, especially in patients with unilateral symptoms.
FACTOR V LEIDEN

Collin R. Jones, MD, BBA • George G.A. Pujalte, MD, FACSM

BASICS

DESCRIPTION

- Factor V Leiden is a genetic mutation at the activated protein C (APC) cleavage site on the factor V and Va molecule leading to the most common form of inherited thrombophilia.
- System(s) affected: cardiovascular, gastrointestinal, hemo-/lymphatic/immunologic, nervous, pulmonary, reproductive
- Synonym(s): factor V Leiden thrombophilia; factor V Leiden mutation, hereditary APC resistance

Pediatric Considerations
Potential for increased thrombosis risk in patients with factor V Leiden and concomitant risks

Pregnancy Considerations
- Recurrent pregnancy loss is a possible complication.
- Increased thrombotic risk in pregnancy and postpartum (additive) especially in homozygous state
- Possible increased risk of IUGR, preeclampsia, placental abruption, evidence mixed

EPIDEMIOLOGY

Prevalence
Studies estimate ~5–8% occurrence of heterozygosity in Caucasians, Hispanic Americans ~2%, African American ~1%, and Asian Americans ~0.45%.

ETIOLOGY AND PATHOPHYSIOLOGY

- Factor V circulates in the plasma. When exposed to tissue factor, factor V amplifies the production of thrombin which further promotes clotting by activating factor V into procoagulant factor Va.
For balance, thrombin also promotes APC production which will cleave and inactivate factor V, Va, and VIII, thereby keeping the clotting cascade in check (negative feedback loop).

In factor V Leiden, a point mutation at the binding site of APC (Arg506Glu) renders it less able to cleave factor V or Va. This, in turn, reduces the anticoagulant role of factor V as a cofactor to APC and increases the procoagulant role of activated factor V, as there is now 20-fold slower degradation of factor Va.

**RISK FACTORS**

- Risk for venous thromboembolism (VTE) is ~7-fold in heterozygous and ~80-fold in homozygous factor V Leiden individuals, compared with individuals without the mutation (1). This risk is compounded/increased by the presence of the following:
  - Having non-O blood type (A, B, or AB) (2- to 4-fold)
  - Oral contraceptives: homozygotes up to 100-fold; heterozygotes, 35-fold. The increased risk is halved when the patient uses desogestrel-containing oral contraceptives.
  - Hormone replacement therapy (HRT) and selective estrogen receptor modulators (SERMs) both increase the risk of thrombosis; in patients with factor V Leiden, that risk is compounded.
  - Pregnancy and homozygous factor V Leiden increase the risk of thrombosis 7- to 16-fold during pregnancy and the puerperium.

- Data are conflicting with regard to risk for recurrent VTE for patients with factor V Leiden but trend toward an increased risk (2,3).

**GENERAL PREVENTION**

**ALERT**
Patients with factor V Leiden without thrombosis do not require prophylactic anticoagulation.

**COMMONLY ASSOCIATED CONDITIONS**
Venous thrombosis

**DIAGNOSIS**
HISTORY

- Previous thrombosis
- Family history of thrombosis

PHYSICAL EXAM

- Family history of factor V Leiden mutation
- Findings suggestive of VTE in any form (DVT, PE, cerebral brail thrombosis):
  10–26% of patients with VTE are carriers of the factor V Leiden mutation.
- Thrombosis in unusual locations, such as the sagittal sinus or mesentery and portal systems, although these are less common in patients with factor V Leiden than in patients with deficiency of protein C or S
- There is a weak, however significant, association between procoagulant states (including factor V Leiden) and coronary events in younger patients (4).

DIFFERENTIAL DIAGNOSIS

- Protein C deficiency
- Protein S deficiency
- Antithrombin deficiency
- Other causes of APC resistance (e.g., antiphospholipid antibodies)
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocystinemia
- Prothrombin 20210 mutation
- Elevated factor VIII levels

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- For evaluation of a new clot in patient at risk: CBC with peripheral smear, PT/INR, activated partial thromboplastin time (aPTT), thrombin time, lupus anticoagulant, antiphospholipid antibodies, factor VIII, anticardiolipin antibody, anti-β2 glycoprotein I antibody, APC resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A
- Genetic test: DNA-based test for factor V mutation; will be unaffected by anticoagulation and other drugs
- Functional test: plasma-based coagulation assay using factor V–deficient plasma to which patient plasma is added along with purified APC. The
relative prolongation of the aPTT is used to assay for the defect. Heparin, direct thrombin inhibitors, and factor Xa inhibitor may cause false-negative results. In the absence of exposure to anticoagulants, functional testing is preferred to genomic due to cost and time to diagnosis (5)[A].

- Extremity US for DVT
- V/Q scan or spiral CT for PE

**Follow-Up Tests & Special Considerations**
- US may not show DVT acutely; repeat in 5 to 7 days if strong suspicion.
- V/Q scan for evaluation of PE may be difficult to interpret in smokers or those with underlying lung disease.

**Diagnostic Procedures/Other**
Magnetic resonance angiography (MRA), venography, or arteriography to detect thrombosis

---

**TREATMENT**
Only indicated if thrombotic event

**GENERAL MEASURES**
- Like general VTE treatment, patients with factor V Leiden and a first thrombosis should be anticoagulated initially with heparin or low-molecular-weight heparin (LMWH) and warfarin for at least 3 months.
  - Treatment with LMWH is recommended over unfractionated heparin, unless the patient has severe renal failure (6)[A].
  - Treat as outpatient, if possible (6)[A].
  - Initiate warfarin with LMWH on the first treatment day and discontinue LMWH after minimum of 5 days and when INR >2 for 2 consecutive days (6)[A].
  - Patients should be maintained on warfarin with an INR of 2 to 3 for at least 3 months (6)[A].
- For those patients with recurrence, the risks and benefits of indefinite anticoagulation need to be assessed.

**MEDICATION**

**First Line**
- **LMWH:**
  - Enoxaparin (Lovenox): 1 mg/kg SC BID; start warfarin simultaneously; continue enoxaparin for minimum of 5 days and until INR is >2 for 2 consecutive days, at which time enoxaparin can be stopped.
  - Fondaparinux (Arixtra): 5 mg (body weight <50 kg), 7.5 mg (body weight 50 to 100 kg), or 10 mg (body weight >100 kg) SC daily
  - Tinzaparin (Innohep): 175 anti-Xa IU/kg SC daily for minimum of 5 days and patient is adequately anticoagulated with warfarin (INR of at least 2 for 2 consecutive days)
  - Dalteparin (Fragmin): 200 IU/kg SC daily

- **Oral anticoagulant**
  - Warfarin (Coumadin) PO with dose adjusted to an INR of 2 to 3 (3)[A]

- **Contraindications**
  - Active bleeding precludes anticoagulation.
  - Risk of bleeding is a relative contraindication to long-term anticoagulation.
  - Warfarin is contraindicated in patients with history of warfarin skin necrosis (6)[A].
  - Warfarin is contraindicated in pregnancy.

- **Precautions**
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Avoid IM injections. Periodically check stool and urine for occult blood; monitor CBCs, including platelets.
  - Heparin: thrombocytopenia and/or paradoxic thrombosis with thrombocytopenia
  - Warfarin: necrotic skin lesions (typically breasts, thighs, or buttocks)
  - LMWH: Adjust dosage in renal insufficiency; may also need dose adjustment in pregnancy

- **Significant possible interactions**
  - Agents that intensify the response to oral anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfinpyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
  - Agents that diminish the response to anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

**Second Line**
- Heparin 80 mg/kg IV bolus followed by 18 g/kg/hr continuous infusion
• Adjust dose depending on aPTT.
• In patients requiring large daily doses of heparin, measure an anti-Xa level for dose guidance.
• Alternatively, for outpatients, weight-adjusted subcutaneous unfractionated heparin with 333 U/kg first and then 250 U/kg, without monitoring (6)[A].
• Consider deficiency of antithrombin as a comutation in patients with significant elevated heparin requirements.
• Factor Xa inhibitors are FDA-approved for VTE/PE prophylaxis and treatment but there is not enough evidence to support their long-term use in factor V Leiden patients yet.

ISSUES FOR REFERRAL
• Recurrent thrombosis on anticoagulation
• Difficulty anticoagulating
• Genetic counseling
• Homozygous state in pregnancy

SURGERY/OTHER PROCEDURES
• Anticoagulation must be held for surgical interventions.
• For most patients with DVT, recommendations are against routine use of vena cava filter in addition to anticoagulation except when there is contraindication for anticoagulation (6)[A].
• Thrombectomy may be necessary in some cases.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Admission criteria/initial stabilization: complicated thrombosis, such as PE
• Nursing
  – Teach LMWH and warfarin use.
  – See earlier for drug interactions.
• Discharge criteria: stable on anticoagulation

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
• Patient Monitoring
Warfarin use requires periodic (~monthly after initial stabilization) INR measurements, with a goal of 2 to 3 (6[A].

**Diet**
- No restrictions
- Large amounts of foods rich in vitamin K may interfere with anticoagulation with warfarin.

**Patient Education**
- Patients should be educated about the following:
  - Use of oral anticoagulant therapy
  - Avoidance of NSAIDs while on warfarin
- The role of family screening is unclear, as most patients with this mutation do not have thrombosis. In a patient with a family history of factor V Leiden, consider screening during pregnancy or if considering oral contraceptive use.

**Prognosis**
- Most patients heterozygous for factor V Leiden do not have thrombosis.
- Homozygotes have about a 50% lifetime incidence of thrombosis.
- Recurrence rates after a first thrombosis are not clear, with some investigators finding rates as high as 5% and others finding rates similar to the general population.
- Despite the increased risk for thrombosis, factor V Leiden does not increase overall mortality.

**Complications**
- Recurrent thrombosis
- Bleeding on anticoagulation

**References**

ADDITIONAL READING

SEE ALSO

Deep Vein Thrombophlebitis

CODES

ICD10

D68.51 Activated protein C resistance

CLINICAL PEARLS

- Extremely rare in Asian and African populations
- Asymptomatic patients with factor V Leiden do not need anticoagulation.
- For pregnant women homozygous for factor V Leiden but no prior history of VTE, postpartum prophylaxis with prophylactic or intermediate-dose LMWH or vitamin K antagonists with target INR 2 to 3 for 6 weeks is recommended. Antepartum prophylaxis is added if there is positive family of VTE.
FAILURE TO THRIVE

Durr-e-Shahwaar Sayed, DO

BASICS

DESCRIPTION

- Failure to thrive (FTT) is not a diagnosis but a sign of inadequate nutrition in young children manifested by a failure of physical growth, usually affecting weight. In severe cases, decreased length and/or head circumference may develop.
- Various parameters are used to define FTT, but in clinical practice, it is commonly defined as either weight for age that falls below the 5th percentile on more than one occasion or weight that drops two or more major percentile lines on standard growth charts.
- A combination of anthropometric criteria rather than one criterion should be used to identify children at risk of FTT (1)[C].

Pediatric Considerations

- Children with genetic syndromes, intrauterine growth restriction (IUGR), or prematurity follow different growth curves.
- 25% of children will decrease their weight or height crossing ≥2 major percentile lines in the first 2 years of life. These children are failing to reach their genetic potential or demonstrating constitutional growth delay (slow growth with a bone age < chronologic age). After shifting down, these infants grow at a normal rate along their new percentile and do not have FTT.

EPIDEMIOLOGY

Incidence

- Predominant age: 6 to 12 months; 80% <18 months
- Predominant sex: male = female

Prevalence

- As many as 10% of children seen in primary care have signs of growth failure.
- 1–5% of pediatric inpatient admissions are for FTT.
- Occurs more frequently in children living in poverty (1)
ETIOLOGY AND PATHOPHYSIOLOGY

- Mismatch between caloric intake and caloric expenditure
- Often grouped into four major categories:
  - Inadequate caloric intake (most frequent)
  - Inadequate caloric absorption
  - Excessive caloric expenditure
  - Defective utilization
- Traditionally, FTT was classified as organic or nonorganic, but most cases are multifactorial.
- FTT often begins with a specific event and may lead to persistent difficulties.
- Causes of FTT can be grouped by pathophysiology (including examples):
  - Inadequate intake: breastfeeding difficulty, incorrect formula preparation, poor transition to food (6 to 12 months), poor feeding habits (e.g., excessive juice, restrictive diets), mechanical problems (e.g., oromotor dysfunction, congenital anomalies, GERD, CNS, or PNS anomalies), oral aversion, poverty, neglect, poor parent–child interaction, caregiver feeding style
  - Inadequate absorption: necrotizing enterocolitis, short gut syndrome, biliary atresia, liver disease, cystic fibrosis, celiac disease, milk protein allergy, vitamin/mineral deficiency, environmental enteric dysfunction
  - Increased expenditure: hyperthyroidism, congenital/chronic cardiopulmonary disease, HIV, immunodeficiencies, malignancy, renal disease
  - Defective utilization: metabolic disorders, congenital infections (TORCH: toxoplasmosis, other agents, rubella, cytomegalovirus, herpes simplex)

Genetics
Multiple genetic disorders can cause FTT.

RISK FACTORS

- Psychosocial risks
  - Poverty, parent(s) with mental health disorder or cognitive impairment, poor parenting skills or hypervigilant parents, families with unique health/nutritional beliefs, physical or emotional abuse, substance abuse, and social isolation
- Medical risks
  - Intrauterine exposures, history of IUGR (symmetric or asymmetric), congenital abnormalities, oromotor dysfunction, premature or sick newborn, infant with physical deformity, acute or chronic medical
conditions, developmental delay, lead poisoning, anemia

**Pregnancy Considerations**

FTT is linked to intrauterine exposures, IUGR, and prematurity.

**GENERAL PREVENTION**

- Educate parents on normal feeding and parenting skills.
- Access to supplemental feeding programs (Women, Infants, and Children [WIC])

**DIAGNOSIS**

**HISTORY**

- Successful treatment of FTT almost always is accomplished by a careful and detailed history as most cases are due to underfeeding or inappropriate feeding.
- Prenatal and developmental history
- Past medical history: acute/chronic disease affecting caloric intake, digestion, absorption, or causing increased energy need or defective utilization
- Medication history, including complementary and alternative medications
- Family history: stature of parents and growth trajectories of siblings, chronic diseases, genetic disorders, developmental delay
- Diet history from birth: breastfeeding or formula feeding; timing and introduction of solids; who feeds the child, when, and how often; placement of child during feeds; amounts consumed/caloric intake; beverages consumed; snacking; vomiting or stooling associated with feeds; oral aversions or unusual behaviors during feeding
- Social history: family composition, socioeconomic status, hygiene practices, child-rearing beliefs, stressors, parental depression, parental substance abuse, caretaker personal history of abuse/neglect
- Review of systems: anorexia, activity level, mental status, fevers, dysphagia, vomiting, gastroesophageal reflux, stooling pattern/consistency, dysuria, urinary frequency

**PHYSICAL EXAM**

- A combination of anthropometric criteria, rather than one criterion, should be used (1)[C].
Accurate measurement of height, weight, and head circumference on National Center for Health Statistics (NCHS) growth charts (www.cdc.gov/growthcharts)

The World Health Organization (WHO) growth charts may be more appropriate for breastfed infants (www.who.int/childgrowth/standards/en/).

Growth charts exist for many other syndromes/conditions such as Down syndrome, Turner syndrome, and the premature infant.

Exam should assess for the following:
- Signs of dehydration or severe malnutrition are as follows:
  - Severity of malnutrition estimated via Gomez classification: Compare current weight for age with expected weight for age (50th percentile): severe, <60% of expected; moderate, 61–75%; mild, 76–90%.
- Underlying medical disease
- Dysmorphic features
- Mental status (alert, responsive to stimuli)
- Any signs of physical abuse and/or neglect

Observe interaction with caregivers and feeding techniques, specifically bonding and social/psychological cues.

**DIFFERENTIAL DIAGNOSIS**

Differentiate based on growth patterns.

- FTT classically presents as low weight for age, normal linear growth, normocephalic or low weight for age, followed by decreased linear growth or low weight for age, leading to decreased linear growth and decreased head circumference (without neurologic signs).
- In this situation, consider differential diagnosis as outlined in “Etiology and Pathophysiology.”

- If low linear growth with normal weight for length or low linear growth and proportionately low weight and decreased head circumference:
  - Consider genetic potential (constitutional short stature or growth delay), genetic syndromes, teratogens, endocrine disorders.

- If microcephaly with prominent neurologic signs, with poor growth secondary to presumed neurologic disorder:
  - Consider TORCH infections, genetic syndromes, teratogens, brain injury (i.e., hypoxic/ischemic).

**DIAGNOSTIC TESTS & INTERPRETATION**

- Labs useful only in ~1% of cases and are generally not recommended (1)[C],
A period of addressing nutritional causes is preferable prior to extensive labs and other workup.

**Initial Tests (lab, imaging)**

Labs should be ordered based on history and physical exam findings and the age of the patient.

- Tests often considered in initial evaluation:
  - CBC, ESR
  - Electrolytes, BUN/creatinine, liver function tests
  - Urinalysis and urine culture
  - Lead level

- Other tests as dictated by the history and exam:
  - TSH, amylase/lipase, serum zinc level, iron studies, karyotype, genetic testing, sweat chloride test, stool for ova and parasite or fat/reducing substances, guaiac, α₁-antitrypsin and elastase, radioallergosorbent test for IgE food allergies, tissue transglutaminase and total IgA (celiac sprue), p-ANCA and anti–*Saccharomyces cerevisiae* antibodies (for inflammatory bowel disease [IBD]), TB test, HIV, ELISA, hepatitis A and B, other infections

**Follow-Up Tests & Special Considerations**

- Prospective 3-day food diary for accurate record of caloric intake should be obtained.
- Home visit by a clinician to observe infant feeding, interaction of caretakers, and home environment
- Observe breastfeeding and/or formula preparation to ensure adequacy and offer instruction.
- Additional indicated evaluations may be performed by dietitians; occupational, physical, and speech therapists; social workers; developmental specialists; psychiatrists; psychologists; visiting nurses; lactation consultants; and/or child protection services.
- Can consider
  - Skeletal survey if suspicion of physical abuse
  - Bone age if possible endocrine disorder
  - Swallowing studies, small bowel follow-through if possible oromotor dysfunction, GERD, structural abnormalities
  - Brain imaging if microcephalic and/or neurologic findings on examination
– Echocardiogram if murmur auscultated

**TREATMENT**

**GENERAL MEASURES**

- Treat underlying conditions.
- Caregiver and infant interaction should be evaluated in infants and children with FTT.
- Age-appropriate nutritional counseling should be provided (1)[C].
  - The goal is to improve nutrition to allow catch-up growth (weight gain 2 to 3 times > average for age).
- Calculate energy needs based on recommended energy intake for age and then increase by 50%.
  - Recommended energy intake (use expected median weight for age, not actual weight)
    - 0 to 1 month: 120 kcal/kg/day
    - 1 to 2 months: 115 kcal/kg/day
    - 2 to 3 months: 105 kcal/kg/day
    - 3 to 6 months: 95 kcal/kg/day
    - 6 months to 3 years: 90 kcal/kg/day (2)[C]
- Alternatively, may calculate caloric requirements for infants to achieve catch-up growth
  - kcal/kg/day required = RDA for age (kcal/kg) × ideal weight for height/actual weight, where ideal weight for height is the median weight for the patient’s height
- Try various strategies to increase caloric intake, such as the following:
  - Optimize breastfeeding support; consider supplementation.
  - Higher calorie formulas
  - Addition of rice cereal or fats to current foods
  - Limit intake of milk to 24 to 32 oz/day.
  - Avoid juice and soda.
  - Vitamin and/or nutritional supplements
  - Assist with social and family problems (WIC, food stamps, and other transitional assistance).
- Rapid high-calorie intake can cause diarrhea, malabsorption, hypokalemia, and hypophosphatemia. Therefore, increasing formulas >24 kcal/oz is not recommended.
• The target energy intake should be slowly increased to goal over 5 to 7 days.
• Catch-up growth should be seen in 2 to 7 days.
• Accelerated growth should be continued for 4 to 9 months to restore weight and height.

MEDICATION
Use only for identified underlying conditions.

ISSUES FOR REFERRAL
• Refer as indicated for underlying conditions.
  • Multidisciplinary care is beneficial (1)[A]. Specialized multidisciplinary clinics may be of benefit for children with complicated situations, failure to respond to initial treatment, or when the PCP does not have access to specialized services such as nutrition, psychology, PT/OT, and speech therapy.

ADDITIONAL THERAPIES
In severe cases, nasogastric tube feedings or gastrostomy may be considered.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Most cases of FTT can be managed as outpatients.
• Hospitalization should be considered if (1)[C]:
  – Outpatient management fails.
  – There is evidence of severe dehydration or malnutrition.
  – There are signs of abuse or neglect.
  – There are concerns that the psychosocial situation presents harm to child.
  – During catch-up growth, some children will develop nutritional recovery syndrome:
    o Symptoms include sweating, increased body temperature, hepatomegaly (increased glycogen deposits), widening of cranial sutures (brain growth > bone growth), increased periods of sleep, fidgetiness, and mild hyperactivity.
    – There may also be an initial period of malabsorption with resultant diarrhea.
• Catch-up growth should be seen in 2 to 7 days. If this is not seen, reevaluation of causes is needed.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- If specific disease is identified, follow up as indicated.
- Close, long-term follow-up with frequent visits is important to create and maintain a healthy, supportive environment (3)[B],(4).
- Children with history of FTT are at increased risk of recurrent FTT, and long-term sequelae and growth should be monitored closely (1,2),(3)[B].
- If the family fails to comply, child protection authorities must be notified.

DIET

Nutritional requirements for a “normal” child:

- Infant
  - 120 kcal/kg/day, decreased to 95 kcal/kg/day at 6 months; if breastfed, ensure appropriate frequency and duration of feeding.
  - Between 6 and 12 months, continue breast milk and/or formula, but pureed foods should be consumed several times a day during this period.
- Toddler
  - Three meals plus two nutritional snacks, 16 to 32 oz of milk/day; avoid juice and soda and feed in a social environment.
  - Do not restrict fat and cholesterol in children <2 years.
- Rate of weight gain expected for age:
  - 0 to 3 months: 26 to 31 g/day
  - 3 to 6 months: 17 to 18 g/day
  - 6 to 9 months: 12 to 13 g/day
  - 9 to 12 months: 9 g/day
  - 1 to 3 years: 7 to 9 g/day

PATIENT EDUCATION

- Counsel parents regarding the need to avoid “food battles,” which worsen the problem.
- Educate parents regarding infant social and physiologic cues, formula/food preparation, proper feeding techniques, and importance of relaxed and social mealtimes.
- When environmental deprivation is identified, educating in a nonpunitive way is essential.
- “Failure to thrive: What this means for your child,” available from AAFP at:
WIC provides grants to states for supplemental foods, health care referrals, and nutrition education for low-income pregnant, breastfeeding, and nonbreastfeeding postpartum women and to infants and children up to age 5 years at nutritional risk: [www.fns.usda.gov/wic/](www.fns.usda.gov/wic/).

**PROGNOSIS**

- Many children with FTT show adequate improvement in dietary intake with intervention.
- Some studies looking at children with FTT have demonstrated an association with later problems with cognitive development, behavioral issues, and growth, but there is no consensus on these long-term outcomes or their clinical significance (1).
- Children with FTT are at increased risk for future undernutrition, overnutrition, and eating disorders.

**REFERENCES**

**ADDITIONAL READING**

- Larson-Nath C, Biank VF. Clinical review of failure to thrive in pediatric

**CODES**

**ICD10**
- R62.51 Failure to thrive (child)
- P92.6 Failure to thrive in newborn

**CLINICAL PEARLS**
- FTT is a sign of inadequate nutrition. It is rarely due to a medical condition.
- Underlying medical and/or social issues are generally suggested by history and physical exam, and extensive laboratory or imaging tests are rarely needed.
- A multidisciplinary team approach to diagnosis and treatment is critical to help children with FTT and their families.
- Prompt diagnosis and intervention is important to decrease the risk of adverse effects.
FEMALE ATHLETE TRIAD

Kyle Meyer, DO • Rahul Kapur, MD

BASICS

Syndrome of three interrelated clinical entities: low energy availability (EA) (with or without disordered eating [DE]), menstrual dysfunction (MD), and low bone mineral density (BMD) (1)

DESCRIPTION

• Female athlete triad was first described in 1992: Patients may meet criteria for only one or two parts of the triad.
• Prevention and early intervention are essential to prevent progression to serious clinical end points of eating disorders, amenorrhea, and osteoporosis.
• 2014 Female Athlete Triad Coalition Consensus Statement and the 2007 American College of Sports Medicine (ACSM) Position Stand suggest (1):
  – Each component of the triad represents a spectrum ranging from health to dysfunction.
  – EA is fundamental to the propagation of the triad.
  – Full recovery is not possible without correction of low EA.
• The International Olympic Committee’s updated position statement from 2014 now considers Relative Energy Deficiency in Sport (RED-S) to be a more accurate representation of the psychological and physiologic stresses placed on the athlete’s body.
• Metabolic rate, menstrual function, bone health, immunity, protein synthesis, cardiovascular and psychological health are all effected (2).
• RED-S also takes into account the effects of relative energy deficiency on male athletes, who are often affected in weight-sensitive sports (gymnastics, wrestling, cycling, etc.) (2).
• The changes in physiology should be viewed as a spectrum, with normal EA, BMD, and regular menses at one extreme and clinical eating disorders, osteoporosis, and amenorrhea at the other (2).
• EA
  – Dietary energy intake minus exercise energy expenditure; the core element of the triad
  – Represents the amount of dietary energy remaining for bodily functions after correcting for exercise training
- EA (kcal/kg FFM/day) = [EI (kcal/day) − EEE (kcal/day)] where EEE is effective energy expenditure and FFM is fat free mass
- Low EA results in reduced capacity for cellular maintenance, thermoregulation, and growth.
- Low EA serves a causal role in the induction of exercise-associated menstrual disturbances.
- Low EA occurs either intentionally or inadvertently. Examples include increasing training disproportionately to energy intake; DE; and reducing energy intake by restricting, fasting, binging, and purging or use of diet pills, laxatives, diuretics, or enemas. Not all athletes meet diagnostic criteria from Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) for eating disorders.
  - MD
    - Low EA alters the hypothalamic-pituitary axis, resulting in decreased estrogen levels.
    - MD ranges from eumenorrhea to amenorrhea.
    - MD includes athletes who have low estrogen levels but still experience menstruation.
    - Energy deficit results in MD at ~30 kcal/kg lean body mass per day.
    - MD includes luteal suppression (shortened luteal phase, prolonged follicular phase, and decreased estradiol level), anovulation, oligomenorrhea (menstrual cycle >35 days), and primary and secondary hypothalamic amenorrhea.
    - Primary amenorrhea (no menarche by age 15 years), although less common, can occur in young athletes. Secondary amenorrhea is defined as the absence of menstrual cycles for >3 months after menarche established.
    - Although hypothalamic suppression is the most common cause of secondary amenorrhea in these athletes, other causes must be ruled out.
  - BMD
    - Ranges from optimal bone health to osteoporosis.
    - Peak BMD occurs at 19 years in females and 20.5 years in males.
    - Bone health encompasses bone strength as well as bone quality. The current practice standard (dual energy x-ray absorptiometry [DEXA]) measures bone density, not bone quality. This research may help providers better understand why two athletes with the same BMD may have very different bone fracture histories (3).
      - ACSM Position Stand recommends using the International Society of Clinical Densitometry (ISCD) guidelines for BMD Z-scores <−2.0.
      - Because most athletes have a higher BMD than nonathletes, ACSM
recommends further workup for any athlete with a Z-score $<-1$, even in the absence of fracture.

- **Endothelial dysfunction**
  - Emerging evidence suggests that the female athlete triad is associated with endothelial dysfunction. Reduced levels of estrogen alter vasodilation. Athletic amenorrhea is associated with reduced brachial artery flow-mediated dilation, which has a 95% positive predictive value for coronary endothelial dysfunction. Consequences include decreased blood flow to muscles during exercise and accelerated atherosclerosis. In the future, this clinical syndrome may be considered a tetrad (4).

**EPIDEMIOLOGY**

**Prevalence**

- Overall prevalence: 0–16% of female athletes (5). Prevalence of two criteria varies: MD + BMD 0–8% ($n = 460$), MD + LE 18% ($n = 80$), and BMD + LE 4% ($n = 80$) (3)
- DE higher than general population (3)
- MD: Prevalence of secondary amenorrhea is as high as 60% in female athletes compared to 2–5% in the general population (3).
- Bone health: Using the World Health Organization (WHO) criteria for low BMD, prevalence of osteopenia (T-score between −1 and −2) ranges from 0% to 40% in female athletes, as compared to ~12% in the general population (3).

**ETIOLOGY AND PATHOPHYSIOLOGY**

- In functional hypothalamic amenorrhea, low EA disrupts the hypothalamic-pituitary-ovarian axis, decreasing pulsatile gonadotropin-releasing hormone (GnRH) release (5).
- Low GnRH levels decrease luteinizing hormone (LH) and follicle-stimulating hormone (FSH) levels, decreasing estrogen production with resultant MD.
- Estrogen deficiency negatively affects bone density. A chronic state of malnutrition reduces the rate of bone formation and increases the rate of bone resorption. Changes in bone metabolism occur within 5 days of reductions in EA.

**RISK FACTORS**

- History of menstrual irregularities and amenorrhea; history of stress fractures and recurrent or non-healing injuries; history of critical comments about eating or weight from parent or coach; history of depression; history of
dieting; personality factors including perfectionism and/or obsessiveness, overtraining, and inappropriate coaching behaviors (1)

- Lean physique, sports with an aesthetic component (ballet, figure skating, gymnastics, distance running, diving, and swimming), or sports with weight classifications (martial arts and wrestling). Frequent weigh-ins, consequences for weight gain, and win-at-all-cost attitude all increase risk (2).
- A lack of family or social support; intense training hours; social isolation, or entering a new environment (boarding school or college); an athlete with comorbid psychological conditions (anxiety, depression, and/or obsessive-compulsive disorder)

**GENERAL PREVENTION**

- Education of athletes (middle school through college), coaches, trainers, parents, and physicians. Young athletes are extremely impressionable and may turn negative comments and unhealthy advice into maladaptive eating and exercising habits.
- General screening during preparticipation exam (PPE) and annual physicals are endorsed by AAP, AAFP, ACSM, AAOSM, and AMSSM (6).
- Female Athlete Triad Coalition has 11-question screening to use during PPE (1).
- Screen athletes presenting with “red flag” conditions such as fractures, weight changes, fatigue, amenorrhea, bradycardia, orthostatic hypotension, syncope, arrhythmias, electrolyte abnormalities, or depression.

**COMMONLY ASSOCIATED CONDITIONS**

- Anorexia nervosa, bulimia nervosa, avoidant or restrictive food intake disorder, and other psychological disorders, including low self-esteem, depression, and anxiety (5)
- Low BMD predisposes athletes to stress fractures and may not be fully reversible. This may lead to a higher rate of fractures after menopause.

**DIAGNOSIS**

- The female athlete triad is a clinical diagnosis based primarily on patient history; screening for the female athlete triad at annual sports physicals or during routine exams and acute visits if there are concerns (1,5)[A]
- EDE-17 is the gold standard for eating disorder diagnosis.
HISTORY
Assess menstrual history (including oral contraceptive use), fracture history, and symptoms of depression. Assess dietary practices, eating behaviors, and history of weight changes. Dietary intake logs and a nutritional assessment by a sports dietitian can help. Assess body image, fear of weight gain, fluctuations in weight, history of DE, and use of laxatives, diet pills, or enemas.

PHYSICAL EXAM
- Height, weight, body mass index (BMI) <17.5% kg/m² or <85% of expected body weight in adolescents (1)]A
- Common findings include bradycardia, orthostatic hypotension, hypothermia, cold or cyanotic extremities, lanugo, parotid gland enlargement or tenderness, epigastric tenderness, eroded tooth enamel, and knuckle or hand calluses (Russell sign).
- Patients with amenorrhea should undergo a pelvic exam to verify the presence of a uterus and evaluate for outflow tract abnormalities. Vaginal atrophy may be present if the patient is hypoestrogenic.

DIFFERENTIAL DIAGNOSIS
Screen for anorexia nervosa, bulimia nervosa, avoidant/restrictive food intake disorder, and rumination disorder using the DSM-5 criteria. Rule out the following in amenorrheic patients:
- Pregnancy
- Endocrine abnormalities: thyroid dysfunction, Cushing syndrome
- Hypothalamic dysfunction: psychological stress-induced amenorrhea, medication-induced amenorrhea, Kallmann syndrome
- Pituitary dysfunction: prolactinoma, Sheehan syndrome, sarcoidosis, empty sella syndrome
- Ovarian dysfunction: polycystic ovarian syndrome, premature ovarian failure, menopause, gonadal dysgenesis, Turner syndrome, ovarian neoplasm, autoimmune disease
- Uterine dysfunction: Asherman syndrome, absence of uterus

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Basic metabolic panel, magnesium, phosphorus, albumin, CBC with differential, ESR, thyroid-stimulating hormone (TSH), calcium, 25-OH
vitamin D, and urinalysis (1,5)
- Evaluation for secondary amenorrhea includes urine hCG, FSH, LH, prolactin, and TSH.
- Pelvic ultrasound in patients with hyperandrogenism to exclude polycystic ovaries or virilizing ovarian tumors
- ECG to rule out prolonged QT interval

Follow-Up Tests & Special Considerations
- BMD testing by DEXA is based on a risk stratification model (1). Risk factors include DE, eating disorders >6 months, hypoestrogenism, amenorrhea, oligomenorrhea, and/or in patients with a history of stress fractures or fractures from minimal impact.
- In components of the triad persist, ISCD 2013 guidelines suggest reevaluation by the same DEXA machine every 1 to 2 years.

TREATMENT
- The goal is to optimize nutritional status and treat maladaptive behavioral disorders (1,3)[A].
- A multidisciplinary team includes a physician, registered dietitian, and behavioral health provider. Build open lines of communication with coaches, trainers, and family.
- A positive EA of >30 kcal/kg of fat-free muscle mass per day is sufficient to restore menses (5)[A].
- Physically active females should strive for an EA of >45 kcal/kg of fat-free muscle mass per day (1)[A].

MEDICATION
First Line
- Increasing EA through appropriate nutrition is the best strategy for normalizing gonadotropin pulsatility and release. The use of combination oral contraceptive pills (cOCPs), hormone replacement therapy (HRT), and/or bisphosphonates has not been clearly shown to increase BMD or aid in the restoration of normal menstrual cycling. cOCPs or transdermal estradiol with cyclic progesterone can be considered in patients with particularly low BMD Z-scores and fracture histories who do not respond to 1 year of nonpharmacologic management.
cOCP or transdermal estradiol can also be given to minimize further bone loss in patients >16 years and <21 years who, despite adequate nutrition and body weight gain, continue to have decreasing BMD and functional hypothalamic amenorrhea.

cOCPs do have potential to mask signs of RED-S and do not correct underlying energy deficiency. They can also suppress androgen release, potentially causing a decrease in BMD. Therefore, their use should be reserved for above scenarios (2).

Provide calcium (1,500 mg/day) and vitamin D supplementation to maintain serum levels within 32 to 50 mg/mL (1)[A].

In male athletes, with RED-S, testosterone replacement therapy can be helpful in patients with hypogonadism and osteoporosis (2).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Evaluate patients with eating disorders for potentially life-threatening conditions requiring hospital admission, including bradycardia, severe orthostatic hypotension, significant electrolyte imbalances, hypothermia, arrhythmias, or prolonged QT interval.

ONGOING CARE

Patients should have regular follow-up with a multidisciplinary treatment team (6)[A].

Cognitive-behavioral therapy (CBT) is effective for exercising women with ED and may be more beneficial than nutritional counseling alone in women with DE behavior.

“Clearance and Return to Play (RTP) Guidelines by Medical Risk Stratification” help determine when to allow an athlete to return to competition. More research is needed to validate this model (1)[A].

To continue training and competing, athletes with eating disorders must agree to the following stipulations as part of a behavioral contract: to comply with all treatment strategies; to be closely monitored by health care providers; to place treatment goals over training goals; and to modify the type, duration, and intensity of training or competition as necessary.

The RED-S Risk Assessment Model can be used to aide decision to clear athletes to return to play (2).
PATIENT EDUCATION

- All young female patients should be counseled on the importance of proper nutrition, calcium and vitamin D intake, and the benefits of regular weight-bearing exercise. Patients presenting with ≥1 components of the triad should be educated about the short- and long-term effects of low BMD (1,3)[A].
- RED-S effects on performance: decrease endurance, increased injury risk, decreased training response, impaired judgment, decreased coordination, decreased concentration, irritability, depression, decreased glycogen stores, decreased muscle strength (2)

PROGNOSIS

- The short- and long-term prognosis for patients with female athlete triad depends on time to diagnosis and response to treatment.
- It is estimated that amenorrheic women will lose 2–3% of bone mass per year without intervention.
- With early diagnosis and treatment using a multidisciplinary team, the prognosis for patients with the female athlete triad is good. Patients regain normal menstrual cycling and increase BMD.
- Because the triad often occurs within the age window of optimal bone strengthening, patients with a prolonged disease course may suffer from complications of decreased BMD throughout their adolescent and adult life.
- Patients with DE behaviors often require long-term therapy to manage their disease.

**ADDITIONAL READING**

**SEE ALSO**

Algorithms: Amenorrhea, Primary (Absence of Menarche by Age 16); Amenorrhea, Secondary; Weight Loss, Unintentional

**CODES**

**ICD10**

- F50.9 Eating disorder, unspecified
- N91.2 Amenorrhea, unspecified
- R53.83 Other fatigue

**CLINICAL PEARLS**

- The female athlete triad consists of low EA (with or without DE), MD, and low BMD. Athletes may exhibit varying degrees of dysfunction in any of these three areas.
- Screen at-risk women to allow for early diagnosis and intervention.
- Early intervention by a multidisciplinary team, including physicians, registered dietitians, mental health professionals, coaches, trainers, and parents, is the most successful strategy to minimize further bone loss, recover BMD, and regain normal menstrual function.
- Current guidelines recommend screening for abnormal BMD using DEXA studies for patients with DE, eating disorders >6 months, hypoestrogenism, amenorrhea, oligomenorrhea, and/or in patients with a history of stress fractures or fractures from minimal impact.
FEVER OF UNKNOWN ORIGIN (FUO)

Scott T. Henderson, MD

BASICS

DESCRIPTION

- Classic definition
  - Repeated fever >38.3°C
  - Fever duration at least 3 weeks
  - Uncertain diagnosis after 1 week of study in the hospital
- The definition of fever of unknown origin (FUO) has evolved and is based on patient characteristics and presentation. The need for in-hospital evaluation has been eliminated in previously healthy people.
- Some expand the definition to include nosocomial, neutropenic (immunodeficient), and HIV-associated fevers.

EPIDEMIOLOGY

Incidence

Incidence unclear

ETIOLOGY AND PATHOPHYSIOLOGY

- >200 causes; each with prevalence of ≤5%
- Most commonly, FUO is an atypical presentation of a common condition.
- Spectrum of causes varies geographically and temporally.
  - Noninfectious inflammatory diseases are the most frequent causes in high-income countries. Common causes include temporal arteritis, polymyalgia rheumatica, or rheumatoid arthritis.
- Infection
  - Abdominal or pelvic abscesses
  - Amebic hepatitis
  - Catheter infections
  - Cytomegalovirus
  - Dental abscesses
  - Endocarditis/pericarditis
  - HIV (advanced stage)
  - Mycobacterial infection (often with advanced HIV)
– Osteomyelitis
– Pyelonephritis or renal abscess
– Sinusitis
– Wound infections
– Other miscellaneous infections

• Neoplasms
  – Atrial myxoma
  – Colorectal cancer and other GI malignancies
  – Hepatoma
  – Lymphoma
  – Leukemia
  – Solid tumors (renal cell carcinoma)

• Noninfectious inflammatory disease
  – Connective tissue diseases
    o Adult Still disease
    o Rheumatoid arthritis
    o Systemic lupus erythematosus
  – Granulomatous disease
    o Crohn disease
    o Sarcoidosis
  – Vasculitis syndromes
    o Giant cell arteritis
    o Polymyalgia rheumatica

• Other causes
  – Alcoholic hepatitis
  – Cerebrovascular accident
  – Cirrhosis
  – Medications
    o Allopurinol, captopril, carbamazepine, cephalosporins, cimetidine, clofibrate, erythromycin, heparin, hydralazine, hydrochlorothiazide, isoniazid, meperidine, methyldopa, nifedipine, nitrofurantoin, penicillin, phenytoin, procainamide, quinidine, sulfonamides
  – Endocrine disease
  – Factitious/fraudulent fever
  – Occupational causes
  – Periodic fever
  – Pulmonary emboli/deep vein thrombosis
  – Thermoregulatory disorders

• In up to 20–30% of cases, the cause of the fever is never identified despite a
thorough workup.

**RISK FACTORS**
- Recent travel (malaria, enteric fevers)
- Exposure to biologic or chemical agents
- HIV infection (particularly in acute infection and advanced stages)
- Elderly
- Drug abuse
- Immigrants
- Young female health care workers (consider factitious fever)

**Geriatric Considerations**
Common causes of geriatric infections include intra-abdominal abscess, urinary tract infection, tuberculosis, and endocarditis. Other common causes of FUO in patients >65 years include malignancies (particularly hematologic cancers) and drug-induced fever.

**Pediatric Considerations**
- ~50% of FUO in pediatric cases are infectious. Collagen vascular disease, malignancy are common.
- Inflammatory bowel disease is a common cause of FUO in older children and adolescents.

**DIAGNOSIS**

**HISTORY**
- Onset and pattern of fever
- Constitutional symptoms:
  - Chills, night sweats, myalgias, weight loss with an intact appetite (infectious etiology)
  - Arthralgias, myalgias, fatigue (inflammatory etiology)
  - Fatigue, night sweats, weight loss with loss of appetite (neoplastic etiology)
- Past medical history: chronic infections, abdominal diseases, transfusion history, malignancy, psychiatric illness, and recent hospitalization
- Past surgical history: type of surgery performed, postoperative complications, and any indwelling foreign material
- Comprehensive medication history, including over-the-counter and herbal
Family history, such as periodic fever syndromes and recent febrile illnesses in close contacts

Social history: travel, exposures, living environment, sexual activity, recreational drug use

**ALERT**
Obtain a thorough travel, psychosocial, occupational, sexual, and drug use history.

**PHYSICAL EXAM**
- Physical findings with high diagnostic yield
  - Funduscopic exam for choroid tubercles or Roth spots
  - Temporal artery tenderness
  - Oral-mucosal lesions
  - Cardiac auscultation for bruits and murmurs
  - Pulmonary exam: consolidation or effusion
  - Abdominal palpation for organomegaly and tenderness or peritoneal signs
  - Rectal examination for blood, fluctuance and/or tenderness
  - Testicular examination
  - Lymph node examination
  - Skin and nail bed exam for clubbing, nodules, lesions, and erosions
  - Focal neurologic signs
  - Musculoskeletal exam for tenderness or effusion
  - Serial exams help identify evolving physical signs (e.g., findings associated with endocarditis).

**DIFFERENTIAL DIAGNOSIS**
See “Etiology and Pathophysiology.”

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- CBC; C-reactive protein; ESR
- Peripheral blood smear
- Electrolytes, BUN and creatinine; LFT; calcium
- Lactate dehydrogenase
- HIV testing
- Blood cultures (not to exceed six sets)
Urinalysis and urine culture
Chest x-ray
CT or MRI of abdomen and pelvis (with directed biopsy, if indicated) (1)[C]

**Follow-Up Tests & Special Considerations**

- Rheumatoid factor and antinuclear antibody test
- Serologies: Epstein-Barr, hepatitis, syphilis, Lyme disease, Q fever, cytomegalovirus, brucellosis, amebiasis, coccidioidomycosis
- Serum ferritin
- Serum procalcitonin
- Serum protein electrophoresis
- Sputum and urine cultures for TB
- Tuberculin skin test
  - May not be helpful if anergic or acute infection
  - If test negative, repeat in 2 weeks.
  - If indicated, consider an interferon gamma release assay (IGRA) test.
- Thyroid function tests
- Technetium-based scan (infection tumor) (1)[B]
- FDG-PET/CT scan if infectious process, inflammatory process, or tumor suspected; PET scans have a high negative predictive value and good sensitivity (but may have false positives) (2)[A].
- Ultrasound of abdomen and pelvis (with directed biopsy, if indicated) if renal obstruction or biliary pathology suspected
- Echocardiogram if endocarditis, atrial myxomas, or pericardial effusion is suspected
- Lower extremity Doppler if deep vein thrombosis/pulmonary embolism suspected
- CT scan of chest if pulmonary embolism suspected
- Indium-labeled leukocyte scanning if inflammatory process or occult abscess suspected
- Bone scan if osteomyelitis or metastatic disease suspected

**Diagnostic Procedures/Other**

- Liver biopsy if granulomatous disease suspected (1)[C]
- Temporal artery biopsy, particularly in the elderly
- Lymph node, muscle, or skin biopsy, if clinically indicated
- Bone marrow aspiration biopsy with smear, culture, histologic examination, and flow cytometry
Spinal tap, if clinically indicated

**TREATMENT**

**GENERAL MEASURES**
- Treatment depends on the specific etiology.
- Therapeutic trials are a last resort and should be as specific as possible based on available clinical evidence. Avoid “shotgun” approaches as they obscure the clinical picture, have untoward effects, and do not provide a diagnostic solution (1)[C].

**MEDICATION**

*First Line*
- First-line drugs depend on the diagnosis.
- Evidence does not support isolated treatment of fever (3)[C].

*Second Line*
Consider a therapeutic trial only if the patient has localizing symptoms associated with the fever or continues to decline. Consultation with appropriate specialists (infectious disease, rheumatology) is recommended in this case.
- Antibiotic trial based on patient’s history and suspected culture negative endocarditis
- Antituberculous therapy if there is a high risk for TB pending definitive culture results
- Corticosteroid trial based on patient’s history (once occult malignancy is ruled out) if temporal arteritis is suspected

**ALERT**
If a steroid trial is initiated, patient may have a relapse after treatment or if certain conditions (e.g., TB) have been undiagnosed.

**ADDITIONAL THERAPIES**
Febrile patients have increased caloric and fluid demands.

**SURGERY/OTHER PROCEDURES**
The need for exploratory laparotomy has been largely eliminated with the advent
of more sophisticated tests and imaging modalities.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Reserved for the ill and debilitated
- Consider if factitious fever has been ruled out or an invasive procedure is indicated.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
If the etiology of the fever remains unknown, repeat the history, physical exam, and screening lab studies.

DIET
No specific dietary recommendations have been shown to ameliorate undiagnosed fever.

PATIENT EDUCATION
Maintain an open line of communication between physician and patient/family as the workup progresses:
- The extended time required in establishing a diagnosis can be frustrating.

PROGNOSIS
- Depends on etiology and age
  - Patients with HIV have the highest mortality.
- 1-year survival rates (reflecting deaths due to all causes)

<table>
<thead>
<tr>
<th>Age</th>
<th>Survival</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;35 years</td>
<td>91%</td>
</tr>
<tr>
<td>35–64 years</td>
<td>82%</td>
</tr>
<tr>
<td>&gt;64</td>
<td>67%</td>
</tr>
</tbody>
</table>

COMPLICATIONS
Depends on etiology
Pregnancy Considerations
Fever increases the risk of neural tube defects in pregnancy and can also trigger preterm labor.

- Algorithms: Fever in the First 3 Months of Life; Fever of Unknown Origin

CODES
ICD10
R50.9 Fever, unspecified
CLINICAL PEARLS

- A sequential approach to FUO based on a careful history, physical examination, with targeted testing and imaging typically yields an appropriate diagnosis and avoids excessive nontargeted testing.
- Use empiric therapy only in carefully defined circumstances.
- FUO cases that defy precise diagnosis after intensive investigation and prolonged observation generally have a favorable prognosis.
- FUO in older persons may represent an atypical presentation of a common disease.
- The most common causes of FUO in high-income countries are noninfectious inflammatory diseases and idiopathic causes.
FIBROCYSTIC CHANGES OF THE BREAST

Sharon L. Koehler, DO, FACS • Maria A. Pino, PhD

BASICS

DESCRIPTION

- Fibrocystic changes (FCC) is not a disease but refers to a constellation of benign histologic findings. It is the most frequent female benign clinical breast finding.
- FCC may also be described as aberrations of normal development and evolution.
- The most common symptoms are cyclic pain, tenderness, swelling, and fullness.
- The breast tissue may feel dense with areas of thicker tissue having an irregular, nodular, or ridge-like surface.
- Women may experience sensitivity to touch with a burning sensation. For some, the pain is so severe that it limits exercise or the ability to lie prone. Usually affects both breasts, most often in the upper outer quadrant where most of the milk-producing glands are located.
- Histologically, in addition to macrocysts and microcysts, FCC may contain solid elements including adenosis, sclerosis, apocrine metaplasia, stromal fibrosis, and epithelial metaplasia and hyperplasia.
  - Depending on the presence of epithelial hyperplasia, FCC is classified as nonproliferative, proliferative without atypia, or proliferative with atypia (1).
  - Nonproliferative lesions are generally not associated with an increased risk of breast cancer.
- System(s) affected: endocrine/metabolic, reproductive
- Synonym(s): diffuse cystic mastopathy; fibrocystic disease; chronic cystic mastitis; or mammary dysplasia

EPIDEMIOLOGY

FCC occurs with great frequency in the general population. It affects women between the ages of 25 and 50 years, and it is rare below the age of 20 years.
Incidence
Unknown but very frequent

Prevalence
Up to 1/3 of women aged 30 to 50 years have cysts in their breasts (1). It most commonly presents in the 3rd decade, peaks in the 4th decade when hormonal function is at its peak, and sharply diminishes after menopause.

- With hormone replacement therapy, FCC may extend into menopause.
- Less common in East Asian races

ETIOLOGY AND PATHOPHYSIOLOGY
- FCC originates from an exaggerated response of breast stroma and epithelium to a variety of circulating and locally produced hormones (mainly estrogen and progesterone) and growth factors.
- Cysts may form due to dilatation of the lobular acini possibly due to imbalance of fluid secretion and resorption or due to obstruction of the duct leading to the lobule.

RISK FACTORS
- In many women, methylxanthine-containing substances (e.g., coffee, tea, cola, and chocolate) can potentiate symptoms of FCC, although a direct causality has not been established.
- Diet high in saturated fats may increase risk of FCC.

COMMONLY ASSOCIATED CONDITIONS
FCC categorized as proliferative with atypia confers a higher risk of breast cancer.

DIAGNOSIS

HISTORY
- Obtain personal history of breast biopsy and family history of breast disease (benign or malignant). It is important to ascertain if the patient has a known family history of BRCA1- or BRCA2-related cancer.
- Inquire regarding pertinent signs/symptoms, such as breast pain, engorgement, nipple discharge, palpable lumps, and tenderness.
  - Symptomatically, the condition is manifested as premenstrual cyclic
mastalgia, with pain and tenderness to touch.

**PHYSICAL EXAM**

- The patient should be examined in the following positions while disrobed down to the waist:
  - With the patient standing with arms at sides, observe for elevation of the level of a nipple, dimpling, bulging, and peau d’orange.
  - With the patient’s arms raised above her head, observe for dimpling and elevation/retraction of the nipple (may accentuate a mass fixed to the pectoral fascia). If so, have the patient push her hands down against her hips to flex and tense the pectoralis major muscles; move the mass to determine fixation to the underlying fascia.
  - If the patient has large and pendulous breasts, ask her to lean forward, so that her breasts hang free from the chest wall (retraction and masses may become more evident).
  - With the patient lying supine, palpate with the pads of the three middle fingers (with varying pressures from light, to medium, to deep), rotating the fingers in small circular motions and moving in vertical overlapping passes from rostral to caudal and then back caudal to rostral in the next pass. The lateral half of the breast is best palpated with the patient rolled onto the contralateral hip and the medial half with the patient supine, both with the ipsilateral hand behind the head. The entire breast from the 2nd to 6th rib and from the left sternal border to the midaxillary line must be palpated against the chest wall.
  - Be certain to examine the creases under and between the breasts. If the patient has noted a lump, ask her to point it out; always palpate the opposite breast first.
  - Patients with FCC have clinical breast findings that range from mild alterations in texture to dense, firm breast tissue with palpable masses.

**DIFFERENTIAL DIAGNOSIS**

- Pain
  - Mastitis
  - Costochondritis
  - Pectoralis muscle strain
  - Neuralgia
  - Breast cancer
  - Angina pectoris
  - Gastroesophageal reflux (GERD)
- Superficial phlebitis of the thoracoepigastric vein (Mondor disease)

- **Masses**
  - Breast cancer
  - Sebaceous cyst
  - Fibroadenoma
  - Lipoma
  - Fat necrosis
  - Phyllodes tumor

- **Skin changes**
  - Breast cancer (peau d’orange: thickened skin similar to peel of an orange)
  - Eczema
  - Infection
  - Fungus
  - Paget disease

**DIAGNOSTIC TESTS & INTERPRETATION**

- Evaluation should focus on excluding breast cancer.
- Testing may be conducted based on a level of clinical suspicion.
- FCC can be evaluated with mammogram, although dense breast tissue may appear normal in women <35 years of age.
- Ultrasound (US) is the most important method in assessing a cyst.

**Initial Tests (lab, imaging)**

- On mammogram, FCC appears as nodular densities of breast tissue; solitary cysts can appear as round or ovoid or well-circumscribed masses, usually with low to intermediate density. FCC may also contain calcifications.
- On US, if a simple cyst is demonstrated as an anechoic structure with imperceptible wall and posterior acoustic enhancement, benign diagnosis is confirmed and no further imaging or intervention is indicated. However, if the cyst appears to be thick-walled and/or contains internal echoes, differential diagnosis should include a complicated cyst, an abscess, a galactocele, or a focal duct ectasia in the appropriate clinical contexts.
- MRI is indicated in patients with *BRCA1* or *BRCA2* mutation or in any woman with ≥25% lifetime risk for breast cancer.
- On MRI, cystic changes are well-circumscribed lesions of high-signal intensity on T2-weighted sequences and of low-signal intensity on T1-weighted images (1).
Diagnostic Procedures/Other
- Fine-needle aspiration (FNA) biopsy:
  - Allows differentiation of cystic and solid lesions
  - Aspirate may be straw-colored, dark brown, or green.
  - Cells sent for cytology can reveal cancer with high accuracy.
  - Low morbidity
- If mass disappears, no further evaluation is necessary (including cytologic evaluation of aspirated fluid).
- On the basis of the presence and degree of epithelial hyperplasia, FCC is comprised of nonproliferative (approximately 65% of the total), proliferative without atypia (approximately 30% of the total), and proliferative with atypia (approximately 5–8% of the total) (2).

Test Interpretation
Certain histologic changes in the setting of FCC confer an increased risk for breast cancer:
- Nonproliferative changes: relative risk of 1.2 to 1.4
- Proliferative disease (PD) without atypia: relative risk of 1.7 to 2.1
- PD with atypia: relative risk ≥4 (3)[B]

TREATMENT
- After ruling out malignancy by means of examination and/or imaging and diagnostic procedures, FCC may not require treatment and often resolves with time.
- Cool compresses, avoiding trauma, and around-the-clock wearing of a well-fitting, supportive brassiere may be useful for symptom relief.
- Reduction in caffeine, additional supplementation with vitamin E, and/or evening primrose oil have been advocated. Recent trials have not proven benefit (1).

MEDICATION
First Line
Analgesics and anti-inflammatory drugs are used to reduce cyclic breast pain and swelling. This includes oral and topical NSAIDs or acetaminophen.
- Acetaminophen: 1,000 mg every 6 hours; maximum daily dose of 3,000 mg
unless directed by health care provider
- Ibuprofen: 400 mg every 4 to 6 hours as needed
- Naproxen: 500 mg every 12 hours as needed

**Second Line**
- Oral contraceptives (OCPs) may be useful in modulating symptoms or in preventing the development of new changes in females with cyclic symptoms.
- For severe pain, consider the following (4,5)[B]:
  - Danazol is effective for reducing breast pain and tenderness, but has androgenic effects and is associated with hepatotoxicity and teratogenicity, which limits its use. This drug is administered orally at a dosage of 100 to 400 mg/day in 2 divided doses.
  - Tamoxifen 10 mg/day for 3 to 6 months. Along with teratogenicity, this selective estrogen receptor modulator (SERM) can increase the risk of thromboembolism and endometrial carcinoma in treated females.
  - Several other medications, such as bromocriptine and GnRH agonists have been studied, but are associated with toxicities.

**ISSUES FOR REFERRAL**
- If discrete palpable lesion in a woman <35 years: US, then refer to a surgeon
- If discrete palpable lesion in a woman >35 years: diagnostic mammography ± US, then refer to surgeon

**SURGERY/OTHER PROCEDURES**
- Breast cyst aspiration can be both diagnostic and therapeutic.
- Core-needle biopsies performed under stereotactic guidance with vacuum assistance has similar accuracy in distinguishing between malignant and benign lesions compared to open surgical biopsy (6)[A].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- The use of vitamin E has shown effectiveness in treating breast pain due to FCC (3)[B].
- Little evidence supports the use of evening primrose oil for FCC.

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS
Condition is benign, chronic, and recurrent.

Patient Monitoring
- Follow-up times are variable, depending on the clinical situation and pertinent family history.
- US is useful to differentiate cysts from solid lesions and in evaluating women <35 years of age for FCC but is not useful for screening.
- Screening mammograms: Refer to the USPSTF, ACOG, or ACS recommendations for screening schedules.

DIET
The role of caffeine consumption in the development and treatment of FCC has never been proven; however, some patients report relief of symptoms after abstinence from coffee, tea, and chocolate.

PATIENT EDUCATION
- Patient information on fibrocystic breasts from the Mayo Foundation for Medical Education and Research: www.mayoclinic.com/health/fibrocystic-breasts/DS01070
- Information on breast cancer prevention from the National Cancer Institute: www.cancer.gov
- Information on fibrocystic breasts from the American Cancer Society: www.cancer.org/Healthy/FindCancerEarly/WomensHealth/Non-CancerousBreastConditions/non-cancerous-breast-conditions-fibrocystic-changes

REFERENCES

**ADDITIONAL READING**

**CODES**
ICD10

- N60.19 Diffuse cystic mastopathy of unspecified breast
- N60.09 Solitary cyst of unspecified breast
- N60.29 Fibroadenosis of unspecified breast

CLINICAL PEARLS

- FCC of the breast comprise a spectrum of histopathologic changes are a common finding in reproductive-aged women. The former term of fibrocystic disease is a misnomer.
- Atypia, as demonstrated histopathologically, confers an increased cancer risk.
- NSAIDs are the first-line treatment.
- OCPs, danazol, and tamoxifen are second-line treatments, with considerable adverse effects.
- Consultation with a breast specialist is recommended for symptomatic disease refractory to simple measures, or for diagnostic issues.
FIBROMYALGIA
F. Stuart Leeds, MD, MS

BASICS

DESCRIPTION

- Chronic, widespread noninflammatory musculoskeletal pain syndrome with multisystem manifestations. Although the specific pathophysiology has not been elucidated, it is generally thought to be a disorder of altered central pain regulation.
- Synonym(s): FMS; fibrositis, fibromyositis (misnomers); “psychogenic rheumatism” (archaic and inaccurate)

EPIDEMIOLOGY

Incidence
- Predominant sex: female (70–90%) > male (1)
- Predominant age range: 20 to 65 years

Prevalence
2–5% of adult U.S. population (2); 8% of primary care patients

ETIOLOGY AND PATHOPHYSIOLOGY

- Idiopathic; appears to be a primary disorder of central pain processing (central sensitization) with afferent augmentation of peripheral nociceptive stimuli
- Alterations in neuroendocrine, neuromodulation, neurotransmitter, neurotransporter, biochemical, and neuroreceptor function/physiology
- Sleep abnormalities—α-wave intrusion
- Inflammation is not a feature of fibromyalgia.

Genetics
- Genetics
  - High familial aggregation
  - Inheritance is unknown but likely polygenic.
  - Odds ratio may be as high as 8.5 for a first-degree relative of a familial proband.
- Environmental—several triggers have been described:
– Physical trauma or severe illness
– Stressors (e.g., work, family, life events, and physical or sexual abuse)
– Viral and bacterial infections

RISK FACTORS
- Female gender
- Poor functional status
- Negative/stressful life events
- Low socioeconomic status

GENERAL PREVENTION
No known strategies for prevention

COMMONLY ASSOCIATED CONDITIONS
- Often a comorbid condition with other rheumatologic or neurologic disorders
- Obesity is common and associated with increased severity of symptoms

DIAGNOSIS
- Original 1990 ACR criteria, still widely used: (i) pain in all four quadrants, (ii) axial (neck/spine) involvement, (iii) tender points (TPs) ≥11, (iv) no other explanation for symptoms (2)
- 2010 revised ACR criteria (2)
  - Based on Widespread Pain Index (WPI) and Symptom Score (SS)
    - Must have WPI ≥7 + SS ≥5 or WPI ≥3 and SS ≥9; and
    - Symptoms for >3 months; and
    - No other explanation for these symptoms
- WPI/SS patient scoring and diagnosis tool: https://www.umassmed.edu/uploadedFiles/cme/CME_Members_Area/C1-Handout-Fibromyalgia.pdf
- The Visual Analogue Scale Fibromyalgia Impact Questionnaire (VASFIQ) is recommended for initial and serial assessment of patient’s functional status: http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3383533/figure/fig1-1759720X11416863/.
- Enhancements to the 2010 criteria, termed 2011modCr and 2013altCr (2), have been proposed but are not yet widely accepted.

HISTORY
Universal symptoms include
- Chronic widespread pain ≥3 months: bilateral limbs and in the axial skeleton
- Fatigue and sleep disturbances

Often present:
- Mood disorders, including depression, anxiety, and panic symptoms
- Cognitive impairment: qualitatively different from that seen in isolated mood disorders (“fibro fog”)
- Headaches: typically, tension and migraine types
- Other regional pain syndromes, such as irritable bowel syndrome, chronic pelvic pain, vulvodynia, and interstitial cystitis
- Paresthesias, often “nonanatomic”
- Exercise intolerance, dyspnea, and palpitations
- Sexual dysfunction
- Ocular dryness
- “Multiple chemical sensitivity” and an increased tendency to report drug reactions
- Impaired social/occupational functioning
- Symptoms can wax and wane on a day-to-day basis, varying in quality, intensity, and location.

PHYSICAL EXAM
- Classic fibromyalgia TPs: 9 symmetric pairs (5 anterior, 4 posterior). Diagram available from: http://tinyurl.com/fibroTP
- The presence of ≥11 TPs carries a sensitivity of 88.4% and specificity 81.1% for the disease (2).
- TPs in fibromyalgia are distinct from the “trigger points” found in myofascial pain syndromes and are not sites for therapeutic injection.
- Examine joints for swelling, tenderness, erythema, decreased range of motion, crepitus, and cystic or mass lesions. These are typically absent in fibromyalgia.
- Document absence of inflammatory features (e.g., no synovitis, enthesopathy, dermatologic or ocular findings).
- Neurologic exam: may demonstrate generalized or “nonanatomic” dysesthesia, hyper- or hypesthesia

DIFFERENTIAL DIAGNOSIS
- RA, SLE, sarcoidosis, and other inflammatory connective tissue disorders
- Diffuse/advanced OA
- Seronegative spondyloarthropathies (AS, psoriatic arthritis, etc.)
- Polymyalgia rheumatica
- Inherited myopathies
- Drug-induced and endocrine myopathies
- Viral/postviral polyarthralgia
- Anemia and iron deficiency
- Electrolyte disturbances: Mg, Na, K, Ca
- Obstructive sleep apnea
- Restless leg syndrome
- Osteomalacia/vitamin D deficiency
- Opioid-induced hyperalgesia
- Hypothyroidism
- Multiple sclerosis
- Lyme disease
- Hepatitis B and C (chronic)
- Inclusion-body myositis
- Spinal stenosis/neuropathies
- Generalized muscular deconditioning
- Peripheral vascular disease
- Somatoform disorder
- Overlap syndromes
  - Chronic fatigue syndrome/chronic fatigue immune dysfunction syndrome (CFIDS)
  - Myofascial pain syndrome (more anatomically localized than fibromyalgia, but they may co-occur)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- CBC with differential, ESR or CRP, CPK, TSH, comprehensive metabolic profile; consider 25-OH vitamin D, Mg, B₁₂, folate, and urine drug screen
- ANA, RF, and other rheumatologic labs generally unnecessary, unless there is evidence of an inflammatory connective tissue disorder.
- Imaging is not indicated, except to exclude other diagnoses.

**Diagnostic Procedures/Other**
- Sleep studies may be indicated to rule out obstructive sleep apnea or narcolepsy.
- Consider psychiatric or neuropsychiatric evaluation for mood disorders and
TREATMENT
Evidence-based interventions include (3):
- Nonpharmacologic treatment are central to successful outcomes. Patients should be active participants in their care, especially with exercise and lifestyle.
- Regular exercise and sleep hygiene are foundational to improved outcomes.
- Nonpharmacologic
  - Educate about diagnosis, signs, symptoms, and treatment options: On-line resources include:
    - [www.fmaware.org](http://www.fmaware.org) [https://www.fmcpaware.org/](http://www.fmcpaware.org/)
  - VASFIQ for initial assessment and interval evaluation during treatment
  - Cognitive-behavioral therapy improves mood, energy, pain, and functional status.
  - Aerobic exercise: moderately intense, with gradual progression to minimize symptom exacerbation
  - Weight loss may augment the benefits of exercise.
  - Strength/resistance training—mild to moderate
  - Aquatic exercise training
  - Sleep hygiene
  - Mitigate tobacco, alcohol, and substance use.
- Pharmacologic
  - Three FDA-approved drugs: duloxetine, milnacipran, and pregabalin; others are off-label.
  - **Caution**: Fibromyalgia patients are frequently treated with multidrug therapy; monitor for drug interactions, sedative, and anticholinergic burden.

MEDICATION

**First Line**
- Amitriptyline 10 to 50 mg PO at bedtime to treat pain, fatigue, and sleep disturbances (4)[A]
- Duloxetine initially 30 mg/day for 1 week and then increase to 60 mg/day as tolerated. Taper if discontinued (4)[A].
- Milnacipran day 1: 12.5 mg/day; days 2 to 3, begin dividing doses: 12.5 mg
BID; days 4 to 7: 25 mg BID; after day 7: 50 mg BID; max dose 100 to 200 mg BID. Taper if discontinued (4)[A].

- Pregabalin: Start with 75 mg BID, titrate over 1 week to 150 mg BID; max dose 450 mg/day divided BID–TID (4)[A]
- Cyclobenzaprine 5 mg qHS; titrate to 10 mg BID–TID as tolerated (3)[B].

**Second Line**

- Gabapentin: Start at 300 mg HS, titrate to 1,200 to 2,400 mg/day divided BID–TID; max dose 3,600 mg daily (3)[B]
- Venlafaxine: XR 37.5 to 225 mg; likely to be as effective as other SNRIs (duloxetine, milnacipran)
- Tramadol 50 to 100 mg q6h; likely more effective in combination with acetaminophen (3)[C]
- Quetiapine 25–100 mg qHS (5)[B]
- Several investigational agents show some promise of benefit, including, naltrexone, sodium oxybate, cannabinoids, and pirlindole (5).
- Cholecalciferol may be beneficial in patients with low 25-OH vitamin D levels.
- Use of two or more agents may be more effective than monotherapy. Watch for overall sedative and anticholinergic burden.
- Trigger point (not Tender Point) injections for regional myofascial dysfunction may provide relief (6).

**Alert**

Ineffective or dangerous treatment modalities

- NSAIDs, full-agonist opioids (except in refractory cases), benzodiazepines, SSRIs (may have efficacy in combination therapy), magnesium, guaifenesin, thyroxine, corticosteroids, DHEA, valacyclovir, interferon, calcitonin, and antiepileptic agents (other than those listed above) (5)[A]
- Fibromyalgia often presents concurrently with other pain syndromes that may respond to NSAIDs, corticosteroids, opioids, and other agents.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Acupuncture and electroacupuncture, biofeedback, hypnotherapy
- Balneotherapy (mineral-rich baths)
- Yoga, tai chi, and qi gong—improve sleep, fatigue, and quality of life but may not decrease pain
Limited double-blind trials have shown effectiveness of supplementation with S-adenosyl methionine and acetyl-L-carnitine.

Some evidence for transcranial direct current or magnetic stimulation and repetitive transcranial magnetic stimulation

Likely to be ineffective: chiropractic treatment, massage, electrotherapy, ultrasound

**ISSUES FOR REFERRAL**
In cases of unclear diagnosis or poor response to therapy, refer to rheumatology, neurology, and/or pain management

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- For efficacy of initial therapy: at 2- to 4-week intervals; then every 1 to 6 months, tailored to patient’s needs
- Advance exercise gradually to maintain tolerability.

**DIET**
No specific diet is recommended, but patient should be urged to make healthy choices and address negative dietary habits. Caloric or carbohydrate restriction may be helpful in obese patients.

**PROGNOSIS**
- 50% with partial remission after 2 to 3 years of therapy; complete remission possible but rare.
- Typically has fluctuating, chronic course
- Poorer outcome tied to greater duration and severity of symptoms, depression, advanced age, lack of social support

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: *Fatigue*

**CODES**

ICD10

M79.7 Fibromyalgia

**CLINICAL PEARLS**

- Use ACR criteria to make the formal diagnosis.
- Fibromyalgia is not a somatoform disorder and is not merely a manifestation of depression or anxiety. As with all chronic pain syndromes, fibromyalgia is frequently associated with mood and anxiety disorders.
- The best clinical outcomes occur in patients who understand their illness and actively engage in a multimodal treatment plan that includes exercise, sleep
hygiene, judicious medication use, CBT, and lifestyle modifications.
FOLLICULITIS
David L. Anderson, MD

BASICS
DESCRIPTION

- Superficial inflammation of a follicle, usually a hair follicle, caused by infection, local trauma, or chemical irritation (1)
- Can occur anywhere on the body where hair is found
- Most frequent symptom is pruritus.
- Painless or tender pustules, vesicles, or pink/red papulopustules up to 5 mm in size
- Most commonly infectious in etiology:
  - *Staphylococcus aureus* bacteria (most common)
  - *Pseudomonas aeruginosa* infects areas of the body exposed to poorly chlorinated hot tubs, pools, or contaminated water.
  - *Aeromonas hydrophila* with recreational water exposure
  - Fungal (dermatophytic, *Pityrosporum*, *Candida*)
  - Viral (*VZV*, herpes simplex virus [HSV])
  - Parasitic (*Demodex* spp. mites, schistosomes)
- Noninfectious types
  - Acneiform folliculitis
  - Actinic superficial folliculitis
  - Acne vulgaris
  - Keloidal folliculitis
  - Folliculitis decalvans
  - Perioral dermatitis
  - Rosacea
  - Fox-Fordyce disease
  - Pruritus folliculitis of pregnancy
  - Eosinophilic pustular folliculitis (three variants: Ofuji disease in patients of Asian descent, HIV-positive/immunocompromised, infantile)
  - Toxic erythema of the newborn
  - Eosinophilic folliculitis (seen in HIV-positive/immunocompromised)
  - Follicular mucinosis
- Skin disorders may produce a follicular eruption that includes the following:
– Pseudofolliculitis: similar in appearance; occurs after shaving; affects the face, scalp, pubis, and legs. Pseudofolliculitis barbae, or razor bumps, occurs frequently in black men.
– Atopic dermatitis
– Follicular psoriasis

EPIDEMIOLOGY
Affects persons of all ages, gender, and race

ETIOLOGY AND PATHOPHYSIOLOGY
Predisposing factors to folliculitis
● Chronic staphylococcal carrier
● Diabetes mellitus
● Malnutrition
● Pruritic skin disease (e.g., scabies, eczema)
● Exposure to poorly chlorinated swimming pools/hot tubs or water contaminated with *P. aeruginosa*, *A. hydrophila*, or schistosomes
● Occlusive corticosteroid use (for multiple hours)
● Bacteria
  – Superficial or deep
  – Most frequently due to *S. aureus* (increasing number of methicillin-resistant *S. aureus* [MRSA] cases)
  – Also due to *Streptococcus* species, *Pseudomonas* (following exposure to water contaminated with the species), or *Proteus*
  – May progress to furunculosis (painful pustular nodule with central necrosis that leaves a permanent scar after healing)
● Fungal
  – Dermatophytic (tinea capitis, corporis, pedis)
  – *Pityrosporum* (Pityrosporum orbiculare) commonly affecting teenagers and men, predominantly on upper chest and back
  – *Candida albicans*, although rare, has been reported with broad-spectrum antibiotic use, glucocorticoid use, immunosuppression, and in those who abuse heroin, resulting in candidemia that leads to pustules and nodules in hair-bearing areas.
● Viral
  – HSV
  – May be due to molluscum contagiosum, usually a sign of immunosuppression
• Parasitic
  – Demodex spp. mites (most commonly Demodex folliculorum)
  – Schistosomes (swimmer’s itch)
• Acneiform type commonly drug-induced (systemic and topical corticosteroids, lithium, isoniazid, rifampin), EGFR inhibitors
• Severe vitamin C deficiency
• Actinic superficial type occurs within 24 to 48 hours of exposure to the sun, resulting in multiple follicular pustules on the shoulders, trunk, and arms.
• Acne vulgaris
• Keloidal folliculitis is a chronic condition affecting mostly black patients; involves the neck and occipital scalp, resulting in hypertrophic scars and hair loss; usually secondary to folliculitis barbae from shaving
• Folliculitis decalvans is a chronic folliculitis that leads to progressive scarring and alopecia of the scalp.
• Rosacea consists of papules, pustules, and/or telangiectasias of the face; individuals are genetically predisposed. Helicobacter pylori and D. folliculorum have also been implicated.
• Perioral dermatitis seen most commonly in children and young women; restricted to the perioral region as well as the lower eyelids; may be due to cosmetics, hyperandrogenemia, or use of fluorinated topical corticosteroids
  – Typically spares vermilion border
• Fox-Fordyce disease affects the skin containing apocrine sweat glands (i.e., axillae), resulting in chronic pruritic, annular, follicular papules.
• Eosinophilic pustular folliculitis has three variants: classic (Ofuji disease), associated with HIV infection, and infantile.
• Toxic erythema of the newborn is a self-limiting pustular eruption usually appearing during the first 3 to 4 days of life and subsequently fading in the following 2 weeks.
• Malassezia infections in adult males with lesions on trunk (2)

**RISK FACTORS**
• Hair removal (shaving, plucking, waxing, epilating agents)
• Other pruritic skin conditions: eczema, scabies
• Occlusive dressing or clothing
• Personal carrier or contact with MRSA-infected persons
• Diabetes mellitus
• Immunosuppression (medications, chemotherapy, HIV)
• Use of hot tubs or saunas
• Use of EGFR inhibitors
• Chronic antibiotic use (gram-negative folliculitis)

**GENERAL PREVENTION**
• Good hygiene practices
  – Wash hands frequently.
  – Antimicrobial soap
  – Wash towels, clothes, and linens frequently with hot water to avoid reinfection.
• Good hair removal practices
  – Exfoliate beforehand.
  – Use witch hazel, alcohol, or Tend Skin afterward.
  – Shave in direction of hair growth; use moisturizer/warm water.
  – Decrease frequency of shaving.
  – Use clippers primarily or single-blade razors if straight shaving is desired.

**COMMONLY ASSOCIATED CONDITIONS**
• Impetigo
• Furunculosis
• Scabies
• Acne
• Follicular psoriasis
• Eczema

**DIAGNOSIS**

**HISTORY**
• Recent use of hot tubs, swimming pools, topical corticosteroids, certain hair styling and shaving practices, antibiotics or systemic steroids
• HIV status
• History of STDs (specifically syphilis)
• MRSA exposures/carrier status
• Ask about home and work environment (risk/exposure potential).
• Pityrosporum folliculitis occurs more often in warm, moist climates.
• Inquire about the timeline in which the lesions have occurred, including previous similar episodes.

**PHYSICAL EXAM**
Characteristic lesions are 1- to 5-mm–wide vesicles, pustules, or papulopustules with surrounding erythema.

Rash occurs on hair-bearing skin, especially the face (beard), proximal limbs, scalp, and pubis.

Pseudomonal folliculitis appears as a widespread rash, mainly on the trunk and limbs.

In pseudofolliculitis, the growing hair curls around and penetrates the skin at shaved areas.

**DIFFERENTIAL DIAGNOSIS**

- Acne vulgaris/acneiform eruptions
- Arthropod bite
- Contact dermatitis
- Cutaneous candidiasis
- Milia
- Atopic dermatitis
- Follicular psoriasis
- Hidradenitis suppurativa

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Diagnosis is usually made clinically, taking risk factors, history, and location of lesion into account.
- Culture and Gram stain of the pustule by scraping the pustule with a no. 15 blade and not directly swabbing the skin to identify infectious agent and sensitivities to antibiotics
- KOH preparation as well as Wood lamp fluorescence to identify *Candida* or yeast
- Tzanck smear where suspicion of herpetic simplex viral folliculitis is high

**Follow-Up Tests & Special Considerations**

- If risk factors or clinical suspicion exist, consider serologies for HIV or syphilis.
- If recurrent, consider HIV testing and A1C/fasting blood sugar testing to evaluate for diabetes.
- Punch biopsy may be considered if lesions persist despite treatment (3)[C].

**Test Interpretation**
TREATMENT

GENERAL MEASURES

- Lesions usually resolve spontaneously.
- Avoid shaving and waxing affected areas (5)[C].
- Warm compresses may be applied TID.
- Systemic antibiotics are typically unnecessary.
- Topical mupirocin may be used in presumed S. aureus infection.
- Topical antifungals for fungal folliculitis (2)[B]
- Preventive measures are keys to avoidance of recurrence:
  - Antibacterial soaps (Dial soap, chlorhexidine, or benzoyl peroxide wash when showering/bathing)
  - Bleach baths (1/2 cup of 6% bleach per standard bathtub, and soak for 5 to 15 minutes followed by water rinse 1 to 2 times a week)
  - Keep skin intact; daily skin care with noncomedogenic moisturizers; avoid scratching.
  - Clean shaving instruments daily or use disposable razor, disposing after 1 use.
  - Change washcloths, towels, and sheets daily.

MEDICATION

Antiseptic and supportive care is usually enough. Systemic antibiotics may be used with questionable efficacy.

First Line

- Staphylococcal folliculitis
  - Mupirocin ointment applied TID for 10 days
  - Cephalosporin (cephalexin): 250 to 500 mg PO QID for 7 to 10 days
  - Dicloxacillin: 250 to 500 mg PO QID for 7 to 10 days

- For MRSA
  - Bactrim DS: 1 to 2 tablets (160 mg/800 mg) BID PO for 5 to 10 days
  - Clindamycin: 300 mg PO TID for 10 to 14 days
– Minocycline: 200 mg PO initially and then 100 mg BID for 5 to 10 days
– Doxycycline: 50 to 100 mg PO BID for 5 to 10 days

*Pseudomonas* folliculitis
– Topical dilute acetic acid baths
– Ciprofloxacin: 500 to 750 mg PO BID for 7 to 14 days only if patient is immunocompromised or lesions are persistent

Eosinophilic folliculitis/eosinophilic pustular folliculitis
– HAART treatment for HIV-positive–related causes
– Topical corticosteroids: betamethasone 0.1% BID for 3 to 24 weeks or
– Antihistamines (hydroxyzine, cetirizine) or
– Tacrolimus topically BID for 3 to 24 weeks or
– Isotretinoin 0.5 mg/kg/day PO for 4 to 8 weeks or
– Itraconazole or metronidazole

Fungal folliculitis
– Topical antifungals: ketoconazole 2% cream or shampoo or selenium sulfide shampoo daily or
– Econazole cream applied to affected area BID for 2 to 3 weeks
  o Systemic antifungals for relapses fluconazole (100 to 200 mg/day for 3 weeks) or itraconazole (200 mg/day for 1 to 3 weeks)
  o Griseofulvin (tinea capitis in children; 10 to 20 mg/kg/day for 6 weeks minimum)

Parasitic folliculitis
– 5% permethrin: Apply to affected area, leave on for 8 hours, and wash off.
– Ivermectin: 200 μg/kg × 1 followed by topical permethrin

Herpetic folliculitis
– Valacyclovir: 500 mg PO TID for 5 to 10 days or
– Famciclovir: 500 mg PO TID for 5 to 10 days or
– Acyclovir: 200 mg PO 5 times daily for 5 to 10 days

**ISSUES FOR REFERRAL**
Unusual or persistent cases should be biopsied and then referred to dermatology.

**ADDITIONAL THERAPIES**

Public Health Measures
– Outbreaks of culture-positive *Pseudomonas* hot tub folliculitis should be reported so that source identification can be determined and superchlorination (14 parts/million) can occur.
SURGERY/OTHER PROCEDURES
Incision and drainage is unlikely to be necessary and typically not preferred due to potential for scar formation.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Resistant cases should be followed every 2 weeks until cleared.
- One return visit in 2 weeks if symptoms abate

DIET
For obese patients, weight reduction will decrease skin-on-skin friction.

PATIENT EDUCATION
Avoid shaving in involved areas.

PROGNOSIS
- Usually resolves with treatment; however, *S. aureus* carriers may experience recurrences.
- Mupirocin nasal treatment for carrier status and for family/household members might be helpful.
- Resistant or severe cases may warrant testing for diabetes mellitus or immunodeficiency (HIV) (3)[C].

COMPLICATIONS
- Primary complication is recurrent folliculitis.
- Extensive scarring with hyperpigmentation
- Progression to furunculosis or abscesses

REFERENCES
2. Song HS, Kim SK, Kim YC. Comparison between *Malassezia* folliculitis and

**ADDITIONAL READING**

Algorithm: Rash
CODES

ICD10
- L73.9 Follicular disorder, unspecified
- L66.2 Folliculitis decalvans
- L73.8 Other specified follicular disorders

CLINICAL PEARLS
- Folliculitis lesions are typically 1- to 5-mm clusters of pruritic erythematous papules and pustules.
- Most commonly due to \textit{S. aureus}. If community has increased incidence of MRSA, consider anti-MRSA treatment.
  - It is extremely important to educate patients on proper hygiene and skin care techniques in order to prevent chronic or recurrent cases.
FOOD ALLERGY
Stanley Fineman, MD

BASICS

DESCRIPTION
- Hypersensitivity reaction caused by certain foods
- System(s) affected: gastrointestinal, hemic/lymphatic/immunologic, pulmonary, skin/exocrine
- Synonym(s): allergic bowel disease; dietary protein sensitivity syndrome

EPIDEMIOLOGY
- Predominant age: all ages but more common in infants and children
- Predominant sex: male > female (2:1)

Incidence
Prospective studies indicate ~2.5% of infants experience hypersensitivity reactions to cow’s milk in their 1st year of life (1)[B].

Prevalence
- The prevalence of IgE-mediated food allergy assessed by food challenge is 3% (1)[B].
- The self-reported prevalence of food allergy is 12% in children and 13% in adults (1)[B].
- In young children, the most common food allergies are cow’s milk (2.5%), egg (1.3%), peanut (0.8%), and wheat (0.4%) (2)[B].
- Adults tend to have allergies to shellfish (2%), peanut (0.6%), tree nuts (0.5%), and fish (0.4%).
- In general, only 3–4% of children >4 years of age have persisting food allergy; food allergy is frequently a transient phenomenon (2)[B].
- 20% of children with peanut protein allergy may outgrow their sensitivity by school age.

ETIOLOGY AND PATHOPHYSIOLOGY
Allergic response triggered by immunologic mechanisms (e.g., IgE-allergic response) or nonimmunologic-mediated mechanisms
Any ingested substance can cause allergic reactions:
- Most commonly implicated foods include cow’s milk, egg whites, wheat, soy, peanuts, fish, tree nuts (walnut and pecan), and shellfish.
- Several food dyes and additives may elicit non–IgE-mediated allergic-like reactions.

Genetics
In family members with a history of food hypersensitivity, the probability of food allergy in subsequent siblings may be as high as 50%.

Risk Factors
- Persons with allergic or atopic predisposition have increased risk of hypersensitivity reaction to food.
- Family history of food hypersensitivity

General Prevention
- Avoid the offending food.
- In patients at risk for anaphylaxis, epinephrine autoinjectors should be readily available.

Diagnosis

History
- It is important to have a history of a temporal relationship of symptoms after food ingestion/exposure.
- Symptoms are usually within 30 minutes of ingestion but could be delayed 4 to 8 hours.

Physical Exam
- GI (system usually affected)
  - More common: nausea, vomiting, diarrhea, abdominal pain, occult bleeding, flatulence, and bloating
  - Less common: malabsorption, protein-losing enteropathy, eosinophilic enteritis, colitis
- Dermatologic
  - More common: urticaria/angioedema, atopic dermatitis, pallor, or flushing
  - Less common: contact rashes
- Respiratory
  - More common: allergic rhinitis, asthma and bronchospasm, cough, serous otitis media
  - Less common: pulmonary infiltrates (Heiner syndrome), pulmonary hemosiderosis
- Neurologic
  - Less common: migraine headaches
- Other symptoms
  - Systemic anaphylaxis, vasculitis

**DIFFERENTIAL DIAGNOSIS**
- A careful history is necessary to document a temporal relationship with the manifestations of suspected food hypersensitivity.
- True food allergy or hypersensitivity should be differentiated from food intolerance which may present with similar symptoms.
- GI (irritable bowel syndrome, celiac sprue, dumping syndrome, inflammatory bowel diseases, etc.), dermatologic, respiratory, neurologic, psychiatric (generalized anxiety disorder, personality disorders, etc.), or other systemic manifestations may mimic a variety of clinical entities (e.g., vasovagal symptoms).

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- CBC with differential: Eosinophilia in blood or tissue suggests atopy.
- Serum IgA antitissue transglutaminase (IgA-anti-tTG)
- Epicutaneous (prick or puncture) allergy skin tests are used to document IgE-mediated immunologic hypersensitivity and can be done using commercially available extracts (variable sensitivities) or fresh food skin testing.
- Skin testing using the suspect food is helpful. If negative on skin test, an oral challenge may aid in diagnosis. The overall correlation between commercially available allergy skin testing and oral food challenge is 60% but increases to 90% when fresh food skin testing is done (i.e., the positive skin test correlates with a positive challenge).
  - Skin testing has a high sensitivity (low false-negative rate) *but* a low specificity (high false-positive rate), so *only* skin test against antigens found on history (3)[C].
- Food-specific IgE assays (radioallergosorbent test [RAST] and fluorescent enzyme immunoassay [FEI]) detect specific IgE antibodies to offending foods
and are less sensitive to skin testing.
– In certain laboratories, the ImmunoCAP food-specific IgE was almost as accurate as a skin test in predicting positive oral challenges.
– Using a serum assay alone to diagnose food allergy can result in misdiagnosis of true food allergic sensitivity, particularly in children with atopic dermatitis. Do not use a panel. Test for specific IgE to foods based on patient history.

- Periodic monitoring of peanut-specific IgE levels every 2 years may be helpful. If the level of peanut-specific IgE falls to <0.5 kU/L, a supervised oral challenge can be helpful. Consider a fresh food skin test with peanut protein prior to the oral challenge (3)[B].
- Component-resolved diagnosis (CRD) is a new diagnostic tool that measures specific allergenic proteins in various foods to help identify sIgE to allergenic proteins rather than the whole allergen. These can be particularly helpful for certain nuts (e.g., peanuts) (4)[B].
- Patch testing for patients with eosinophilic esophagitis and atopic dermatitis for foods to determine delayed-sensitivity immunologic reactions is of marginal benefit (1)[B].
- Widespread allergy skin testing or serum IgE tests are *not* recommended because of their poor predictive value without a clinical correlating history (2)[B].
- Leukocyte histamine release and assays for circulating immune complexes are of limited clinical use:
  – Assays for IgG and IgG 4 subclass antibodies are commercially available.
  – No convincing data suggest that these tests are reliable for the diagnosis of food allergy (2)[B].
- The provocative injection and sublingual provocative tests have been proven to be of little benefit for diagnosis of food allergy.
- The leukocytotoxic assay is an unproven diagnostic procedure (1)[B].
- Other unproven diagnostic procedures that are not recommended include provocative neutralization, lymphocyte stimulation, hair analysis, and applied kinesiology (2)[B].

**Diagnostic Procedures/Other**
Elimination and challenge test is the best procedure for confirming food allergy:
- Eliminate the suspected food from the diet for 1 to 2 weeks.
- Monitor the patient’s symptoms. If they disappear or substantially improve, perform an oral challenge with the suspected food under medical supervision.
Optimally, this challenge should be performed in a double-blind, placebo-controlled manner.

Patients with history of anaphylaxis should not have an oral challenge without a documented lack of IgE sensitivity.

Most allergic reactions occur within 30 minutes to 2 hours after challenge. Late reactions have been described from 12 to 24 hours.

Consider referral to gastroenterology for endoscopy and continue monitoring carefully if history and testing are inconclusive.

**Test Interpretation**

Pathologic findings on tissue biopsy are not common in food allergies; inflammatory changes can sometimes be seen in the GI tract. The diagnosis of eosinophilic esophagitis is defined by the finding of >15 to 20 eosinophils per high-power field on esophageal biopsy (2)[C].

**TREATMENT**

**GENERAL MEASURES**

- Avoidance of offending foods is the most effective mode of treatment.
- Patients with severe food allergy should be meticulous about food avoidance. They should carry epinephrine for self-administration in the event that the offending food is ingested unknowingly and an immediate reaction develops.
- Immunotherapy may be effective for certain food allergies. Oral immunotherapy (OIT), sublingual immunotherapy (SLIT), and epicutaneous immunotherapy (EPIT). These techniques are still considered experimental and are not recommended for patients who are not participating in appropriately controlled and monitored clinical trials (5)[C].
- Immunotherapy or hyposensitization with food extracts by various routes, including SC immunotherapy or sublingual neutralization, are not recommended. Research studies are in progress, but immunotherapy is considered experimental at this time.

**MEDICATION**

- Patients with significant type 1, IgE-mediated hypersensitivity should have epinephrine available for autoinjection in case of an anaphylactic reaction.
- After receiving epinephrine for a systemic anaphylactic reaction to a food, patients should be monitored in a medical facility (15–25% of patients may
require >1 dose of epinephrine).
- Symptomatic treatment for milder reactions with antihistamines is generally sufficient.
- Cromolyn is not recommended for use in most patients with food allergy.

COMPLEMENTARY & ALTERNATIVE MEDICINE
There are reports of benefit using various Chinese herbal medicines in laboratory animals with induced food allergy. Benefits have not been reported in humans at this time.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
As needed

DIET
- As determined by tests and clinical evaluation
- Strict avoidance of offending food

PATIENT EDUCATION
- Dietary counseling is advised to maintain a nutritionally sound diet avoiding foods to which the patient is sensitive.
- Food Allergy Research & Education, Inc.: 7925 Jones Branch Drive Suite 1100 McLean, VA 22102 Toll-Free: 800-929-4040; Web site www.foodallergy.org

PROGNOSIS
- Most infants outgrow food hypersensitivity by 2 to 4 years:
  - It may be possible to reintroduce the offending food cautiously into the diet (particularly helpful if food is one that is difficult to avoid). Check IgE specific to the offending food by fresh food allergy skin test. Ensure test negative prior to oral challenge.
  - 20% of peanut allergies resolve by age 5 years.
– 42% of children with egg allergy and 48% of children with milk allergy develop clinical tolerance and lose their sensitivity over time (1)[C].

- Adults with food hypersensitivity (particularly to milk, fish, shellfish, or nuts) tend to maintain their allergy for many years (2)[B].

COMPLICATIONS

- Anaphylaxis
- Angioedema
- Bronchial asthma
- Enterocolitis
- Eosinophilic esophagitis
- Eczematoid lesions

ADDITIONAL READING

**临床珠串**

- 上述 20% 的儿童患花生过敏可能脱敏。
  - 期监测花生特异性 IgE 水平每 2 年可能有帮助。如果花生特异性 IgE 水平降至 <0.5 kU/L，则在过敏专家的监督下进行谨慎的口服挑战可能被考虑。花生蛋白新鲜食物皮肤测试应在口服挑战前进行。
  - 口腔过敏症是与食物相关蛋白交叉反应的结果（例如，对桦树花粉过敏的患者常对新鲜苹果和梨有交叉反应）。
  - 孕期和哺乳期的膳食限制不防止婴儿的过敏性疾病。
  - 哺乳建议在前 6 个月内进行，特别是在有家族过敏史时。
  - 延迟 6 个月以后引入固体食物对过敏的发展没有显著保护作用。
  - 4 至 11 个月大有湿疹或其他食物过敏的儿童可能从早期引入花生蛋白获益。考虑过敏皮肤测试前引入花生蛋白。
FOOD POISONING, BACTERIAL

Jewell P. Carr, MD • Daniel J. Fisher, MD

BASICS

DESCRIPTION

- A condition resulting from the consumption of contaminated food or water
- Symptoms commonly include vomiting, diarrhea, dehydration, abdominal discomfort, and fever (1).
- Foodborne illness may be caused by bacterial, parasitic, or viral infection (2).

EPIDEMIOLOGY

- Roughly 1 in 6 Americans (48 million) become ill, 128,000 are hospitalized, and 3,000 die of foodborne diseases annually (3).
- 80% of foodborne illness is due to unclear agents (3).
- Bacterial pathogens most commonly contributing to foodborne illness are Salmonella (nontyphoidal), Campylobacter, Clostridium perfringens, Staphylococcus aureus, Listeria monocytogenes, and Escherichia coli (1,3).
- Norovirus is the most common viral cause of foodborne illness in the United States (4).

ETIOLOGY AND PATHOPHYSIOLOGY

- Short incubation period (1 to 6 hours)
  - Bacillus cereus toxin
    o Food sources: improperly cooked rice/fried rice and red meats (2)
    o Symptoms: sudden onset of severe nausea and vomiting. Diarrhea may be present.
  - S. aureus (1)
    o Food sources: nonrefrigerated or improperly refrigerated meats and potato and egg salads
    o Symptoms: sudden onset of severe nausea and vomiting. Abdominal cramps and fever may be present.

- Medium incubation period (8 to 16 hours)
  - B. cereus (1)
    o Food sources: meat, stews, gravy, vanilla sauce
    o Symptoms: watery diarrhea, abdominal cramps, nausea
- **C. perfringens** (1,2)
  - Food sources: dry/precooked or undercooked meats and poultry
  - Symptoms: watery diarrhea, nausea, abdominal cramps

**Long incubation period (>16 hours)**

Toxin-producing organisms:

- *Clostridium botulinum* (1)
  - Food source: commercially canned or improperly home-canned foods
  - Symptoms: vomiting, diarrhea, slurred speech, diplopia, dysphagia, and descending muscle weakness/flaccid paralysis

- Enterohemorrhagic *E. coli* (e.g., 0157:H7) (1,2)
  - Food sources: undercooked beef, especially hamburger; unpasteurized milk; raw produce; and contaminated water
  - Symptoms: severe diarrhea that often becomes bloody, abdominal pain, vomiting

- Enterotoxigenic *E. coli* (“traveler’s diarrhea”) (5)
  - Food sources: food or water contaminated by human feces
  - Symptoms: watery diarrhea, abdominal cramps, tenesmus, fecal urgency, and vomiting

- *Vibrio cholerae* (2)
  - Food sources: contaminated water, fish, and shellfish, especially food sold by street vendors
  - Symptoms: profuse watery “rice water” diarrhea and vomiting, which can lead to severe dehydration and death within hours

**Invasive organisms**

- *Salmonella, nontyphoidal* (1,2,4)
  - Food sources: contaminated eggs, poultry, unpasteurized milk or juice, cheese, contaminated raw fruit and vegetables, and contaminated peanut butter
  - Symptoms: small volume, mucopurulent and possibly bloody diarrhea, fever, abdominal cramps, vomiting

- *Campylobacter jejuni* (1,2)
  - Food sources: raw and undercooked poultry, unpasteurized milk, and contaminated meats
  - Symptoms: diarrhea (possibly bloody), cramps, vomiting, fever

- *Shigella* (1,2)
  - Food sources: contaminated water, raw produce, uncooked foods, foods handled by infected food worker
  - Symptoms: abdominal cramps, fever, mucopurulent and bloody diarrhea
– *Vibrio parahaemolyticus* (1,2)
  o Food source: undercooked or raw seafood, especially shellfish
  o Symptoms: nausea, vomiting, diarrhea, abdominal pain
– *Vibrio vulnificus* (1,2)
  o Food source: undercooked or raw seafood, particularly oysters
  o Symptoms: vomiting, diarrhea, abdominal pain, bacteremia, wound infections; can be fatal in patients with liver disease or those who are immunocompromised
– *Yersinia enterocolitica* (2)
  o Food sources: undercooked beef and pork, unpasteurized milk, tofu, contaminated water
  o Symptoms: abdominal pain, fever, diarrhea (possibly bloody), vomiting
– *L. monocytogenes* (1)
  o Food sources: unpasteurized/contaminated milk, soft cheese, and processed deli meats
  o Symptoms: nausea, vomiting, fever, watery diarrhea; pregnant women may have a flu-like illness leading to premature delivery or stillbirth; immunocompromised patients may develop meningitis and bacteremia.

**RISK FACTORS**
- Recent travel to a developing country (4)
- Food handlers, daycare attendees, nursing home residents, and recently hospitalized patients (2)
- Altered immunity due to underlying disease or use of certain medications, including antacids, H₂ blockers, and proton pump inhibitors (4)
- Cross-contamination and subsequent ingestion of improperly prepared and stored foods

**GENERAL PREVENTION**
- When preparing food:
  – Wash hands, cutting boards, and food preparation surfaces before and after preparing each item.
  – Wash fresh produce thoroughly before eating.
  – Keep raw meat, poultry, fish, and their juices away from other food (e.g., salad).
  – Do not put cooked protein or washed produce into containers or on surfaces where unwashed or raw food was stored.
  – Thoroughly cook meat to the following internal temperature:
- Fresh beef, veal, pork, and lamb: 145°F
- Ground meats and egg dishes: 160°F
- Poultry: 165°F
- Cook eggs thoroughly until the yolk is firm.
- Seafood: 145°F
  - Refrigerate leftovers within 2 to 3 hours in clean, shallow, covered containers. If the temperature is >90°F, refrigerate within 1 hour.

- When traveling to underdeveloped countries:
  - Eat only freshly prepared foods.
  - Avoid beverages and foods prepared with nonpotable water.
  - Other risky foods include raw or undercooked meat and seafood, unpeeled raw fruits, and vegetables.
  - Bottled, carbonated, and boiled beverages are generally safe to drink.
- Improved hygiene and sanitation reduces the risk of traveler’s diarrhea. The prevention strategy “Boil it, Cook it, Peel it, or Forget it” has inconsistent and limited evidence (5).
- Chemoprophylaxis for traveler’s diarrhea is recommended for high-risk travelers (e.g., immunocompromised) (5).

**DIAGNOSIS**

**HISTORY**

- Onset, duration, frequency, severity, and character (i.e., watery, bloody, mucus-filled, etc.) of diarrhea (2)
- The definition of diarrhea is >3 or more unformed stools daily or the passage of >250 g of unformed stool per day (4).
- Suspect bacterial food poisoning when multiple persons have rapid onset of symptoms after eating the same meal; high fever, blood, or mucus in stool; severe abdominal pain; signs of dehydration; or recent travel to a foreign country (2,4).
- Further evaluation and treatment with high fever (≥101.3°F), ≥6 stools per day, blood in the stools, elevated white blood cell count, signs of dehydration, or diarrheal illness that lasts >2 to 3 days (4)

**PHYSICAL EXAM**

- Focus on signs of dehydration: delayed capillary refill, decreased skin turgor, dry mucous membranes, and orthostatic hypotension (2)
• Fever may be suggestive of a more invasive or toxin-producing bacteria (2).
• Abdominal exam: Assess for pain, peritoneal signs, and bowel activity to
differentiate from other acute abdominal processes (2).
• Rectal exam for blood, rectal pain, stool consistency

DIFFERENTIAL DIAGNOSIS
• Other infectious gastrointestinal illnesses (i.e., viral or parasitic)
  
  Clostridium difficile colitis
• Inflammatory bowel disease
• Appendicitis
• Acute cholecystitis
• Acute diverticulitis
• Acute hepatitis
• Malabsorption

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• For most cases of mild, self-limiting food poisoning, a stool culture is not
  necessary and will not change management (1)[C].
• Testing for fecal leukocytes and fecal occult blood is not mandatory. Presence
  of fecal WBC or RBC increases the likelihood of inflammatory diarrhea (2).
• Consider ova and parasites if dehydration, history of foreign travel, or
  symptoms lasting >2 weeks (4).
• CBC, BMP for severe cases with dehydration, inpatient, and nursing home
  exposure (4)
• Endoscopic evaluation may be considered for severe cases or in patients with
  symptoms persisting for 14 to 30 days and negative stool cultures (4,6).
• Abdominal CT may be helpful when intra-abdominal pathology is in the
differential (4).

Follow-Up Tests & Special Considerations
Epidemiologic investigation may be warranted. Reporting requirements vary by
state and organism (1).

TREATMENT
Most cases of food poisoning are self-limited and do not require medication.
**MEDICATION**

**First Line**
- Oral rehydration is the first-line therapy for treating acute diarrheal illness (2).
- A balanced oral rehydration solution (ORS) is particularly recommended for elderly or pediatric patients with severe diarrhea, or for travelers with severe, cholera-like watery diarrhea (6)[B].
- Most patients with mild illness do not need formal ORS and can rehydrate with fluids in a typical diet (6).
- Empiric antibiotic therapy is not recommended for most cases of acute diarrhea (unless traveler’s diarrhea is suspected) (6)[A].

**Second Line**
Consider antibiotics only for patients with severe illness requiring hospitalization and those with fever and hematochezia or when diagnostic testing confirms a bacterial source (1). Pathogen-specific therapy:
- *B. cereus* (2)
  - Supportive care only
- *C. jejuni* (2,4)
  - Mild: supportive care only—antibiotics may induce resistance.
  - Severe: azithromycin 500 mg/day for 3 to 5 days. Fluoroquinolones are no longer recommended due to resistance (1).
- *C. botulinum*
  - Supportive care only. Antitoxin can be helpful early during illness.
- *C. perfringens*
  - Supportive care only
- Enterohemorrhagic *E. coli* (e.g., 0157:H7) (4)
  - Supportive care only. Closely monitor renal function, hemoglobin, and platelets. Infection associated with hemolytic uremic syndrome (HUS). Antibiotics may increase this risk.
- Enterotoxigenic *E. coli* (common cause of traveler’s diarrhea) (2,4,5)
  - Generally self-limited. Antibiotics shorten course of illness (5)[A].
  - Ciprofloxacin 500 mg BID or 750 mg daily for 1 to 3 days; azithromycin 1 g × single dose or daily for 3 days; or rifaximin 200 mg TID for 3 days
- *Salmonella, nontyphoidal* (2,4–6)
  - No therapy in mild disease (Antibiotics may lengthen shedding.)
  - Moderate: ciprofloxacin 500 mg BID for 5 to 7 days, levofloxacin 500 mg daily for 7 to 10 days, or TMP/SMX DS 160/800 mg twice per day for 5 to
7 days
- Severe diarrhea, immunocompromised, systemic signs, positive blood cultures: IV ceftriaxone 1 to 2 g daily for 7 to 10 days

- **Shigella (2,4)**
  - Ciprofloxacin 500 mg BID or 750 mg daily for 3 days, or 2-g single dose; alternative options: azithromycin 500 mg twice per day for 3 days, TMP/SMX DS 160/800 mg twice per day for 5 days, or ceftriaxone 2 to 4 g single dose

- **S. aureus (4)**
  - Supportive care only

- **Noncholeraic Vibrio (4)**
  - Ciprofloxacin 750 mg daily for 3 days or azithromycin 500 mg daily for 3 days

- **V. cholerae (4)**
  - Doxycycline 300 mg 1-time dose in most cases, or tetracycline 500 mg QID for 3 days, or erythromycin 250 mg TID for 3 days, or azithromycin 500 mg/day for 3 days

- **Yersinia (2)**
  - Usually supportive care only
  - Severe: doxycycline combine with aminoglycoside; TMP/SMX DS 160/800 mg BID for 5 days; or ciprofloxacin 500 mg BID for 7 to 10 days

### ADDITIONAL THERAPIES
- For severe nausea and vomiting, promethazine is effective in adults. Ondansetron is effective in children (5).
- Loperamide 4 mg initially then 2 mg after each loose stool to a maximum of 8 mg in a 24-hour period may be used unless high fever, bloody diarrhea, and/or severe abdominal pain present (signs of enteroinvasion) (5).
- Bismuth subsalicylate (Pepto-Bismol) 525 mg QID is moderately effective in traveler’s diarrhea (5).
- Evidence for the effectiveness of probiotics and prebiotics is limited and inconsistent. Currently, their use is not recommended (6).
- Diligent hand washing throughout the course of illness decreases spread (2).

### ONGOING CARE

### DIET
Avoid food if nausea is present or vomiting prevents intake. Drink plenty of fluids in frequent sips.
As nausea subsides, drink adequate fluids; add in bland, low-fat meals; and rest. Avoid alcohol, coffee, nicotine, and spicy foods.
Breastfeed nursing infants on demand. Infants and older children should be offered usual food.
For diarrhea, consider a bland diet (BRAT: Bananas, Rice, Apples, Toast-dry).
Limiting dairy to 24 hours after last diarrhea episode may assist in symptom reduction.

PROGNOSIS
Most infections are self-limited and resolve over several days. Antibiotics for moderate to severe traveler’s diarrhea shortens duration by several days (5).

COMPLICATIONS
- Dehydration (2)
- HUS following E. coli 0157:H7 infection (4)
- Guillain-Barré syndrome following Campylobacter enteritis (4)
- Reactive arthritis following salmonella, shigella, or yersinia infections (4)
- Postinfectious irritable bowel (4)

REFERENCES

ADDITIONAL READING

SEE ALSO
Appendicitis, Acute; Botulism; Brucellosis; Dehydration; Diarrhea, Acute; Guillain-Barré Syndrome; Hypokalemia; Intestinal Parasites; Salmonella Infection; Typhoid Fever

CODES
ICD10
- A05.9 Bacterial foodborne intoxication, unspecified
- A02.0 Salmonella enteritis
- A04.5 Campylobacter enteritis

CLINICAL PEARLS
- Consider bacterial food poisoning when multiple people present after ingesting the same food with fevers and blood/mucus in stool or having recently returned from a developing nation.
- Consider culture and antibiotics if there is persistent fever with blood/mucus in stool, concern for sepsis, and/or for symptoms lasting >7 days.
- Withhold antispasmodics and antidiarrheal agents if there is concern for enteroinvasion (high prolonged fever, bloody diarrhea, severe pain, septicemia).
- Consider empiric antibiotic therapy for traveler’s diarrhea for cases of moderate to severe disease.
BASICS

DESCRIPTION

- A severe localized injury due to cold exposure, causing tissue to freeze, resulting in direct cellular injury and progressive dermal ischemia (most commonly of exposed hands, feet, face, and ears)
- Systems affected: integumentary, vascular, muscular, skeletal, nervous
- Synonym: dermatitis congelationis

EPIDEMIOLOGY

- Predominantly adults but can affect all ages
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY

- Prolonged exposure to cold
- Refreezing thawed extremities
- Ice crystals form intracellularly and extracellularly.
- Vasoconstriction reduces blood flow and microvascular endothelial injury leads to ischemia.
- Cellular dehydration leads to abnormal electrolyte concentrations and cell death.
- In severe cases, tissue injury extends to muscle and bone leading to necrosis and mummification.
- Rewarming injured endothelium results in edema and bullae.
- Inflammatory mediators such as prostaglandins and thromboxane A2 induce vasoconstriction and platelet aggregation, worsening ischemia.

RISK FACTORS

- Prolonged exposure to below freezing temperatures, especially combined with wind and/or water exposure
- High-altitude activities, such as mountaineering
- Military operations in cold environments
- Constricting or wet clothing with inadequate insulation
- Altered mental status due to alcohol, drugs, or psychiatric illness
- Homelessness
- Previous cold-related injury
- Dehydration and/or malnutrition
- Smoking
- Raynaud phenomenon
- Peripheral vascular disease
- Diabetes

**GENERAL PREVENTION**
- Dress in layers with appropriate cold weather gear and avoid clothing that is too constricting.
- Cover exposed areas and extremities appropriately.
- Stay dry; avoid alcohol and minimize wind exposure.
- Ensure adequate hydration and caloric intake.
- Use supplemental oxygen at very high altitudes (>7,500 meters).
- Exercise can protect against frostbite by increasing core and peripheral temperatures.
- Appropriate use of chemical or electric hand and foot warmers can help maintain peripheral warmth.

**COMMONLY ASSOCIATED CONDITIONS**
- Hypothermia
- Alcohol or drug abuse

**DIAGNOSIS**

**HISTORY**
- Significant cold exposure—determine length and severity.
- Throbbing pain
- Paresthesias
- Numbness
- Loss of coordination and dexterity

**PHYSICAL EXAM**
- Hands, feet, face, and ears are most commonly affected.
- Before rewarming, skin may be insensate, white or grayish-yellow in color,
cyanotic, or hard and waxy to touch.

- After rewarming, immediate physical exam findings can be categorized as:
  - Grade 1: no cyanosis on the extremity
  - Grade 2: cyanosis isolated to the distal phalanx
  - Grade 3: intermediate and proximal phalangeal cyanosis
  - Grade 4: cyanosis over the carpal or tarsal bones (1)[C]

- Frostbite can alternatively be categorized into four degrees (similar to burn injuries):
  - 1st degree: numbness and erythema. A white or yellow, firm, slightly raised plaque develops. No gross tissue infarction occurs; there may be slight epidermal sloughing. Mild edema is common.
  - 2nd degree: superficial skin vesiculation; a clear or milky blisters, surrounded by erythema and edema
  - 3rd degree: deeper hemorrhagic blisters
  - 4th degree: extends through the dermis to involve subcutaneous tissues, with necrosis extending into muscle and bone
  - 1st- and 2nd-degree injuries are superficial.
  - 3rd- and 4th-degree injuries are deep (2)[C].

Differential Diagnosis

- Frostnip: a superficial cold injury that resolves spontaneously without tissue loss
- Chilblains (pernio): a localized inflammatory reaction to cold and wet exposure without tissue freezing; typically presents as edematous, erythematous to violaceous skin lesions
- Immersion foot (trench foot): inflammatory reaction of the feet to prolonged exposure to cold and moisture

Diagnostic Tests & Interpretation

Initial Tests (lab, imaging)

- Baseline labs: CBC, CMP, UA for myoglobinuria, culture wound if suspected infection
- Technetium (Tc)-99m scintigraphy can identify tissue viability at early stage and identify candidates for thrombolytic therapy.
- MRI/MRA, duplex ultrasonography, and standard or digital subtraction angiography are occasionally used.
- Consider serial photographs at time of injury, at 24 hours and every several days until hospital discharge.
TREATMENT

GENERAL MEASURES

- Correct hypothermia.
- Assess for additional injuries.
- Remove jewelry from affected extremities.
- Initiate rewarming of affected body part only if there is no risk of refreezing.
- Warm affected parts of body in 37–39°C water for approximately 30 minutes until the involved part takes on a red or purple appearance and becomes pliable to touch.
- A whirlpool bath can help with rewarming.
- Avoid using other heat sources, such as a fire or space heater to rewarm affected parts avoided.
- Apply topical aloe vera gel before dressing.
- Selectively drain clear or cloudy blisters; leave hemorrhagic blisters intact.
- Splint and elevate affected extremity.
- Tetanus prophylaxis
- Oral hydration if patient is alert and has no GI symptoms, otherwise IV hydration with warm normal saline in small boluses
- Daily bathing in warm water with active and passive mobilization
- Dry, loose bulky dressings, including in between fingers/toes (2)[C]

ALERT

- Avoid rubbing the affected area as this can lead to further tissue damage.
- Patients should not walk on a frostbitten foot prior to definitive care.

MEDICATION

First Line

- tPA for deep injury, administered (either IV or intra-arterially) within 24 hours of injury may prevent damage from microvascular thrombosis and reduce amputation rates (3–5)[B].
- Precaution: tPA should not be used with history of recent bleeding, stroke, peptic ulcer, or recent surgery.
- Heparin is recommended as adjunctive therapy in tPA protocols. Heparin is not recommended as monotherapy (5)[C].
- Consider low-molecular-weight dextran in patients not given other systemic treatments (e.g., tPA) (2)[C].
Aspirin 250 mg plus buflomedil 400 mg IV followed by 8 days of iloprost 0.5 to 2.0 mg/kg/min for 6 hr/day may reduce amputation rates in patients with frostbite extending to the proximal phalanx (3)[B].

- Update tetanus toxoid (2)[C].
- Ibuprofen 400 mg q12h (inhibit prostaglandins) (2)[C]
- NSAIDs for mild to moderate pain; narcotic analgesia for moderate to severe pain
- Use systemic antibiotics for proven infection. Prophylactic antibiotics are not recommended (2)[C].

**Second Line**
Pentoxifylline 400 mg q8 hours (6)[C]

**ADDITIONAL THERAPIES**
- Heated oxygen
- Warm IV fluids

**SURGERY/OTHER PROCEDURES**
- Urgent surgery is rarely needed.
- Fasciotomy is indicated if the patient develops elevated compartment pressures (2)[C].
- Surgical débridement, as needed, to remove necrotic tissue
- Amputation only if tissues are necrotic: may take 4 to 12 weeks for the demarcation of tissue necrosis to become definitive
- Consider imaging with 99mTc bone scan and/or MRA in severe cases to determine extent of injury; assess viability of surrounding tissue and determine need for surgery.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Hospitalization is generally recommended unless no blisters are present after rewarming (e.g., grade 1/1st-degree frostbite) (1,2)[C].
- Patients are typically best cared for in a hospital with experience treating frostbite injuries (trauma center or burn unit).
- Administer tPA in intensive care setting.
- Ensure proper hydration and nutrition.
- Treat pain (often requires narcotic analgesia).
- Wound care—clean dressings and twice daily whirlpool baths
- Apply aloe vera gel every 6 to 8 hours through resolution of blisters.
- Elevate injured extremities above heart level to minimize edema.
- Physical therapy and early mobilization
- If patient cannot tolerate oral fluids or has altered mental status, give warmed normal saline in small boluses (2)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Protect injured body parts.
- Continue physical therapy.
- Avoid smoking.
- Avoid recurrent cold exposure.
- Ensure properly fitting clothing and footwear.

**Patient Monitoring**
- Follow-up for physical therapy progress, infection, and other complications listed below
- Monitor growth of affected extremity in pediatric patients.

**DIET**
- As tolerated
- Warm oral fluids

**PATIENT EDUCATION**
Provide education on:
- Protection from cold injuries
- Risk factors for frostbite
- Early signs and symptoms of frostbite
- Field treatment of cold injuries
- Wound care

**PROGNOSIS**
- Grade 1: no amputation and no sequelae
- Grade 2: potential soft tissue amputation and nail sequelae
- Grade 3: potential bone amputation of the digit and functional sequelae
- Grade 4: potential bone amputation of the limb with functional sequelae (1)
COMPPLICATIONS

- Tissue loss: Distal parts of an extremity may undergo spontaneous amputation.
- Tissue necrosis requiring amputation
- Gangrene
- Hyperhidrosis due to nerve injury
- Decreased hair and nail growth
- Raynaud phenomenon
- Changes in skin color
- Joint stiffness and arthritis
- Chronic regional pain
- Neuropathy
- Localized osteoporosis
- Premature closure of epiphyses in pediatric patients

REFERENCES

ADDITIONAL READING

SEE ALSO

- Hypothermia
- Algorithm: Hypothermia

CODES

ICD10

- T33.90XA Superficial frostbite of unspecified sites, init enctr
- T34.90XA Frostbite with tissue necrosis of unsp sites, init enctr
- T33.829A Superficial frostbite of unspecified foot, initial encounter

CLINICAL PEARLS

- Frostbite is a tetanus-prone injury. Provide appropriate tetanus prophylaxis.
- Avoid rewarming en route to the hospital if there is a chance of refreezing; rewarm only with water.
- Assess for additional injuries to areas which may be insensate.
- tPA can reduce amputation rates. Use within 24 hours of injury in appropriate clinical settings.
- Early assessment of the degree of tissue involvement is difficult. Delay surgery until a definite tissue demarcation of necrosis occurs (may take 4 to 12 weeks).
FURUNCULOSIS
Zoltan Trizna, MD, PhD

BASICS
DESCRIPTION
- Acute bacterial abscess of a hair follicle (often Staphylococcus aureus)
- System(s) affected: skin/exocrine
- Synonym(s): boils

EPIDEMIOLOGY
Incidence
- Predominant age
  - Adolescents and young adults
  - Clusters have been reported in teenagers living in crowded quarters, within families, or in high school athletes.
- Predominant sex: male = female

Prevalence
Exact data are not available.

ETIOLOGY AND PATHOPHYSIOLOGY
- Infection spreads away from hair follicle into surrounding dermis.
- Pathogenic strain of S. aureus (usually); most cases in United States are now due to community-acquired methicillin-resistant S. aureus (CA-MRSA), whereas methicillin-sensitive S. aureus (MSSA) is most common elsewhere.

Genetics
Unknown

RISK FACTORS
- Carriage of pathogenic strain of Staphylococcus sp. in nares, skin, axilla, and perineum
- Rarely, polymorphonuclear leukocyte defect or hyperimmunoglobulin E–Staphylococcus sp. abscess syndrome
● Diabetes mellitus, malnutrition, alcoholism, obesity, atopic dermatitis
● Primary immunodeficiency disease and AIDS (common variable immunodeficiency, chronic granulomatous disease, Chédiak–Higashi syndrome, C3 deficiency, C3 hypercatabolism, transient hypogammaglobulinemia of infancy, immunodeficiency with thymoma, Wiskott-Aldrich syndrome)
● Secondary immunodeficiency (e.g., leukemia, leukopenia, neutropenia, therapeutic immunosuppression)
● Medication impairing neutrophil function (e.g., omeprazole)
● The most important independent predictor of recurrence is a positive family history.

GENERAL PREVENTION
Patient education regarding self-care (see “General Measures”); treatment and prevention are interrelated.

COMMONLY ASSOCIATED CONDITIONS
● Usually normal immune system
● Diabetes mellitus
● Polymorphonuclear leukocyte defect (rare)
● Hyperimmunoglobulin E–*Staphylococcus* sp. abscess syndrome (rare)
● See “Risk Factors.”

DIAGNOSIS

HISTORY
● Located on hair-bearing sites, especially areas prone to friction or repeated minor traumas (e.g., underneath belt, anterior aspects of thighs, nape, buttocks)
● No initial fever or systemic symptoms
● The folliculocentric nodule may enlarge, become painful, and develop into an abscess (frequently with spontaneous drainage).

PHYSICAL EXAM
● Painful erythematous papules/nodules (1 to 5 cm) with central pustules
● Tender, red, perifollicular swelling, terminating in discharge of pus and necrotic plug
Lesions may be solitary or clustered.

Differential Diagnosis
- Folliculitis
- Pseudofolliculitis
- Carbuncles
- Ruptured epidermal cyst
- Myiasis (larva of botfly/tumbu fly)
- Hidradenitis suppurativa
- Atypical bacterial or fungal infections

Diagnostic Tests & Interpretation

Initial Tests (lab, imaging)
Obtain culture if with multiple abscesses marked by surrounding inflammation, cellulitis, systemic symptoms such as fever, or if immunocompromised.

Follow-Up Tests & Special Considerations
- Immunoglobulin levels in rare (e.g., recurrent or otherwise inexplicable) cases
- If culture grows gram-negative bacteria or fungus, consider polymorphonuclear neutrophil leukocyte functional defect.

Test Interpretation
Histopathology (although a biopsy is rarely needed)
- Perifollicular necrosis containing fibrinoid material and neutrophils
- At deep end of necrotic plug, in SC tissue, is a large abscess with a Gram stain positive for small collections of S. aureus.

Treatment

General Measures
- Moist, warm compresses (provide comfort, encourage localization/pointing/drainage) 30 minutes QID
- If pointing or large, incise and drain: Consider packing if large or incompletely drained.
- Routine culture is not necessary for localized abscess in nondiabetic patients with normal immune system.
Sanitary practices: Change towels, washcloths, and sheets daily; clean shaving instruments; avoid nose picking; change wound dressings frequently; do not share items of personal hygiene (2)[B].

MEDICATION

First Line
- Systemic antibiotics usually unnecessary, unless extensive surrounding cellulitis or fever. Other indications include a single abscess >2 cm, immunocompromise.
- If suspecting MRSA, see “Second Line.”
- If multiple abscesses, lesions with marked surrounding inflammation, cellulitis, systemic symptoms such as fever, or if immunocompromised: Place on antibiotics therapy directed at S. aureus for 10 to 14 days.
  - Dicloxacillin (Dynapen, Pathocil) 500 mg PO QID or cephalexin 500 mg PO QID or clindamycin 300 mg TID, if penicillin-allergic

Second Line
- Resistant strains of S. aureus (MRSA): clindamycin 300 mg q6h or doxycycline 100 mg q12h or trimethoprim-sulfamethoxazole (TMP-SMX DS) 1 tab q8–12h or minocycline 100 mg q12h
- If known or suspected impaired neutrophil function (e.g., impaired chemotaxis, phagocytosis, superoxide generation), add vitamin C 1,000 mg/day for 4 to 6 weeks (prevents oxidation of neutrophils).
- If antibiotic regimens fail:
  - May try PO pentoxifylline 400 mg TID for 2 to 6 months
  - Contraindications: recent cerebral and/or retinal hemorrhage; intolerance to methylxanthines (e.g., caffeine, theophylline); allergy to the particular drug selected
  - Precautions: prolonged prothrombin time (PT) and/or bleeding; if on warfarin, frequent monitoring of PT

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Instruct patient to see physician if compresses are unsuccessful.
DIET
Unrestricted

PROGNOSIS
- Self-limited: usually drains pus spontaneously and will heal with or without scarring within several days
- Recurrent/chronic: may last for months or years
- If recurrent, usually related to chronic skin carriage of staphylococci (nares or on skin). Treatment goals are to decrease or eliminate pathogenic strain or suppress pathogenic strain.
  - Culture nares, skin, axilla, and perineum (culture nares of family members)
  - Mupirocin 2%: Apply to both nares BID for 5 days each month.
  - Culture anterior nares every 3 months; if failure, retreat with mupirocin or consider clindamycin 150 mg/day for 3 months.
- Especially in recurrent cases, wash entire body and fingernails (with nailbrush) daily for 1 to 3 weeks with povidone-iodine (Betadine), chlorhexidine (Hibiclens), or hexachlorophene (pHisoHex soap), although all can cause dry skin.

COMPLICATIONS
- Scarring
- Bacteremia
- Seeding (e.g., septal/valve defect, arthritic joint)

REFERENCES

ADDITIONAL READING
- Ibler KS, Kromann CB. Recurrent furunculosis—challenges and management:

SEE ALSO

Folliculitis; Hidradenitis Suppurativa

CODES

ICD10

- L02.92 Furuncle, unspecified
- L02.12 Furuncle of neck
- L02.429 Furuncle of limb, unspecified

CLINICAL PEARLS

- Pathogens may be different in different localities. Keep up-to-date with the locality-specific epidemiology.
- If few, furuncles/furunculosis do not need antibiotic treatment. If systemic symptoms (e.g., fever), cellulitis, or multiple lesions occur, oral antibiotic therapy is used.
- Other treatments for MRSA include linezolid PO or IV and IV vancomycin.
- Folliculitis, furunculosis, and carbuncles are parts of a spectrum of pyodermas.
- Other causative organisms include aerobic (e.g., *Escherichia coli*, *Pseudomonas aeruginosa*, and *Streptococcus faecalis*), anaerobic (e.g.,
Bacteroides, Lactobacillus, Peptobacillius, and Peptostreptococcus), and Mycobacteria.

- Decolonization (treatment of the nares with topical antibiotic) is only recommended if the colonization was confirmed by cultures because resistance is common and treatment is of uncertain efficacy.
GALACTORRHEA
Christine K. Jacobs, MD

**BASICS**

**DESCRIPTION**
- Milky nipple discharge not associated with gestation or present >1 year after weaning. Galactorrhea does not include serous, purulent, or bloody nipple discharge.
- System(s) affected: endocrine/metabolic, nervous, reproductive

**Pregnancy Considerations**
- Most cases of galactorrhea during pregnancy are physiologic.
- Pregnancy stimulates lactotroph cells, so pituitary prolactin-secreting macroadenomas may increase by 21% \( (1) \)[A].

**EPIDEMIOLOGY**
- Predominant age: 15 to 50 years (reproductive age)
- Predominant sex: female > male (rare, e.g., in patients with multiple endocrine neoplasia type 1 [MEN1], the most common anterior pituitary tumors are prolactinomas)

**Prevalence**
6.8% of women referred to physicians with a breast complaint have nipple discharge.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Lactation is stimulated by prolactin, which is secreted in pulses by the anterior pituitary, inhibited by dopamine produced in the hypothalamus.
- Galactorrhea results either from prolactin overproduction or loss of inhibitory regulation by dopamine.
  - Afferent neural stimulation
    - Nipple stimulation
    - Chest wall trauma
    - Spinal cord injury
    - Herpes zoster
- **Organic hyperprolactinemia**
  - Prolactinoma
  - Craniopharyngiomas
  - Meningiomas or other tumors
  - Sarcoid
  - Irradiation
  - Vascular malformations (aneurysms)
  - Pituitary stalk compression
  - Multiple sclerosis (MS) (with hypothalamic lesion)
  - Post-breast augmentation surgery (1%)
  - Traumatic injury
- **Functional hyperprolactinemia**
  - Hypothyroidism
  - Adrenal insufficiency
  - Cirrhosis
  - Chronic kidney disease
  - Lung cancer
  - Renal cell cancer
- **Medications that suppress dopamine:**
  - Typical and atypical antipsychotics
  - SSRIs (prolactin not always elevated)
  - Tricyclic antidepressants
  - H₂ blockers
  - Reserpine
  - α-Methyldopa
  - Verapamil
  - Estrogens
  - Isoniazid
  - Opioids
  - Stimulants
  - Neuroleptics
  - Metoclopramide
  - Domperidone
  - Protease inhibitors
- **Postoperative condition, especially oophorectomy**
- **Idiopathic**
  - Normal prolactin levels
GENERAL PREVENTION
- Frequent nipple stimulation can cause galactorrhea.
- Avoid medications that can suppress dopamine.

COMMONLY ASSOCIATED CONDITIONS
See “Etiology and Pathophysiology.”

DIAGNOSIS
- Findings vary with causes.
- Look for signs/symptoms of associated conditions:
  - Adrenal insufficiency
  - Acromegaly
  - Hypothyroidism
  - Polycystic ovarian syndrome
  - Chest wall conditions

HISTORY
- Usually bilateral milky nipple discharge; may be spontaneous or induced by stimulation
- Determine possibility of pregnancy or recent discontinuation of lactation.
- Signs of hypogonadism from hyperprolactinemia
  - Oligomenorrhea, amenorrhea
  - Inadequate luteal phase, anovulation, infertility
  - Decreased libido (especially in affected males)
- Mass effects from pituitary enlargement
  - Headache, cranial neuropathies
  - Bitemporal hemianopsia, amaurosis, scotomata

PHYSICAL EXAM
Breast examination should be performed with attention to the presence of spontaneous or induced nipple discharge.

DIFFERENTIAL DIAGNOSIS
- Pregnancy-induced lactation or recent weaning
- Nonmilky nipple discharge
  - Intraductal papilloma
– Fibrocystic disease
• Purulent breast discharge
  – Mastitis
  – Breast abscess
  – Impetigo
  – Eczema
• Bloody breast discharge: Consider malignancy (Paget disease, breast cancer).

**DIAGNOSTIC TESTS & INTERPRETATION**

Perform formal visual field testing if pituitary adenoma suspected.

**Initial Tests (lab, imaging)**

• Prolactin level, thyroid-stimulating hormone, pregnancy test, liver, and renal functions
• Situations that may alter lab results:
  – Lab evaluation of prolactin may be falsely elevated by a recent breast examination.
  – Vigorous exercise
  – Sexual activity
  – High-carbohydrate diet
  – Consider repeating the test under different circumstances if the value is borderline (30 to 40) elevated.
• Prolactin levels may fluctuate. Elevated prolactin levels should be confirmed with at least one additional level drawn in a fasting, nonexercised state, with no breast stimulation (2)[C].
• Prolactin levels >250 ng/mL are highly suggestive of a pituitary adenoma (3)[C].
• If a breast mass is palpated in the setting of nipple discharge, evaluation of that mass is indicated with mammogram and/or ultrasound.
• Pituitary MRI with gadolinium enhancement if the serum prolactin level is significantly elevated (>200 ng/mL) or if a pituitary tumor is otherwise suspected

**Follow-Up Tests & Special Considerations**

• Consider evaluation of follicle-stimulating hormone and luteinizing hormone if amenorrheic.
• Consider evaluation of growth hormone levels if acromegaly suspected.
• Measure adrenal steroids if signs of Cushing disease present.
Diagnostic Procedures/Other
If diagnosis is in question, confirm by microscopic evaluation that nipple secretions are lipoid.

TREATMENT
- Avoid excess nipple stimulation.
- Idiopathic galactorrhea (normal prolactin levels) does not require treatment.
- Discontinue causative medications, if possible.
- If SSRI is implicated, trial of mirtazapine
- Medication is preferred therapy, with surgery or radiotherapy for patients not responding to medication (4)[C].
- Medical treatment is preferred except for tumors >10 mm (even if asymptomatic) which should be removed to reduce pituitary tumor size or prevent progression to avoid neurologic sequelae.
- If microadenoma, watchful waiting can be appropriate because 95% do not enlarge.

MEDICATION
- Dopamine agonists work to reduce prolactin levels and shrink tumor size. Therapy is suppressive, not curative (5)[C].
- Treatment is discontinued when tumor size has reduced or regressed completely or after pregnancy has been achieved.
- Dopamine agonists are class B in pregnancy and may be resumed if a macroadenoma grows significantly (1)[A].
- Cabergoline (Dostinex)
  - Start at 0.25 mg PO twice weekly and increase by 0.25 mg monthly until prolactin levels normalize. Usual dose ranges from 0.25 to 1.00 mg PO once or twice weekly.
  - More effective and better tolerated than bromocriptine (6)[A]
  - Check ESR and creatinine at baseline and then periodically.
  - ECG at baseline and every 6 to 12 months
  - DC after prolactin level normal for 6 months.
- Bromocriptine
  - Start at 1.25 mg QHS PO with food and increase every 3 to 7 days by 2.5 mg/day until therapeutic response achieved (usually 2.5 to 15.0 mg/day).
  - More expensive and more frequent dosing; however, most providers have
experience with this effective drug.
- Long-term treatment can cause woody fibrosis of the pituitary gland.
- Check creatinine, CBC, LFTs, cardiovascular evaluation. Pregnancy test every 4 weeks during amenorrhea and after menses restored if period is >3 days late.

- Contraindications are similar for all and include the following:
  - Uncontrolled hypertension
  - Sensitivity to ergot alkaloids
- Precautions
  - Dopamine antagonists may cause nausea, vomiting, psychosis, or dyskinesia.
- Significant possible interactions
  - $H_2$ blockers, CYP3A4; weak serotonin effect; hypotensive effect.
  - For women with microadenomas who do not wish to become pregnant, oral contraceptives may be a treatment option (1)[C].

**SURGERY/OTHER PROCEDURES**

- Surgery
  - Macroadenomas need surgery if (i) medical management does not halt growth, (ii) neurologic symptoms persist, (iii) size >10 mm, or (iv) patient cannot tolerate medications; also considered in young patients with microadenomas to avoid long-term medical therapy
  - Transsphenoidal pituitary resection
  - 50% recurrence after surgery
- Radiotherapy
  - Radiation is an alternative tumor therapy for macroprolactinomas not responsive to other modes of treatment:
    - 20–30% success rate
    - 50% risk of panhypopituitarism after radiation
    - Risk of optic nerve damage, hypopituitarism, neurologic dysfunction, and increased risk for stroke and secondary brain tumors

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Outpatient care unless pituitary resection required
- Bromocriptine patients need adequate hydration.
Dopamine agonist therapy should be discontinued in pregnancy.

**Patient Monitoring**
- Varies with cause
- Check prolactin levels every 6 weeks until normalized and then every 6 to 12 months.
- Monitor visual fields and/or MRI at least yearly until stable for prolactinoma.

**Diet**
No restrictions

**Patient Education**
- Warn about symptoms of mass enlargement in pituitary.
- Discuss treatment rationale, risks of treating, and expectant management.
- Patient education material available from American Family Physician: www.aafp.org/afp/20040801/553ph.html

**Prognosis**
- Depends on underlying cause
- Symptoms can recur after discontinuation of a dopamine agonist.
- Surgery can have 50% recurrence.
- Prolactinomas <10 mm can resolve spontaneously.
- Postsurgical hyperprolactinemia is associated with better outcomes in node-negative breast cancer.

**Complications**
- If enlarging pituitary adenoma, risk of permanent visual field loss
- Panhypopituitarism can complicate radiation or surgical therapy.
- Osteoporosis if amenorrhea persists without estrogen replacement.
- Hyperprolactinemia does not increase breast cancer risk.

**References**

**ADDITIONAL READING**

**SEE ALSO**

Hyperprolactinemia

**CODES**

**ICD10**

- N64.3 Galactorrhea not associated with childbirth
- N64.52 Nipple discharge

**CLINICAL PEARLS**

- Galactorrhea is a common disorder, affecting up to 50% of reproductive-age women.
- Common causes include idiopathic, from excess nipple stimulation, dopamine-suppressing medications, or pituitary prolactinoma.
- Most cases may be adequately evaluated by thyroid-stimulating hormone, prolactin, and human chorionic gonadotropin measurement, with additional testing only as suggested by the presence of other symptoms or signs.
- Lab evaluation of prolactin may be falsely elevated due to recent sexual activity, breast examination, exercise, or a high-carbohydrate diet. Repeat any
borderline elevation before continuing evaluation or initiating treatment.

- Evaluate prolactin >200 ng/mL (or signs of suspicion for a pituitary macroadenoma) with a gadolinium-enhanced MRI.
GASTRITIS

Samrawit A. Tekle, MD • Naureen Rafiq, MBBS

BASICS

DESCRIPTION

- Inflammation of the gastric mucosa
- Patchy erythema of gastric mucosa
  - Common on endoscopy; usually insignificant
- Erosive gastritis or reactive gastropathy
  - A reaction to mucosal injury by a noxious agent (especially NSAIDs or alcohol)
  - Damage to the surface epithelium caused by mucosal hypoxia or the direct action of NSAIDs
- Reflux gastritis
  - A reaction to protracted reflux exposure to biliary and pancreatic fluid
  - Typically limited to the prepyloric antrum
- Hemorrhagic gastritis (stress ulceration)
  - A reaction to hemodynamic disorder (e.g., hypovolemia or hypoxia [shock])
  - Common in ICU patients, particularly after severe burns and trauma
  - Seen rarely with dabigatran (oral thrombin inhibitor)
- Infectious gastritis
  - Acute and/or chronic *Helicobacter pylori* infection
  - Viral infection, usually as a component of systemic infection.
- Atrophic gastritis
  - Autoimmune versus environmental
  - Frequent in the elderly
  - Primarily from long-standing *H. pylori* infections
  - May be caused by prolonged proton pump inhibitor (PPI) use
  - Major risk factor for gastric cancer
  - Associated with primary (pernicious) anemia

Geriatric Considerations

Persons age >60 years often harbor *H. pylori* infection.

Pediatric Considerations
Gastritis rarely occurs in infants or children; increasing prevalence with age

EPIDEMIOLOGY
- Predominant age: all ages (more common in elderly)
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY
- Noxious agents cause a breakdown in the gastric mucosal barrier, exposing epithelium to injury.
- Infection: *H. pylori* (most common cause), *Staphylococcus aureus* exotoxins, and viral infection
- Alcohol
- Aspirin and other NSAIDs
- Bile reflux
- Pancreatic enzyme reflux
- Portal hypertensive gastropathy
- Emotional stress

Genetics
Unknown, but observational studies show that 10% of a given population is never colonized with *H. pylori*, regardless of exposure. Genetic variations in TLR1 may help explain some of this observed variation in individual risk for *H. pylori* infection.

RISK FACTORS
- Age >60 years—prevalence of 50–60% by age 60 years
- Exposure to potentially noxious drugs or chemicals (e.g., alcohol or NSAIDs)
- Hypovolemia, hypoxia (shock), burns, head injury, complicated postoperative course
- Autoimmune diseases (thyroid disease and diabetes)
- Family history of *H. pylori* and/or gastric cancer
- Stress (hypovolemia or hypoxia)
- Tobacco use
- Radiation
- Ischemia
- Pernicious anemia
- Gastric mucosal atrophy
GENERAL PREVENTION
- Avoid injurious drugs or chemical agents.
- Patients with hypovolemia or hypoxia (especially ICU patients) should receive prophylactic therapy. H₂ receptor antagonists, prostaglandins, or sucralfate are commonly used for gastric mucosal protection.
- Consider testing for *H. pylori* (and eradicating if present) in patients on long-term NSAID therapy.

COMMONLY ASSOCIATED CONDITIONS
- Gastric or duodenal peptic ulcer
- Primary (pernicious) anemia—atrophic gastritis
- Portal hypertension (HTN), hepatic failure
- Mucosa-associated lymphoid tissue (MALT) lymphoma

DIAGNOSIS

HISTORY
- Epigastric discomfort, often aggravated by eating
- Burning epigastric pain
- Anorexia
- Nausea, with or without vomiting
- Significant bleeding is unusual except in hemorrhagic gastritis.
- Rectal bleeding/melena
- Hiccups
- Bloating or abdominal fullness

PHYSICAL EXAM
- Vital signs to assess hemodynamic stability
- Abdominal exam often normal
- Mild epigastric tenderness
- May have heme-positive stool
- Examine for stigmata of chronic alcohol abuse.

DIFFERENTIAL DIAGNOSIS
- Functional abdominal pain (dyspepsia)
- Peptic ulcer disease
- Viral gastroenteritis
Gastric cancer (elderly)
Cholecystitis
Pancreatic disease (inflammation vs. tumor)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Usually normal
- CBC to evaluate for blood loss/anemia
- $^{13}$C-urea breath test for H. pylori
  - 95% specificity and sensitivity
- H. pylori, serology serum IgG
  - Inexpensive; 85% sensitivity, 79% specificity
  - Positive in history of colonization or prior infections; cannot be used to assess eradication
- Stool analysis for fecal H. pylori antigen
  - 95% specificity and sensitivity
- Gastric acid analysis may be abnormal but is not a reliable indicator of gastritis.
- Low serum pepsinogen I (PG I) relative to PG II is associated with fundal intestinal metaplasia.
- Drugs that may alter lab results: Antibiotics or PPIs may affect urea breath test for H. pylori.
  - Hold PPIs for 2 weeks, H$_2$ receptor antagonists for 24 hours, and antibiotics for 4 weeks prior to stool or breath tests (1)[C].

Follow-Up Tests & Special Considerations
Endoscopy for H. pylori
- Culture; polymerase chain reaction (PCR); histology; rapid urease testing

Diagnostic Procedures/Other
- Gastroscopy with biopsy is first-line diagnostic tool in:
  - Age >55 years with new-onset signs and symptoms
  - Weight loss, persistent vomiting, or GI bleed (1)[C]
- Gastric biopsies (multiple) in both body and antrum recommended if there is a poor response to initial treatment. Patients must discontinue PPIs for 2 weeks prior to endoscopy to improve diagnostic accuracy.
**Test Interpretation**
Acute or chronic inflammatory infiltrate in gastric mucosa, often with distortion or erosion of adjacent epithelium. Presence of *H. pylori* often confirmed

---

**TREATMENT**

**GENERAL MEASURES**
- *H. pylori* treatment is required to relieve symptoms.
- Parenteral fluid and electrolyte supplements if unable to tolerate oral intake
- Discontinue NSAID use if possible.
- Abstinence from alcohol; smoking cessation
- Endoscopy in patients not responsive to treatment

**MEDICATION**

**First Line**
- Antacids: best given in liquid form, 30 mL 1 hour after meals and at bedtime; useful mainly as an emollient
- H₂ receptor antagonists (e.g., cimetidine [Tagamet]): oral cimetidine 300 mg q6h (or ranitidine [Zantac] 150 mg BID or famotidine [Pepcid] 20 mg BID or nizatidine [Axid]); 150 mg BID not shown to be clearly superior to antacids
- Sucralfate (Carafate): 1 g q4–6h on an empty stomach; rationale uncertain but empirically helpful
- Prostaglandins (misoprostol [Cytotec]): can help allay gastric mucosal injury; dosage 100 to 200 μg QID
- PPIs if no response to antacids or H₂ receptor blockers (e.g., omeprazole 20 mg daily or BID or esomeprazole 20 mg daily or BID)
- *H. pylori* eradication
  - Clarithromycin triple therapy (CTT)
    - A short-course therapy (10 to 14 days) of amoxicillin 1 g BID, standard dose PPI BID (omeprazole 20 mg BID, etc.), and clarithromycin 500 mg BID (2)[A]
    - 70–85% eradication
    - Optimal treatment still undefined
    - IF PCN ALLERGIC: Substitute amoxicillin with metronidazole 500 mg TID.
  - Bismuth quadruple therapy (BQT)
**PPI (omeprazole 20 mg) BID plus bismuth (Pepto-Bismol) 30 mL liquid or 2 tablets QID plus metronidazole 250 mg QID plus tetracycline 500 mg QID for 10 to 14 days (2)[A]**

- 75–90% eradication
- Use as initial therapy in areas of high clarithromycin resistance (>15%).
- Consider in penicillin-allergic patients.

**Alternative H. pylori treatment: sequential antibiotic therapy with standard dose PPI (i.e., omeprazole 20 mg) and amoxicillin 1 g BID for 5 days followed by clarithromycin 500 mg and tinidazole mg BID with standard-dose PPI (omeprazole 20 mg) BID for 5 days; equivalent to triple therapy (1) [B],(2)[A]**

**H. pylori treatment failure: Use a different regimen, avoid clarithromycin (unless resistance testing confirms susceptibility):**

- BQT for 7 to 14 days (1,2)[A].
- Consider levofloxacin 250 mg BID, amoxicillin 1 g BID, and standard-dose PPI BID for 14 days in those who fail twice (1,2)[A].

**Consider probiotics in known symptomatic H. pylori. May decrease density of H. pylori in gastric antrum and body; decrease severity of gastritis, peptic ulcers; and possibly slow progression toward atrophic gastritis and gastric adenocarcinoma (3)[A],(4)[C].**

- Probiotics alone likely do not eradicate H. pylori.
- Possible regimens as used in trials: Bifidobacterium infantis BID × 14 days (5)[C]

**Contraindications:** hypersensitivity

**Precautions:**

- Bismuth may turn stool black.

- Refer to the manufacturer’s profile of each drug for precautions and potential drug interactions.

---

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Gastritis prophylaxis in ICU patients
- Outpatient management, except for severe hemorrhagic gastritis

---

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Usually no restrictions

- Confirm *H. pylori* eradication 4+ weeks after treatment.

**Patient Monitoring**

- Consider repeat gastroscopy after 6 weeks if gastritis was severe or if patient has a poor treatment response.
- Surveillance gastroscopy every 3 to 5 years in patients with atrophic gastritis in both the antrum and body, within 1 year for patients with low-grade dysplasia (with extensive biopsy sampling), 6 and 12 months in patients with high-grade dysplasia

**DIET**

Restrictions, if any, depend on symptom severity (e.g., bland, light, soft foods); avoid caffeine and spicy foods and alcohol.

**PATIENT EDUCATION**

- Smoking cessation; limit alcohol.
- Dietary changes
- Relaxation therapy
- Avoid NSAIDs as possible.

**PROGNOSIS**

- Most cases clear with identification and treatment of the underlying cause.
- Recurrence of *H. pylori* infection requires a repeated course of treatment.

**COMPLICATIONS**

- Bleeding from extensive mucosal erosion or ulceration
- Clearing *H. pylori* before chronic gastritis develops may prevent development of gastric cancer.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- K29.70 Gastritis, unspecified, without bleeding
- K29.71 Gastritis, unspecified, with bleeding
- K29.00 Acute gastritis without bleeding

**CLINICAL PEARLS**

- *H. pylori* is the most common cause of gastritis.
- >50% of adult patients are colonized with *H. pylori*.
- *H. pylori* antibodies decline in the year after treatment and should not be used to determine eradication. *H. pylori* antibody titers rise significantly with reinfection.
- *H. pylori* stool antigen tests can be used before and after therapy to assess for eradication and reinfection.
- Several courses of rescue therapy may be necessary to eradicate *H. pylori*. 
- In cases of suspected gastritis, discontinue PPI 2 weeks prior to endoscopy to improve diagnostic accuracy.
- Consider probiotics as adjunct treatment in symptomatic *H. pylori* gastritis.
GASTROESOPHAGEAL REFLUX DISEASE

Fozia Akhtar Ali, MD • Anna Cecilia S. Tenorio, MD • Adriana S. Sanchez, MD

BASICS

DESCRIPTION
- Changes of the esophageal mucosa resulting from reflux of gastric contents into the esophagus
- Often described as “heartburn,” “acid indigestion,” and “acid reflux”

EPIDEMIOLOGY

Incidence
Incidence: 5 per 1,000 person-years

Prevalence
- 10–20% in the United States
- 40% of adults in the United States have reflux symptoms.
- 50–85% of gastroesophageal reflux disease (GERD) patients have nonerosive reflux disease.
- Chronic GERD is a risk factor for Barrett esophagus.
- 10% of patients with chronic GERD have Barrett esophagus.
- Risk of adenocarcinoma without Barrett esophagus and no dysplasia: 0.1–0.5% per patient-year
- Risk of adenocarcinoma with Barrett esophagus and high-grade dysplasia: 6–19% per patient-year
- Pediatric population: Regurgitation occurs at least once a day in 2/3 of 4-month-old infants, decreasing to 21% at age 6 to 7 months, and 5% at 10 to 12 months.

ETIOLOGY AND PATHOPHYSIOLOGY
- The pattern and mechanism of reflux varies depends on the severity of disease.
● GERD begins when acidic stomach contents contact the squamous mucosal lining of the esophagus, at the esophagogastric junction (EGJ).
● Inappropriate transient lower esophageal sphincter (LES) relaxation. Foods that are spicy; acidic; and high in fat, caffeine, alcohol, tobacco, anticholinergic medications, nitrates, smooth muscle relaxants affect LES relaxation.
● Patients with severe GERD often have evidence of a hiatal hernia, which can (1):
  – Trap acid in the hernia sac
  – Impair acid emptying
  – Increase retrograde acid flow rate
  – Reduce the EGJ sphincter pressure
  – Increase frequency of transient LES relaxations

**Genetics**
Genetic heterogeneity has been associated with GERD.

**RISK FACTORS**
● Obesity
● Hiatal hernia
● Scleroderma
● Alcohol use
● Tobacco use
● Pregnancy

**GENERAL PREVENTION**
● Decrease consumption of food and beverage triggers such as spicy, fatty foods, alcohol, and caffeine.
● Weight loss
● Avoid lying down after meals.
● Tobacco and alcohol cessation
● Elevate head of bed at night.
● Avoid meals close to bedtime.
● Infants: Use car seat for 2 to 3 hours after meals; thickened feedings

**COMMONLY ASSOCIATED CONDITIONS**
● Nonerosive esophagitis
● Erosive esophagitis
- Irritable bowel syndrome
- Peptic ulcer disease
- Extraesophageal reflux: aspiration, chronic cough, laryngitis, vocal cord granuloma, sinusitis, otitis media
- Halitosis
- Hiatal hernia: acid pocket (zone of high acidity in the proximal stomach above the diaphragm) (2)[B]
- Peptic stricture: 10% of patients with GERD
- Barrett esophagus
- Esophageal adenocarcinoma

**DIAGNOSIS**

**HISTORY**

- Typical symptoms: acid regurgitation, heartburn, dysphagia (mostly postprandial)
- Atypical symptoms: epigastric fullness/pressure/pain, dyspepsia, nausea, bloating, belching, chest pain, lump in throat
- Extraesophageal signs and symptoms: chronic cough, bronchospasm, wheezing, hoarseness, sore throat
- Heartburn: retrosternal burning sensation
- Regurgitation; sour or acid taste in mouth (“water brash”)
- Symptoms worse with bending or lying down
- Diet, alcohol and tobacco use

**PHYSICAL EXAM**

Often unremarkable. Make note of:

- BMI
- Epigastric tenderness or palpable epigastric mass
- Stigmata of chronic systemic disease or alcohol use
- Dental erosions

**DIFFERENTIAL DIAGNOSIS**

- Infectious esophagitis (*Candida*, herpes, HIV, cytomegalovirus)
- Chemical esophagitis; pill-induced esophagitis
- Eosinophilic esophagitis
- Nonulcer dyspepsia
• Biliary tract disease
• Radiation injury
• Crohn disease
• Angina/coronary artery disease
• Esophageal stricture or anatomic defect (ring, sling)
• Esophageal adenocarcinoma
• Achalasia; scleroderma
• Peptic ulcer disease

**DIAGNOSTIC TESTS & INTERPRETATION**
Diagnosis often based on history and clinical symptoms. Treat patients with typical symptoms of GERD and no alarm symptoms (dysphagia odynophagia, weight loss, early satiety, anemia, new onset, male >50 years) empirically with antisecretory agents without any further diagnostic testing.

*Initial Tests (lab, imaging)*
• Indication for blood work depends on clinical presentation. Check for anemia (history of bleeding; or possible poor vitamin B₁₂ absorption due to chronic proton pump inhibitor [PPI] use).
• Appropriately evaluate patients with GERD who present with symptoms suspicious for cardiac disease.

*Diagnostic Procedures/Other*
• Upper endoscopy
  – First-line diagnostic test for those with alarm signs and uncontrolled symptoms (2)[B]
  – Indications for endoscopy:
    o Alarm symptoms such as dysphagia, bleeding, anemia, weight loss, recurrent vomiting
    o Persistent typical GERD symptoms despite treatment with twice-daily PPI for 4 to 8 weeks
    o Men >50 years with chronic GERD (>5 years) and other risk factors: hiatal hernia, high BMI, tobacco use, high abdominal fat distribution
    o History of severe erosive esophagitis (Assess healing and check for UGI pathology including Barrett esophagus.)
    o Surveillance (history of Barrett esophagus)
  – ~50–70% of patients with heartburn have negative endoscopic findings.
  – Savary-Miller classification (endoscopic grading)
Grade I: ≥1 nonconfluent reddish spots, with or without exudate
Grade II: erosive and exudative lesions in the distal esophagus; may be confluent but not circumferential
Grade III: circumferential erosions in the distal esophagus
Grade IV: chronic complications such as deep ulcers, stenosis, or scarring with Barrett metaplasia

● Esophageal manometry
  – Not recommended for primary GERD diagnosis; a second option for those with GERD and normal endoscopy (2)[B]
  – Used to evaluate peristaltic function preoperatively and to record LES pressure

● Ambulatory reflux (pH) monitoring
  – Evaluate excessive acid exposure in those with GERD symptoms, normal endoscopy, and no response to PPI (2)[B].
  – Used to document frequency of reflux
  – Discontinue PPI for 7 days prior to procedure.

● Barium swallow: not used for GERD diagnosis; used to evaluate complaints of dysphagia or to outline anatomic abnormalities (hiatal hernia)

**Test Interpretation**
● Acute inflammation (especially eosinophils)
● Epithelial basal zone hyperplasia seen in 85%
● Barrett epithelial change: Gastric columnar epithelium replaces squamous epithelium in distal esophagus (metaplasia).

**TREATMENT**

**GENERAL MEASURES**
Lifestyle changes are first-line intervention:

● Elevate head of bed (2)[B].
● Avoid meals 2 to 3 hours before bedtime (2)[B].
● Avoid stooping, bending, and tight-fitting garments.
● Avoid medications that relax LES (anticholinergic drugs; calcium channel blockers).
● Promote weight loss (2)[B].
Tobacco cessation and alcohol avoidance
Limit consumption of patient-specific food triggers (global elimination of all reflux-causing foods is not necessary, practical, or beneficial).
Stepped therapy
  – Phase I: lifestyle and diet modifications, antacids plus H₂ blockers or PPIs
  – Phase II: If symptoms persist, consider endoscopy.
  – Phase III: If symptoms still persist, consider surgery.

MEDICATION

First Line
H₂ blockers in equipotent oral doses (e.g., cimetidine 800 mg BID or 400 mg QID, ranitidine 150 mg BID, famotidine 20 mg BID, or nizatidine 150 mg BID)
  – Renally dosed: Decrease dose to 50 mg and for creatinine clearance <50 mL/min.
  – Although less effective than PPIs, H₂ blockers given in divided doses will provide symptomatic relief in patients with less severe symptoms of GERD (3)[A].

PPIs: irreversibly bind proton pump (H⁺/K⁺ ATPase), effective onset within 4 days; omeprazole 20 to 40 mg/day, lansoprazole 15 to 30 mg/day, dexlansoprazole 30 mg/day, pantoprazole 40 mg/day, rabeprazole 20 mg/day, esomeprazole 40 mg/day
  – No major differences in efficacy among PPIs
  – Dose 30 to 60 minutes before meals with the exception of dexlansoprazole (2)[A].
  – PPIs may increase risk of hypomagnesemia, hip fracture, *Clostridium difficile* infection, vitamin B₁₂ deficiency, and community-acquired pneumonia.

Pediatric Considerations
Antacids or liquid H₂ blockers and PPIs are available. Prokinetics have a minimal role due to safety concerns and limited efficacy.

Second Line
Antacids or barrier agents (sucralfate 1 g PO QID 1 hour before meals and at bedtime for 4 to 8 weeks) may relieve breakthrough symptoms.

Prokinetics: metoclopramide 5 to 10 mg before meals

Baclofen as add-on therapy with a PPI

Precautions
- Blood dyscrasias and anemia with PPIs and H₂ blockers
- Metoclopramide is a dopamine blocker; risk of dystonia and tardive dyskinesia
- Tachyphylaxis may occur with H₂ blockers.

Significant possible interactions
- PPIs and H₂ blockers: multiple cytochrome P450 drug interactions; that is, warfarin, phenytoin, antifungals, digoxin

SURGERY/OTHER PROCEDURES
- Laparoscopic fundoplication (wrapping gastric fundus around distal esophagus) increases pressure gradient between stomach and esophagus.
- Bariatric surgery
  - Surgery indicated if patient desires to discontinue medical therapy, has side effects with medical therapy, has a large hiatal hernia, has esophagitis refractory to medical therapy, or has refractory symptoms (4)[A]
  - Preop ambulatory pH monitor mandatory in patients with no evidence of erosive esophagitis (4)[A]
  - Manometry to rule out esophageal dysmotility, achalasia, or scleroderma prior to surgery (4)[A]
  - Best surgical response in patients with typical symptoms who respond well to PPI therapy
  - If patient is expected to require >10 years of PPI treatment, surgery may be more cost-effective.
  - Consider bariatric surgery for morbidly obese patients. Gastric bypass is preferred (4)[A].

Pediatric Considerations
Surgery for severe symptoms (apnea, choking, persistent vomiting)
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Track symptoms over time.
- Repeat endoscopy in 4 to 8 weeks if there is a poor symptomatic response to medical therapy, especially in older patients.
- In patients with Barrett esophagus who would opt for treatment if cancer is detected; perform endoscopic surveillance every 2 to 3 years.

DIET
Avoid foods that can trigger or make symptoms worse.

PATIENT EDUCATION
Lifestyle and dietary modifications: Eat small meals; avoid lying down after meals; elevate head of bed; weight loss; smoking cessation; avoid alcohol and caffeine.

PROGNOSIS
- Symptoms and esophageal inflammation often return promptly when treatment is withdrawn. To prevent relapse of symptoms, continue antisecretory therapy (in addition to lifestyle and dietary modifications).
  - PPI maintenance therapy likely improves quality of life more than $H_2$ blockers.
  - Full-dose PPIs are more effective than half-dose for maintenance (4)[A].
  - In erosive esophagitis, daily maintenance therapy with PPI prevents relapse; intermittent PPI therapy not as effective (1)[A].
- Medical and surgical therapy are equally effective for symptom reduction (4) [A].
- Antireflux surgery
  - 90–94% symptom response. Patients with persistent symptoms should have repeat anatomic evaluation (endoscopy or esophagram).
  - Some surgically treated patients eventually require medical therapy due to recurrence of symptoms.
- Regression of Barrett epithelium does not routinely occur despite aggressive medical or surgical therapy.

COMPLICATIONS
- Peptic stricture: 10–15%
Barrett esophagus: 10%
- Adenocarcinoma cancer develops at an annual rate of 0.5%.
- Primary treatment for Barrett esophagus with high-grade dysplasia is endoscopic radiofrequency ablation.

Extraesophageal symptoms: hoarseness, aspiration, (including pneumonia)
- Bleeding due to mucosal injury
- Noncardiac chest pain

Geriatric Considerations
Complications more likely (e.g., aspiration pneumonia)

Algorithms: Abdominal Pain, Upper; Dyspepsia
CODES

ICD10
- K21.9 Gastro-esophageal reflux disease without esophagitis
- K21.0 Gastro-esophageal reflux disease with esophagitis

CLINICAL PEARLS
- GERD is primarily a historical diagnosis.
- Consider GERD in nonsmokers who have a chronic cough (>3 weeks).
- Antisecretory therapy is the mainstay of pharmacotherapy for GERD.
- PPIs provide the most rapid symptomatic relief and healing of esophagitis.
- Endoscopy is recommended for patients with alarm symptoms, onset age >50 years, or prolonged severe symptoms.
A recent national survey showed that 3.4% of all Americans identify themselves as lesbian, gay, bisexual, or transgender (LGBT). This may be an underestimation as men and women between 18 and 29 years old are more likely to identify themselves as LGBT at 4.6% and 8.3%, respectively. These percentages may not reflect all men who have sex with men (MSM). MSM may identify themselves as gay, bisexual, homosexual, or heterosexual. Current studies suggest 8% of the U.S. population engage in homosexual activity.

The 2015 U.S. census reported a total of >410,000 households headed by male same-sex partners.

LGBT individuals may hide their orientation in fear of stigma and discrimination, which may greatly affect their health.

Health disparities exist among sexual minority groups (gay or lesbian and bisexual) and between sexual minority groups and heterosexuals; disparities are far reaching and include differences in health conditions, health behaviors, health care access, and health care utilization. Sexual minority groups tend to fare worse across all realms.

Primary care specified toward MSM will be addressed here; lesbian and transgender health care will be discussed under their respective topic headings.

It is recommended that MSM should receive hepatitis A and B immunizations (1)[A].

Centers for Disease Control and Prevention (CDC) recommends testing for hepatitis B (1)[A].

CDC does not recommend testing for hepatitis C unless individuals were born from 1945 through 1965, have HIV, or engage in risky behaviors (i.e., sharing needles or other equipment of injected drugs, unprotected sex, or multiple partners) (1)[A].
Screening for hepatitis A infection is not recommended.

Annual screening of HIV, syphilis, chlamydia, gonorrhea in individuals at risk

**DIAGNOSIS**

Sexually transmitted infections (STIs)
- STIs among MSM are increasing. Behaviors that increase risk of non-HIV STI also increase risk of HIV acquisition.
- Risk factors include the following:
  - Higher numbers of lifetime sex partners
  - Higher rates of partner change
  - Unprotected sex
- Studies among Black and Hispanic MSM have linked financial hardship and poor emotional or social support with increased sexual risk-taking behaviors.
- Physicians should advocate for safe sex practices to include routine use of barrier methods and preexposure prophylaxis (PrEP) if indicated.
- In 2014, MSM accounted for approximately 75% of new cases of primary and secondary syphilis (1).
- Annual screening of asymptomatic sexually active gay men should include syphilis, chlamydia, and gonorrhea.
  - Urine testing with nucleic acid amplification test (NAAT) for *Neisseria gonorrhoeae* and *Chlamydia trachomatis* for insertive intercourse within the last year
  - Rectal swab NAAT for *N. gonorrhoeae* and *C. trachomatis* for anal receptive intercourse within the last year
  - Pharyngeal swab NAAT for *N. gonorrhoeae* for oral receptive intercourse within the last year. Pharyngeal swab for *C. trachomatis* is not recommended (1)[A].

**HIV**
- 55% of persons living with HIV in the United States were MSM in 2014.
- 83% of new cases of HIV diagnosed in 2014 were among MSM (2). New HIV cases disproportionately affect African American and Hispanic/Latino MSM.
- Sexually active MSM should be screened at least annually for HIV (1)[A].
- Educate MSM on PrEP and postexposure prophylaxis (PEP) in the case of an unsafe sexual encounter.
- Indications for PrEP
Adult man without HIV infection
• Any male sex partners in last 6 months
• Not in monogamous relationship with an HIV-negative man
• And at least one of the following:
  • Anal sex without condoms in past 6 months (receptive or insertive)
  • Any STI diagnosed in past 6 months
  • In a sexual relationship with HIV-positive partner

The only FDA-approved regimen for PrEP includes daily oral combination of tenofovir disoproxil fumarate (TDF) 300 mg and emtricitabine (FTC) 200 mg in a single daily pill, which has shown to be safe and effective in reducing the risk of sexual transfer of HIV (3)[A].
• Additional medications or replacement with other antiretroviral medications is not recommended (3)[A].
• Although TDF alone is approved for heterosexual men and women as well as intravenous (IV) drug users, its use is not recommended in MSM as it has not been studied in this patient population (3)[A].
• Monitor HIV status every 3 months and renal function at least every 6 months.

Indications for PEP
• ≤72 hours after exposure to known HIV-positive partner
• PEP not recommended if >72 hours or partner HIV negative
• PEP generally involves 28-day course of highly active antiretroviral therapy (HAART) in a three-drug combination:
  • Two nucleoside reverse transcriptase inhibitors (NRTIs) and either a protease inhibitor (PI) or a nonnucleoside reverse transcriptase inhibitor (NNRTI) or integrase inhibitor
  • There are no data on the most efficacious PEP regimens.
  • Selection of medications are based on side effect profiles, patient compliance, and patient convenience.
  • “Preferred” regimens include the following:
    • Efavirenz plus lamivudine or emtricitabine plus zidovudine or tenofovir
    • Lopinavir/ritonavir (Kaletra) plus lamivudine or emtricitabine plus zidovudine
  • Counsel on safer sex and risk reduction for repeated exposures.

Cancer
• MSM are 17 times more likely to get anal cancer than heterosexual men; this is an 80-fold increase for HIV-positive MSM.
• Anal carcinoma has been linked to certain high-risk subtypes of HPV.
– Screening for anal dysplasia with anal cytology may be considered for at-risk populations, which include HIV-infected MSM, but further research is needed for appropriate screening intervals (4)[A].

– HPV vaccine is recommended for all boys age 11 to 12 years and young MSM through age 26 years (5)[C].

- Substance and tobacco abuse
  – Alcohol and substance dependence is 1.5 times higher in gay, lesbian, and bisexual populations (6).
  – Smoking is more common among gay men than heterosexual men.
    o Counseling on tobacco cessation should be provided when appropriate.
  – Alcoholism has also been found to be more prevalent among gay men than the general population.
  – There is an increased use of methamphetamines among MSM.
    o Substance abuse treatment programs implementing cognitive behavioral intervention from a harm reduction perspective is beneficial in reducing stimulant use and sexual risk-taking behavior.

- Behavioral health
  – Risk of major depressive, bipolar, and anxiety disorders are 1.5 times higher in lesbian, gay, and bisexual population (6).
  – Risk of deliberate self-harm is also increased among gay and bisexual men (6).
  – Lifetime prevalence of suicide attempt is up to 4 times greater among gay and bisexual men compared to the general population (6).
  – Rates of body image and eating disorders among gay adolescent and young men are also increased.

- Intimate partner violence (IPV) (domestic violence)
  – Screen for IPV.
    o Screen patient alone.
    o “Does your partner ever hit, kick, hurt, or threaten you?”
    o “Do you feel safe at home?”
  – Despite rates of IPV among gay couples being equal to heterosexual couples, there is a lack of attention to IPV among the LGBT population as a whole.
  – A National Violence Against Women survey found 21.5% of men reporting a history of cohabitation with a same-sex partner had experienced physical abuse in their lifetimes.
ONGOING CARE

Obtaining a history

- Establish with patients that information related to sexual orientation is asked of all patients to assist in health care prevention decisions.
- Providers should discuss with patients in an open and nonjudgmental fashion.
- Avoid labeling patient as gay, lesbian, bisexual, or transgender unless prompted by the patient.
- Issues to target include HIV/AIDS, infectious disease including STI, substance and tobacco abuse, behavioral health, IPV, and immunizations.
- Take into account the context in which risk-taking behaviors occur.
- Identify their sexual lifestyle with key questions.
  - During your life, with whom have you had sexual contact?
  - Do you have a significant other?
  - Do you feel comfortable with your sexuality?
  - Are you sexually attracted to men, women, or both?
  - Have you ever been sexually active with men, women, or both?

PATIENT EDUCATION

- Counsel patients on importance of safe sexual practices to include barrier methods (i.e., condoms), PrEP, and PEP.
- Educate patients regarding substance and tobacco abuse, IPV, mental health concerns, and resources for treatment.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- Z11.59 Encounter for screening for other viral diseases
- Z11.4 Encounter for screening for human immunodeficiency virus
- Z72.52 High risk homosexual behavior

CLINICAL PEARLS

- Sexually active gay men should be offered annual screening for HIV, syphilis, gonorrhea, and chlamydia.
- Immunize gay men for hepatitis A and B as well as HPV for all young men through age 26 years.
- Routine screening for substance misuse, behavioral health conditions as well as IPV in this population should be performed regularly.
GENITO-PELVIC PAIN/PENETRATION DISORDER (VAGINISMUS)

Jeffrey D. Quinlan, MD, FAAFP

**BASICS**

Genito-pelvic pain/penetration disorder is the name of the conditions formally known as vaginismus and dyspareunia. Vaginismus results from involuntary contraction of the vaginal musculature. Primary vaginismus occurs in women who have never been able to have penetrative intercourse. Women with secondary vaginismus were previously able to have penetrative intercourse but are no longer able to do so.

**DESCRIPTION**

- Persistent or recurrent difficulties for 6 months or more with at least one of the following:
  - Inability to have vaginal intercourse/penetration on at least 50% of attempts
  - Marked genito-pelvic pain during at least 50% of vaginal intercourse/penetration attempts
  - Marked fear of vaginal intercourse/penetration or of genito-pelvic pain during intercourse/penetration on at least 50% of vaginal intercourse/penetration attempts
  - Marked tensing or tightening of the pelvic floor muscles during attempted vaginal intercourse/penetration on at least 50% of occasions
- The disturbance causes marked distress or interpersonal difficulty.

- Dysfunction is not as a result of:
  - Nonsexual mental disorder
  - Severe relationship stress
  - Other significant stress
  - Substance or medication effect

- Specify if with a general medical condition (e.g., lichen sclerosus, endometriosis) (1).

**Pregnancy Considerations**

May first present during evaluation for infertility

- Pregnancy can occur in patients with genito-pelvic pain/penetration disorder
when ejaculation occurs on the perineum.

- Vaginismus may be an independent risk factor for cesarean delivery.

**EPIDEMIOLOGY**

**Incidence**

The incidence of vaginismus is thought to be about 1–17% per year worldwide. In North America, 12–21% of women have genito-pelvic pain of varying etiologies (2).

**Prevalence**

- True prevalence is unknown due to limited data/reporting.
- Population-based studies report prevalence rates of 0.5–30%.
- Affects women in all age groups
- Approximately 15% of women in North America report recurrent pain during intercourse.

**ETIOLOGY AND PATHOPHYSIOLOGY**

Most often multifactorial in both primary and secondary vaginismus

- Primary
  - Psychological and psychosocial issues
    - Negative messages about sex and sexual relations in upbringing may cause phobic reaction.
    - Poor body image and limited understanding of genital area
    - History of sexual trauma
  - Abnormalities of the hymen
  - History of difficult gynecologic examination
- Secondary
  - Often situational
  - Often associated with dyspareunia secondary to:
    - Vaginal infection
    - Inflammatory dermatitis
    - Surgical or postdelivery scarring
    - Endometriosis
    - Inadequate vaginal lubrication
    - Pelvic radiation
    - Estrogen deficiency
  - Conditioned response to pain from physical issues previously listed
RISK FACTORS

- Most often idiopathic
- Although the exact role in the condition is unclear, many women report a history of abuse or sexual trauma.
- Often associated with other sexual dysfunctions

COMMONLY ASSOCIATED CONDITIONS

- Marital stress, family dysfunction
- Anxiety
- Vulvodynia/vestibulodynia

DIAGNOSIS

DSM-5 has combined vaginismus and dyspareunia in a condition called genito-pelvic pain/penetration disorder.

HISTORY

- Complete medical history
- Full psychosocial and sexual history, including the following:
  - Onset of symptoms (primary or secondary)
  - If secondary, precipitating events, if any
  - Relationship difficulty/partner violence
  - Inability to allow vaginal entry for different purposes
    - Sexual (penis, digit, object)
    - Hygiene (tampon use)
    - Health care (pelvic examination)
  - Infertility
  - Traumatic experiences (exam, sexual, etc.)
  - Religious beliefs
  - Views on sexuality

PHYSICAL EXAM

- Pelvic examination is necessary to exclude structural abnormalities or organic pathology.
- Educating the patient about the examination and giving her control over the progression of the examination is essential, as genital/pelvic examination may induce varying degrees of anxiety in patients.
• Referral to a gynecologist, family physician, or other provider specializing in the treatment of sexual disorders may be appropriate.
• Contraction of pelvic floor musculature in anticipation of examination may be seen.
• Lamont classification system aids in the assessment of severity:
  – First degree: perineal and levator spasm relieved with reassurance
  – Second degree: perineal spasm maintained throughout the pelvic exam
  – Third degree: levator spasm and elevation of buttocks
  – Fourth degree: levator and perineal spasm and elevation with adduction and retreat

DIFFERENTIAL DIAGNOSIS
• Vaginal infection
• Vulvodynia/vestibulodynia
• Vulvovaginal atrophy
• Urogenital structural abnormalities
• Interstitial cystitis
• Endometriosis

DIAGNOSTIC TESTS & INTERPRETATION
No laboratory tests indicated unless signs of vaginal infection are noted on examination. When diagnosing of this disorder has been conducted, five factors should be considered.
• Partner factors
• Relationship factors
• Individual vulnerability factors
• Cultural/religious factors
• Medical factors

Test Interpretation
Not available; may be needed to check for secondary causes

TREATMENT
• Genito-pelvic pain penetration disorder may be successfully treated (2)[B].
• Outpatient care is appropriate.
• Treatment of physical conditions, if present, is first line (see “Secondary”)

mebooksfree.com
Role for pelvic floor physical therapy and myofascial release

Some evidence suggests that cognitive-behavioral therapy may be effective, including desensitization techniques, such as gradual exposure, aimed at decreasing avoidance behavior and fear of vaginal penetration (3)[A].

Based on a Cochrane review, a clinically relevant effect of systematic desensitization cannot be ruled out (4)[A].

Evidence suggests that sex therapy may be effective (4)[B].

- Involves Kegel exercises to increase control over perineal muscles
- Stepwise vaginal desensitization exercises
  - With vaginal dilators that the patient inserts and controls
  - With woman’s own finger(s) to promote sexual self-awareness
  - Advancement to partner’s fingers with patient’s control
  - Coitus after achieving largest vaginal dilator or three fingers; important to begin with sensate-focused exercises/sensual caressing without necessarily a demand for coitus
  - Female superior at first; passive (nonthrusting); female-directed
  - Later, thrusting may be allowed.

Topical anesthetic or anxiolytic with desensitization exercises may be considered.

Patient education is an essential component of treatment (see “Patient Education” section).

MEDICATION

Antidepressants and anticonvulsants have been used with limited success. Low-dose tricyclic antidepressant (amitriptyline 10 mg) may be initiated and titrated as tolerated (3)[B].

Topical anesthetics or anxiolytics may be utilized in combination with either cognitive-behavioral therapy or desensitization exercises as noted above (4)[B].

Botulinum neurotoxin type A injections may improve vaginismus in patients who do not respond to standard cognitive-behavioral and medical treatment for vaginismus.

- Dosage: 20, 50, and 100 to 400 U of botulinum toxin type A injected in the levator ani muscle have been shown to improve vaginismus (4)[B].

Intravaginal botulinum neurotoxin type A injection (100 to 150 U) followed by bupivacaine 0.25% with epinephrine 1:400,000 intravaginal injection (20 to 30 mL) while the patient is anesthetized may facilitate progressive
placement of dilators and ultimately resolution of symptoms (5)[B].

ISSUES FOR REFERRAL
For diagnosis and treatment recommendations, the following resources may be consulted:
- Obstetrics/gynecology
- Pelvic floor physical therapy
- Psychiatry
- Sex therapy
- Hypnotherapy

SURGERY/OTHER PROCEDURES
Contraindicated

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Biofeedback
- Functional electrical stimulation

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Desensitization techniques of gentle, progressive, patient-controlled vaginal dilation

Patient Monitoring
General preventive health care

DIET
No special diet

PATIENT EDUCATION
- Education about pelvic anatomy, nature of vaginal spasms, normal adult sexual function
- Handheld mirror can help the woman to learn visually to tighten and loosen perineal muscles.
Important to teach the partner that spasms are not under conscious control and are not a reflection on the relationship or a woman’s feelings about her partner.

Instruction in techniques for vaginal dilation

Resources
- American College of Obstetricians & Gynecologists (ACOG), 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG. http://www.acog.org/

PROGNOSIS
Favorable, with early recognition of the condition and initiation of treatment

REFERENCES

ADDITIONAL READING

SEE ALSO

*Dyspareunia; Sexual Dysfunction in Women*

**CODES**

**ICD10**

• N94.2 Vaginismus
• N94.1 Dyspareunia

**CLINICAL PEARLS**

• In a patient with suspected genito-pelvic pain penetration disorder, a complete medical history, including a comprehensive psychosocial and sexual history and a patient-centric, patient-controlled educational pelvic exam should be conducted.
• This condition can be treated effectively.
• Cognitive-behavioral therapy may be effective for the treatment of this condition.
• Botox injection therapy is in the experimental stages but looks promising for the treatment of vaginismus. Bupivacaine and dilation under general anesthesia has also been tried as a treatment for vaginismus.
GERIATRIC CARE: GENERAL PRINCIPLES

Erica K. Cichowski, MD • Mohammad Selim, MBBCh

BASICS

DESCRIPTION
The optimal approach to caring for our elderly patient population requires an understanding of the physiology of normal aging, as well as unique geriatric considerations for access to care, diagnosis, treatment, and ongoing care.

EPIDEMIOLOGY
The percentage of the U.S. population anticipated to be >65 years by the year 2050 exceeds 20%, and the percentage of those who are >85 years may reach 24%.

ETIOLOGY AND PATHOPHYSIOLOGY
Physiology of aging

- Although patients age 65 years and beyond are typically considered elderly, there is variability in the rate of decline in organ function associated with aging dependent on genetic, environmental, socioeconomic factors as well as disease burden.
- The aging process is not pathologic but part of the developmental continuum. However, physiologic changes associated with aging tend to diminish the body’s compensatory reserve and increase susceptibility to disease.
  - Aging increases body fat and decreases total body water and lean body mass. This results in hydrophilic drugs having a smaller apparent volume of distribution. Lipophilic drugs will have an increased volume of distribution and longer half-life.
  - Aging decreases renal elimination of drugs.
  - Declines in lung capacity, oxygen uptake, cardiac output, muscle mass, glomerular filtration rate as well as blood flow to the brain, liver, and kidneys are associated with aging and must be considered in the diagnosis and treatment of elderly patients.
RISK FACTORS
Access to care

- Despite Medicare or dual health care coverage, persistent perceived barriers to health care include:
  - Lack of provider responsiveness to patient concerns
  - Mounting medical bills
  - Transportation challenges
- Barriers tend to be more prevalent in the female population and with increasing age.
- Alternatives to the traditional face-to-face visit should be considered to enhance access to care:
  - Encrypted email or home telehealth for those who are technologically equipped
  - Phone visits for those with adequate hearing

GENERAL PREVENTION

- Functional status
  - Activities of daily living (ADLs)
  - Instrumental ADLs (IADLs)
- Hearing assessment via hearing
  - Handicapped inventory
- Depression via:
  - Geriatric Depression Scale: [https://consultgeri.org/try-this/general-assessment/issue-4.pdf](https://consultgeri.org/try-this/general-assessment/issue-4.pdf)
- Falls: Those with two or more falls in the past year, fall with injury requiring medical treatment, or fear of falling due to difficulty with gait or balance require a full fall risk assessment: [https://www.cdc.gov/steadi/pdf/STEADI-Algorithm-a.pdf](https://www.cdc.gov/steadi/pdf/STEADI-Algorithm-a.pdf).
- Urinary incontinence: Inquire if patient has lost urine >5 times in past year.
- Polypharmacy
  - Utilize pill bottles, pharmacy records, patient and caregiver input to reconcile medication lists.
  - Ask about use of over-the-counter and alternative medications.
- Substance use: CAGE criteria: [https://www.mdcalc.com/cage-questions-]
Advanced care planning

- Completion of an advanced directive among most important interventions
- Definition: Advanced directives are documents a person completes while still in possession of decisional capacity to ensure their values are reflected when considering how treatment decisions should be made on her or his behalf in the event she or he loses the capacity to make such decisions.
- Instruments:
  - Durable power of attorney: Patient (called the principal) appoints an agent to handle specific health, legal, and financial responsibilities.
  - Health care proxy: a durable power of attorney specifically for health care decisions; their role is to express the patient’s wishes and make health care decisions if the patient cannot speak for themselves.
  - Living will: a legal document that allows patients to express their wishes for end-of-life medical care, in case they become unable to communicate their decisions

**DIAGNOSIS**

**HISTORY**

Optimizing communication

- Speak directly to your patient unless directed toward their surrogate.
- Utilize emotional intelligence to assess and manage emotionally charged interactions and overly helpful loved ones.
- Assess patient and caregiver health literacy and adjust explanations accordingly.
- Gauge the degree of social and financial support.
- Establish patient’s values, preferences, and goals of care.

**PHYSICAL EXAM**

Geriatric-specific considerations:

- Orthostatic hypotension: contributes to poor energy, diminished functional status, increased risk of falls, and decline in renal function due to ineffective organ perfusion
- Hypothermia/hyperthermia: increased susceptibility in the elderly; less likely to mount a fever in the setting of infection; consider thyroid derangement.
- Weight loss: Assess access to food; may be presenting feature in mood
disorder, thyroid derangement, dementia, malignancy

- Hearing: Check for cerumen impaction; perform Whisper Test: https://www.youtube.com/watch?v=PzRzpW6JKzQ

DIFFERENTIAL DIAGNOSIS

Geriatric-specific presentations:

- CAD: Elderly patients with coronary heart disease often present with atypical symptoms, including exertional dyspnea. Silent myocardial ischemia is also common.
  - Constipation: In older adults, constipation may be associated with fecal impaction and overflow fecal incontinence.
  - Delirium: Nearly 30% of older patients experience delirium at some time during hospitalization.
  - Urinary tract infection (UTI): UTI is the most common infectious illness in adults age 65 years and over.
  - Depression: It is more common in elderly females.
  - Insomnia: Late-life insomnia is often persistent and may prompt self-medication with over-the-counter sleep aids or alcohol.
  - Hearing difficulties: Some studies showed increased incidence of dementia in patient with hearing difficulties (1).

DIAGNOSTIC TESTS & INTERPRETATION

Informed decision making

- Decision-making capacity: Evaluate in four areas: ability to understand information about treatment, ability to appreciate how that information applies to their situation, ability to reason with that information, and ability to make a choice and express it: http://www.aafp.org/afp/2001/0715/p299.html.
- Surrogate decision maker
  - Patient-identified agent (durable power of attorney for health care, medical power of attorney, health care agent)
  - Court-appointed surrogate (legal guardian or conservator)

Diagnostic Procedures/Other

- Avoid unnecessary patient/caregiver burden if results will not significantly enhance the plan of care.
  - Cost
– Time
– Travel
– Pain
– Anxiety
– Recovery time

- Avoid unnecessary risk; taking into consideration renal function, cognitive impact, cost, diagnostic yield in the geriatric population
- Factor in estimated life expectancy
- Geriatric-specific reference values (e.g., TSH, A1C)

---

**TREATMENT**

**GENERAL MEASURES**

- Optimize nonpharmacologic options first.
- Align with patients’ goals of care.
- Feasibility for patient and caregivers
  - Cost
  - Availability
  - Travel burden
- Compliance
- Nonpharmacologic (2)
  - OT/PT
  - Speech therapy
  - Hearing aids
  - Walking assist devices
  - Nonpharmacologic treatment of depression and insomnia
- Pharmacologic
  - Start low and go slow.
  - Dose adjustments for renal and hepatic function
  - Be respectful of pill burden, drug–drug interactions, and polypharmacy.
  - Beers criteria: assists in selecting medications with best geriatric benefit to risk ratio;
- Geriatric pain management:
  - Treatment goal is to improve functionality.
  - Stepwise care
  - Nonpharmacologic:
Physical intervention (e.g., PT/aquatic therapy, aquapuncture, 
chiropractic manipulation, massage)
- Psychoeducational interventions (such as cognitive-behavioral therapy, 
meditation, and patient education)
  - Pharmacologic: Consider Beers criteria.
- Assess the home environment.
  - Social work
  - Home safety evaluations
    - OT/PT
  - Diagnose and address social isolation (3):
    - Group support
    - Social activities
    - Home visitations

SURGERY/OTHER PROCEDURES
- Assess surgical risk.
- Weigh risks versus benefits.
- Explore alternatives thoroughly.
- Align with goals of care.
- Preoperative discharge planning with caregiver input

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Use of CAM is on the rise in geriatric patients (4).
- Discuss potential risks and limitations.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Inpatient prevention measures
- Falls
- Acute delirium
- Skin breakdown
- Pain
- Infections
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Realistic expectations
- Consider pharmacologic débridement.

**Patient Monitoring**
Utilize team members optimally.

- Home health care
- Social work
- RN care managers

**PATIENT EDUCATION**

- Caregiver support (5)
  - Screening:
    o Frustrations
    o Depression
    o Social support
    o Financial burden
    o Time spent on providing care
    o Coping mechanisms
    o Need for help
  - Resources
    o Local agency on aging
    o Respite care: Taking care of an older or ill family member can be enormously rewarding, but it can be physically and emotionally draining as well. That’s why it’s important for caregivers to seek occasional respite from their responsibilities.
    o Support group: Alzheimer association 800-272-3900
    o Targeted education
    o Skills training to address caregiver concerns
  - Follow-up
    o Home and phone visits
    o Frequent touch points

- Elder mistreatment
  - Screening
    o Brief Abuse Screen for the Elderly (BASE)
- Elder Assessment Instrument (EAI)
- Warning signs
  - Skin findings (e.g., lacerations and bruises)
  - Fractures
  - Malnutrition
  - Dehydration
  - Pressure ulcers
  - Signs of sexual abuse
  - Change in the ability to manage and control finances
- Forms
  - Abuse (e.g., physical, sexual)
  - Neglect
  - Financial exploitation
- Interventions:
  - Prevention by caregiver support
  - Documentation
  - Reporting
  - Social and medical interventions
- Palliative care
  - A philosophy of care for those with serious illnesses that focuses on symptom, pain and stress relief with a goal of optimizing functional status and quality of life
  - Ideal for patients with:
    - Complex or refractory symptoms, pain, or stress
    - Frequent admissions
    - Complex care needs
    - Decline in function or quality of life
- Hospice
  - A model of end-of-life care
  - Provide physical, emotional, and spiritual support to patients with <6 months life expectancy to maintain optimal quality of life and die with dignity.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

Z71.89 Other specified counseling

**CLINICAL PEARLS**

- Establish patient goals of care and align all clinical decisions within the context of these goals.
- Utilize an interdisciplinary team approach to optimize holistic care for elders and their caregivers.
GIARDIASIS

Carol Hope Hungerford, DO • Pamela R. Hughes, MD

BASICS

DESCRIPTION

- Intestinal infection caused by the protozoan parasite Giardia lamblia:
  - G. lamblia is also called Giardia duodenalis and Giardia intestinalis.
- Infection results from ingestion of cysts, which transform into trophozoites and colonize the small intestine to cause symptoms.
  - Infectious cycle is continued when the trophozoites encyst in the small intestine and are transmitted through water, food, or hands contaminated by feces of an infected person.
- Most infections result from fecal–oral transmission or ingestion of contaminated water (e.g., swimming).
- Less commonly acquired through contaminated food

EPIDEMIOLOGY

- Predominant age:
  - All ages but most common in early childhood ages 1 to 9 years and adults 35 to 44 years
- Predominant gender:
  - Male > female (slightly)
- Minimal seasonal variability; slight increase in summer and early fall

Pediatric Considerations

- Most common in early childhood
- Chronic infection in children can lead to intestinal malabsorption (may also be associated with growth restriction).

Prevalence

- 5% of patients with traveller’s diarrhea
- >19,000 cases/year from reportable U.S. states:
  - Giardia is not reportable in Indiana, Kentucky, Mississippi, North Carolina, and Texas.
ETIOLOGY AND PATHOPHYSIOLOGY

*Giardia* trophozoites colonize the surface of the proximal small intestine: The mechanism of diarrhea is unknown.

**Genetics**
No known genetic risk factors

**RISK FACTORS**
- Daycare centers
- Anal intercourse
- Wilderness camping
- Travel to developing countries
- Children adopted from developing countries
- Public swimming pools
- Pets with *Giardia* infection/diarrhea

**GENERAL PREVENTION**
- Hand hygiene
- Water purification when camping and when traveling to developing countries
- Properly cook all foods.

**COMMONLY ASSOCIATED CONDITIONS**
Hypogammaglobulinemia, IgA deficiency, and immunosuppression are associated with prolonged course of the disease and treatment failures.

**DIAGNOSIS**

**HISTORY**
- 25–50% of infected persons are symptomatic.
- Symptoms usually appear 1 to 2 weeks after exposure.
- Diarrhea >3 weeks (95%)
- Abdominal cramps (70%)
- Nausea (60%)
- Bloating (50%)
- Flatulence (50%)
- Weight loss (50%), up to 10–20% of ideal body weight
- Fever (20%), usually early on. If persistent, consider another diagnosis.
PHYSICAL EXAM
- Typically normal vital signs
- Nonspecific; abdominal exam; may have bloating, tenderness, or increased bowel sounds

DIFFERENTIAL DIAGNOSIS
- Cryptosporidiosis, microsporidiosis, strongyloidiasis, cyclosporiasis
- Other causes of malabsorption include celiac sprue, tropical sprue, bacterial overgrowth syndromes, and Crohn ileitis.
- Irritable bowel (diarrhea without weight loss)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Light microscopy of stool for ova and parasites:
  - Repeat 3 times on separate days.
  - Cysts in fixed or fresh stools, and occasionally, trophozoites are found in fresh diarrheal stools.
  - Test limitations: labor intensive; experienced operator is necessary for interpretation; intermittent shedding means that ova may not be present in stool sample.
- ELISA: sensitivity and specificity of 100% and 92%, (compared to 50% and 70% with microscopy) (1)
- Polymerase chain reaction (PCR) techniques are more sensitive than microscopy but have not been widely adopted due to high cost.

Follow-Up Tests & Special Considerations
String test (entero-test):
- The patient swallows a gelatin capsule on a string which is left in the duodenum for several hours or overnight. The string is removed and evaluated for presence of trophozoites by microscopy.

Diagnostic Procedures/Other
Esophagagogastroduodenoscopy (EGD) with biopsy and sample of small intestinal fluid

Test Interpretation
Intestinal biopsy shows flattened, mild lymphocytic infiltration and trophozoites
on the surface.

**TREATMENT**
Outpatient for mild cases; inpatient if symptoms are severe enough to cause dehydration warranting parenteral fluid replacement

**GENERAL MEASURES**
- No treatment required in asymptomatic patients
- Prophylactic therapy indicated for asymptomatic patients in close contact with pregnant or immunocompromised individuals
- Fluid replacement if dehydrated

**MEDICATION**

*First Line*
- Metronidazole (Flagyl): 250 mg PO TID for 5 to 10 days
- Tinidazole: 2 g PO single dose (50 mg/kg up to 2 g for children)
- Albendazole: 400 mg/day PO daily for 5 days:
  - Albendazole has comparable effectiveness to metronidazole with fewer side effects (2)[A].
- Precautions:
  - Theoretical risk of carcinogenesis with metronidazole
- Significant possible interactions: occasional disulfiram reaction with metronidazole or tinidazole
- Paromomycin (Humatin): a nonaminoglycoside recommended in pregnancy due to lower risk of teratogenicity in the 1st trimester

*Pregnancy Considerations*
Medications to treat giardiasis are relatively contraindicated during pregnancy.

*Pediatric Considerations*
Limited evidence to suggest vitamin A reduces prevalence of *G. lamblia* (3)[A]

*Second Line*
- Nitazoxanide suspension was approved by the FDA in 2003 for treatment of giardiasis in children age 1 to 11 years; children age 1 to 4 years: 100 mg BID and age 5 to 11 years 200 mg BID for 3 days
Several other medications effective against *Giardia* are not available in the United States.

Treatment failures may be treated with a longer course of original agent or change to a different agent class.

Combination therapies are still being investigated with multiple reported successful combinations; however, there are no definitive guidelines (4)[C].

**ADDITIONAL THERAPIES**

There have been anecdotal reports of herbal products containing *Mentha crispa* for the treatment of *Giardia* (efficacy is unclear).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*

Symptoms, weight, and stool exams if patients fail to improve

**DIET**

Low lactose/lactose free for at least 1 month, low fat

**PATIENT EDUCATION**

- Hand washing more important than water purification to prevent transmission in outdoor enthusiasts
- Lactose intolerance may follow *Giardia* infection and cause persistent diarrhea posttreatment. Recommend low-lactose/lactose-free diet to mitigate.
  - Don’t swim if you have diarrhea.
  - Wash hands with soap after changing diapers before returning to the pool.
  - Do not ingest pool, lake, or river water.
  - Use chlorine to kill *Giardia* in water used for recreational activities.

**PROGNOSIS**

- Untreated giardiasis lasts for several weeks.
- Most (90%) patients respond to treatment within a few days:
Most nonresponders or relapses respond to a second course with the same or a different agent.

COMPLICATIONS
Malabsorption, weight loss, and lactose intolerance

ALERT
Reportable disease to the CDC

REFERENCES

ADDITIONAL READING
SEE ALSO
Algorithm: Diarrhea, Chronic

CODES

ICD10
A07.1 Giardiasis [lambliasis]

CLINICAL PEARLS

- Daycare facilities and public swimming pools are common sources of *Giardia* transmission (don’t assume camping or travel is required).
- Commonly presents with abdominal bloating and loose, foul-smelling stool
- Metronidazole has high cure rates (but is often poorly tolerated).
- Most treatment failures respond to a second course of antibiotics (with same or other drugs).
- A single fluorescence antibody (FA) or ELISA is as sensitive as three stool samples (looking for ova and parasites) to detect *Giardia*. 
BASICS

DESCRIPTION
A benign, inherited syndrome, in which mild, intermittent unconjugated hyperbilirubinemia occurs in the absence of hemolysis or liver dysfunction.

Pediatric Considerations
Rare for the disorder to be diagnosed before puberty.

Pregnancy Considerations
The relative fasting that may occur with morning sickness can elevate bilirubin level.

EPIDEMIOLOGY
- Predominant age: present from birth but most often presents in the 2nd or 3rd decade of life.
- Predominant sex: male > female (2 to 7:1)

Prevalence
Prevalence in the United States: ~8% of the population; ~1 in 3 of those affected are not aware that they have the disorder.

ETIOLOGY AND PATHOPHYSIOLOGY
Indirect hyperbilirubinemia in Gilbert syndrome (GS) results from impaired hepatic bilirubin clearance (~30% of normal) due to decreased levels of the enzyme uridine diphosphoglucuronate-glucuronosyltransferase (UDPGT). Hepatic bilirubin conjugation (glucuronidation) is thus reduced, although this may not be the only defect.

Genetics
Inherited defects within the promoter region of the gene that encodes the enzyme UDPGT yields reduced conjugation of bilirubin with glucuronic acid.
RISK FACTORS

- Male gender
- Family history

COMMONLY ASSOCIATED CONDITIONS

GS is part of a spectrum of hereditary disorders that includes types I and II Crigler-Najjar syndrome (1). However, bilirubin levels in these cases will be >6 mg/dL.

DIAGNOSIS

HISTORY

- A nonpruritic jaundice can occur in the setting of fasting, dehydration, infection, lack of sleep, physical exertion, or surgery. Other symptoms that may present during an episode of jaundice, including fatigue, are caused by the triggering factor and are not directly a result of GS.
- Some medications may also trigger episodes of jaundice in patients with GS due to abnormal metabolism. These include drugs that inhibit glucuronyl transferase (i.e., gemfibrozil) as well as selective protease inhibitors (i.e., atazanavir and indinavir) (2). There is some evidence that tocilizumab (3), a monoclonal antibody used to treat rheumatoid arthritis, and ribavirin, an antiviral for hepatitis C treatment, may also induce jaundice (4). The aforementioned drugs have not been associated with liver toxicity. However, irinotecan, an antineoplastic therapy used in the individualized treatment of metastatic colorectal cancer, has been associated with an increased risk of toxicity in patients with GS (5).

PHYSICAL EXAM

Occasional mild jaundice precipitated by the aforementioned triggers (fasting, dehydration, infection, lack of sleep, physical exertion, surgery, and some medications). Exam should be devoid of the stigmata of chronic liver disease.

DIFFERENTIAL DIAGNOSIS

- Hemolysis
- Ineffective erythropoiesis (megaloblastic anemias, certain porphyrias, thalassemia major, sideroblastic anemia, severe lead poisoning, congenital dyserythropoietic anemias)
- Cirrhosis
- Chronic persistent hepatitis
- Pancreatitis
- Biliary tract disease

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Bilirubin: elevated but <6 mg/dL (103 μmol/L) and usually <3 mg/dL (51 μmol/L), virtually all unconjugated (indirect), with conjugated bilirubin within the normal range and/or <20% of the total bilirubin (2)
- CBC with peripheral smear is normal.
- Reticulocyte count, haptoglobin, and lactate dehydrogenase levels are normal.
- Liver function tests (LFTs) (aspartate aminotransferase [AST], alanine transaminase [ALT], alkaline phosphatase, and gamma-glutamyl transpeptidase [GGT]) are normal.
- Direct Coombs test is normal.
- Up to 60% of patients with GS have a clinically insignificant mild hemolysis that frequently can only be detected with sophisticated red cell survival studies (1).
- Drugs that may alter lab results: Bilirubin level may be raised by nicotinic acid and some other medications and lowered by phenobarbital (1).
- Disorders that may alter lab results: Bilirubin levels increase during fasting and may increase during a febrile illness.

**Follow-Up Tests & Special Considerations**

GS should be suspected if unconjugated hyperbilirubinemia persists in the absence of hemolysis or other liver dysfunction. A definitive diagnosis may be reported after 3 to 12 months of follow-up if the exam and diagnostic work up is otherwise normal.

**Diagnostic Procedures/Other**

Confirmatory testing is typically not performed. A 48-hour fast is impractical and nonspecific for GS (2). Provocation testing with rifampin could be employed if there is significant diagnostic doubt:

- After 12 hours of fasting, an increase of total bilirubin to >1.9 mg/dL 2 hours after an oral dose of rifampin 900 mg distinguishes patients with GS with a sensitivity of 100% and a specificity of 100% (6).
ALERT
A liver biopsy is not usually needed to exclude other diagnoses unless concomitant liver disease is present.

TREATMENT
- Outpatient
- Avoid unnecessary testing and procedures.
- Specific treatment is not necessary.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Once GS has been confidently diagnosed, no further monitoring is required.

PATIENT EDUCATION
- Reassure patients that GS is benign.
- Educate patients on common triggers for jaundice.
- Recommend patients to inform medical providers of their diagnosis.
- Instruct patients to seek medical help if severe or prolonged jaundice occurs as these may be signs of a separate disease process.

PROGNOSIS
- GS is benign with an excellent prognosis.
- Preliminary evidence suggests that patients with GS may have protective properties against cardiovascular disease and Hodgkin lymphoma (5).
- Patients with GS are able to serve as donors for right lobe of liver for transplantation.

COMPLICATIONS
There are no known complications from GS.

ALERT
Caution before using irinotecan in patients with GS. Once metabolized, this
colorectal cancer treatment affects the enzyme responsible for GS, significantly increasing risk of toxicity (5).

REFERENCES

CODES

- E80.4 Gilbert syndrome
- E80.6 Other disorders of bilirubin metabolism

CLINICAL PEARLS

- GS is a benign, inherited syndrome in which mild, intermittent unconjugated hyperbilirubinemia causing jaundice occurs with otherwise normal liver function.
- Reduced hepatic bilirubin conjugation (glucuronidation) occurs due to altered UDPGT1A1 gene promotion.
- GS is diagnosed when a mild, persistent or recurrent elevation in unconjugated hyperbilirubinemia persists in the absence of hemolysis or other liver dysfunction.
- Confirmatory tests are not frequently needed, and a liver biopsy is not recommended unless there is serious concern for concomitant liver disease.
- Patient education and reassurance is essential, and unnecessary testing and
procedures should be avoided.
GINGIVITIS
Sheila O. Stille, DMD • Hugh Silk, MD, MPH, FAAFP

BASICS
DESCRIPTION
Gingivitis is a reversible form of inflammation of the gingiva. It is a mild form of periodontal disease. Classification includes the following:

- Plaque-induced
- Not plaque-induced (bacterial, viral, or fungal; e.g., necrotizing ulcerative gingivitis, Vincent disease [“trench mouth”], denture-related)
- Modified by systemic factors (e.g., pregnancy, puberty, HIV, diabetes, smoking, leukemia)
- Modified by medications (calcium channel blockers, antipsychotics, antiepileptics, antirejection medications, hormones)
- Modified by malnutrition (vitamin deficiencies)
- Acute or chronic
- System(s) affected: gastrointestinal; ears, nose, throat; dental
- Synonym(s): mild periodontal disease; gum disease

Geriatric Considerations
More frequent in this age group (due more to additive effects than to increased susceptibility)

Pediatric Considerations
Cases of plaque-induced gingivitis are common in children (most common form of pediatric periodontal disease) and usually require no specific interventions other than improved oral hygiene.

Pregnancy Considerations
- Very common in pregnant women; hormonal effect
- Self-limited

EPIDEMIOLOGY
- Predominant age: children, teenagers, and young adults
- Predominant sex: slightly more males than female
Prevalence ~50% of children
~90% of adolescents and adult population
~30–75% of pregnant women
47% of adults in United States have periodontal diseases (1).

ETIOLOGY AND PATHOPHYSIOLOGY
Inflammation of the marginal gingiva. This can progress to deeper, destructive inflammation; if involving supporting bone, will be classified as periodontitis, not gingivitis (2)

- Usually noncontagious
- Inadequate plaque removal
- Blood dyscrasias (pregnancy)
- Medication induced (e.g., oral contraceptives, antiepileptics)
- Allergic reactions
- Nutritional deficiencies
- Vasoconstriction (nicotine, methamphetamine)
- Endocrine/hormonal variations
  - Pregnancy, menses, menarche
- Chronic debilitating disease
- Vincent disease, necrotizing ulcerative gingivitis
  - Synergistic infection with fusiform bacillus (*Fusobacterium* spp.) and spirochete (*Borrelia vincentii*)
- Pathology
  - Acute or chronic inflammation
  - Hyperemic capillaries
  - Polymorphonuclear infiltration
  - Papillary projections in subepithelial tissue
  - Fibroblasts

**Genetics**
Possible genetic link (up to 30% of population); rare condition called hereditary gingival fibromatosis, where severe gingival hyperplasia covers teeth, associated with hirsutism

**RISK FACTORS**
- Poor dental hygiene/plaque formation
- Pregnancy
- Uncontrolled diabetes mellitus
• Malocclusion or dental crowding
• Smoking
• Mouth breathing
• Xerostomia
• Faulty dental restorations
• HIV-positive; AIDS
• Stress
• Hospitalization
• Vitamin C deficiency; coenzyme Q10 deficiency
• Dental appliances (dentures, braces)
• Eruption of primary or secondary teeth
• Necrotizing ulcerative gingivitis
  – Stress
  – Lack of sleep
  – Malnutrition
  – Viral illness
  – Typically teens and young adults
• Bronchial asthma and other respiratory diseases (2)
• Rheumatoid arthritis
• Epilepsy

GENERAL PREVENTION
• Good oral hygiene
  – Adults
    o Regular twice-daily brushing with fluoride toothpaste and increased benefit of using circular oscillating electric brush rather than regular brush or sonic/vibration (2,3)[A]
    o Daily “high-quality” flossing (studies show that flossing only helps when it is done correctly) and interdental brushes (2,4)[A]
    o Chlorhexidine with oral hygiene better than other oral rinse agents (2,5) [A]
      ▪ Use in acute phase (2)[A]
  – Pediatrics
    o Regular twice-daily brushing with fluoride toothpaste under parental supervision until full manual dexterity (~8 years of age)
    o Regular flossing if no spaces between teeth
• Cleaning by a dentist or hygienist every 6 months or more frequently, as indicated (2)[A]
• Mouth rinse with essential oils (menthol, thymol, eucalyptol; e.g., Listerine)
combined with brushing (2)[A]  
- It had been thought that long-term use of alcohol-based mouth rinse may be associated with an increased risk of oral cancer. A recent systematic review, found no evidence (2)[A].

COMMONLY ASSOCIATED CONDITIONS
- Periodontitis
- Glossitis
- Pedunculated growths (pyogenic granulomata)

DIAGNOSIS

HISTORY
- Gingival erythema, edema, and bleeding
- Gingiva is tender to touch but otherwise painless.
- Bleeding of gingiva when brushing, flossing, or eating
- Inquire about HIV risk, pregnancy, nutritional deficiencies, diabetes, and other risk factors as indicated (see “Risk Factors”).
- Smoking history
- Poor oral hygiene, infrequent dental visit history

PHYSICAL EXAM
- Normal gums should appear pink, firm, stippled, and scalloped.
- Gingivitis—marginal gingiva edematous with blunted papilla (usually painless, except to touch)
- Gingiva erythema: bright red or red-purple appearance
- Bleeding with manipulation of gingiva
- Biofilm of plaque (soft) and calculus (calcified, not easily removed)
- Edema of interdental papillae
- HIV gingivitis
  - Also called linear gingival erythema
  - Narrow band of bright red inflamed gum surrounding neck of tooth
  - Painful
  - Bleeds easily
  - Rapid destruction of gingival tissue and can progress to periodontitis with destruction of underlying support tissues (periodontal ligament, supporting alveolar bone)
Vincent disease/necrotizing ulcerative gingivitis
- Ulcers
- Fever
- Malaise
- Regional lymphadenopathy
- Pain
- Mouth odor

DIFFERENTIAL DIAGNOSIS
- Periodontitis (deeper inflammation, causing destruction to connective tissue, ligaments, and alveolar bone)
- Glossitis
- Desquamative gingivitis (painful, persistent, usually middle-aged women)
- Pericoronitis (gum flap traps food and plaque over partially erupted 3rd molar), common in adolescence
- Gingival ulcers (aphthous, herpetic, malignancy, TB, syphilis)
- Specific forms of gingivitis: See “Description,” including acute necrotizing ulcerative gingivitis (Vincent disease) and HIV gingivitis (linear gingival erythema), adrenal crisis, leukemia.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- No tests usually needed
- Possible smear or culture to identify causative agent (HIV gingivitis includes gram-negative anaerobes, enteric strains, and Candida.)
- Labs for contributing conditions (HIV, pregnancy, diabetes, nutritional deficiencies)
  - Increase in C-reactive protein (5)[A]

TREATMENT

GENERAL MEASURES
- Stop any contributing medications.
- Remove irritating factors (plaque, calculus, faulty dental restorations, or partial dentures).
- Good oral hygiene (see “General Prevention”)
- Regular dental checkups (for scaling and polishing if plaque and/or tartar are
Smoking cessation
Warm saline rinses BID
Special needs patients: use of tray-applied 10% carbamide peroxide gels (5) [A]

MEDICATION

**First Line**
- Chlorhexidine rinses or varnishes may be used. (Note: Prolonged use of chlorhexidine can lead to blackening of the tongue and taste bud problems.)
- Essential oil mouthwash (EOMW) may be equally effective to chlorhexidine for reduction of gingival inflammation (although EOMW is not as effective for plaque control) (2)[A].
- Both chlorhexidine and EOMW rinses are as clinically effective as dental prophylaxis and oral hygiene instruction at 6-month recall (2)[A].
- Antibiotics indicated only for acute necrotizing ulcerative gingivitis (Vincent disease)
- Antibiotics
  - Penicillin V: pediatric dose, 25 to 50 mg/kg/day divided q6h; adult dose, 250 to 500 mg q6h, OR
  - Metronidazole: pediatric dose, 30 mg/kg/day PO/IV divided q6h; maximum 4 g/day; adult dose, 500 mg BID or TID for 10 days OR
  - Amoxicillin/clavulanic acid: pediatric dose, 30 mg/kg/day PO divided q12h; info: use 125 mg/31.25 mg/5 mL susp; adult dose, 875 mg/125 mg PO BID for 10 days
  - Erythromycin: pediatric dose, 30 to 40 mg/kg/day divided q6h; adult dose, 250 mg q6h
  - Clindamycin: penicillin allergy; pediatric dose, 8 to 20 mg/kg/day in 3 to 4 divided doses as hydrochloride; adults, 300 mg q6h (maximum 1.8 g/day
  - Doxycycline: adult dose, 100 mg BID 1st day and then QD for 10 days
- Topical corticosteroids
  - Triamcinolone 0.1% in Orabase (spray or ointment), applied locally TID, QID
    - Contraindications
      - Allergy to specific medication
- Precautions
  - Erythromycin frequently causes GI issues.
**Second Line**
- Acetaminophen or ibuprofen for any pain (rare)
- Other antibiotics or antifungal rinses or systemic according to culture or smear
- Decapinol oral rinse (surfactant that acts as a physical barrier, making it harder for bacteria to stick to tooth and mucosal surfaces) to reduce bacteria (not recommended for pregnant women or children <12 years); should be used in conjunction with other oral hygiene practices when those practices alone are not enough

**ISSUES FOR REFERRAL**
- Dental referral for acute gingivitis and routine cleanings and further treatment, as needed
- If gingivitis becomes periodontitis, deep root scaling, root planing, and antibiotics may be indicated.

**SURGERY/OTHER PROCEDURES**
- Débridement for acute necrotizing gingivitis
- Minor surgery may be necessary to correct tissue overgrowth for gingivitis caused by medicines/hereditary gingival fibromatosis.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Bilberry: potentially helpful in reducing inflammation and stabilizing collagen tissue
- Coenzyme Q10: topically, to restore coenzyme Q10 deficiency
- Replace any other nutritional deficiencies (e.g., vitamin C).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Outpatient
- No restrictions

**Patient Monitoring**
Until clear; dental follow-up for continued cleanings and secondary prevention
DIET
- Well-balanced diet that includes fruits, vegetables, vitamin C; avoid sugary snacks and drinks, which contribute to plaque formation.
- Soft foods during flare, if significant inflammation/bleeding

PATIENT EDUCATION
- Good oral hygiene, including twice-daily brushing with circular oscillating electric brush, fluoridated toothpaste, and daily flossing; regular dental visits

PROGNOSIS
- Usual course: acute, relapsing, intermittent; chronic
- Prognosis: generally favorable, responds well to appropriate treatment
- Left untreated, may progress to periodontitis (controversial), which is a major cause of tooth loss

COMPLICATIONS
Severe periodontal disease (which is associated with tooth loss, heart disease, diabetes, dementia, and preterm birth)

REFERENCES
5. Prasad M, Patthi B, Singla A, et al. The clinical effectiveness of post-

**ADDITIONAL READING**

**SEE ALSO**

- Dental Infection; Glossitis
- Algorithm: Bleeding Gums

**CODES**

**ICD10**

- K05.10 Chronic gingivitis, plaque induced
- K05.11 Chronic gingivitis, non-plaque induced
- K05.00 Acute gingivitis, plaque induced

**CLINICAL PEARLS**

- Gingivitis may be prevented and treated with regular dental cleanings, good oral hygiene, and use of certain mouth rinses including chlorhexidine.
- Untreated, gingivitis may progress to periodontitis, a possible contributor to systemic inflammation and its consequences (e.g., coronary artery disease and uncontrolled diabetes).
- New-onset or difficult-to-treat gingivitis, consider differential of etiology: pregnancy, HIV, diabetes, medications, and vitamin deficiencies.
GLAUCOMA, PRIMARY CLOSED-ANGLE
Sunil Bellur, MD • Salman S. Dar, MD • David A. Belyea, MD, MBA, FACS

BASICS

DESCRIPTION
Glaucoma is a progressive decline in vision that is usually associated with elevated intraocular pressure (IOP) in the eye, which leads to damage of the optic nerve. Primary angle closure (PAC) is one reason for glaucoma and can be classified as the following:

- Primary angle-closure suspect (PACS) is >180 degrees of iridotrabecular contact (ITC), normal IOP with no optic nerve damage.
- PAC is >180 degrees ITC with peripheral anterior synechiae (PAS) or elevated IOP but with no optic neuropathy.
- Primary angle-closure glaucoma (PACG) is >180-degree ITC with PAS, elevated IOP, and optic neuropathy.
- Acute angle-closure crisis (AACC) is occluded angle with symptomatic high IOP.
- Plateau iris configuration is any ITC persisting after a patent laser peripheral iridotomy (LPI) or a plateau iris syndrome which is any ITC persisting after a patent LPI with pressure elevation after dilation.

Geriatric Considerations
Increased risk with age and prior history of cataract, hyperopia, and/or uveitis

Pregnancy Considerations
Medications used may cross the placenta and be excreted into breast milk. Majority of IOP lowering medications are within class C and the risk of adverse effects to the fetus must be balanced with risk of vision loss in the mother.

EPIDEMIOLOGY
- Older age
- Female sex
- More likely in those of Inuit and East or South Asian descent
**Prevalence**
In 2013, it is estimated to have a worldwide prevalence of 20.2 million people aged 40 to 80 years with majority (15.5 million) in Asia (1). PACG is not as common in the United States; accounts for 10% of all glaucoma.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- PAC happens when iris touches the trabecular meshwork at the anterior chamber angle. This is called ITC. ITC causes obstruction of aqueous humor outflow through the trabecular meshwork, which causes elevation in IOP. Prolonged ITC can cause scarring, degradation of trabecular meshwork, and loss of vision (1).
- Most common underlying mechanism of angle closure is pupillary blockage of the aqueous flow from posterior to anterior chamber. This causes increase in pressure in the posterior chamber as compared to the anterior chamber. The buildup of pressure in the posterior chamber leads to anterior bowing of the iris and closing of the angle (1,2).
- Other mechanisms include predisposing ocular anatomy, such as plateau iris configuration (2).

**Genetics**
First-degree relatives have a 1–12% increased risk in whites; 6 times greater risk in Chinese patients with positive family history.

**RISK FACTORS**
- Age >50 years
- Female gender
- Asian or Inuit descent
- Family history of angle closure
- Shallow anterior chamber
- Hyperopia
- Short axial length
- Thick crystalline lens
- Anterior positioned lens
- Plateau iris
- Drugs that can induce angle closure:
  - Adrenergic agonists (albuterol, phenylephrine), anticholinergics (oxybutynin, atropine, botulinum toxin A), topiramate, antihistamines, antidepressants including selective serotonin reuptake inhibitors (SSRIs)
and tricyclic antidepressants (TCAs), sulfa-based drugs, cocaine, ecstasy

GENERAL PREVENTION
- Routine eye exam with gonioscopy for high-risk populations
- U.S. Preventive Services Task Force: insufficient evidence to recommend for or against screening adults for glaucoma without visual symptoms (3)[A]
- Prophylactic laser iridotomy may be considered in patients with PACS for preventing PACG.

COMMONLY ASSOCIATED CONDITIONS
- Cataract
- Hyperopia
- Microphthalmos
- Systemic hypertension

DIAGNOSIS

HISTORY
- Patient may be asymptomatic as in PACS or may have acute symptoms as in AACC.
- Acute symptoms commonly include unilateral:
  - Severe eye pain
  - Blurred vision
  - Eye redness
  - Halos around lights/objects
  - Frontal headache
  - Nausea and vomiting
- Patients with PACG can be asymptomatic, have subacute symptoms (intermittent subacute attacks), or compromised peripheral vision.
- Family history of acute angle-closure glaucoma
- Obtain history of prescription, over-the-counter, and herbal medications.
- Precipitating factors (dim light, medicines)
- Review of symptoms

PHYSICAL EXAM
Includes, but is not limited to, the following in the undilated eye:
- Visual acuity with refractive error (hyperopic eyes especially in older phakic
patients)
- Visual field testing and ocular motility
- Pupil size and reactivity (mid-dilated, asymmetric or oval, minimally reactive, and may have relative afferent papillary pupillary defect)
- Slit-lamp biomicroscopy–conjunctival hyperemia (in acute cases), central and peripheral anterior chamber depth narrowing, corneal swelling, iris abnormalities (diffuse and focal iris atrophy, posterior synechiae), lens changes (cataract and glaukomflecken-patchy localized anterior subcapsular lens opacities)
- IOP as measured by applanation tonometry
- Gonioscopy: visualization of anatomy of the angle of both eyes and to look for ITC and PAS
- Anterior segment imaging with ultrasound (US) biomicroscopy and anterior segment optical coherence tomography (AS-OCT) to understand the angle anatomy
- Undilated fundus exam (congestion, cupping, atrophy of optic nerve)

**DIFFERENTIAL DIAGNOSIS**

- Acute orbital compartment syndrome
- Traumatic hyphema
- Conjunctivitis, episcleritis
- Corneal abrasion
- Glaucoma, malignant, or neovascular
- Herpes zoster ophthalmicus
- Iritis and uveitis
- Orbital/periorbital infection
- Vitreous or subconjunctival hemorrhage
- Lens-induced angle closure

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
US biomicroscopy AS-OCT (1)[C]

*Diagnostic Procedures/Other*
Careful undilated ophthalmic examination including possible evaluation of fundus and optic nerve head, slit lamp biomicroscopy, gonioscopy, and tonometry (1)[C]
Test Interpretation
- Narrow or closed anterior angle
- Corneal stromal and epithelial edema
- Endothelial cell loss (guttata)
- Iris stromal necrosis
- Anterior subcapsular opacities (glaukomflecken)
- Optic nerve atrophy, pallor, or excavation

TREATMENT

GENERAL MEASURES
- Goals of treatment (1)[C]:
  - Reverse or prevent angle-closure process.
  - Control IOP.
  - Prevent damage to the optic nerve.
- PACS
  - Majority will not develop PAC or PACG.
  - May be either observed for development of PAC or be treated with iridotomy (1)[C]
- PAC and PACG
  - Iridotomy performed using argon or neodymium-doped yttrium aluminium garnet (Nd:YAG) laser (1)[A]
  - Complications of iridotomy: cataract, increased IOP, laser burn to the cornea, lens, vitreous, or retina; late-onset corneal edema; development of posterior synechiae; hyphema; iritis; and ocular dysphotopsia
- AACC
  - Initial treatment of AACC is to lower the IOP with medications to relieve the acute symptoms followed by iridotomy as soon as possible (1)[A]. For acute attack: ocular emergency
    - Manage nausea and pain.
    - Immediate ophthalmology consultation

MEDICATION
- During acute attack, medical therapy lowers IOP to relieve symptoms and clear corneal edema so that iridotomy can be performed as soon as possible.
- Medical therapy aims at:
  - Reduction of aqueous production:
Carbonic anhydrase inhibitors (CAI): acetazolamide 10 mg/kg IV or orally. May repeat 250 mg in 4 hours to a maximum of 1 g/day. CAI are contraindicated in sulfia allergy and hepatic insufficiency. Topical CAI are not potent enough to break the papillary block.

- Topical β-blockers: timolol 0.5%, levobunolol 0.5%, or carteolol 1%
- Topical α₂-agonists: brimonidine 0.2% or apraclonidine 0.5%

- Withdrawing aqueous from vitreous body and posterior chamber using hyperosmotic agents:
  - Glycerol 1.0 to 1.5 g/kg orally
  - Mannitol 1.0 to 1.5 g/kg IV
    - Hyperosmotic agent should be used with caution in patients with heart and kidney disease. Glycerol can increase blood sugar level and should not be given to diabetic patients.

- Pupillary constriction to open the chamber angle: topical pilocarpine 1% or 2% or aceclidine 2%. Miotic therapy is ineffective when IOP is markedly elevated due to sphincter ischemia. They may cause forward rotation of ciliary muscle, increasing the papillary block and worsening the IOP.

- During acute attack, acetazolamide 500 mg IV is given followed by 500 mg PO. Topical therapy is initiated with 0.5% timolol maleate and 1% apraclonidine drops 1 minute apart. Reduction of inflammation is accomplished with frequent topical steroids. In addition, systemic therapy with mannitol 20% 1.5 to 2.0 g/kg infused over 30 to 60 minutes or oral glycerol (Osmoglyn) (50%) 6 oz PO may be needed. Also treat pain and nausea with analgesics and antiemetics. About an hour after initiating treatment, 2 doses of pilocarpine drops administered 15 minutes apart to cause miosis in an attempt to open the angle (2)[C].

- After corneal edema clears, a peripheral iridotomy is done.

**ADDITIONAL THERAPIES**

- Keep patient supine.
- Can give antiemetics if needed
- Can do retrobulbar block for nausea and pain control

**SURGERY/OTHER PROCEDURES**

- Definitive therapy for PAC, PACG, and AACC is Nd:YAG or argon laser iridotomy (1,2)[B].

- Surgical iridectomy may be performed if cornea is cloudy and laser iridotomy cannot be performed.
Corneal indentation with four-mirror gonioscopic lens, cotton-tipped applicator, or muscle hook may be used to break a pupillary block in AACC (1)[C].

Effectiveness of phacoemulsification with IOL implantation in PACG is unclear (1),(2)[B]. Other procedures to reduce IOP that have been studied include argon laser peripheral iridoplasty (especially for plateau iris configuration/syndrome), anterior chamber paracentesis, goniosynechialysis, and trabeculectomy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Patient requires metabolic ± electrolyte and volume status monitoring (with osmotic agents).
- Facilitate close ophthalmology follow-up.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Schedule immediate ophthalmology follow-up.

Patient Monitoring

- Postsurgical follow-up and routine monitoring after acute attack as per ophthalmologist.
- Half of the fellow eye of patients with AACC will develop AACC within 5 years. Hence, prophylactic LPI should be performed in the fellow eye as soon as possible (1)[B].

PATIENT EDUCATION

- Advise patient to seek emergency medical attention if experiencing a change in visual acuity, blurred vision, eye pain, or headache.
- Patients with PACS and no iridotomy; avoid use of decongestants, motion sickness medications, adrenergic agents, antipsychotics, antidepressants, and anticholinergic agents.
- Correct eyedrop administration technique, including the following:
  - Remove contact lenses before administration.
  - Allow at least 5 minutes between administration of multiple ophthalmic
products.
- Patient education materials:
  - Glaucoma Research Foundation: http://www.glaucoma.org

PROGNOSIS
- With timely treatment, most patients do not have permanent vision loss.
- Prognosis depends on ethnicity, underlying eye disease, and time to treatment.

COMPLICATIONS
- Chronic angle closure, corneal edema, corneal fibrosis, and vascularization
- Iris atrophy
- Cataract
- Optic atrophy
- Malignant glaucoma
- Central retinal artery/vein occlusion
- Permanent decrease in visual acuity
- Repeat episode
- Fellow (contralateral) eye attack

REFERENCES

ADDITIONAL READING
SEE ALSO
Glaucoma, Primary Open-Angle

CODES

ICD10
- H40.20X0 Unsp primary angle-closure glaucoma, stage unspecified
- H40.219 Acute angle-closure glaucoma, unspecified eye
- H40.2290 Chronic angle-closure glaucoma, unsp eye, stage unspecified

CLINICAL PEARLS
- Examiner can determine if patient is hyperopic by observing the magnification of the patient’s face through his or her glasses (myopic lenses minify).
- A careful history may reveal similar episodes of angle closure that resolved spontaneously. Miotics, such as pilocarpine, can be effective during mild attacks but ineffective in the setting of high IOP (due to pressure-induced iris sphincter ischemia).
- In patients with AACC, the fellow eye should undergo prophylactic laser iridotomy.
GLAUCOMA, PRIMARY OPEN-ANGLE
Richard W. Allinson, MD

BASICS
DESCRIPTION
- Primary open-angle glaucoma (POAG) is an optic neuropathy resulting in visual field loss frequently associated with increased intraocular pressure (IOP).
- Normal IOP is 10 to 22 mm Hg. However, glaucomatous optic nerve damage also can occur with normal IOP and as a secondary manifestation of other disorders such as corticosteroid-induced glaucoma.
- System(s) affected: nervous
- Synonym(s): chronic open-angle glaucoma

Pregnancy Considerations
Prostaglandins should be avoided during pregnancy in the treatment of POAG.

EPIDEMIOLOGY
Incidence
- Predominant age: usually >40 years
- Increases with age
- Predominant gender: male = female

Prevalence
Prevalence in persons >40 years of age is ~1.8%.

Geriatric Considerations
Increasing prevalence with increasing age

ETIOLOGY AND PATHOPHYSIOLOGY
- Abnormal aqueous outflow resulting in increased IOP
- Normally, aqueous is produced by the ciliary epithelium of the ciliary body and is secreted into the posterior chamber of the eye.
  - Aqueous then flows through the pupil and enters the anterior chamber to be drained by the trabecular meshwork (TM) in the iridocorneal angle of the
eye. It then drains into the Schlemm canal and then into the episcleral venous system.

- 5–10% of the total aqueous outflow leaves via the uveoscleral pathway.
- Impaired aqueous outflow through the TM
  - Increased resistance within the aqueous drainage system

**Genetics**

- A family history of glaucoma increases the risk for developing glaucoma.
- TMCO1 genotype has been found to increase the risk of developing glaucoma among non-Hispanic whites (1)[A].
- The myocilin (MYOC) gene was the first gene associated with POAG.
  - MYOC cascade genetic testing for POAG allows identification of at-risk individuals (2)[C].

**RISK FACTORS**

- Increased IOP
- Myopia
- Diabetes mellitus (DM)
- African American
- Elderly
- Hypothyroidism
- Positive family history
- Central corneal thickness <550 μm
- Larger vertical cup-to-disc ratio (CDR)
- Larger horizontal CDR
- CDR asymmetry
- Disc hemorrhage
- Prolonged use of topical, periocular, inhaled, or systemic corticosteroids
- Obstructive sleep apnea
- Hypertension
- Corneal hysteresis (CH)
  - A measure of the viscoelastic damping of the cornea
  - Lower CH associated with faster rates of visual field loss

**GENERAL PREVENTION**

- Possible reduced risk of open-angle glaucoma with long-term use of oral statins among persons with hyperlipidemia
- Higher dietary nitrate and green leafy vegetable intake has been associated
with a lower POAG risk (3)[A].

- Evidence suggests that nitrate, a precursor of nitric oxide, is beneficial for blood circulation.
  - The vascular endothelium regulates the microcirculation via vasoactive factors with nitric oxide being one of them.
  - Nitric oxide reduces IOP by causing relaxation of the TM and Schlemm canal, resulting in increased aqueous humor outflow.

**COMMONLY ASSOCIATED CONDITIONS**

**DM**

**DIAGNOSIS**

**HISTORY**

Painless, slowly progressive visual loss; patients are generally unaware of the visual loss until late in the disease. Central visual acuity remains unaffected until late in the disease.

**PHYSICAL EXAM**

- Visual acuity and visual field assessment
- Ophthalmoscopy to assess optic nerve for glaucomatous damage
- Increased IOP
- CDR >0.5: Normal eyes show a characteristic configuration for disc rim thickness of inferior ≥ superior ≥ nasal ≥ temporal (ISNT rule).
- Earliest visual field defects are paracentral scotomas and peripheral nasal steps.

**DIFFERENTIAL DIAGNOSIS**

- Normal-tension glaucoma
- Optic nerve pits
- Anterior ischemic optic neuropathy
- Compressive lesions of the optic nerve or chiasm
- Posthemorrhagic (shock optic neuropathy)

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

Optical coherence tomography (OCT) can be useful in the detection of glaucoma.
by measuring the thickness of the retinal nerve fiber layer (RNFL).

- RNFL is thinner in patients with glaucoma.
- RNFL tends to be thinner with older age, in Caucasians, greater axial length, and smaller optic disc area.

**Diagnostic Procedures/Other**

- Visual field testing: perimetry
  - A multifocal intraocular lens may reduce visual sensitivity on standard automated perimetry.
- Tonometry to measure IOP

**Test Interpretation**

- Atrophy and cupping of optic nerve
- Loss of retinal ganglion cells (RGCs) and their axons produces defects and thinning in the RNFL.
- Significant RGC loss may occur at specific location before corresponding visual field loss is detected.
  - Trend-based analysis of ganglion cell-inner plexiform layer thickness on spectral-domain OCT may be useful for assessing glaucoma progression objectively and quantitatively (4)[C].
- Assessment of RNFL thickness with OCT can detect glaucomatous damage before the appearance of visual field defects on standard automated perimetry.
- OCT angiography of the peripapillary retina and optic nerve in eyes with POAG demonstrates microvascular reduction associated with visual field defects in a region-specific manner.

**TREATMENT**

**GENERAL MEASURES**

- Early Manifest Glaucoma Trial
  - Early treatment delays progression.
  - The magnitude of initial IOP reduction influences disease progression.
- Ocular Hypertension Treatment Study
  - Patients who only had increased IOP in the range of 24 to 32 mm Hg were treated with topical ocular hypotensive medication.
  - Treatment produced ~20% reduction in IOP.
  - At 5 years, treatment reduced the incidence of POAG by >50%: 9.5% in the
observation group versus 4.4% in the medication-treated group.

- The Advanced Glaucoma Intervention Study
  - Eyes were randomized to laser trabeculoplasty or filtering surgery when medical therapy failed.
  - In follow-up, if IOP was always <18 mm Hg, visual fields tended to stabilize. When IOP was >17 mm Hg, >1/2 the time, patients tended to have worsening of visual fields.

- Collaborative Initial Glaucoma Treatment Study
  - Both initial medical and surgical (trabeculectomy) treatment achieved significant IOP reduction, and both had little visual field loss over time.
  - There was a 5-year risk of endophthalmitis of 1.1% after trabeculectomy.

MEDICATION

>1 medication, with different mechanisms of action, may be needed. Ocular hypotensive agent categories include the following:

- Prostaglandin analogues: generally used as first-line treatment. Enhance uveoscleral outflow and increase aqueous outflow through the TM:
  - latanoprost 0.005% one drop at bedtime;
  - travoprost 0.004% one drop at bedtime;
  - bimatoprost 0.01% one drop at bedtime
  - Contraindications/precautions
    - Prostaglandin analogues may cause increased pigmentation of the iris and periorbital tissue.
    - Increased pigmentation and growth of eyelashes
    - Should be used with caution in active intraocular inflammation (iritis/uveitis)
    - Caution is also advised in eyes with risk factors for herpes simplex, iritis, and cystoid macular edema.
    - Macular edema may be a complication associated with treatment.
    - Avoid during pregnancy.

- β-Adrenergic antagonists (nonselective and selective): decrease aqueous formation; best when used as an add-on therapy: timolol 0.25% (initial) to 0.5% one drop in affected eye q12h; gel-forming solution (0.25% or 0.5%) one drop in affected eye once daily; betaxolol 0.5% one drop affected eye twice daily
  - Nonselective β-adrenergic antagonists: Avoid in asthma, chronic obstructive pulmonary disease (COPD), 2nd- and 3rd-degree atroventricular (AV) block, and decompensated heart failure. Betaxolol is a selective β-adrenergic antagonist and is safer in pulmonary disease.
- β-adrenergic antagonists: caution in patients taking calcium antagonists because of possible AV conduction disturbances, left ventricular failure, or hypotension

- Adrenergic agonists (nonselective and selective α2-adrenergic agonists)
  - Epinephrine 0.5–2%: one drop BID and Propine (dipivefrin) 0.1%; one drop BID are both nonselective agents that increase aqueous outflow through the TM and increase uveoscleral outflow.
  - Brimonidine tartrate 0.1%: One drop TID (α2-adrenergic agonist) decreases aqueous formation and increases uveoscleral outflow.
    - Brimonidine should not be used in infants and young children because of the risk of CNS depression, apnea, bradycardia, and hypotension.
    - Monoamine oxidase inhibitors and tricyclic antidepressants may interfere with the metabolism of brimonidine and result in toxicity.

- Carbonic anhydrase inhibitors (oral, topical): decrease aqueous formation
  - Acetazolamide: 250 mg PO 1 to 4 times per day
  - Dorzolamide 2%: one drop TID
  - Brinzolamide 1%: one drop TID
  - Carbonic anhydrase inhibitors
    - Do not use with sulfa drug allergies.
    - Do not use with cirrhosis because of the risk of hepatic encephalopathy.

- Parasympathomimetics (miotic), including cholinergic (direct-acting) and anticholinesterase agents (indirect-acting parasympathomimetic): increase aqueous outflow
  - Pilocarpine 1–4%: one drop in affected eye BID to QID (cholinergic)
  - Parasympathomimetics (miotic): cause pupillary constriction and may cause decreased vision in patients with a cataract; may cause eye pain or myopia due to increased accommodation. All miotics break down the blood–aqueous barrier and may induce chronic iridocyclitis.
    - Parasympathomimetics (miotic): Indirect-acting parasympathomimetic agents increase risk of ocular and systemic side effects and are used rarely.
    - Parasympathomimetics (miotic): Indirect-acting parasympathomimetic agents, anticholinesterase eye drops, can reduce serum pseudocholinesterase levels. If succinylcholine is used for induction of general anesthesia, prolonged apnea may result.

- Hyperosmotic agents: increase blood osmolality, drawing water from the vitreous cavity
  - Mannitol 20% solution: administered IV at 2 g/kg of body weight
- Glycerin 50% solution: administered PO; dosage is usually 4 to 7 oz.
  - Glycerin can produce hyperglycemia or ketoacidosis in diabetic patients.
  - Can cause congestive heart failure
  - Do not use in patients with anuria.
  - Hyperosmotic agents: caution in diabetics; dehydrated patients; and those with cardiac, renal, and hepatic disease

- Latanoprostene bunod, 0.024% solution, is being investigated. This is a combination drug with one of the actions being the release of nitric oxide (5) [B].

- Contact lens wearers: Many glaucoma drops contain benzalkonium chloride; remove contact lens prior to administration and wait 15 minutes before reinsertion.
- When ≥3 medications are required, compliance is difficult, and surgery may be needed.

SURGERY/OTHER PROCEDURES

- ALT
  - Can be applied up to 180 degrees of the TM
  - Improves aqueous outflow
  - The Glaucoma Laser Trial Research Group showed in newly diagnosed, previously untreated patients with POAG that ALT was as effective as topical glaucoma medication within the first 2 years of follow-up.
  - Usually reserved for patients needing better IOP control while taking topical glaucoma drops

- Selective laser trabeculoplasty (SLT)
  - 532-nm Nd:YAG laser
  - Appears to be as effective as ALT in lowering IOP
  - May be repeated if necessary

- Trabeculectomy (glaucoma filtering surgery)
  - Usually reserved for patients needing better IOP control after maximal medical therapy and who may have previously undergone an ALT
  - Mitomycin C can be applied at the time of surgery to increase the chances of a surgical success.
  - Subconjunctival bevacizumab may be a beneficial adjunctive therapy for reducing late surgical failure after trabeculectomy.

- Shunt (tube) surgery
  - For example, Molteno and Ahmed devices
  - Generally reserved for difficult glaucoma cases in which conventional filtering surgery has failed or is likely to fail
● Tube Versus Trabeculectomy (TVT) Study
  – After 5 years of follow-up, both procedures were associated with similar IOP reduction and the number of glaucoma medications needed.
● Ciliary body ablation: indicated to lower IOP in patients with poor visual potential or those who are poor candidates for filtering or shunt procedures.
● Minimally invasive glaucoma surgery (MIGS) is frequently combined with cataract surgery; currently targeted at patients with mild-to-moderate glaucoma.
  – Schlemm canal stents
    o iStent, Hydrus
  – Suprachoroidal stents
    o CyPass, iStent supra
    ■ CyPass Micro-Stent demonstrated sustained reduction in IOP and glaucoma medication after a 2-year follow-up for mild to moderate POAG (6)[B].
  – Subconjunctival stents
    o Xen, InnFocus
  – The Trabectome system performs a trabeculotomy via an internal approach, removing both a strip of TM and the inner wall of the Schlemm canal.
● Cataract extraction can decrease IOP in patients with ocular hypertension.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
● Monitor vision and IOP every 3 to 6 months.
● Visual field testing every 6 to 18 months
● Optic nerve evaluation every 3 to 18 months, depending on POAG control
● A worsening of the mean deviation by 2 dB on the Humphrey field analyzer and confirmed by a single test after 6 months had a 72% probability of progression.
● The IOP response to ocular hypotensive agents tends to be reduced in persons with thicker corneas.

PATIENT EDUCATION
POAG is a silent robber of vision, and patients may not appreciate the significance of their disease until much of their visual field is lost.
**PROGNOSIS**
- With standard glaucoma therapy, the rate of visual field loss in POAG is slow.
- Patients still may lose vision and develop blindness, even when treated appropriately.
- The rate of legal blindness from POAG over a follow-up of 22 years was 19%.
- The rate of progression of visual field loss increases with older age.

**COMPLICATIONS**

**Blindness**

**REFERENCES**

**CODES**
ICD10
- H40.11X0 Primary open-angle glaucoma, stage unspecified
- H40.11X1 Primary open-angle glaucoma, mild stage
- H40.11X2 Primary open-angle glaucoma, moderate stage

CLINICAL PEARLS
- Pain is not a frequent symptom of POAG.
- Painless, slowly progressive visual loss; patients generally are unaware of the visual loss until late in the disease. Central visual acuity remains unaffected until late in the disease.
- Patients still may lose vision and develop blindness, even when treated appropriately.
- Topical or system steroids can cause the IOP to increase.
BASICS

DESCRIPTION

- Acute glomerulonephritis (GN) is an inflammatory process involving the glomerulus of the kidney, resulting in a clinical syndrome consisting of hematuria, proteinuria, and renal insufficiency, often in association with hypertension and edema.
- Acute GN may be caused by primary glomerular disease or secondary to systemic disease.
  - Infection-related GN (also postinfectious GN)
  - IgA nephropathy/Henoch-Schönlein purpura (HSP)
  - Antiglomerular basement membrane disease (anti-GBM disease)
  - Antineutrophil cytoplasmic antibody (ANCA)-associated GN
  - Membranoproliferative GN (MPGN)
  - Lupus nephritis
  - Cryoglobulin-associated GN
- Clinical severity ranges from asymptomatic microscopic or gross hematuria to a rapid loss of kidney function over days to weeks, termed rapidly progressive GN (RPGN).
  - In patients with RPGN, kidney biopsy often demonstrates crescentic GN, which usually warrants urgent and aggressive treatment.

ALERT

Urgent investigation and treatment are required to avoid irreversible loss of kidney function.

EPIDEMIOLOGY

- Infection-related GN
  - Most commonly follows group A β-hemolytic Streptococcus infection (poststreptococcal) but can occur as a result of other bacterial infections, such as infective endocarditis, or less commonly with viral or parasitic infections
  - Accounts for 80% of acute GN in children
IgA nephropathy
- Most common primary GN in the world
- Most common in the 2nd and 3rd decades but can occur at any age
- Male > female (2:1)
- Incidence differs geographically: Asia > United States
- HSP, the form with extrarenal manifestations, typically occurs in children <10 years old.

Anti-GBM disease
- Can cause Goodpasture disease, a notable cause of the pulmonary–renal syndrome
- Peak distribution in 3rd and 6th decades

ANCA-associated GN
- Often has a relapsing and remitting course
- Four disease presentations:
  - Granulomatosis with polyangiitis (GPA), formerly Wegener granulomatosis
  - Microscopic polyangiitis (MPA)
  - Isolated pauci-immune GN—when isolated to kidneys
  - Eosinophilic GPA, formerly Churg-Strauss disease—GN relatively common but renal involvement rarely severe
- Older patients are more commonly affected, although this GN can affect any age group.

MPGN
- May be primary or secondary, as in viral illness (hepatitis B or hepatitis C), rheumatologic disease (lupus, Sjögren syndrome, systemic sclerosis), or dysproteinemia such as monoclonal gammopathy
- Immunofluorescence aids in determining mechanism of injury (mediated by immune complex formation, monoclonal immunoglobulins, or complement).

Lupus nephritis
- 30–70% of systemic lupus patients will have renal involvement.
- Several histologic variants but diffuse proliferative GN are the most severe and require urgent treatment.

Cryoglobulin-associated vasculitis
- 80% of cases with hepatitis C virus infection
- May also be associated with autoimmune disease or dysproteinemia

ETIOLOGY AND PATHOPHYSIOLOGY
- In general, systemic and/or local immune activation causes glomerular injury.
• Immune-complex mediated: from antigen–antibody formation and deposition in the kidneys
  – Postinfectious GN: host immune reaction to nephritogenic streptococci strains as a trigger
  – IgA nephropathy: from abnormal glycosylation of IgA, related to genetic and environmental factors
  – MPGN: typically secondary to systemic disease but otherwise idiopathic
  – Lupus nephritis: autoimmune disease
  – Cryoglobulin-associated GN: inflammation from complexes known as cryoglobulins, named for their property of precipitating as lower temperatures

• Direct antibody-mediated injury:
  – Anti-GBM disease: caused by autoantibodies that target type IV collagen of basement membranes

• Pauci-immune GN
  – ANCA-associated GN: autoantibodies against neutrophil granules typically involved in pathogenesis

• Alternative complement pathway dysregulation:
  – C3 glomerulopathy: subtype of MPGN with predominant C3 without immunoglobulin staining on immunofluorescence; includes dense deposit disease (DDD) and C3GN

**Genetics**

Genetic factors are likely to play a role in susceptibility to many of the acute GNs, although these have not been sufficiently defined to be clinically useful in most circumstances.

**RISK FACTORS**

• Epidemics of nephritogenic strains of streptococci are triggers for postinfectious GN.
• Persons of East Asian ancestry are at increased risk for IgA nephropathy, and some genetic factors have been identified.
• Anti-GBM disease has been associated with prior pulmonary injury and inhalation exposures, such as hydrocarbon solvents.
• ANCA-associated GN may be drug-induced (e.g., hydralazine, levamisole-contaminated cocaine) and is also associated with environmental exposures such as silica.
• Infection with hepatitis B or C is known to be associated with MPGN.
• Infection with hepatitis C is a risk factor for developing cryoglobulinemic GN.
Mutations in alternate complement pathway genes are associated with complement-mediated MPGN.

**GENERAL PREVENTION**
Early detection is paramount.

**DIAGNOSIS**

**HISTORY**
- Patients may report cola- or tea-colored urine and decreased urine volume.
- Edema occurs in many patients, typically in face and lower extremities.
- Shortness of breath may occur with significant fluid overload.
- Generalized malaise
- Timing
  - Poststreptoccal GN typically occurs 1 to 3 weeks after pharyngitis or 2 to 6 weeks after skin infection.
- IgA nephropathy may present within several days after an acute infection.
- Patients may also present with complaints more specific to the associated disease:
  - Joint pain or rash in lupus nephritis
  - Hemoptysis in pulmonary–renal syndromes (see “Physical Exam”)
  - Sinusitis, pulmonary infiltrates, arthralgias in ANCA-associated GN
  - Abdominal or joint pain and purpura in IgA–HSP
  - Purpura and skin vasculitis in cryoglobulinemia-associated GN

**PHYSICAL EXAM**
- A complete physical exam may discover clues to systemic disease as a potential cause.
- Sinus disease: often with ANCA-associated GN/GPA
- Pharyngitis or impetigo: postinfectious GN or IgA nephropathy
- Pulmonary hemorrhage (pulmonary–renal syndrome): anti-GBM disease/Goodpasture, ANCA-associated GN, or lupus nephritis
- Hepatomegaly or liver tenderness could point to cryoglobulinemia-associated GN or IgA nephropathy.
- Purpura may point to ANCA-associated GN or HSP/IgA nephropathy.

**DIFFERENTIAL DIAGNOSIS**
Nonglomerular hematuria: trauma, prostate diseases, urologic cancer, cystitis, nephrolithiasis, renal cysts, thrombotic microangiopathy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Urinalysis with examination of sediment
  - Dysmorphic RBCs or RBC casts on urine microscopy indicate glomerular hematuria and strongly suggest the diagnosis of an acute GN.
  - Pyuria and white blood cell casts may also be present.
- Proteinuria: 24-hour collection or random urine protein/creatinine ratio
  - Can be mild to severe proteinuria, occasionally nephrotic range
- Electrolytes, BUN, creatinine, CBC
- Serologies, depending on clinical presentation, may help clarify etiology:
  - Antistreptolysin O titer, streptozyme: often positive in poststreptococcal GN
  - Complement levels (C3, C4):
    - C3 low in infection-related GN
    - Both C3 and C4 can be low in lupus nephritis and MPGN.
    - C4 typically low in cryoglobulinemia
  - Antinuclear antibody (ANA) to rule out lupus nephritis
  - ANCA antibody screen: MPO and PR3 antibodies
  - Anti-GBM antibody
  - Hepatitis B surface antigen and antibody
  - Hepatitis C antibody
  - HIV testing
- A chest x-ray may be useful in the setting of hemoptysis or a suspected infiltrate on exam.

**Test Interpretation**

- Renal biopsy
  - If clinical picture is consistent with postinfectious GN in a child, a biopsy may not be required.
  - If there is clinical suspicion for other causes of acute GN, renal biopsy should be done.
  - Light microscopy
    - Diffuse hypercellularity suggests a proliferative disease such as IgA nephropathy, lupus nephritis, or postinfectious GN.
    - Presence of glomerular crescents correlates with RPGN and disease
severity.

- Immunofluorescence
  - Pattern of IgG, IgA, IgM, C3, and C4 staining may aid in characterizing the GN.
  - Isolated mesangial IgA staining is pathognomonic for IgA nephropathy.
  - Crescentic GN in absence of immune complex staining suggests ANCA-associated GN.
  - Lupus nephritis typically positive for all immunoglobulins and complements (“full house”)

- Electron microscopy: The location of immunoglobulin deposits is useful in pointing to a particular diagnosis.

**TREATMENT**

Supportive in postinfectious GN

**MEDICATION**

**First Line**
- Hypertension
  - Diuretics are useful for management of salt retention and edema.
  - Calcium channel blockers
  - Avoid angiotensin-converting enzyme inhibitors (ACE-I) or angiotensin receptor blockers (ARBs) if acute renal dysfunction is present.
- Peripheral edema: Loop diuretics are often required due to the degree of edema.
- Pulmonary edema: oxygen and diuretics

**Second Line**
- Each of the glomerular diseases often requires a specific treatment plan based on renal biopsy results; therefore, a nephrologist is often guiding care.
- Empiric pulse methylprednisolone prior to kidney biopsy may be indicated with RPGN (1)[C].
- Crescents on renal biopsy may be an indication for steroids in postinfectious GN and, in other cases, are often an indication for additional potent immunosuppressive medications (2)[C].
- Commonly used immunosuppressive medications include:
  - Cyclophosphamide
- Mycophenolate mofetil
- Calcineurin inhibitors (cyclosporine, tacrolimus)
- Rituximab

Choice of immunosuppressive agent depends on patient characteristics and the disease process.

- Steroids plus either cyclophosphamide, rituximab, or mycophenolate may be used to treat ANCA-associated renal disease and proliferative forms of lupus nephritis (2–4)[A].
- IgA nephropathy: ACE-Is or ARBs recommended for patients with proteinuria (1,2)[C]. Additional immunosuppression may be considered, but strong evidence for therapies are still lacking (5)[A].
- Plasmapheresis may also be considered in some cases for RPGN or anti-GBM disease or ANCA-associated renal disease with diffuse pulmonary hemorrhage (2)[C],(3,6)[A].
- Dialysis may be needed for uremia, hyperkalemia refractory to medical management, intractable acidosis, and diuretic-resistant pulmonary edema.

ISSUES FOR REFERRAL

- Consultation with a nephrologist is usually required to assist with renal biopsy to confirm diagnosis and assist with management.
- Consultation with a rheumatologist may also be helpful in cases with systemic manifestations.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Consider admission for patients with no urine output, rapidly deteriorating renal function, significant hypertension, and suspicion of pulmonary hemorrhage or fluid overload that is compromising heart or respiratory function.
- Hemodynamically stable patients without complications may be managed as outpatients.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Depends on type of GN
- Regular BP checks and urinalysis to detect recurrence, assessment of renal function to detect acute or follow chronic renal disease as a result of the primary event, and regular clinical assessment to detect suspicious symptoms that may herald a recurrence (i.e., rash, joint complaint, hemoptysis)
- Periodic reassessment of serology tests to follow asymptomatic individuals

Diet
- No-added-salt diet and fluid restriction until edema and hypertension clear
- Avoid high-potassium foods if significant renal dysfunction is present.

Patient Education
National Kidney Foundation: http://www.kidney.org/atoz/content/glomerul

Prognosis
- In general, the prognosis depends on the cause of the GN.
- The GN may be self-limited (as often is the case in postinfectious GN) or part of a chronic disease that makes the possibility of recurrence of acute disease likely, with the potential for progressive loss of renal function over time.
- Some forms of acute GN (including ANCA-associated and severe lupus) require long-term immunosuppression to prevent recurrence.

Complications
- Hypertensive retinopathy and encephalopathy
- Microscopic hematuria may persist for years.
- Chronic kidney disease
- Nephrotic syndrome (~10%)

**ADDITIONAL READING**

**SEE ALSO**

- Glomerulonephritis, Postinfectious; Henoch-Schönlein Purpura; Hyperkalemia; Hypertensive Emergencies; IgA Nephropathy; Lupus Nephritis; Nephrotic Syndrome; Vasculitis
- Algorithm: Acute Kidney Injury (Acute Renal Failure); Hematuria

**CODES**

**ICD10**

- N00.9 Acute nephritic syndrome with unsp morphologic changes
- N00.2 Acute nephritic syndrome w diffuse membranous glomrlneph
- N00.8 Acute nephritic syndrome with other morphologic changes

**CLINICAL PEARLS**

- Dysmorphic RBCs and RBC casts are a key component of the urinalysis in
GN.

- Postinfectious GN in children is typically a self-limited disease.
- Searching for other organ involvement is useful in establishing a definitive diagnosis.
- With the discovery of a GN, monitor the initial renal function labs frequently to identify an RPGN.
- Clinical course and treatment strategies depend on the underlying disease process.
GLOMERULONEPHRITIS, POSTINFECTIOUS

Frances M. Rusnack, DO • Theodore B. Flaum, DO, FACOFP

BASICS

DESCRIPTION

Postinfectious glomerulonephritis (PIGN) is an immune complex disease associated with nonrenal infection by certain strains of bacteria, most commonly Streptococcus and Staphylococcus. The most common form of PIGN, poststreptococcal glomerulonephritis (PSGN), is preceded by Streptococcus and predominantly affects children. The clinical presentation varies from asymptomatic to the acute nephritic syndrome, characterized by gross hematuria, proteinuria, edema, hypertension (HTN), and acute kidney injury.

EPIDEMIOLOGY

A global decline in incidence, especially in developed countries is attributed to better hygiene and a decreased incidence of streptococcal skin infections. Of cases, 97% occur in developing countries. PSGN is primarily a pediatric disease, but a recent increase has been seen in nonstreptococcal GN in adults.

Incidence

- Pediatrics: 24.3 cases/100,000 persons per year in developing countries; 6 cases/100,000 persons per year in developed countries
- Adults: 2 cases/100,000 persons per year in developing countries; 0.3 cases/100,000 persons per year in developed countries
- Worldwide: 34% of cases are now seen in adults with a global burden of 68,000 cases per year.
- Male > female (2:1) (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Glomerular immune complex disease induced by specific nephritogenic strains of bacteria:
  - Group A β-hemolytic Streptococcus (GAS)
– *Staphylococcus* (predominantly *Staphylococcus aureus*; more commonly methicillin-resistant *S. aureus* [MRSA], occasionally coagulase-negative *Staphylococcus*)
– Gram-negative bacteria including *Escherichia coli*, *Yersinia*, *Pseudomonas*, and *Haemophilus* (1)

- Proposed mechanisms for the glomerular injury (2):
  - Deposition of circulating immune complexes with streptococcal or staphylococcal antigens—these complexes can be detected in patients with streptococcal- or staphylococcal-related GN but do not correlate to disease activity (3).
  - Note: IgG is the most frequent immunoglobulin in PSGN (1).
  - In situ immune complex formation from deposition of antigens within the glomerular basement membrane (GBM) and subsequent antibody binding
  - In situ glomerular immune complex formation promoted by antibodies to streptococcal or staphylococcal antigens
  - Alteration of normal renal antigen leading to molecular mimicry that elicits an autoimmune response

- Glomerular immune complex causing complement activation and inflammation:
  - Nephritis-associated plasmin receptor (NAPlr): activates plasmin, contributes to activation of the alternative complement pathway
  - Streptococcal pyrogenic exotoxin B (SPE B): binds plasmin and acts as a protease; promotes the release of inflammatory mediators

- Activation of the alternative complement pathway causes initial glomerular injury as evidenced by C3 deposition and decreased levels of serum C3. The lectin pathway of complement activation has also been recently implicated in glomerular injury (4).

**RISK FACTORS**
- Children 5 to 12 years of age
- Older patients (>65 years of age) (1):
  - Patients with immunocompromising comorbid conditions
  - Diabetes
  - Alcohol abuse

**GENERAL PREVENTION**
- Early antibiotic treatment for streptococcal and staphylococcal infections, when indicated, although efficacy in preventing GN is uncertain
- Improved hygiene
Prophylactic penicillin treatment to be used in closed communities and household contacts of index cases in areas where PIGN is prevalent

COMMONLY ASSOCIATED CONDITIONS
Commonly streptococcal or staphylococcal infection

DIAGNOSIS

HISTORY
- Patients present with acute nephritic syndrome, characterized by sudden onset of hematuria associated with edema and HTN 1 to 2 weeks after an infection.
- A triad of edema, hematuria, and HTN is classic.
- Urine described as “tea-colored” or “cola-colored”
- PIGN in children usually follows GAS skin/throat infection.
- The latent period between GAS infection and PIGN depends on the site of infection: 1 to 3 weeks following GAS pharyngitis and 3 to 6 weeks following GAS skin infection.
- Adult PIGN most commonly follows staphylococcal infections (3 times more common than streptococcal infections) of the upper respiratory tract, skin, heart, lung, bone, or urinary tract. Studies show 7–16% of cases of adult PIGN have no preceding evidence of infection and, in 24–59%, the offending microorganism cannot be identified (5)[A].

PHYSICAL EXAM
- Edema: present in ~2 of 3 adult patients due to sodium and water retention; less common in pediatric patients
- Gross hematuria: present in 25–60% of patients
- HTN: present in 80–90% of patients and varies from mild to severe; secondary to fluid retention. Hypertensive encephalopathy is an uncommon but serious complication.
- Microscopic hematuria: subclinical cases of PIGN
- Respiratory distress: due to pulmonary edema (rare)

DIFFERENTIAL DIAGNOSIS
The diagnosis of PIGN is generally by history once the diagnosis of acute nephritis is made, with documentation of a recent infection and nephritis beginning to resolve 1 to 2 weeks after presentation. However, with progressive
disease >2 weeks, persistent hematuria/HTN >4 to 6 weeks, or no adequate documentation of a GAS or other infection, the differential diagnosis of GN needs to be considered and renal biopsy ordered:

- Membranoproliferative glomerulonephritis (MPGN): The presentation of MPGN may be indistinguishable initially with hematuria, HTN, proteinuria, and hypocomplementemia after an upper respiratory infection. However, patients with MPGN continue to have persistent nephritis and hypocomplementemia beyond 4 to 6 weeks and possibly also have a further elevation in serum creatinine. Patients with PIGN tend to have resolution of their disease and a return of normal C3 and CH50 levels within 2 to 4 weeks.

- Secondary causes of GN: Lupus nephritis and Henoch-Schönlein purpura nephritis have features similar to PIGN. Extrarenal manifestations and laboratory tests for these underlying systemic diseases help differentiate them from PIGN. Hypocomplementemia is not characteristic of Henoch-Schönlein purpura, and the hypocomplementemia that occurs in lupus nephritis is with reductions in both C3 and C4, whereas C4 levels are normal in PIGN.

- IgA nephropathy often presents after an upper respiratory infection. It can be distinguished from PIGN based on a shorter time frame between the upper respiratory illness and hematuria, as well as history of gross hematuria, as PIGN recurrence is rare. IgA nephropathy is a chronic illness and will recur. Patients with IgA nephropathy have normal C3/C4 levels.

- IgA-dominant acute PIGN: a recently recognized form of PIGN occurring in poststaphylococcal GN. This differs from primary IgA nephropathy in that these patients do not have a history of renal disease. The terms IgA-dominant PIGN and poststaphylococcal GN have been debated because such cases are described in association with active staphylococcal infection. Emerging terms include IgA-dominant infection-related GN or staphylococcus-associated GN (1)[A].

- Pauci-immune crescentic GN: In elderly patients with severe renal failure and active urine sediment, this is much more common, so antineutrophil cytoplasmic antibody (ANCA) testing should be done (1)[A].

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

Urinalysis shows hematuria; can be with/without RBC casts and pyuria. Proteinuria is present, but nephrotic range proteinuria is uncommon in children (more likely in adults).
Follow-Up Tests & Special Considerations

- Culture: PSGN usually presents weeks after a GAS infection; only ~25% of patients will have either a positive throat or skin culture.
- Complement: 90% of pediatric patients (slightly fewer adult patients) will have depressed C3 and CH50 levels in the first 2 weeks of the disease, whereas C2 and C4 levels remain normal. C3 and CH50 levels return to normal within 4 to 8 weeks after presentation.
- Creatinine: elevated to the point of renal insufficiency in 25–83% of cases, more commonly in adults (83%) (4)[A]
- Serology: Elevated titers of antibodies support evidence of a recent GAS infection. Streptozyme test measuring antistreptolysin O (ASO), antihyaluronidase (AHase), antistreptokinase (ASKase), anti–nicotinamide-adenine dinucleotidase (anti-NAD), and anti-DNAse B antibodies: positive in >95% of patients with PSGN due to pharyngitis and 80% with skin infections. In pharyngeal infection, ASO, anti-DNAse B, anti-NAD, and AHase titers are elevated. In skin infections, only the anti-DNAse and AHase titers are typically elevated.

Diagnostic Procedures/Other

Renal biopsy is rarely done in children; recommended in most adults to confirm the diagnosis and rule out other glomerulopathies with similar clinical presentations that require immunosuppressive treatment

Test Interpretation

- Light microscopy: diffuse proliferative glomerulonephritis with prominent endocapillary proliferation and numerous neutrophils within the capillary lumen. Deposits may also be found in the mesangium (“starry sky”). Severity of involvement varies and correlates with clinical findings. Crescent formation is uncommon and is associated with a poor prognosis.
- Immunofluorescence microscopy: deposits of C3 and IgG distributed in a diffuse granular pattern
- Electron microscopy: dome-shaped subepithelial electron-dense deposits that are referred to as “humps.” These deposits are immune complexes, and they correspond to the deposits of IgG and C3 found on immunofluorescence. Rate of clearance of these deposits affects recovery time.
- Renal biopsy: usually not performed in most patients to confirm the diagnosis of PIGN as clinical history is highly suggestive and resolution of PIGN typically begins within 1 week of presentation. A biopsy is done when other
glomerular disorders are being considered, such as in the case of persistently low C3 levels beyond 6 weeks for possible diagnosis of MPGN, recurrent episodes of hematuria suggestive of IgA nephropathy, or a progressive increase in serum creatinine not characteristic of PIGN.

**TREATMENT**

**MEDICATION**

- No specific therapy exists for PIGN, and no randomized controlled trials indicate that aggressive immunosuppressive therapy has a beneficial effect in patients with rapidly progressive crescentic disease. Despite this, patients with >30% crescents on renal biopsy are often treated with steroids (4)[A].
- Older patients often require hospitalization to prevent and treat complications of heart failure (HF) from volume overload (1).
- Management is supportive, with focus on treating the clinical manifestations of PIGN. These include HTN and pulmonary edema:
  - General measures include salt and water restriction and loop diuretics.
  - Calcium channel blockers/angiotensin-converting enzyme (ACE) inhibitors may be used in cases of severe HTN (4)[A].
- Patients with evidence of persistent bacterial infection should be given a course of antibiotic therapy.

**SURGERY/OTHER PROCEDURES**

Acute dialysis is required in approximately 50% of elderly patients (1).

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Admission and inpatient observation may be necessary, specifically for elderly patients who are at greater risk for complications such as new-onset or exacerbation of preexisting HF (1).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*
Repeat urinalysis to check for clearance of hematuria and/or proteinuria.
Consider other diagnosis if no improvement within 2 weeks.
Recurrence is rare.

DIET
Renal diet if requiring instances of dialysis

PROGNOSIS
- Most children with PIGN have an excellent outcome, with >90% of cases achieving full recovery of renal function.
- Elderly patients, especially adults, develop HTN, recurrent proteinuria, and renal insufficiency long after the initial illness. Adults with multiple comorbid factors have the worst prognosis and highest incidence of chronic renal injury following PIGN (1).
- Complete remission in adult PIGN is only 26–56%. This has declined since the 1990s, suggesting prognosis is worsening (5).
- The presence of diabetes, higher creatinine levels, and more severe glomerular disease (e.g., crescents) on biopsy are all risk factors for developing end-stage renal disease (1).

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**

- N05.9 Unsp nephritic syndrome with unspecified morphologic changes
- N00.9 Acute nephritic syndrome with unsp morphologic changes

**CLINICAL PEARLS**

- PIGN is an immune complex disease occurring after infection with certain strains of bacteria, most commonly group A *Streptococcus pyogenes*.
- The clinical presentation varies from asymptomatic to the acute nephritic syndrome, characterized by gross hematuria, proteinuria, edema, HTN, and acute kidney injury.
- Treatment is primarily supportive and includes treating HTN and edema, along with antibiotics for any ongoing bacterial infection.
- Persistent nephritis and low C3 levels for >2 weeks should prompt evaluation for other causes of GN, such as MPGN or systemic lupus erythematosus nephritis.
GLUCOSE INTOLERANCE

Daniel G. Hurtt, MD  •  Amy M. Davis, MD

BASICS
DESCRIPTION

- Glucose intolerance is a chronic condition defined as blood glucose higher than considered normal yet does not meet criteria levels for diabetes.
- Individuals with impaired fasting glucose (IFG) and/or impaired glucose intolerance (IGT) have been referred to as having prediabetes:
  - IFG: 100 to 125 mg/dL
  - IGT: 140 to 199 mg/dL 2 hours after ingestion of 75 g oral glucose load
  - Hemoglobin A1c 5.7–6.4% (1)

EPIDEMIOLOGY

- As of 2010, it is estimated that one of every three U.S. adults ≥20 years of age have prediabetes (2).
- An estimated 86 million people in the United States are living with prediabetes.
- Only 11% of people with prediabetes are aware of their condition (3).
- Prediabetes has a 37% prevalence among adults >20 years old and 51% of adults ≥65 years in the United States (4).

Incidence

- Systematic review indicates a 5-year cumulative incidence of developing diabetes of 9–25% for people with an A1c of 5.5–6.0% and 25–50% with an A1c of 6.0–6.5% (1).
- Highest incidence in American Indians/Alaska Natives, non-Hispanic blacks, and Hispanics (2)

ETIOLOGY AND PATHOPHYSIOLOGY

Progressive loss of insulin secretion on the background of insulin resistance (1)

RISK FACTORS

- Body mass index (BMI) ≥25: overweight
- Obesity and metabolic syndrome
- History of gestational diabetes mellitus (GDM)
- Sedentary lifestyle
- Medications (see “Differential Diagnosis”)

**GENERAL PREVENTION**
- Lifestyle modification with weight reduction and increased physical activity
- A decrease in excess body fat provides the greatest risk reduction.

**Pregnancy Considerations**
- Screening for diabetes in pregnancy is based on risk factor analysis:
  - High risk: first prenatal visit
  - Average risk: 24 to 28 weeks’ gestation
- Women with GDM should be screened for diabetes 6 to 12 weeks’ postpartum with 75-g OGTT, then every 1 to 3 years via any method (5).

**COMMONLY ASSOCIATED CONDITIONS**
- Obesity (abdominal and visceral obesity)
- Dyslipidemia with high triglycerides (TG)
- Metabolic syndrome
- PCOS
- GDM
- Low HDL
- HTN
- Congenital diseases (Down, Turner, Klinefelter, and Wolfram syndromes)

**DIAGNOSIS**

Who to screen

- BMI ≥25 or ≥23 for Asian Americans (1)[B]
- Age ≥45 years (1)[B]
- First-degree relative with diabetes
- High TG >250 mg/dL
- Low HDL <35 mg/dL
- HTN: BP >140/90 mm Hg or on treatment
- Hx of GDM
- Physical inactivity
- Hx of cardiovascular disease
- Ethnic group at increased risk (non-Hispanic black, Native American, Hispanics, Asian American, Pacific Islander)
- HbA1c ≥5.7%, IGT, or IFG on previous testing
- PCOS
- Conditions associated with insulin resistance such as severe obesity or acanthosis nigricans

**HISTORY**
- No clear symptoms
- Polyuria
- Polydipsia
- Weight loss
- Blurred vision
- Polyphagia

**PHYSICAL EXAM**
- General physical exam
- BMI assessment

**DIFFERENTIAL DIAGNOSIS**
- Type A insulin resistance
- Leprechaunism
- Rabson-Mendenhall syndrome
- Lipoatrophic diabetes
- Pancreatitis
- Cystic fibrosis
- Hemochromatosis
- Acromegaly
- Cushing syndrome
- Glucagonoma
- Pheochromocytoma
- Hyperthyroidism
- Somatostatinoma
- Aldosteronoma
- Drug-induced hyperglycemia
  - Thiazide diuretics (high doses)
  - β-Blockers
  - Corticosteroids (including inhaled corticosteroids)
– Thyroid hormone
– α-Interferon
– Pentamidine
– Protease inhibitors
– Atypical antipsychotics
– Selective serotonin reuptake inhibitors

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Fasting glucose, 2-hour OGTT, or HbA1c is equally appropriate (1)[B].
- Repeat screen at 3-year intervals with normal results, sooner depending on risk status, and yearly in patients with prediabetes (1)[C].

Follow-Up Tests & Special Considerations

- Fasting lipid profile
- Creatinine and GFR
- Urinalysis
- Microalbumin-to-creatinine ratio
- Thyroid-stimulating hormone with free T4
- Periodic measurement of vitamin B12 levels for patients on long-term metformin therapy especially those with anemia or peripheral neuropathy

TREATMENT

- Therapeutic lifestyle modification to include physical activity focused on weight loss and medical nutrition therapy (preferably via a registered dietitian)
- Lifestyle intervention reduced 3-year diabetes incidence by 58% compared to 31% with metformin alone (6).
- Mediterranean diet and diets high in fiber-rich foods such as vegetables, fruits, whole grains, seeds, and nuts, plus white meat sources are protective against type 2 diabetes (7).
- Patients with prediabetes should be referred to an intensive diet and physical activity behavioral counseling program adhering to the tenets of the Diabetes Prevention Program targeting a loss of 7% of body weight and should increase their moderate-intensity physical activity (such as brisk walking to at least 150 min/week) (7)[A].
Resistance training and endurance exercise both reduce diabetes risk.

Interrupt prolonged sitting every 30 minutes with short bouts of physical activity (7)[B].

Follow-up counseling (7)[B]

Diabetes prevention programs are cost-effective and should be covered by third-party payers (7)[B].

Screening and treating for modifiable risk factors for cardiovascular disease is suggested (7)[B].

Diabetes self-management education and support systems are appropriate venues for people with prediabetes to receive education and support to develop and maintain behaviors that can prevent or delay the onset of diabetes (7)[B].

Technology-assisted tools including internet-based social networks, distance learning, DVD-based content, and mobile applications can be useful elements of effective lifestyle modification to prevent diabetes (7)[B].

MEDICATION
Metformin therapy for prevention of type 2 diabetes should be considered in those with prediabetes, especially in those with BMI >35, those aged <60 years, and women with prior GDM and/or rising A1c despite lifestyle intervention (7) [A].

First Line
Metformin (drug of choice): started at 500 mg BID or 500 mg XR. Observational data suggest it can be used safely down to GFR of 30 to 45 but may require dose adjustments.

Second Line
Acarbose: started at 50 mg PO once daily and titrated to 100 mg PO TID; GI upset is common.

ISSUES FOR REFERRAL
- Nutritionist
- Diabetes educator/registered dietitian upon diagnosis
- Exercise physiologist
- Lifestyle coaching

ADDITIONAL THERAPIES
Alternative/botanical therapy:
- Although studies lack large sample size and ideal design, there is some evidence that fenugreek, bitter melon, and cinnamon can reduce hyperglycemia and improve insulin sensitivity (8).

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- At least annual monitoring for development of diabetes with HbA1c, 2-hour OGTT, or fasting glucose
- BP should be routinely measured.
- Annual testing for lipid abnormalities and microalbuminuria (for detection and therapy modification of incipient diabetic nephropathy)

DIET
- Monitor carbohydrate intake.
- Consider Mediterranean diet.
- Limit high glycemic and sucrose-containing foods.
- Diets high in fiber, vegetables, nuts, seeds, and whole grains

PROGNOSIS
- Individuals with IFG and/or IGT have high risk for the future development of diabetes.
- Prediabetes increases the risk of developing type 2 diabetes, heart disease, and stroke.
- 20–70% of individuals with prediabetes who do not lose weight, change their dietary habits, and/or engage in moderate physical activity will progress to type 2 diabetes within 3 to 6 years (9).

COMPLICATIONS
- Cardiovascular disease
- Peripheral artery disease
- Stroke: 2 to 4 times higher risk
- Ketoacidosis
- Sexual dysfunction
• Gastroparesis
• Nephropathy and potential for renal failure
• Retinopathy and potential for loss of vision
• Peripheral and autonomic neuropathy

REFERENCES

ADDITIONAL READING

CODES

ICD10
- E74.39 Other disorders of intestinal carbohydrate absorption
- R73.09 Other abnormal glucose
- R73.01 Impaired fasting glucose

CLINICAL PEARLS
- Lifestyle optimization is essential for all patients with prediabetes.
- Research shows that you can lower your risk for type 2 diabetes by 58% by losing 7% of your body weight (or 15 lb if you weigh 200 lb).
- Recommend exercising moderately (such as brisk walking) 30 min/day, 5 days a week.
- Consider concurrent cardiovascular risks and further workup as indicated clinically.
- Patient education and lifestyle reinforcement should be emphasized in all clinical encounters.
GONOCOCCAL INFECTIONS
Paul Lyons, MD

BASICS

DESCRIPTION
A sexually or vertically transmitted bacterial infection caused by Neisseria gonorrhoeae:

- *N. gonorrhoeae* is a fastidious gram-negative intracellular diplococcus (1)[A].
- Present as conjunctival, pharyngeal, urogenital, or anorectal infections. Urogenital infections are the most common (1)[A].
- Hematogenous dissemination leads to fever, cutaneous lesions, arthralgias, purulent or sterile arthritis, tenosynovitis, endocarditis, or (rarely) meningitis (1)[A].

- Asymptomatic carrier states occur in both sexes.
- In newborns, gonococcal ophthalmia neonatorum, a purulent conjunctivitis, may occur after vaginal delivery by an infected mother, potentially leading to blindness if not treated promptly (1,2)[A].

- System(s) affected: cardiovascular, musculoskeletal, nervous, reproductive, skin/exocrine
- Synonym(s): gonococcal infection (GC); clap

EPIDEMIOLOGY

- Predominant age: 15 to 24 years (1,2)[A]
- Predominant sex: women 105/100,000; men 92/100,000 (2)[A]

Incidence
CDC 2016: 468,514 reported cases

Prevalence
Incidence and prevalence are roughly equal. The true prevalence is higher due to asymptomatic cases (2)[A]:

- Rates peaked in mid-1970s and fell 74% over the next 20 years with national control program. Rates have been slowly increasing since 2012 (2)[A].
- Rates in men now higher than women (2)[A]
ETIOLOGY AND PATHOPHYSIOLOGY

Infection requires four steps: (i) mucosal attachment. Bacterial proteins bind to receptors on host cells, (ii) local penetration/invasion, (iii) local proliferation, (iv) inflammatory response or dissemination. *N. gonorrhoeae* spreads most commonly through sexual relations.

**Genetics**

Deficiency of late components of complement cascade (C7–C9) makes individuals prone to develop dissemination of local gonococcal infections.

**RISK FACTORS**

- History of previous gonorrhea infection or other STIs
- Sexual exposure to an infected individual without use of barrier protection (condom)
- New/multiple sexual partners
- Inconsistent condom use
- Commercial sex work or drug use
- Infants: infected mother
- Children: sexual abuse by infected individual
- Autoinoculation (finger to eye)

**GENERAL PREVENTION**

- Condoms offer partial protection and must be used appropriately during oral, anal, and vaginal sex.
- Treat sexual contacts; consider expedited partner therapy (EPT) (2)[A].

**COMMONLY ASSOCIATED CONDITIONS**

Other STIs: *Chlamydia*, syphilis, HIV, hepatitis B, herpes (2,3)[A]

**DIAGNOSIS**

**HISTORY**

- Sexual history
  - Number of partners; age of onset of sexual activity; STI history
  - New/recent change in sexual partners
  - Contact with commercial sex workers
  - Condom use
– Menses and possibility of pregnancy

- 10% of men and 20–40% of women are asymptomatic (2)[A].
- If symptomatic, explore the onset, context, duration, timing, severity, and associated symptoms:
  - Symptoms (when present) typically appear within 1 to 14 days after exposure (1)[A].
- Ocular symptoms: discharge, itch, redness (1)[A]
- Pharyngeal symptoms: asymptomatic infection (98%), sore throat (1)[A]
- GI symptoms: acute diarrhea (1)[A]
- Urinary symptoms: frequency, urgency, dysuria (1)[A]
- Urethral symptoms: discharge (1,2)[A]
  - Males: scant to copious purulent urethral discharge (82%), dysuria (53%), testicular pain (1%), asymptomatic (10%), proctitis
  - Females: asymptomatic cervical infection (20%), endocervical discharge (96%), vaginal discharge, Bartholin gland swelling, dysmenorrhea, menometrorrhagia, abdominal pain/tenderness, dyspareunia, cervical motion tenderness, rebound, infertility, chronic pelvic pain
- Either sex, with receptive anal intercourse: rectal discharge, tenesmus, rectal burning or can be asymptomatic
- Disseminated syndromes (1,2)[A]
  - Fever, chills, malaise, skin rash, arthralgia
  - Endocarditis: high fevers
  - Meningitis: meningeal signs, headache, skin lesions, fever, altered mental status

**PHYSICAL EXAM**

- General: fever, chills (1)[A]
- Ocular: purulent discharge, conjunctivitis, chemosis, eyelid edema, corneal ulceration (1)[A]
- Pharynx: exudative pharyngitis (<1%) (1)[A]
- GI: acute diarrhea, hyperactive bowel sounds (1)[A]
- Genitourinary (GU) (1)[A]
  - Males: urethral discharge, testicular tenderness
  - Females: endocervical discharge, Bartholin gland abscess, abdominal pain/tenderness, cervical motion tenderness, rebound tenderness
- Either sex, for receptive anal intercourse: rectal discharge; rectal exam may be normal (1)[A].
- Disseminated syndromes (1)[A]:

mebooksfree.com
– Fever, chills, malaise, tenosynovitis, maculopapular-pustular rash, polyarthralgia—typically large joints (knee, wrist, ankle), purulent arthritis
– Endocarditis: rapid cardiac valve destruction, heart murmurs, high fevers
– Meningitis: meningeal signs, headache, skin lesions, fever, altered mental status

DIFFERENTIAL DIAGNOSIS
*Chlamydia trachomatis*, UTIs, other vaginitis, or urethritis (bacterial, viral, or parasitic)

DIAGNOSTIC TESTS & INTERPRETATION

*Initial Tests (lab, imaging)*

- Nucleic acid amplification (NAAT) is the most sensitive and specific test for *N. gonorrhoeae* (2)[A]. Other options:
  - Genital culture
  - Add pharyngeal culture in adolescents.
  - Gram stain (recommended for urethritis)
  - Urethral smear, sensitivity in symptomatic male: ≥95%; sensitivity of endocervical smear in infected woman: 40–60%; specificity: 100%
- DNA probes and polymerase chain reaction (PCR) sensitivity: 92–99% dependent on population; specificity: >97%; can replace culture
- Blood culture is 50% sensitive in disseminated disease. Joint fluid culture is 50% sensitive in septic arthritis. Screen for additional STIs, especially chlamydia, syphilis, and HIV.
- Imaging is not generally recommended.

*Follow-Up Tests & Special Considerations*

- Test of cure not generally recommended (1,2)[A].
- Consider follow-up testing in cases of recurrent infection, when oral cephalosporin treatment is used, and/or in areas with significant antibiotic resistance (2)[A].
- Pelvic ultrasound or CT scan may demonstrate thick, dilated fallopian tubes or abscess formation.

*Diagnostic Procedures/Other*

Culdocentesis may demonstrate free purulent exudate and provide material for Gram staining and culture. Gram-staining material from unroofed skin lesions may show typical organisms.
**Test Interpretation**
- Gram-negative intracellular diplococci
- Nonpathologic gram-negative diplococci may be found in extragenital locations. For this reason, Gram stain of pharyngeal or rectal swabs is not recommended.

**TREATMENT**

### GENERAL MEASURES
- STI counseling and condom use
- In children and adolescents, suspect sexual abuse.

### MEDICATION
- *N. gonorrhoeae* multidrug antimicrobial resistance continues to increase.
  - CDC recommends dual therapy (treat for chlamydia and drug-resistant strains) (2,3)[A].
- Quinolones are not recommended (2,4)[A].
- If treatment fails, check culture and sensitivities and report to CDC through local health authorities (2,3)[A].
- Treat with regimen that is also effective against uncomplicated genital chlamydial infection (2–4)[A].

**First Line**
- Uncomplicated urogenital, anorectal, and pharyngeal gonorrheal infection (2) [A]
  - Ceftriaxone 250 mg IM in a single dose
  - PLUS treatment for chlamydia (azithromycin 1 g PO single dose)
  - Alternative: cefixime 400 mg PO once PLUS azithromycin 1 g PO
- Pharyngitis: ceftriaxone 250 mg IM once PLUS treatment for chlamydia (azithromycin 1 g PO) (1,2)[A]
- Conjunctivitis: ceftriaxone, 1 g IM single dose PLUS azithromycin 1 g PO (1,2)[A]
- Disseminated infection in adults (1,2)[A]
  - Ceftriaxone 1 g IM or IV q24h until 24 to 48 hours after improvement begins, PLUS azithromycin 1 g PO to complete at least 1 week of antibiotic treatment
- Meningitis and endocarditis (1,2)[A]
- Ceftriaxone 1 to 2 g IV q12h 10 to 14 days for meningitis; 4 weeks for endocarditis PLUS azithromycin 1 g PO
- Contraindications: Doxycycline is contraindicated in pregnancy and young children.

**Pediatric Considerations**
- Children >45 kg: same dosing as adults (1,2)[A]
- Children <45 kg: uncomplicated urethral, cervical, rectal, or pharyngeal gonococcal infections (1,2)[A]
  - Ceftriaxone 125 mg IM in single dose
  - Disseminated infections: ceftriaxone 50 mg/kg IV or IM daily (max dose 1 g) in single dose; bacteremia: 7 days; meningitis: 10 to 14 days; endocarditis: 4 weeks
- Ophthalmic neonatorum prophylaxis: single application of erythromycin 0.5% ophthalmic ointment to each eye immediately after delivery (1,2)[A]
- Neonatal conjunctivitis: ceftriaxone 25 to 50 mg/kg IV or IM in a single dose (not to exceed 125 mg) (1,2)[A]
- *Conjunctival exudates should be cultured for definitive diagnosis* (1,2)[A].
- Scalp abscesses (from scalp electrodes) (1,2)[A]
  - Ceftriaxone 25 to 50 mg/kg/day IV or IM in a single daily dose for 7 days. Treat for a duration of 10 to 14 days if meningitis is documented.
- Asymptomatic infants born to mothers with untreated gonorrhea (1,2)[A]
  - Ceftriaxone 25 to 50 mg/kg IV or IM, not to exceed 125 mg in a single dose.

**Pregnancy Considerations**
Pregnant women should be treated with cephalosporin or recommended alternative (1,2,4)[A].
- Azithromycin 2 g orally in single dose for women intolerant to cephalosporin
- Treat concurrently with azithromycin or amoxicillin for presumed *C. trachomatis* coinfection.
- Women with 1st-trimester gonococcal infection should be retested within 3 to 6 months.
- High-risk uninfected pregnant women should be retested during the 3rd trimester.

**Second Line**
- Due to antimicrobial resistance, combination therapy using two agents with different mechanisms of action improves treatment efficacy and decreases
• Resistance to cephalosporins (1,2)[A].
  – Azithromycin as the second antimicrobial is preferred to doxycycline because of convenience and compliance of single-dose therapy as well as higher resistance with tetracyclines (1,2)[A].

• For additional treatment options, see CDC STD treatment guidelines: http://www.cdc.gov/std/tg2015/

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

• Hematogenously disseminated infection
• Pneumonia or eye infection in infants

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

U.S. Preventive Services Task Force (USPSTF) (3)[A]

• Screen all sexually active women 24 years of age and younger and in older women at increased risk for infection: Grade B recommendation
• Insufficient evidence to recommend for or against screening men at increased risk of infection: Grade I recommendation
• Report cases of gonorrhea to public health (3,4)[A].

PATIENT EDUCATION

• Counseling concerning risk reduction, condom use, future fertility, and full STI testing
• Encourage patient to notify partners (from past 60 days); consider EPT.

PROGNOSIS

Complete cure with return to normal function with adequate and timely treatment.

COMPLICATIONS

• Infertility
• Urethral stricture
• Corneal scarring
Destruction of joint articular surfaces
Cardiac valvular damage

**Pediatric Considerations**

Vertical transmission is a significant risk among patients with gonococcal infection at the time of delivery (1,2)[A].

**REFERENCES**

**SEE ALSO**

Chlamydia Infection (Sexually Transmitted); HIV/AIDS; Pelvic Inflammatory Disease; Syphilis

**CODES**

**ICD10**

- A54.9 Gonococcal infection, unspecified
- A54.03 Gonococcal cervicitis, unspecified
- A54.31 Gonococcal conjunctivitis

**CLINICAL PEARLS**
Antibiotic resistance is a significant problem as many new gonorrheal infections are resistant.

Treatment for uncomplicated gonorrhea should include two drugs, one of which is effective against chlamydia.

Screen patients with gonorrhea for chlamydia, syphilis, HIV, and hepatitis.
BASICS

DESCRIPTION

- Gout is an inflammatory arthritis related to a hyperuricemia (serum uric acid [SUA] level >6.8 mg/dL) (1).
- Acute gouty arthritis can affect ≥1 joint; the 1st metatarsophalangeal joint is most commonly involved at presentation (podagra).
- Although hyperuricemia is necessary for the development of gout, it is not the only determining factor.
- Characterized by deposition of monosodium urate (MSU) crystals that accumulate in joints and soft tissues, resulting in acute and chronic arthritis, soft-tissue masses called tophi, urate nephropathy, and uric acid nephrolithiasis.
- After an initial flare, a second flare occurs in ~60% of patients within 1 year and 78% within 2 years of the initial attack (2).
- Management involves treating acute attacks and preventing recurrent disease by long-term reduction of SUA levels through pharmacology and lifestyle adjustments.

EPIDEMIOLOGY

Incidence

Annual incidence of gout (3):
- Uric acid 7.0 to 8.9 mg/dL is 0.5%.
- Uric acid >9 mg/dL is 4.5%.

Prevalence

- Increasing prevalence over the past decades (3)
- Overall prevalence of 3.9% (8.3 million) in the United States in 2008 (3)
  - Men 5.8% (6.1 million)
  - Women 2.0% (2.2 million)
- 2008 prevalence of hyperuricemia in the United States (3):
  - Men 21.2% (SUA >7.0 mg/dL)
Women 21.6% (SUA >5.7 mg/dL)

ETIOLOGY AND PATHOPHYSIOLOGY

- Hyperuricemia results from urate overproduction, underexcretion, or often a combination of the two.
- Gout occurs when MSU, a product of purine metabolism, precipitates out of solution and accumulates in joints and soft tissues.
- Transient changes in urate solubility caused by local temperature decrease, trauma, or acidosis may lead to an acute gouty attack.
- Urate crystals that precipitate trigger an immune response.
- Left untreated, this crystal deposition leads to permanent joint damage and tophus formation.

Genetics

- Phosphoribosyl pyrophosphate (PRPP) deficiency and hypoxanthine-guanine phosphoribosyltransferase (HGPRT) deficiency (Lesch-Nyhan syndrome) are inherited enzyme defects associated with overproduction of uric acid.
- Polymorphisms in the URAT1 and SLC2A9 (GLUT9) renal transporters are hereditary enzyme defects resulting in primary underexcretion of uric acid.

RISK FACTORS

- Age >40 years
- Male gender
- Increased purine uptake (meats and seafood)
- Alcohol intake (especially beer)
- High fructose intake
- Obesity
- Congestive heart failure
- Coronary artery disease
- Dyslipidemia
- Renal disease
- Organ transplant
- Hypertension
- Smoking
- Diabetes mellitus
- Urate-elevating medications:
  - Thiazide diuretics: ethambutol
  - Loop diuretics (less of a risk vs. thiazides)
– Niacin
– Calcineurin inhibitors (cyclosporine and tacrolimus)

GENERAL PREVENTION
- Maintain optimal weight.
- Regular exercise
- Diet modification (purine-rich foods)
- Reduce alcohol consumption (beer and liquor).
- Smoking cessation
- Maintain fluid intake and avoid dehydration.

COMMONLY ASSOCIATED CONDITIONS
- Hypertension
- Dyslipidemia
- Nontraumatic joint disorders
- Heart disease
- Diabetes mellitus
- Metabolic syndrome
- Obesity
- Renal disease

DIAGNOSIS
HISTORY
- Classic presentation of acute gouty arthritis:
  - Intense pain and tenderness in the 1st metatarsophalangeal joint (podagra)
  - Can occur in the midtarsal, ankle, or knee joints
  - Joint may be swollen, warm, and red
  - Often awakes patients from sleep due to an intolerance to contact with clothing or bed sheets
  - There is a rapid onset of intense pain, often beginning in the early morning and progressing rapidly over 12 to 24 hours.
  - In the absence of treatment, flares can last up to 10 days.
- Fever can be present.
- Subcutaneous or intraosseous nodules, referred to as tophi, can be seen.
- Pain with urination secondary to uric acid renal stones
PHYSICAL EXAM
- Examine suspected joint(s) for tenderness, swelling, and range of motion (ROM).
- Assess for presence of firm nodules known as tophi.
- In patients with chronic gout, tophi can frequently be found in the helix of the ear, over the olecranon process, or on the Achilles tendon.
- Patients with untreated chronic gout can have evidence of joint inflammation and deformity.

DIFFERENTIAL DIAGNOSIS
Acute bursitis, tendonitis, septic arthritis, pseudogout (calcium pyrophosphate deposition disease), cellulitis, osteoarthritis

DIAGNOSTIC TESTS & INTERPRETATION
- SUA (may be normal during an acute flare)
- CBC (can see elevation of WBC during gout flare)
- Synovial fluid analysis: urate crystals (negatively birefringent under polarizing microscopy), cell count (WBC usually 2,000 to 5,000 cells/mm³); culture to rule out infection.
- Screen for uric acid overproduction using 24-hour urinary uric acid in those patients with gout onset before the age of 25 years or with a history of urolithiasis (1)[C].
- Radiographs are normal early in disease but can reveal
  - Swelling in acute gout
  - Periarticular erosions with periosteum overgrowth in chronic gout
- Urate kidney stones are radiolucent and thus invisible on radiograph.
- Ultrasound evidence of urate deposition—hyperechoic enhancement over surface of hyaline cartilage (4).
- Dual energy CT (DECT) imaging can show urate deposition at articular or periarticular sites (4)
- ACR-EULAR Gout Classification calculator (goutclassificationcalculator.auckland.ac.nz): validated classification criteria with sensitivity 92%, specificity 89% (with clinical criteria only sensitivity of 85% and specificity of 78%) (4)

TREATMENT
GENERAL MEASURES

Topical ice as needed (5)[B]

MEDICATION

- Acute treatment
  - General principles:
    - Acute gouty arthritis attacks should be treated with pharmacologic therapy (5)[C].
    - Pharmacologic treatment should be initiated within 24 hours of acute gout attack (5)[C].
    - Ongoing pharmacologic urate-lowering therapy should not be interrupted during an acute gout attack (5)[C].
    - Choice of agent is based on severity of pain and the number of joints involved (5).
  - Mild/moderate gout severity (≤6 of 10 on visual analog pain scale, particularly for an attack involving only one or a few small joints or one to two large joints)
    - NSAIDs:
      - Naproxen (Naprosyn, Anaprox, Aleve): 750 mg followed by 250 mg q8h for 5 to 8 days (5)[A]
      - Indomethacin (Indocin): 50 to 150 mg/day for 2 to 7 days (5)[A]
      - Sulindac (Clinoril): 200 mg BID for 7 to 10 days (5)[A]
      - Celecoxib (Celebrex)
    - Not FDA approved but can be considered in selected patients with contraindications or intolerance to NSAIDs (5)[B]
      - Dose: 800 mg once, then 400 mg on day 1, then 400 mg BID for 1 week (5)[B]
  - Corticosteroids
    - Those with an acute flare involving one to two large joints can consider intra-articular corticosteroids; can consider using oral corticosteroids in combination.
    - Corticosteroids are useful in patients with acute gout flare who cannot tolerate NSAIDs or have contraindications to NSAIDs such as chronic kidney disease.
    - For other acute flares, use oral corticosteroids:
      - Prednisone (Sterapred): 0.5 mg/kg/day for 5 to 10 days followed by discontinuation (5)[A] or alternately 2 to 5 days at full dose followed by tapering for 7 to 10 days and then discontinuing (5)[C]
- Methylprednisolone (Medrol) dose pack (5)[C]
- Triamcinolone acetonide (Trivar): 60 mg IM single dose followed by oral corticosteroids (5)[C]
  - Colchicine (Colcrys)
  - Used for gout attacks where the onset was <36 hours prior to treatment initiation (5)[A]
  - Begin a loading dose of 1.2 mg followed by 0.6 mg 1 hour later, followed by 0.6 mg once or twice daily 12 hours later, until the gout attack resolves (5)[C].
  - Dose reduction recommended in moderate to severe kidney disease and in those on inhibitors of cytochrome P450 3A4 and P-glycoprotein (clarithromycin, erythromycin, cyclosporine, and disulfiram) (5).
  - Severe gout (≥7 of 10 on visual analog pain scale, involving ≥4 joints with arthritis involving >1 region, or involving 3 separate large joints)
    - Initial combination therapy is an option and includes the use of full doses of the following (5)[C]:
      - Colchicine and NSAIDs
      - PO corticosteroids and colchicine
      - Intra-articular steroids
    - For patients not responding to initial pharmacologic monotherapy, add a second agent (5)[C].
- Chronic treatment
  - Indications for pharmacologic urate-lowering therapy include any patient with
    - Tophus or tophi by clinical exam or imaging study (1)[A]
    - Frequent attacks of acute gouty arthritis (≥2 attacks per year) (1)[A]
    - Chronic kidney disease (CKD) stage 2 or worse (1)[C]
    - Past urolithiasis (1)[C]
  - Treat to the serum urate:
    - Minimum serum urate target is <6 mg/dL (1)[A].
    - Serum urate target may need to be <5 mg/dL to improve gout signs and symptoms (1)[B].
  - Urate-lowering agents can be prescribed during an acute attack provided that effective anti-inflammatory prophylaxis has been initiated prior to urate-lowering therapy (1)[C].
  - Anti-inflammatory prophylaxis required when initiating urate-lowering therapy:
    - First line
      - Low-dose colchicine: 0.6 mg once or twice daily (5)[A]
- Low-dose NSAIDs: naproxen 250 mg PO BID (5)[C]
  - Second line: if use of colchicine and NSAIDs both are not tolerated, contraindicated, or ineffective:
    - Low-dose prednisone or prednisolone at ≤10 mg/day (5)[C]
  - Treatment duration for the greater of
    - At least 6 months (5)[A] or
    - 3 months after achieving serum urate appropriate for the patient with no tophi on exam (5)[B], or for 6 months after achieving serum urate appropriate for the patient with ≥1 tophi on exam (5)[C]

- Pharmacologic urate-lowering agents:
  - Allopurinol (Zyloprim): xanthine oxidase inhibitor (1)[A]
    - Starting dose should be no higher than 100 mg/day (1)[B].
    - Starting dose should be 50 mg/day in stage 4 CKD or worse.
    - Gradually titrate the dose upward q2–5wk to appropriate maximum dose (1)[C].
    - Dose can be >300 mg/day, even with renal impairment, as long as accompanied by patient education and monitoring of drug toxicity; maximum FDA-approved dosage is 800 mg/day (1)[B].
    - Regularly monitor for allopurinol hypersensitivity syndrome (AHS), pruritus, rash, elevated hepatic transaminases, and eosinophilia.
    - Screening for the HLA-B*5801 allele for AHS should be performed in those of Korean descent with stage 3 CKD or worse and Han Chinese or Thai descent irrespective of renal function (1)[A].
  - Febuxostat (Uloric): selective xanthine oxidase inhibitor (1)[A]
    - No renal or hepatic adjustments needed for mild-to-moderate hepatic or renal impairment
    - Starting dose 40 mg/day; may be titrated to 80 mg/day
    - In select instances, may dose up to 120 mg/day (not FDA approved) (1)[A]
  - Probenecid: uricosuric agent (1)[B]
    - Alternative first line urate-lowering therapy; use if xanthine oxidase inhibitor is contraindicated or not tolerated (1)[B].
    - May be used in addition to allopurinol or febuxostat if serum urate target not achieved
    - Multiple drug interactions exist, as well as risk of urolithiasis with this agent.
    - Not recommended if creatinine clearance (CrCl) is <50 or with patient history of urolithiasis (1)[C]
Starting dose is 250 mg BID; gradually titrate to 2,000 mg/day.

Other treatment
- Losartan possesses uricosuric properties, therefore it may be an excellent agent if patient is also hypertensive.
- Acute treatment: adrenocorticotropic hormone (ACTH): 25 to 40 IU SC \(^{(5)}\)[A]
- Pegloticase in select severe instances \(^{(1)}\)

SURGERY/OTHER PROCEDURES
Large tophi that are infected or interfering with joint motion may need to be surgically removed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- SUA q2–5wk while titrating urate-lowering treatment to goal \(^{(1)}\)[C]
- Regularly monitor CBC, renal function, liver function test, and urinalysis.

DIET
- General lack of evidence regarding specific recommendations, although the American College of Rheumatology has outlined the following \(^{(1)}\)[C]:
- General measures:
  - Weight loss for obese patients
  - Healthy overall diet and good hydration
  - Smoking cessation
- Avoid
  - Organ meats high in purine content (sweetbreads, liver, kidney) \(^{(1)}\)[A]
  - High-fructose corn syrup–sweetened sodas, other beverages, or foods
  - Alcohol overuse (>2 servings per day for men and >1 serving per day for women) \(^{(1)}\)[A]
  - Any alcohol use in gout during periods of frequent gout attacks or advanced gout under poor control
- Limit
  - Serving sizes of beef, lamb, pork, and seafood with high purine content such as sardines and shellfish \(^{(1)}\)[B]
- Servings of naturally sweetened fruit juices
- Table sugar, sweetened beverages, and desserts
- Table salt, including in sauces and gravies
- Alcohol (particularly beer) in all patients (1)[B]

Encourage
- Low-fat or nonfat dairy products
- Vegetables

PATIENT EDUCATION

- Dietary and lifestyle modifications (1)[B]
- Instructions on initiating treatment on signs and symptoms of an acute gout attack without the need to consult health care provider for each attack (1)[B]
- Discussion that gout is caused by excess uric acid and that effective urate-lowering therapy is essential treatment (1)[B]

PROGNOSIS

Gout can usually be successfully managed with proper treatment.

COMPLICATIONS

- AHS
- Increased susceptibility to infection
- Urate nephropathy
- Renal stones

REFERENCES

**CODES**

**ICD10**
- M10.9 Gout, unspecified
- M10.00 Idiopathic gout, unspecified site
- M10.30 Gout due to renal impairment, unspecified site

**CLINICAL PEARLS**
- MSU crystals found in synovial fluid aspirate are pathognomonic for gout.
- Pharmacologic treatment should begin within 24 hours of acute gout flare.
- Asymptomatic hyperuricemia does not require treatment.
GRANULOMA ANNULARE
Stephen C. Sears, DO • Adam K. Saperstein, MD

BASICS

DESCRIPTION
Granuloma annulare (GA) is a benign skin condition characterized by groups of skin-colored to erythematous papules that are usually in an annular (ring-like) pattern and typically located on the dorsal aspects of the hands and feet. There are five types of GA: localized, generalized, subcutaneous, patch, and perforating.

EPIDEMIOLOGY

Incidence
- GA is a relatively common, noninfectious granulomatous disease. Population-based studies to determine the incidence and/or prevalence of GA are lacking. A single study in 1980 demonstrated that 0.1–0.4% of new patients presenting to dermatologists have GA but did not report similar descriptive statistics in the primary care arena (1).
- Although most lesions resolve spontaneously within 2 years, some persist for 10 years or more.
- Predominant sex: female > male (1 to 2.5:1)
- Onset of symptoms occurs at <30 years old in 2/3 of all patients. Typical ages for onset of each subtype are:
  - Localized: <30 years old
  - Generalized: bimodal: <10 years old, 30 to 60 years old
  - Subcutaneous: 2 to 14 years old
  - Patch: >30 years old
  - Perforating: children and young adults
- Distribution of subtypes is as follows:
  - Localized: 75%
  - Generalized: 10–15%
  - Subcutaneous: <5%
  - Patch type: <5%
  - Perforating: <5%
ETIOLOGY AND PATHOPHYSIOLOGY

The etiology of GA remains unknown. It is hypothesized to be a dermatologic manifestation of a delayed-type hypersensitivity reaction to an unknown antigen in the dermis that is mediated by tumor necrosis factor alpha (TNF-α) and interleukin factors 1 and 2 (IL-1 and IL-2) (2). Characteristic histopathologic features include lymphohistiocytic infiltrates, degeneration of collagen, palisading or interstitial granulomatous inflammation, and mucin deposition.

Genetics

There is some evidence for a genetic predisposition. Two studies reported an increased frequency of HLA-Bw35 in patients with generalized GA. Of note, HLA-Bw35 has also been associated with thyroid disease (1).

RISK FACTORS

No definite risk factors have been identified. There are reported associations between GA and diabetes mellitus (DM), autoimmune thyroid disease, dyslipidemia, human immunodeficiency virus, Epstein-Barr virus, herpes simplex virus, systemic lupus erythematosus, tuberculosis, and hepatitis B and C, among others. There have also been associations with interferon-α therapy, trauma, sun exposure, insect bites, borreliosis, and malignancies (most commonly lymphoma) (2,3).

GENERAL PREVENTION

There are no known preventive measures for GA.

COMMONLY ASSOCIATED CONDITIONS

- DM: The association between GA and DM is controversial. Early studies from the 1980s showed a possible link, but recent case-controlled studies have shown no statistically significant association between GA and DM (3).
- Autoimmune thyroid disease: Multiple case reports have linked thyroid disease with both generalized and localized GA. In one case-control study, 24 women with localized GA were compared to 100 age-matched women with non-GA dermatologic disease. A statistically significant increase in the incidence of autoimmune thyroid disease among those with localized GA as compared with those with other non-GA cutaneous disease was identified (12% vs. 1%, p = .022) (2,3).
- Malignancy: There is no definitive relationship between GA and malignancy. A review of the literature found 14 case reports and two correlation studies in...
which patients who had one or more malignancies also had GA. In a majority of these cases, the malignancies were hematologic, primarily lymphoma (2,3).

- Dyslipidemia: Dyslipidemia may be associated with GA. A single case-control study (n = 140) demonstrated a statistically significant increase in hyperlipidemia among patients with GA compared to controls (79.3% vs. 51.9%, p <.001) (4).

- HIV: Among patients with GA, those who also have HIV appear more likely to have the generalized subtype. In one study of 34 patients with GA and HIV, 20 (59%) had generalized GA (2).

- Note: Conclusions regarding associations between GA and various diseases, including those listed above, are limited by both design and power. Consequently, in the absence of new research, definitive associations between GA and other diseases cannot be made.

**DIAGNOSIS**

**HISTORY**

Cutaneous lesions of GA are generally asymptomatic. Lesions often persist for months or years, especially in patients who have generalized GA. In most cases, regardless of subtype, GA resolves spontaneously but may thereafter recur without obvious trigger.

**PHYSICAL EXAM**

- Localized: asymptomatic, flesh-colored or erythematous annular, or arciform plaque with a moderately firm, rope-like border and central clearing, ranging from 5 mm to 5 cm in diameter. Small 1- to 2-mm papules may be noted peripheral to the primary lesion. The most common locations are the dorsal aspects of the distal upper and lower extremities; involvement of palms is rare. It is common to have multiple lesions at the time of presentation.

- Generalized: Lesions have the same morphology as localized GA lesions, but tend to be larger, greater in number (usually >10), persist for a longer period of time, and are more widespread.

- Subcutaneous: firm, nontender nodules that tend to grow rapidly; usually solitary but may occur in groups; most common location is scalp and/or anterior aspect of the lower extremities, followed by upper extremities and buttocks.

- Patch: erythematous macules and patches distributed symmetrically on the
extremities and trunk. The typical annular configuration may or may not be present; often involves proximal extremities

- Perforating: Damaged collagen from dermis is extruded onto skin surface. Papules may be up to 4 mm in diameter and display yellowish umbilication, crusting, or scale. Lesions are often widely distributed on the body and cause scaring.

**DIFFERENTIAL DIAGNOSIS**

- Localized: tinea corporis, annular lichen planus, necrobiosis lipoidica, pityriasis rosea, erythema migrans, leprosy
- Generalized: sarcoidosis, lichen planus, cutaneous metastases, mycosis fungoides (cutaneous T-cell lymphoma)
- Patch type: erythema migrans
- Subcutaneous: rheumatoid nodules
- Perforating: molluscum contagiosum, sarcoidosis, insect bites

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- Diagnosis is typically established by history and physical examination; laboratory investigations are rarely needed. Microscopic evaluation of skin cells using potassium hydroxide (KOH) preparation may be useful to exclude a fungal process.
- Consider laboratory testing to evaluate comorbid dyslipidemia, DM, thyroid disease, HIV, hepatitis B/C, and malignancy as clinically indicated.

*Diagnostic Procedures/Other*

Punch biopsy and histologic evaluation may aid in confirming the diagnosis and identifying the subtype. Immunohistochemical streptavidin-biotin–horseradish peroxidase (HRP) analysis for CD68/KP-1 (a marker for histiocytic differentiation) may also aid in the diagnosis.

*Test Interpretation*

Dermal infiltrate demonstrating foci of degenerative collagen associated with palisading granulomas around an anuclear dermis with mucin deposition. Histologic variants include interstitial (histiocytic infiltrate between collagen fibers), classic (palisading dermal granulomas), and epithelioid (tuberculoid and sarcoidal granulomas).
TREATMENT

GENERAL MEASURES
GA is a self-limited condition that is likely to regress spontaneously. The clinician’s primary role after making the diagnosis is to educate the patient about the natural history of GA and to consider screening for conditions that may be associated with this disease.

MEDICATION
- Strength of recommendation for therapeutic interventions is B or C (3,5).
- The trauma induced by biopsy alone can cause involution of lesions through an unknown mechanism.
- Given the self-limited nature of the disease, it is incumbent on providers to assess the risk/benefit ratio of treatment. Reassurance is often all that is required for localized, asymptomatic disease.
- The following therapies have been tried with variable success (2,3,5,6). Duration of therapy is often undefined and is based on clinical response.

First Line
Corticosteroids
- High-potency topical (class I or II), with or without occlusion (3,5)[C]
- Intralesional triamcinolone: concentration of 2.5 to 5.0 mg/mL (3,5)[C].
  Technique: Insert the needle into the dermis at the elevated border and slowly inject while withdrawing the needle, with enough volume to cause the lesion to begin to blanch.

Second Line
- Pimecrolimus cream: 1% BID (3)[C]
- Tacrolimus ointment: 0.1% BID (3)[C]
- Chloroquine: 250 mg/day (3)[C]
- Hydroxychloroquine: 9 mg/kg/day for 2 months, 6 mg/kg/day for month 3, 2 mg/kg/day for month 4 (3)[C]
- Doxycycline: 100 mg/day for 10 weeks (3)[C]
- Isotretinoin: 0.50 to 0.75 mg/kg/day (3)[C]
- Rifampin 600 mg, ofloxacin 400 mg, with minocycline 100 mg once daily (3)[C]
- Dapsone: 100 mg/day (3)[C]
- Cyclosporine: 3 to 4 mg/kg/day (3)[C]
- Methotrexate: 15 mg IM weekly (3)[C]
- Niacinamide: 500 mg TID (3)[C]
- Fumaric acid esters: Variable dosing schemes (3)[C]
- Interferon gamma 1b: intralesional injection, $2.5 \times 10^5$ IU/lesion for 7 consecutive days followed by 3 times per week for 2 weeks (3)[C]
- TNF-α inhibitors, such as infliximab 5 mg/kg IV weeks 0, 2, and 6, then variable or adalimumab 80 mg SC at week 0, and then 40 SC at week 1 and every other week, or etanercept 50 mg twice weekly (3)[C]

**ADDITIONAL THERAPIES**
- Cryotherapy (one 10- to 60-second freeze thaw cycle) (3)[B]
- Fractional thermolysis (e.g., YAG fractionated laser) (3)[C]
- 585- to 595-nm pulsed dye laser (3)[C]
- Narrowband ultraviolet B (NB UVB) (6)[C]
- Psoralen ultraviolet A (PUVA) (6)[C]
- Surgical excision (for subcutaneous GA) (2)[C]

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Routine follow-up is not required unless treatment is initiated. In such situations, follow-up is recommended to monitor for possible adverse effects of treatment. Referral to a dermatologist is prudent for patients who have generalized GA, cosmetic concerns, and for patients whose lesions persist despite conservative therapy.

**PATIENT EDUCATION**
Patients should be educated that GA is a benign, self-limited condition that may persist for months to years, spontaneously resolve, and spontaneously recur. Additionally, patients may benefit from knowing that GA is not thought to be of an infectious etiology and is not transmissible to others.

**PROGNOSIS**
>50% of cases resolve spontaneously within 2 months to 2 years after onset, although recurrence, typically at the original site, is common (>40%). Patients <39 years tend to have a shorter duration of illness.
COMPLICATIONS
Complications of treatment are much more likely than complications from GA.

REFERENCES

ADDITIONAL READING
CODES

ICD10
L92.0 Granuloma annulare

CLINICAL PEARLS

- GA is benign, self-limited condition. Consider risk-to-benefit ratio when partnering with patients to determine treatment.
- When initiating therapy for localized GA, start with high-dose topical corticosteroids or intralesional corticosteroids followed by cryotherapy or other listed topical therapies. For widespread disease, consider initiating treatment with antimalarials or phototherapy (2,3)[C].
- Consider GA in the differential diagnosis of lesions that appear to be tinea, especially when these lesions lack scale and are KOH negative.
- Consider fasting lipid panel, fasting blood glucose or HbA1C, TSH, free T4, thyroid antibodies, hepatitis B and C panel, HIV screening test, and age-appropriate cancer screening, especially in those with generalized or atypical presentations of GA (3)[C].
GRANULOMA, PYOGENIC

John M. Doan, DO • Sarah S. Dolbear, MD

BASICS

DESCRIPTION
- Pyogenic granulomas (PG), also called lobular capillary hemangiomas, are benign vascular proliferations that can appear on the skin and mucus membranes. Most common sites are head and neck, the lips and oral cavity, the trunk, and the extremities (1).
- They are friable and tend to bleed profusely due to the vascular nature of the lesion.
- Smooth, red to purple, sessile or pedunculated, grow rapidly over several weeks.
- Rarely regress without intervention.

EPIDEMIOLOGY
- The peak incidence of PG occurs in the 2nd and 3rd decades of life (2).
- Commonly seen in early pregnancy.

ETIOLOGY AND PATHOPHYSIOLOGY
- Definitive cause unknown.
- Thought to be associated with capillary proliferation resulting from aberrant healing response to minor trauma.
- Associated with peripheral nerve injury, inflammatory systemic diseases, and drugs (retinoids, systemic steroids, protease inhibitors, epidermal growth factor receptor inhibitors).
- May be related to hormonal changes in pregnancy.
- Not considered a hemangioma or neoplasm; no true granulomatous histology present.

RISK FACTORS
- Pregnancy
- Trauma
- Intraoral trauma or surgery
- Inflammatory systemic diseases.
GENERAL PREVENTION
Good oral hygiene may be helpful.

DIAGNOSIS

HISTORY
- Solitary lesion that develops rapidly from days to weeks after minor trauma
- Tends to bleed easily
- Grows early in pregnancy and partially regresses postpartum

PHYSICAL EXAM
- Most commonly located at the head, neck, and upper extremities, especially in children
- Among oral lesions, gingiva is the most common location.
- Usually a bright red, friable papule; can also be purple, yellow, or brown
- Moist and sometimes scaly-appearing surface
- Usually <1 cm but ranges from a few millimeters to 2 to 3 cm in diameter
- Giant lesions may occur on areas such as the foot (rare).
- Soft; pedunculated or sessile
- Solitary red papule, grows rapidly, forming a stalk, may bleed, and ulcerate
- On diascopy, red structureless areas surrounded by a white collarette intersected by white lines
- Erythematous, soft compressible papule with serosanguineous crusting and sharp demarcation

DIFFERENTIAL DIAGNOSIS
- Benign lesions
  - Cherry/infantile hemangioma (3)
  - Fibrous papule (1,3)
  - Bacillary angiomatosis, from by Bartonella (1)
- Malignant lesions
  - Basal cell carcinoma (1)
  - Squamous cell carcinoma (1)
  - Amelanotic melanoma (1)
  - Kaposi sarcoma (1)
  - Cutaneous metastases (1)
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
No labs are necessary for the diagnosis.

Diagnostic Procedures/Other
- Excisional/shave biopsy
- Send for pathology.

Test Interpretation
Microscopic examination reveals
- Small, endothelial-lined vascular spaces
- Loose/dense connective tissue stroma
- Acute and chronic inflammatory cells
- *No true granuloma formation*
- Abundant mitotic activity
- Resembles granulation tissue in an edematous matrix, showing immature capillaries with interspersed tissue

TREATMENT
- Full thickness surgical excision is best to yield material for histopathologic analysis and avoid recurrence (1,4,5)[B].
- Excision must be adequate to avoid recurrence. Even a small fragment of tissue left behind may lead to recurrence.
- Shave biopsy can be used for pedunculated lesions; can combine with cautery (5)[B]
- Punch biopsy acceptable for small lesions
- Electrosurgery: electrodessication and curettage (5)[B]

SURGERY/OTHER PROCEDURES
- Cryotherapy with liquid nitrogen (recur 2%) (5)[B]
- Pulsed dye laser or CO2 laser (5)[B]
- Topical imiquimod (5)[B]
- Silver nitrate (5)[A]
- Topical 1.5% phenol solution may be used for periungual lesion (5)[B].
- Recurrence rate of up to 15% depending on treatment modality used
ONGOING CARE

PATIENT EDUCATION
Patient should avoid trauma to area following excision.

PROGNOSIS
- Some lesions spontaneously resolve on their own (usually within 6 months).
- Complete resolution is expected with adequate excision.

COMPLICATIONS
Recurrence: After removal or destruction of solitary lesion, multiple satellite lesions can form around original treatment site.

REFERENCES

ADDITIONAL READING
- Zalaudek I, Kreusch J, Giacomel J, et al. How to diagnose nonpigmented skin

**CODES**

**ICD10**
- L98.0 Pyogenic granuloma
- K06.8 Oth disrd of gingiva and edentulous alveolar ridge
- K13.4 Granuloma and granuloma-like lesions of oral mucosa

**CLINICAL PEARLS**
- Benign, vascular tumor, usually rapidly growing, that involves exposed areas, such as distal extremities and face, as well as in the oral cavity
- Excision must be adequate to avoid recurrence.
- Excisional biopsy recommended to ensure proper diagnosis and rule out malignancy
- Excision with primary closure or excision with cautery should be the first choice for treatment in most lesions.
GRAVES DISEASE

Fozia Akhtar Ali, MD • Christina A. Majd, MD • Melida A. Juarez, MD

BASICS

DESCRIPTION
Autoimmune disease in which thyroid-stimulating antibodies cause increased thyroid function; most common cause of hyperthyroidism. Classic findings are goiter, ophthalmopathy (orbitopathy), and occasionally dermopathy (pretibial or localized myxedema).

EPIDEMIOLOGY

Prevalence
- Overall prevalence of hyperthyroidism in United States: ~2% for women and 0.2% for men
- More common in white and Hispanic populations in comparison to the black population
- Graves disease accounts for 60–80% of all cases of hyperthyroidism.
- Hyperthyroidism occurs in 0.2% of pregnancies, of which 95% is due to Graves disease.
- Predominant age: 30 to 40 years
- Synonym(s): Basedow disease

ETIOLOGY AND PATHOPHYSIOLOGY
- Excessive production of thyroid-stimulating hormone (TSH) receptor antibodies from B cells primarily within the thyroid, likely due to genetic clonal lack of suppressor T cells
- Binding of these antibodies to TSH receptors in the thyroid activates the receptor, stimulating thyroid hormone synthesis and secretion as well as thyroid growth (leading to goiter).
- Binding to similar antigen in retro-orbital connective tissue causes ocular symptoms.

Genetics
Higher risk with personal or family history of any autoimmune disease, especially Hashimoto thyroiditis

**RISK FACTORS**
- Female gender (5 to 10 times more than men)
- Postpartum period
- Family history (15% of patients with Graves disease have an affected relative)
- Medications: iodine, amiodarone, lithium, highly active antiretroviral (HAART); rarely, immune-modulating medications (e.g., interferon therapy)
- Smoking (higher risk of developing ophthalmopathy)

**GENERAL PREVENTION**
Screening TSH in asymptomatic patients is not recommended. No data conclusively show that treatment of subclinical thyroid dysfunction improves quality of life or clinical outcome measures.

**COMMONLY ASSOCIATED CONDITIONS**
- Mitral valve prolapse
- Type 1 diabetes mellitus
- Addison disease, hypokalemic periodic paralysis
- Vitiligo, alopecia areata
- Other autoimmune disorders (myasthenia gravis, celiac disease)

**DIAGNOSIS**
Hyperthyroid patients appear hypermetabolic with increased adrenergic tone.

**HISTORY**
- Tachycardia, palpitations
- Tremor, restlessness
- Hyperactivity, anxiety, emotional lability, insomnia
- Sweating, heat intolerance
- Pruritus, skin changes
- Weight loss with increased appetite
- Fatigue, dyspnea (due to muscle weakness)
- Oligo-/amenorrhea (women), loss of libido, erectile dysfunction (men), gynecomastia
- Loose, frequent stools
• Blurred vision or diplopia, lacrimation, photophobia, gritty sensation in eyes (ocular dryness), retro-orbital discomfort, painful eye movement, loss of color vision or visual acuity
• Worsening of chronic medical conditions (anxiety, bipolar disorder, glucose intolerance, heart failure, or angina)

**Geriatric Considerations**
Elderly patients may not display classic symptoms; may present with atrial fibrillation, weight loss, or shortness of breath

**PHYSICAL EXAM**
• Ophthalmologic (present in 50% of cases): Grittiness/discomfort in the eyes, retrobulbar pressure/pain, lid lag/retraction, proptosis, ophthalmoplegia, papilledema, and loss of color vision may signify optic neuropathy.
• Thyroid: enlarged (goiter), nontender, and without nodules; possible bruit (increased blood flow)
• Integumentary: fine hair, warm skin, onycholysis, palmar erythema, possible pretibial myxedema (orange peel appearance), possible hyperpigmented plaques (dermopathy)
• Cardiac: resting tachycardia, hyperdynamic circulation, possible atrial fibrillation
• Extremities: fine tremor, hyperreflexia, proximal myopathy; rarely, soft tissue edema of extremities and clubbing of digits (acropachy)

**DIFFERENTIAL DIAGNOSIS**
• Toxic multinodular goiter (multiple hormone-producing nodules)
• Toxic adenoma (single hormone-producing nodule)
• Thyroiditis (hormone leakage)
  – Subacute, usually postviral (thyroid will be tender)
  – Lymphocytic, including postpartum
  – Hashimoto thyroiditis (antithyroperoxidase [TPO] antibodies may stimulate TSH receptors)
• Iatrogenic (treatment-induced)
  – Iodine-induced (dietary, radiographic contrast, or medications)
  – Amiodarone
  – Thyroid hormone overreplacement (accidental or intentional)
• Tumor
  – Pituitary adenoma producing TSH
– Human chorionic gonadotropin (hCG)-producing tumors (stimulate TSH receptors)
– Extraglandular thyroid hormone production (e.g., struma ovarii or metastatic thyroid cancer)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- TSH is initial test: suppressed (low or undetectable)
- TSH <0.1 mU/L has >98% sensitivity and >92% specificity in confirming suspected thyroid disease.
- Elevated free T4 with low TSH confirms hyperthyroidism.
- Thyroid peroxidase antibodies (present in 70–80% of patients with Graves disease) and TSH receptor antibodies (thyroid binding inhibitory immunoglobulin) may be useful in differentiating between Graves disease and toxic multinodular goiter.
- After confirming suppressed TSH and high T4, perform radioactive iodine uptake (RAIU) and scan. Patients with Graves disease will have diffuse, elevated RAIU (vs. localized/nodular elevated uptake in adenoma and multinodular goiter and decreased uptake in thyroiditis or exogenous thyroid hormone).
- Thyroid ultrasound is not always required but may be used to distinguish nodular forms of Graves disease from nodular nonautoimmune causes of hyperthyroidism.

Pregnancy Considerations

- Increase in serum T4-binding globulin concentration and initial stimulation of TSH by hCG results in a total T4 and T3 rise during first half of pregnancy. The TSH level is decreased throughout pregnancy and should be compared to the trimester-specific ranges for pregnancy. Measurement of thyrotropin receptor autoantibody (TRAb) is positive in 95% of patients with Graves and should be used if diagnosis is unclear in pregnancy (1)[A].
- Ultrasonography is the primary modality of imaging during pregnancy.

TREATMENT

MEDICATION
Goal is to correct hypermetabolic state with the fewest side effects and lowest incidence of posttreatment hypothyroidism.

**First Line**

- β-Blockers provide prompt control of adrenergic symptoms; start while workup is in progress (2)[A]. Long-acting propranolol is used most commonly and titrated to symptom control (40 to 160 mg/day).

- RAI
  - Concentrates in the thyroid gland and destroys thyroid tissue
  - Radioiodine plus prednisone therapy might have the least probability of leading to an exacerbation or new appearance of ophthalmopathy, and radioiodine therapy might have the least probability of causing a recurrence (3)[A].
  - Treatment of choice for definitive therapy of hyperthyroidism, in the absence of moderate or severe orbitopathy (1)[A]
  - High cure rate with single treatment, especially with high-dose regimen
  - Risks: side effects (neck soreness, flushing, decreased taste); worsening ophthalmopathy (15% incidence, higher in smokers); posttreatment hypothyroidism (80% incidence, not dosage-dependent); radiation thyroiditis (1% incidence); need to adhere to safety precautions until radiation is eliminated from the body
  - Pretreatment with antithyroid medication should be considered in patients with severe disease and the elderly, to reduce risk of posttreatment transient hyperthyroidism and posttreatment radiation thyroiditis as well as quicker return to normal thyroid function.
  - May be repeated in as soon as 3 months if minimal response or after 6 months if not euthyroid (2)[A]

**Pregnancy Considerations**

RAI is contraindicated in pregnancy and during breastfeeding.

- Antithyroid drugs: methimazole (MMI) and propylthiouracil (PTU)
  - Compete with the thyroid for iodine, thereby decreasing the synthesis of thyroid hormone; propylthiouracil blocks peripheral conversion of $T_4$ to $T_3$.
  - Treatment of choice for children and for adults who refuse RAI
  - May use as pretreatment for older or cardiac patients before RAI or surgery
  - Methimazole is now almost exclusively used except during the 1st trimester of pregnancy. It has longer duration of action, allowing for once daily dosing, more rapid efficacy, and lower incidence of side effects (2)[A].
– No improvement in remission rates were noted with higher dose methimazole; lowest effective dose should be used (1)[B].
– Minor side effects (<5% incidence): controlled by switching from one agent to another: skin rash (3–5%), fever, arthralgias, GI side effects
– Major side effects necessitating change in treatment: polyarthritis (1–2%), idiopathic granulocytopenia (0.5%); and cholestasis/jaundice (rare)
– Evidence suggests that the optimal duration of antithyroid drugs is 12 to 18 months; no increased benefit to treatment beyond 18 months (3)[A]
– Relapse rates up to 50% in patients who respond initially; higher rates if smoker, large goiter, or positive thyroid-stimulating antibodies at end of treatment

**Pregnancy Considerations**
Propylthiouracil is preferred in 1st trimester of pregnancy due to teratogenic effects of methimazole. Switch to methimazole in 2nd and 3rd trimesters due to risk of PTU-induced hepatotoxicity (4)[A].

**ISSUES FOR REFERRAL**
- Endocrinologist for RAI therapy; if patient is pregnant or breastfeeding
- Graves ophthalmopathy
- Surgery if failed drug therapy or refusing RAI; obstruction or cosmesis

**ADDITIONAL THERAPIES**
- Symptom control may be achieved with iodides, which block conversion of \( T_4 \) to \( T_3 \) and inhibit TSH release. Use for pregnant patients who do not tolerate antithyroid medication or in conjunction with antithyroid medications; should not be used long term (may cause paradoxical increase in TSH release) or in combination with RAI
- For corneal protection: tinted glasses when outdoors, artificial tears, patching/taping the lids at night
- For orbitopathy: Mild cases can be treated with lubricants, nocturnal ointments, botulinum toxin injection for upper lid retraction, and smoking cessation. Moderate to severe cases should be treated with pulse-dose IV glucocorticoid if no contraindications. Alternative is PO steroid (prednisone 60 to 80 mg/day for 2 to 4 weeks and then taper off).
- For dermopathy, use medium- to high-potency topical corticosteroids.

**SURGERY/OTHER PROCEDURES**
With regard to ophthalmopathy progression, postoperative bleeding, permanent hypoparathyroidism, temporary and permanent recurrent laryngeal nerve palsy—total thyroidectomy (TT) is consistent with subtotal thyroidectomy (ST) in patients with Graves disease. However, TT is associated with a reduced incidence of recurrent hyperthyroidism and results in an increase in temporary hypoparathyroidism (5)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Indications for hospital admission:
- Severe thyrotoxicosis with hemodynamic compromise (thyroid storm). ICU management is indicated.
- Severe ophthalmopathy with visual compromise

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Monitoring is for the resolution of hyperthyroidism and for the development of hypothyroidism.
- Check TSH and T₄ levels every 1 to 2 months for the first 6 months after treatment, then every 3 months for a year, and then every 6 to 12 months thereafter. For patients on treatment with propylthiouracil and methimazole, check CBC yearly. Also, check anti-TSH receptor antibodies at 12 months of treatment to determine possibility of discontinuing medication.

Pregnancy Considerations
Postpartum exacerbation of hyperthyroidism is common for women not currently under treatment, so TSH and symptoms should be monitored.

PATIENT EDUCATION
Adherence to both follow-up surveillance and medication regimens is the most important way to achieve a good outcome.

PROGNOSIS
- Generally good with treatment
May have irreversible ocular, cardiac, and psychiatric consequences
Increased morbidity and mortality due to osteoporosis, atherosclerotic disease, insulin resistance and obesity, and endothelial cell dysfunction (thromboembolic risk)

COMPICATIONS
Hypothyroidism is the most common consequence of treatment. The percentage of patients with Graves disease who become hypothyroid within the 1st year after treatment varies with treatment modality.

SEE ALSO
Algorithms: Anxiety; Cardiac Arrhythmias; Weight Loss, Unintentional
**CODES**

**ICD10**
- E05.00 Thyrotoxicosis w diffuse goiter w/o thyrotoxic crisis
- E05.01 Thyrotoxicosis w diffuse goiter w thyrotoxic crisis or storm
- E05.20 Thyrotoxicosis w toxic multinod goiter w/o thyrotoxic crisis

**CLINICAL PEARLS**
- Graves disease accounts for 60–80% of all cases of hyperthyroidism.
- Potential morbidities of hyperthyroidism include ophthalmopathy, atrial fibrillation, congestive heart failure (CHF), stroke, seizure, and osteopenia/osteoporosis.
GUILLAIN-BARRÉ SYNDROME
Grant M. Reed, DO • Simon B. Griesbach, MD

BASICS
DESCRIPTION

• A group of acquired autoimmune disorders causing acute peripheral neuropathy and ascending paralysis that progressively worsens for up to 4 weeks followed by a slow spontaneous recovery of function

• Subtypes classified by pattern of neural injury:
  – Acute inflammatory demyelinating polyradiculoneuropathy (AIDP): progressive limb weakness with areflexia (~95% of GBS cases in Europe and North America)
  – Axonal subtypes:
    o Acute motor axonal neuropathy (AMAN): pure motor neuropathy strongly associated with Campylobacter jejuni and a higher rate of respiratory failure (~5% of cases in Europe and North America but 30–47% of cases in China, Japan, and Central and South America)
    o Acute motor-sensory axonal neuropathy (AMSAN): combined motor–sensory neuropathy; poor prognosis with prolonged course
  – Regional subtypes:
    o Miller Fisher syndrome (MFS): triad with ophthalmoplegia, ataxia, and areflexia; antibodies to GQ1b present in 90% of patients with MFS
    o Bickerstaff encephalitis: possible variant of MFS with encephalopathy, ophthalmoplegia, ataxia, and hyperreflexia
    o Pharyngeal-cervical-brachial GBS: Parasympathetic and cholinergic dysfunction leads to neck, arm, and oropharyngeal weakness along with upper extremity areflexia.
  – Sensory subtypes:
    o Acute pandysautonomia: orthostatic hypotension, gastroparesis, ileus, constipation/diarrhea, sudomotor/pupillary abnormalities, and neuropathic pain
    o Acute sensory ataxic neuropathy (ASAN): controversial variant with sensory loss and ataxia
  – Polyneuritis cranialis: bilateral cranial nerve involvement and severe peripheral sensory loss associated with cytomegalovirus (CMV) infections
• Synonym(s): GBS, AIDP; Landry-Guillain-Barré-Stroh syndrome, acute inflammatory idiopathic polyneuritis; acute autoimmune neuropathy; Landry ascending paralysis

**ALERT**
Rapidly progressing paralysis and respiratory failure occur in 20–30% of patients. Some require mechanical ventilation within 48 hours.

**ALERT**
Areflexia is a red flag for GBS in patients with rapidly progressive limb weakness.

**ALERT**
A history of weakness preceded by respiratory or GI infection suggests GBS.

**EPIDEMIOLOGY**

**Incidence**
• Most common acute paralytic disease in Western countries
• 0.6 to 2.0/100,000 worldwide
• U.S. incidence: 0.9 to 1.8/100,000
• Increases with age: 0.8/100,000 in children <18 years of age; 3/100,000 in adults > 60 years
• 1.5 times higher incidence in males

**ETIOLOGY AND PATHOPHYSIOLOGY**
• Autoimmune process targets Schwann cell surface membrane, myelin, and/or gangliosides causing peripheral nerve destruction and demyelination.
• Pathogenesis thought to involve molecular mimicry (i.e., an immune response to antigenic targets that are coincidentally shared by infectious organisms and host peripheral nerve tissue)

**Genetics**
Host factors appear to play a role in GBS, but no clear genetic risk has been identified.

**RISK FACTORS**
Influenza vaccinations
• Inactivated seasonal flu vaccines associated with an increase in GBS risk
equivalent to one case/million vaccines above background incidence (far less than the 17 cases of GBS per million people infected with influenza virus)

- Incidence of GBS associated with influenza vaccine has steadily decreased over time.
- Of historical note: Increased incidence during 1976 U.S. National H1N1 Immunization Program had vaccine-attributable risk of 8.8 per million recipients compared to 1.6 per million recipients in the 2009 H1N1 vaccination campaign.

COMMONLY ASSOCIATED CONDITIONS
Infection of the respiratory (22–53%) or GI tract (6–26%) in preceding 6 weeks

- C. jejuni: most common precipitant of GBS, (21–40% of cases):
  - Associated with axonal degeneration, slower recovery, more severe residual disability
- CMV: Primary CMV infection precedes 10–22% of cases.
- Rarely associated with Mycoplasma pneumoniae, influenza infection, Epstein-Barr virus, varicella-zoster virus, HIV infection, and some arboviral infections

DIAGNOSIS

HISTORY

- AIDP presents with onset of progressive limb weakness that reaches its worst within 4 weeks (73% reach a functional nadir in 1 week).
- Preceding respiratory or gastrointestinal infection
- Earliest symptoms include pain, numbness, paresthesias, or limb weakness typically affecting distal extremities and spread proximally.
- Neuropathic pain, sometimes severe, occurs in 30–50%, most commonly in the back and lower extremities.
- Purely sensory symptoms exclude GBS.

PHYSICAL EXAM
Diagnostic criteria for typical GBS:

- Required for diagnosis:
  - Progressive weakness reaching nadir between 12 hours and 28 days
  - Affects >1 limb
  - Areflexia/hyporeflexia
- Strongly supportive:
– Paresthesias with only mild changes in objective sensory function (e.g., pinprick, light touch)
– Relative symmetry
– Cranial nerve involvement, especially bilateral/symmetric weakness of facial muscles
– Recovery beginning within 4 weeks after progression ceases
– Autonomic dysfunction
– Absence of fever at onset

**DIFFERENTIAL DIAGNOSIS**

Differential diagnosis of acute flaccid paralysis:

- **Brain**: basilar artery stroke, brainstem encephalitis
- **Spinal cord**: transverse myelitis, cord compression
- **Motor neuron**: poliomyelitis
- **Peripheral neuropathy other than GBS**: vasculitis, critical illness polyneuropathy, infectious disease (e.g., diphtheria, Lyme disease), chronic inflammatory demyelinating polyradiculoneuropathy (CIDP), acute intermittent porphyria
- **Neuromuscular junction**: myasthenia gravis, Eaton-Lambert syndrome, botulism, toxins (e.g., heavy metals, inhalant abuse, organophosphates)
- **Muscle**: electrolyte disturbance (hypokalemia, hypophosphatemia), inflammatory myopathy, critical illness myopathy, acute rhabdomyolysis, trichonosis, periodic paralysis
- **Psychological causes of weakness**

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- **Studies to establish the diagnosis:**
  - Lumbar puncture (LP): Increased CSF protein without pleocytosis is present in ~80% of cases (CSF protein is often normal within the first 48 hours of symptom onset).
  - Nerve conduction study (NCS): *Most useful confirmatory test*; conduction velocities abnormal in 85% of patients with demyelination, even early in the disease. If nondiagnostic, repeat after 1 to 2 weeks.

- Imaging generally not required. MRI demonstrates spinal nerve root and/or cauda equina enhancement.
- **Studies to find underlying cause:**
  - Stool culture and serology for *C. jejuni*
– Acute and convalescent serology for CMV, EBV, HIV, and *M. pneumoniae*
– Anti-GQ1b antibodies in MFS variant

**Follow-Up Tests & Special Considerations**
- Analyze CSF prior to treatment with intravenous immunoglobulin (IVIG), which can cause aseptic meningitis.
- A repeat NCS 3 to 8 weeks after onset can classify the subtype of GBS.

**Diagnostic Procedures/Other**
Sural nerve biopsy not indicated except to rule out vasculitis or amyloidosis

### TREATMENT

#### GENERAL MEASURES
- Pain treatment: NSAIDs helpful but often insufficient. Gabapentin and carbamazepine decrease opioid requirements in patients with GBS. One is not superior to others (1)[A].
- DVT prophylaxis recommended in nonambulatory patients (2)[C]
- Neostigmine or erythromycin may be effective for ileus, if present (2)[C].

#### MEDICATION

**First Line**
- IVIG 0.4 g/kg/day for 5 days or (less commonly) 1g/kg/day for 2 days
  - In severe disease, IVIG started within 2 weeks of onset hastens recovery as much as plasma exchange (PE) (3)[A].
  - In children, IVIG hastens recovery compared with supportive care alone (3)[A].
  - Combined treatment with IVIG and PE confers no clinically significant benefit (3)[A].
- PE:
  - Compared with supportive treatment alone, those treated with PE are quicker to recover walking (NNT 7), have less requirement and shorter duration for mechanical ventilation (NNT 8), recover full muscle strength more quickly (NNT 8), and have fewer severe sequelae at 1 year (NNT 17) (4)[A].
  - Higher risks of relapse found with PE versus supportive care with no
difference in severe infection or mortality (4)[A]
– In mild GBS, two sessions of PE are superior to none. In moderate GBS, four sessions are superior to two. In severe GBS, six sessions are not significantly better than four (4)[A].
– PE is most beneficial if started within 7 days of disease onset. PE still helpful up to 30 days (4)[A].
– Value of PE in children <12 is unknown.

**Second Line**

- Corticosteroids: not beneficial as monotherapy or as combined treatment. Low-quality evidence suggests steroids delay recovery (5)[A].
- CSF filtration is no different than PE (6)[B].
- Interferon β and brain-derived neurotrophic factor no different than placebo (6)[B]

**ADDITIONAL THERAPIES**

- Physical and occupational therapy improves fatigue and functional abilities (2)[C].
- Speech and language therapy improves swallowing function, if affected (2) [C].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Tripterygium polyglycoside hastened recovery significantly more than corticosteroids (NNT 4), in one small trial (6)[A].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Admit patients with suspected GBS.
- Closely monitor respiratory status with serial measurement of vital capacity (VC) and static inspiratory and expiratory pressures (PI\text{max} and PE\text{max}).
- Predictors of respiratory failure:
  – Rapid progression: ≥3 days between onset of weakness and hospital admission
  – Facial and/or bulbar weakness
  – VC decrease >30%
  – Medical Research Council (MRC) sum score indicating muscle weakness: 0
to 5/5 muscle strength grading for bilateral upper arm abductors, elbow flexors, wrist extensors, hip flexors, knee extensors, and foot dorsal flexors totaling 60 points

- Indications for intubation:
  - VC <20 mL/kg
  - PI\text{max} <30 cm H\text{2}O
  - PE\text{max} <40 cm H\text{2}O
- Prevent complications of immobilization with DVT prophylaxis and frequent turning.
- Respiratory care, aspiration precautions, pulmonary toilet
- Monitor bowel and bladder function for ileus and urinary retention.
- Begin immediate physical therapy to preserve passive range of motion.
- Mildly affected patients who can walk unaided and are stable for >2 weeks are unlikely to experience disease progression and may be managed as outpatients. Monitor bowel and bladder function for ileus and urinary retention.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Patients require close monitoring of respiratory, cardiac, and hemodynamic function, typically in the ICU setting.
- Pulmonary function testing (VC, respiratory frequency) q2–6h in the progressive phase and q6–12h in the plateau phase
- Monitor bulbar weakness and ability to handle airway secretions.
- Telemetry in patients with severe disease

**PATIENT EDUCATION**

Emphasize expectation for significant recovery and explain phases of illness.

**PROGNOSIS**

- If untreated, three phases of illness:
  - Initial progressive phase up to 4 weeks with highest risk of death and complication
  - Variable plateau phase
– Recovery phase (weeks to months): return of proximal then distal strength
• Most recovery occurs within the first year.
• 80% recover within 6 to 12 months with maximum 18 months past onset.
• 20% with residual disability after 1 year:
  – Bilateral footdrop, intrinsic hand muscle wasting, sensory ataxia, dysesthesia
  – Half with severe disability
• Factors associated with poor functional outcome:
  – Age >60 years, rapid progression, severe disease indicated by GBS disability score or MRC sum score, preceding diarrhea, positive C. jejuni or CMV serology, axonal degeneration, need for mechanical ventilation

COMPLICATIONS
• 3–7% mortality in Europe and North America. Older patients, those with severe disease have highest risk.
• 20–30% require mechanical ventilation.
• 70% develop autonomic dysfunction with hemodynamic instability, urinary retention, ileus, and anhidrosis.
• 10% have relapse.
• ~2% develop relapsing CIDP.

REFERENCES
ADDITIONAL READING

CODES

ICD10

G61.0 Guillain-Barré syndrome

CLINICAL PEARLS

- Suspect GBS in cases of ascending flaccid paralysis with areflexia and an antecedent history of viral respiratory illness or gastroenteritis.
- When GBS is suspected, evaluate VC and inspiratory force for signs of respiratory compromise.
- Uncomplicated GBS has a slow spontaneous recovery. Treatment with IVIG or PE speeds rate of recovery and reduces disability.
- The most useful diagnostic tests for GBS are nerve conduction studies and LP.
- GBS risk following native influenza virus infection is 40 to 70 times greater than after seasonal influenza vaccination.
GYNECOMASTIA
Franklyn C. Babb, MD, FAAFP

BASICS
DESCRIPTION
- Benign glandular proliferation of male breast tissue
- Increase in estrogens relative to androgens leads to the development of gynecomastia.
- Gynecomastia can be transient and represent the normal physiologic changes that occur in utero or in adolescence. However, gynecomastia presenting or persisting in adulthood is typically pathologic in nature.
- Pseudogynecomastia which is lipomastia (subareolar fat)

EPIDEMIOLOGY
- 60–90% of infants have transient gynecomastia (1).
- 50–60% of pubertal males have mild transient gynecomastia (onset at 10 to 12 years of age and resolution by age 18 years in most individuals) (1).
- Up to 70% of men between 50 and 69 years of age report gynecomastia (1).

ETIOLOGY AND PATHOPHYSIOLOGY
Increase in estrogen activity relative to androgen activity leads to the development of gynecomastia (2). Estrogen stimulates ductal cell hyperplasia, facilitates ductal branching and lengthening, increases vascularity, and results in the proliferation of periductal fibroblasts. These changes occur within 12 months and are followed by fibrosis in the later stages of gynecomastia. Multiple factors can alter the estrogen to androgen ratio and precipitate gynecomastia:
- Decrease in androgen production
- Increase in estrogen production
- Increase in peripheral conversion to estrogen
- Inhibition of the androgen receptor
- Increase in the level of sex hormone–binding globulin (SHBG) or the affinity of androgens to SHBG (decreases free or bioavailable testosterone)
- Displacement of estrogen relative to testosterone from SHBG due to medications
RISK FACTORS

Gynecomastia can be physiologic or pathologic in nature.

- Physiologic gynecomastia presents in infants and adolescent boys and resolves spontaneously.
  - Neonatal gynecomastia: The placenta converts dehydroepiandrosterone (DHEA) and dehydroepiandrosterone sulfate (DHEA-S) to estrone and estradiol resulting in transient gynecomastia.
  - Adolescent gynecomastia: Transient increases in estradiol levels at the onset of puberty lead to gynecomastia.
- Pathologic gynecomastia refers to persistent or adult-onset gynecomastia. 25% of cases are idiopathic in nature most likely secondary to age-associated decline in free testosterone and adipose tissue-mediated aromatase activity.
- Multiple medications have been implicated (1).

ALERT

Illicit drugs: marijuana, heroin, methadone, alcohol, amphetamines, and over-the-counter body building supplements

- Hormones: androgens, anabolic steroids, estrogens, estrogen agonist, and hCG
- Antiandrogens or inhibitors of androgen synthesis: bicalutamide, flutamide, nilutamide, cyproterone, and GnRH agonists (leuprolide and goserelin)
- Anti-infectives: metronidazole, ketoconazole, minocycline, isoniazid
- Anti-ulcer medications: cimetidine, ranitidine, metoclopramide, and proton pump inhibitors
- Cytotoxic agents: methotrexate, alkylating agents, and vinca alkaloids
- Cardiovascular drugs: digoxin, spironolactone, calcium channel blockers, ACEIs, amiodarone, methylldopa, reserpine, and minoxidil
- Psychoactive drugs: antidepressants, benzodiazepines, phenothiazines, antipsychotics (typical and atypical) (i.e., haloperidol and risperidone)
- Miscellaneous: HIV meds like efavirenz, others like phenytoin, penicillamine, sulindac, or theophylline
- Causes to rule out:
  - Primary hypogonadism: androgen insensitivity syndromes (defect in the androgen receptor), Klinefelter syndrome
  - Testicular tumor: germ cell (secrete human chorionic gonadotropin or hCG), Leydig cell (secrete estrogen), Sertoli cell (excessive aromatization to estrogens)
  - Adrenal tumors (secrete DHEA-S and estrogens)
  - Ectopic hCG tumors (hepatoblastoma, gastric tumors, renal cell
carcinomas)
- Cirrhosis
- Secondary hypogonadism: Kallmann syndrome or prolactinemia, which can also stimulate milk production in breast tissue
- Hyperthyroidism
- Renal disease or dialysis
- Malnutrition/starvation
- Rare (true hermaphroditism [both testicular and ovarian tissue present])

**Pediatric Considerations**
Transient gynecomastia is seen in neonates or pubertal boys; typically resolves within 6 to 24 months

**Geriatric Considerations**
Age-associated decline in testosterone production and increase in SHBG production leads to low free testosterone levels in the elderly population. Furthermore, the increased ratio of fat mass to lean mass noted with aging leads to adipose tissue—mediated peripheral conversion of androgens to estrogen. Medications also play a significant role in the development of gynecomastia in this population.

**COMMONLY ASSOCIATED CONDITIONS**
- Prostate carcinoma—treatment with estrogen and antiandrogen leads to gynecomastia in 50–75% of patients.
- Cirrhosis
- Primary hypogonadism; especially Klinefelter syndrome—congenital abnormality leads to primary hypogonadism and gynecomastia. These patients are at risk for breast cancer and need regular breast exams.
- Testicular tumors; Leydig or Sertoli cell tumors especially when associated with Peutz-Jeghers syndrome or Carney complex

**DIAGNOSIS**

**HISTORY**
- Inquire about duration of breast growth, increase in breast tissue size, and associated breast pain and discharge.
- If suspicious of hypogonadism, ask about erectile dysfunction, muscle mass,
and decreased shaving frequency and libido.

- Obtain a complete medical history including headache, loss of vision, loss of appetite, weight loss, malignancy, thyroid disorders, liver disease, renal disease, and genetic abnormalities.
- Obtain a family history including Carney complex and Peutz-Jeghers syndrome.
- Review medication list extensively and inquire about the use of illicit substances.
- Question about herbal supplements, marijuana use, and OTC cimetidine (Tagamet) use.

**PHYSICAL EXAM**

- Careful breast exam to evaluate characteristics:
  - Firm, concentric glandular tissue beneath the nipple and areola palpable by pinching the thumb and forefinger together from either side of the breast toward the nipple
  - May involve one or both breasts
  - Usually asymptomatic but may be painful or tender if it is of recent onset
  - Off center, hard, fixed mass is concerning for malignancy, although palpation of subareolar fat is more consistent with pseudogynecomastia.
  - Breast discharge should raise concern for malignancy or prolactinemia. In the latter, the discharge is typically clear or milky.
- Thyroid exam (Evaluate for diffuse enlargement and palpable nodules and check extremities for tremor and brisk reflexes.)
- Abdominal exam (Evaluate for masses and liver size.)
- Genitourinary exam (Evaluate for testicular size, hair pattern, and presence of ovary or uterus.)
- Visual field exam (Evaluate for peripheral field defect.)

**DIFFERENTIAL DIAGNOSIS**

- Pseudogynecomastia—fat deposition without glandular proliferation often seen in obesity
- Breast cancer—on exam, the lesion is typically unilateral; firm; eccentric to the nipple; and associated with skin dimpling, nipple retraction/discharge, and lymphadenopathy.
- Lipomas
- Sebaceous cyst
- Dermoid cyst
- Mastitis
Hematoma
Hamartoma

DIAGNOSTIC TESTS & INTERPRETATION

- Laboratory and radiologic investigations should be tailored to fit history and physical exam findings.
- Idiopathic gynecomastia is a diagnosis of exclusion, and therefore, laboratory tests to rule out medical conditions associated with gynecomastia is recommended.

Initial Tests (lab, imaging)

- Luteinizing hormone (LH)—elevated in primary hypogonadism and decreased in secondary hypogonadism [3][C]
- Morning total and free testosterone—decreased testosterone level in hypogonadism [3][C]
- hCG—elevated in germ cell tumors and ectopic hCG tumors [3][C]
- Estradiol—elevated in Leydig cell tumors, Sertoli cell tumors, adrenal tumors, and with increased aromatase activity [3][C]
- Urine for drugs of abuse (UDA)
- Other tests to consider include creatinine, liver function test, thyroid function tests, and prolactin.

Follow-Up Tests & Special Considerations

Consider imaging studies based on laboratory findings.

- Testicular ultrasound (testicular tumor)
- Chest x-ray (CXR) and abdominal CT/MRI (extragonadal germ cell tumor, ectopic hCG tumor, and adrenal tumor)
- MRI of pituitary (pituitary tumor)

Diagnostic Procedures/Other

Based on physical exam findings, consider biopsy of breast mass to rule out malignancy (i.e., off center, hard, fixed, discharge).

Test Interpretation

- Elevated hCG: Check testicular ultrasound. If positive for a mass, likely a testicular germ cell tumor. If the ultrasound is negative, consider extragonadal germ cell tumor or hCG-secreting neoplasm and order a CXR and CT abdomen [3][C].
- **Elevated LH**: if in relation to low testosterone, likely primary hypogonadism. If elevated in relation to high testosterone, check thyroid-stimulating hormone (TSH) and free thyroxine (FT4). If FT4 is elevated and TSH is suppressed, likely hyperthyroidism; if TSH and FT4 are normal, likely androgen resistance (3)[C]

- **Normal or decreased LH in relation to low testosterone**: Check prolactin level. If prolactin is elevated, likely due to a prolactin-secreting pituitary tumor; if normal, likely due to secondary hypogonadism (3)[C]

- **Normal or decreased LH in relation to increased estradiol**: Check testicular ultrasound. If positive for a mass, likely Leydig or Sertoli cell tumor. If negative for mass, check CT abdomen to evaluate the adrenals. If mass is present, possible adrenal neoplasm versus adenoma; if no mass is detected, then likely due to increased aromatase activity in extraglandular tissue (3)[C]

- **hCG, LH, testosterone, and estradiol are normal**: likely idiopathic or medication/drug-induced gynecomastia (3)[C]

---

**TREATMENT**

**GENERAL MEASURES**

- Gynecomastia usually regresses spontaneously within 6 months of onset. This is true even for adult males. Therefore, patients can be monitored for the first 6 months and treatment considered if gynecomastia persists.

- The histologic changes early in the disease process can be reversed with medical therapy. However, with the development of fibrotic tissue, surgery is typically required. Typically, 1 to 2 years after the onset of gynecomastia, fibrotic changes can be seen and medical intervention is less effective (4)[C].

- Neonatal and pubertal gynecomastia spontaneously resolves within 6 to 24 months. Persistent pubertal gynecomastia (>24 months) occurs in 8% of pubertal boys. In adult males, 75% of gynecomastia is secondary to persistent pubertal gynecomastia, medications, and idiopathic conditions. Only 25% is related to an underlying medical condition.

- All illicit drug use and offending medications should be stopped if appropriate and patients monitored for clinical improvement.

- Underlying medical conditions need to be treated (i.e., testosterone replacement for hypogonadal men, dopamine agonist for prolactinoma, appropriate treatment for thyrotoxicosis, and tumor resection).

- Medical and surgical therapy to reduce gynecomastia should be considered in
patients with significant physical or psychological discomfort.

**MEDICATION**

- There are no FDA-approved medications for the treatment of gynecomastia, but clinical trials involving selective estrogen receptor modulators (SERMs) and aromatase inhibitors demonstrate partial regression and symptom relief (i.e., breast tenderness).
  - SERMs: Clinical trials of both tamoxifen (10 to 20 mg/day) and raloxifene (60 mg/day) showed partial reduction in pubertal gynecomastia in 90% of study participants after 3 to 9 months, but 40% of patients in both treatment groups were not satisfied with the final results and underwent surgical removal (4)[B]. Tamoxifen has also been shown to reduce breast tenderness and prevent the development of gynecomastia in prostate cancer patients on androgen deprivation therapy. Therefore, SERMs (particularly tamoxifen) can be considered in men with 6 to 12 months of severe, painful gynecomastia symptoms (5)[B].
  - Aromatase inhibitors block peripheral conversion of androgens to estrogens. In prostate cancer patients, anastrozole prevented the development of gynecomastia in patients undergoing androgen deprivation therapy (2)[B].

**ISSUES FOR REFERRAL**

- Refer patients to an endocrinologist if abnormally elevated hormone levels are confirmed.
- If patients have refractory gynecomastia despite medical therapy and have prolonged gynecomastia characterized by the late fibrotic stage or symptoms concerning for breast cancer, referral to a surgeon would be appropriate.

**ADDITIONAL THERAPIES**

In clinical trials, prophylactic radiotherapy (10 to 15 Gy in one fraction over 3 days) prevented the development of gynecomastia in prostate cancer patients on androgen deprivation therapy. Higher doses (20 Gy in five fractions) improved pain symptoms in the same population (5)[B].

**SURGERY/OTHER PROCEDURES**

Surgery to remove breast tissue is recommended if:

- Gynecomastia does not regress within 12 months either spontaneously or after medical therapy.
• Significant discomfort (i.e., pain, tenderness)
• Causes embarrassment or anxiety
• Biopsy suspicious for malignancy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
• Every 3 to 6 months for 24 months; consider medical therapy (i.e., tamoxifen) if severe, painful symptoms persist after 6 to 12 months and surgery after 12 to 24 months. In individuals with asymptomatic or mild disease, routine yearly breast and physical exam is recommended.
• Patients with Klinefelter syndrome are at increased risk of breast cancer and should have routine breast exams done.

PATIENT EDUCATION
Patients should be encouraged to do periodic breast examination and to alert their clinical provider if a nodule is palpated in the breast or axilla, skin discoloration occurs, or nipple discharge develops.

PROGNOSIS
• Good in physiologic cases, as they often regress spontaneously within 3 to 6 months (3)
• Majority of patients experience regression once underlying disorder is treated or offending agents are eliminated (3).
• The majority of patients, who undergo surgery, are satisfied with the postop cosmetic appearance (6).

Algorithm: Gynecomastia

**CODES**

**ICD10**

N62 Hypertrophy of breast

**CLINICAL PEARLS**

- Gynecomastia can be transient and represents the normal physiologic changes in neonates or adolescents. However, gynecomastia presenting or persisting in adulthood is typically pathologic in nature.
- Thorough history and physical exam should be performed on all patients and offending medications eliminated.
- Lab and radiologic studies should be conducted to rule out medical conditions associated with gynecomastia including thyrotoxicosis, prolactinemia, hypogonadism, testicular tumors, adrenal tumors, and ectopic hCG tumors. Treatment should be tailored to exam findings.
- ~25% of gynecomastia is idiopathic in nature, and treatment should focus on symptom control.
Clinical trials of SERMs, aromatase inhibitors, and radiation therapy seem promising. Surgery is the treatment of choice for refractory gynecomastia.
HAMMER TOES
Nicole Nelson, DO  David Bode, MD

BASICS
Deformities of digits 2 to 5 (“lesser” digits) of the foot

DESCRIPTION
- Plantar flexion deformity of the proximal interphalangeal (PIP) joint with varying degrees of hyperextension of the metatarsophalangeal (MTP) and distal interphalangeal (DIP) joint; primarily in sagittal plane (1)
- Can be flexible, semirigid, or fixed
  - Flexible: passively correctable to neutral position
  - Semirigid: partially correctable to neutral position
  - Fixed: not correctable to neutral position without intervention

EPIDEMIOLOGY
Most common deformity of lesser digits, typically affecting only one or two toes:
- Second toe is the most commonly involved.

Incidence
- Undefined
- Increases with age, duration of deformity (from flexible to rigid)

Prevalence
- Predominant sex: female > male (2)
  - Female predominance from 2.5:1 to 9:1, depending on age group
- Can range from 1% to 20% of population studied
- Blacks are more often affected than whites (2).

ETIOLOGY AND PATHOPHYSIOLOGY
- Can be congenital or acquired
- Biomechanical dysfunction results in loss of function of extensor digitorum longus (EDL) tendon at the PIP joint and the flexor digitorum longus (FDL) tendon at the MTP joint; the intrinsic muscles sublux dorsally as the MTP
hyperextends. This results in plantar flexion of the PIP joint and hyperextension of the MTP joint (2).

- Specific pathomechanics vary by etiology:
  - Toe length discrepancy or narrow footwear toe box induces PIP joint flexion by forcing digit to accommodate shoe.
    - May also lead to MTP joint synovitis secondary to overuse, with elongation of plantar plate and MTP joint hyperextension.
  - Rheumatoid arthritis (RA) causes MTP joint destruction and resultant subluxation.
  - Any condition that compromises intra-articular and periarticular tissues, such as second ray longer than first, inflammatory joint disease, neuromuscular conditions, improper-fitting shoes, and trauma (3)
  - Damage to joint capsule, collateral ligaments, or synovia leads to unstable PIP joint or MTP joint.

**Genetics**
- Significant heritability rates of 49–90% (4)
- Specific genetic markers are not identified.

**RISK FACTORS**
- Pes cavus, pes planus
- Hallux valgus
- Metatarsus adductus
- Ankle equinus
- Neuromuscular disease (rare)
- Trauma; improperly fitted shoes (narrow toe box) and/or tight hosiery
- Abnormal metatarsal and/or digit length
- Inflammatory joint disease (e.g., RA)
- Connective tissue disease
- Diabetes mellitus

**GENERAL PREVENTION**
- Proper fitting of shoes. Use of pressure-dispersive footwear helps reduce pain.
- Foot orthoses modulate biomechanical dysfunction and muscular imbalance, preventing progression (2).
- Control of predisposing factors (e.g., inflammatory joint disease) may also slow progression.
COMMONLY ASSOCIATED CONDITIONS

- Hallux valgus
- Cavus foot
- Metatarsus adductus
- Dorsal callus

DIAGNOSIS

History and physical exam are typically sufficient for diagnosis of hammer toes. Additional tests are available to exclude other conditions.

HISTORY

- Location, duration, severity, and rate of progression of foot deformity
- Type, location, duration of pain
  - Patients often relate sensation of lump on plantar aspect of MTP joint.
- Degree of functional impairment
- Improving/exacerbating factors
- Type of footwear and hosiery worn
- Peripheral neurologic symptoms
- Any prior treatment rendered

PHYSICAL EXAM

- Note MTP joint hyperextension, PIP joint flexion, and DIP joint extension.
- Observe any adjacent toe deformities (e.g., hallux valgus, flexion contractures).
- Assess degree of flexibility and reducibility of deformity in both weight-bearing and non–weight-bearing positions (2)[C].
- Note any hyperkeratosis over the joint, ulcers, clavi (dorsal PIP joint, metatarsal head), adventitious bursa, erythema, or skin breakdown (2)[C].
- Palpate for pain over dorsal aspect of PIP joint or MTP joint.
- Drawer test of MTP joint
- Palpate web spaces to exclude interdigital neuroma.
- Neurovascular evaluation (e.g., pulses, sensation, muscle bulk)

DIFFERENTIAL DIAGNOSIS

- Hammer toe: hyperextension of the MTP and DIP joints and plantar flexion of the PIP joint
Claw toe: dorsiflexion of MTP joint and plantar flexion of the DIP joint
Mallet toe: fixed or flexible deformity of the DIP joint of the toe
Overlapping fifth toe
Interdigital neuroma
Plantar plate rupture
Nonspecific synovitis of MTP joint
Fracture; exostosis
Arthritis (e.g., rheumatoid, psoriatic)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Not required unless clinically indicated to rule out suspected metabolic or inflammatory arthropathies (2)[C]: rheumatoid factor, antinuclear antibodies (ANA), HLA-B27 serologies for inflammatory disease
- Weight-bearing x-rays of affected foot in anteroposterior (AP), lateral, and oblique views (2)[C]:
  - AP view superior for assessing MTP subluxation or dislocation
  - Lateral view is best for the evaluation of hammer toe.

Follow-Up Tests & Special Considerations
MRI or bone scan if osteomyelitis is suspected

Diagnostic Procedures/Other
- Nerve conduction studies or EMG if neurologic disorder is suspected
- Doppler or plethysmography if impaired circulation and surgery is considered
- Computerized weight-bearing pressure testing is indicated only in setting of neuromuscular deficiencies.

Test Interpretation
Histologic evaluation is not necessary before treatment.

TREATMENT
- Goal of treatment is to relieve symptoms and help patients return to their normal activity level.
- Surgical and nonsurgical interventions are available.
- Mild cases may not require treatment.
GENERAL MEASURES
Nonsurgical (conservative) treatments include
- Shoe modifications (wider and/or deeper toe box) to accommodate the deformity and decrease the pressure over osseous prominences. Avoid high-heeled shoes (2)[C].
- Toe sleeve or orthodigital padding of the hammer toe prominence (5)[C]
- Hammer toe–straightening orthotics or taping to reduce flexible deformities
- Débridement of hyperkeratotic lesions can reduce symptoms. Topical keratolytics may be helpful (2)[C].
- Shoe orthotics mitigates abnormal biomechanics.
- Physical therapy for stretching and strengthening of the toes helps preserve flexibility.

MEDICATION
For pain relief

First Line
NSAIDs may be helpful in managing symptoms of pain as well as soft tissue and joint inflammation.

ISSUES FOR REFERRAL
If nonsurgical (conservative) treatment is unsuccessful and/or impractical or patient has combined deformity of MTP joint, PIP joint, and/or DIP joint, then patient may be referred to an orthopedic surgeon or surgical podiatrist.

SURGERY/OTHER PROCEDURES
- Surgical procedures for the correction of hammer toes depend on the degree and flexibility of the contracture(s) and related abnormalities.
- Surgical interventions for flexible hammer toes include (1,3,5,6)[C]
  - PIP joint arthroplasty (most common)
  - Flexor tendon lengthening/flexor tenotomy
  - Extensor tendon lengthening/tenotomy/MTP joint capsulotomy
  - Flexor to extensor tendon transfer
  - Exostosectomy
  - Implant arthroplasty
- Surgical interventions for semirigid/rigid hammer toes include (1,3,5)[C]
  - PIP joint resection arthroplasty or arthrodesis
  - Girdlestone-Taylor flexor-to-extensor transfer
– Metatarsal shortening (Weil osteotomy)
– Exostosectomy
– Diaphysectomy of the proximal phalanx (less common)
– Middle phalangectomy (less common)
– Soft tissue releases/lengthening

- Procedures may be performed as isolated operations or in conjunction with other procedures.
- Contraindications for surgery: active infection, inadequate vascular supply, and desire for cosmesis alone

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Obtain radiographs immediately following surgery or at the first postoperative visit; subsequent x-rays as needed
- Full weight-bearing in a postoperative (surgical) shoe or other device based on the procedure(s) performed and the individual patient
- Elevate the foot to minimize swelling.
- Return to regular shoe wear after pain is controlled, swelling has subsided, and wounds have healed.
- Role and efficacy of postoperative physical therapy (3 times a week for 2 to 3 weeks) unclear

**Patient Monitoring**

In the absence of complications, the patient should be seen initially within the 1st week following the procedure(s). Frequency of subsequent visits is determined based on the procedure(s) performed and the postoperative course.

**PATIENT EDUCATION**
- Patients should be aware of mild to moderate swelling and plantar foot discomfort that may persist for many (1 to 6) months after surgery and may limit footwear options until resolved.
- MTP joint and PIP joint may remain stiff for extended periods of time.
- “Molding” of the operative toe (assuming the contours of adjacent toes) is common.
- Encourage patients to wear shoes of adequate size with “roomy” (rounded or squared) toe box.
PROGNOSIS

- Nonoperative (conservative) treatment usually alleviates pain; however, the deformity may progress.
- Surgical treatment of flexible hammer toe deformity reliably corrects the deformity and alleviates pain. Recurrence and progression are common, especially if the patient continues to wear ill-fitting shoes.
- Surgical treatment of fixed hammer toe deformity provides reliable deformity correction and pain relief. Recurrence is uncommon.

COMPLICATIONS

- Common complications specific to digital surgery include but are not limited to
  - Persistent edema
  - Recurrence of deformity
  - Residual pain
  - Excessive stiffness
  - Metatarsalgia
- Less common complications include
  - Numbness (e.g., digital nerve palsy)
  - Flail toe
  - Symptomatic osseous regrowth
  - Malposition of toe
  - Malunion/nonunion
  - Infection
  - Vascular impairment (e.g., toe ischemia, gangrene)

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Foot Pain

**CODES**

**ICD10**

- M20.40 Other hammer toe(s) (acquired), unspecified foot
- M20.41 Other hammer toe(s) (acquired), right foot
- M20.42 Other hammer toe(s) (acquired), left foot

**CLINICAL PEARLS**

- Hammer toe is a plantar flexion deformity of the PIP joint.
- Initial management of hammer toe deformity is conservative. Consider surgery if pain persists or the deformity worsens.
- Properly fitting footwear helps minimize recurrence. Patients should be aware of mild to moderate swelling and plantar foot discomfort that may persist for months after surgery and may limit footwear options until resolved.
HAND-FOOT-AND-MOUTH DISEASE
Matthew T. Melson, DO • John M. Doan, DO

BASICS

DESCRIPTION
- Common clinical syndrome caused by enterovirus serotypes
- Prevalent cause of viral exanthem often easily recognized
- Classic appearance of oral enanthem along with rash of hands and feet (classically) and potentially located elsewhere
- Rash may be macular, maculopapular, and/or vesicular.
- Synonym(s): herpangina (when affecting oral mucosa and posterior pharynx)

EPIDEMIOLOGY
- Self-limiting illness resolves in 7 to 10 days.
- Moderately contagious
- Infection is spread by direct contact with nasal secretions, saliva, blister fluid, or stool.
- Infected individuals are most contagious during the 1st week of the illness but may continue to spread illness for days to weeks after. Some exposed individuals (especially adults) may be asymptomatic but still contagious.
- The viruses that cause hand-foot-and-mouth disease (HFMD) can persist for weeks after symptoms have resolved, most commonly in stool, allowing transmission following resolution of symptoms.
- The incubation period is 3 to 7 days (1).

Incidence
- Children <5 years of age are most commonly affected, especially in daycare facilities (1,2).
- Can occur as isolated cases, outbreaks, or epidemics
- Occurs worldwide
- Vertical transmission is possible.
- Most large outbreaks occur in Southeast Asia.

ETIOLOGY AND PATHOPHYSIOLOGY
- HFMD is not the same as foot (hoof) and mouth found in cattle, and there is
no cross species infectious concern (3).

- Transmission by the fecal–oral route or contact with skin lesions or oral secretions; caused by viruses that belong to the *Enterovirus* genus and replicated in the GI tract (3)
- Most commonly coxsackievirus A16
- Also coxsackieviruses A5, A7, A9, A10, B2, B5, and enterovirus 71

**GENERAL PREVENTION**

- Hand washing, especially around food handling or diaper changes
- Exclusion of children from group settings during the first few days of the illness in the presence of open lesions in the mouth or on the skin may reduce the spread of infection.
- Hand hygiene measures are effective in reducing transmission.
- Pregnant woman should avoid contact with infected individuals.

**DIAGNOSIS**

**HISTORY**

- 1- to 2-day prodrome of fever, anorexia, malaise, abdominal pain, upper respiratory symptoms
- Fever may last 3 to 4 days
- Maculopapular rash on hands, feet, and mouth. Oral lesions may precede skin.
- Sore throat (follows fever)
- Often history of sick contacts

**PHYSICAL EXAM**

- Oral enanthem along with tender vesicles becoming ulcers on buccal mucosa, sides of tongue, and palate
- May persist for up to 1 week
- Cutaneous vesicles 3 to 5 mm in diameter start as painful maculopapular eruptions, occur typically on dorsal aspect of fingers and toes.
- May also occur on the palms, soles, buttocks, and groin
- Adults are less likely to have cutaneous findings.
- Nail dystrophies are not uncommon and may persist weeks after.
- Be mindful of CNS symptoms. Although rare, CNS involvement is possible

**DIFFERENTIAL DIAGNOSIS**
Herpetic gingivostomatitis
Aphthous stomatitis
Scabies
Chickenpox
Measles
Rubella
Scarlet fever
Roseola infantum
Fifth disease
Other enteroviral infections
Kawasaki disease
Viral pharyngitis
Varicella
Rickettsial infection (RFSF)

DIAGNOSTIC TESTS & INTERPRETATION
Clinical diagnosis is typically adequate.

Initial Tests (lab, imaging)
Culture for responsible virus (virus isolation) can be obtained from oral lesions, cutaneous vesicles, nasopharyngeal swabs, stool, and CSF, although not typically performed. PCR of throat swabs and vesicle fluid is the most efficient test if enterovirus 71 is suspected (3).

TREATMENT
Symptomatic
Avoid spicy or acidic foods to limit oral pain.
IV fluids may be required in more severe cases of dehydration.

MEDICATION
Symptomatic care using ibuprofen or acetaminophen for pain from oral ulcers or fever
Soothing mouthwashes (“magic mouthwash”) containing lidocaine do not appear to be superior to placebo and have risk of side effects when absorbed systemically (4)[B].
Pediatric Considerations
Avoid aspirin use in treating febrile illness in children due to concern of Reye syndrome—an encephalopathy associated with aspirin use in viral illness in children.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Patients with CNS manifestations or autonomic dysregulation should require hospitalization.
- Admit those with dehydration unable to maintain adequate oral hydration.

ONGOING CARE

DIET
- Encourage cold liquids (e.g., ice cream, popsicles) to prevent dehydration.
- Avoid acidic, salty, and spicy foods, as they will increase pain.

COMPLICATIONS
- Dehydration most common due to painful oral ulcerations
- CNS involvement (i.e., aseptic meningitis) is a rare complication.
- Fever >3 days and lethargy are associated with CSF pleocytosis.
- Enterovirus 71 has caused outbreaks and has been implicated in more severe disease associated with CNS infection (5).
- Cardiopulmonary complications include myocarditis, pneumonitis, and pulmonary edema.
- Nail dystrophies (loss of nails, Beau lines) are common.

(HFMD).
http://www.wpro.who.int/publications/docs/Guidancefortheclinicalmanagemeni

**CODES**

**ICD10**

- B08.4 Enteroviral vesicular stomatitis with exanthem
- B34.1 Enterovirus infection, unspecified
- B08.5 Enteroviral vesicular pharyngitis

**CLINICAL PEARLS**

- Most common: May to October
- Children <5 years of age tend to have worse symptoms than older children.
- HFMD is the most common cause of mouth sores in pediatric patients.
- Dehydration is a common problem secondary to swallowing aversions.
- Usually self-limiting, resolving in 7 to 10 days
- Careful hand washing to limit dissemination
HEADACHE, CLUSTER
Samuel C. Wang, MD • Sumana Basu, MD

BASICS
DESCRIPTION
- Primary headache disorder
- Multiple attacks of unilateral, excruciating, sharp, searing, or piercing pain; typically localized in the periorbital area and temple accompanied by signs of ipsilateral parasympathetic autonomic features, along with restlessness and agitation
- Autonomic symptoms: parasympathetic hyperactivity signs (ipsilateral lacrimation, eye redness, nasal congestion) and sympathetic hypoactivity (ipsilateral ptosis and miosis)
- Patients often pace the floor during an acute attack, as lying down seems to exacerbate the pain.
- Symptoms usually remain on the same side during a single cluster attack.
- Individual attacks last 15 to 180 minutes if untreated and occur from once every other day to 8 times per day.
- Attacks usually occur in series (cluster periods) that are often seasonal, lasting for weeks or months; separated by remission periods usually lasting months or years
- About 10–15% of patients have chronic symptoms without remissions (i.e., chronic cluster headache [CH]).

Epidemiology
Incidence
1-year incidence: 2 to 10/100,000

Prevalence
- Lifetime prevalence: 124/100,000
- Predominant sex: male > female; 2.1:1 overall
- Women often develop earlier in life (20s).
- Mean age of onset: 30 years
- Episodic/chronic ratio: 6:1
ETIOLOGY AND PATHOPHYSIOLOGY

- Complex and incompletely understood
- Proposed mechanism include the following:
  - Posterior hypothalamus activation may trigger an attack by activating trigeminal nociceptive pathways through perivascular activation and increased parasympathetic outflow, causing unilateral pain.

**Genetics**

- Usually sporadic: autosomal dominant in 5% of cases; autosomal recessive or multifactorial in other families
- Evidence varies: first-degree relatives carry 5- to 8-fold; second degree, 1- to 3-fold increased relative risk of disease
- >50% with migraine and 18% with CH in family history

**RISK FACTORS**

- Male gender
- Age (70% onset before age 30 years)
- Cigarette smoking or childhood exposure to cigarette smoke
- Family history of CH
- Head trauma

**COMMONLY ASSOCIATED CONDITIONS**

- Depression (24%)
- Increased risk of suicide secondary to the extreme nature of the pain
- Medication-overuse headache
- Asthma (9%)
- History of migraine, frequently in female patients
- Sleep apnea (30–80%)
- Increased prevalence of cardiac right-to-left shunt and patent foramen ovale (relationship unclear)

**DIAGNOSIS**

- Diagnosis is clinical.
- *International Classification of Headache Disorders* (3rd edition) criteria
- At least five attacks of severe or very severe unilateral orbital, supraorbital, and/or temporal pain lasting 15 to 180 minutes if untreated
● At least one of the following:
  – Ipsilateral
    ○ Conjunctival injection and/or lacrimation
    ○ Nasal congestion and/or rhinorrhea
    ○ Eyelid edema
    ○ Forehead and facial sweating/flushing
    ○ Sensation of fullness in the ear
    ○ Miosis and/or ptosis
● Restlessness or agitation during acute attack
● Attack frequency: one every other day to eight per day for more than half of the time during cluster periods
● Episodic CH: at least two cluster periods lasting 7 days to 1 year, separated by a pain-free interval of >1 month (80–90% of cases)
● Chronic CH: cluster-free interval of <1 month, for at least a year

**HISTORY**
● Episodic periods of headache described as excruciating, unilateral, sharp, searing, or piercing pain, typically localized in the periorbital area
● Eye redness, tearing, nasal congestion, clear rhinorrhea, sweating
● Timing of headaches often circadian in nature, usually early morning (12 AM to 3 AM) and early evening
● Presence of triggers, including vasodilators (e.g., alcohol, nitroglycerin, sildenafil), histamine, or strong odors
● Seasonal pattern of cluster periods, often recurring around the same time of the year

**PHYSICAL EXAM**
● Patients are usually seen between attacks, so physical exam is often unremarkable.
● Acute distress, crying, screaming, restlessness, and/or agitation during acute attack
● Ipsilateral lacrimation, injected conjunctivae, ptosis, and miosis during acute attack
● Edematous nasal mucosa or rhinorrhea during acute attack

**DIFFERENTIAL DIAGNOSIS**
● Other trigeminal autonomic cephalgias (e.g., paroxysmal hemicrania, short-lasting unilateral neuralgiform headache attacks with conjunctival injection
and tearing [SUNCT], hemicrania continua, hypnic headaches, trigeminal and other facial neuralgias, migraine, temporal arteritis, herpes zoster

- Secondary CH:
  - Vertebral or carotid artery dissection, brain arteriovenous malformations, intracranial artery aneurysms
  - Pituitary tumors
  - Nasopharyngeal carcinoma
  - Maxillary sinus with foreign body/sinusitis
  - Cavernous hemangioma
  - Meningiomas/carcinomas/metastases

**DIAGNOSTIC TESTS & INTERPRETATION**

- Diagnosis is primarily clinical.
- Diagnosis is often delayed (>40% report 5-year delay in diagnosis).
- Consider neuroimaging (MRI/CT head and vascular imaging of brain) if:
  - Abnormal neurologic exam
  - Suspect secondary CH
  - “Red flag” headache symptoms are present.

**TREATMENT**

Many of the medications discussed in the following section are used off-label in the treatment of CH.

**GENERAL MEASURES**

- Avoid major changes in sleep habits.
- Stop smoking.
- Avoid use of alcohol during cluster period.
- Avoid extreme changes in altitude due to changes in oxygen levels.
- Avoid exposure to chemical agents/solvents or other known triggers for the patient.

**MEDICATION**

- Avoid pain medications, especially narcotic analgesics, for acute attacks.
- Goal is abortion of acute attack and transitional prophylaxis for expected duration of the cluster period; long-term prophylaxis used for chronic CH
- Assess cardiovascular risk before instituting a vasoactive drug, such as triptans or ergot derivatives.
**First Line**

- For acute attacks:
  - Oxygen
    - 100% at 7 to 12 L/min for 15 minutes via nonrebreather mask or demand valve oxygen mask while sitting or standing provides relief within 15 minutes. High flow used if resistant to low-flow oxygen; excellent side effect profile (1,2)[A]

**ALERT**

Avoid high-flow oxygen in severe chronic obstructive pulmonary disease (COPD) as it might reduce respiratory drive.

- Sumatriptan
  - 6 mg SC, max 2 times per day with at least 1 hour between injections is most effective medication for acute attacks; NNT = 2.4 and 3.3 for headache relief and pain free in 15 minutes, respectively
  - Nasal spray: 20 mg. May repeat in 2 hours, max dose 40 mg/24 hr; NNT = 3.2 for headache relief at 30 minutes (1,3)[A]

- Zolmitriptan
  - Nasal spray: 5- and 10-mg dosage both effective. May repeat in 2 hours, max two times per day; NNT = 12 and 4.9 for headache relief in 15 minutes for 5 and 10 mg, respectively
  - Tablet: 5- and 10-mg dosage both effective. May repeat in 2 hours, max dose 10 mg/24 hr; NNT = 6.7 and 4.5 for headache relief in 30 minutes for 5 and 10 mg, respectively (1,3)[A]

**ALERT**

Triptans are contraindicated in ischemic cardiac disease, stroke, uncontrolled hypertension, Prinzmetal angina, basilar migraine, hemiplegic migraine, ischemic bowel disease, and peripheral vascular disease.

- For prophylaxis:
  - Used at start of cluster period to prevent and shorten further attacks. Start as soon as possible:
    - Verapamil
      - Start at 80 mg TID and increase by 80 mg/week to 480 mg and then 80 mg every 2 weeks if needed. Short- or long-acting equivalent. Most patients respond to daily dose of 200 to 480 mg, but up to 960 mg/day may be needed; NNT = 1.2 (4)[C]
**ALERT**
ECG monitoring is required for verapamil dose >400 mg/day because of risk of bradycardia, prolonged PR interval, RBBB, or complete heart block. Avoid grapefruit juice due to CYP3A4 inhibition (4)(C).

**Second Line**
- For acute attacks:
  - Lidocaine/cocaine: 10 mg (1 mL) of lidocaine or 40 to 50 mg of 10% cocaine intranasal. No well-controlled randomized controlled trials (RCTs) done. Most common side effects are nasal congestion, unpleasant taste.
  - Octreotide: SC 100 μg. Can be considered in patients when triptans are contraindicated. Main side effect is GI upset.
- For prophylaxis:
  - Melatonin: 10-mg regular-release tablet in late evening showed reduction in headache frequency versus placebo in small RCT. No side effects were reported.
  - Lithium: Start 300 mg BID; titrate to therapeutic range of 0.4 to 0.8 mEq/L. Can increase to 300 mg TID in 1 week and then as tolerated. Two RCTs done; one was positive, one was negative. Must monitor drug levels, liver, renal, and thyroid function. Caution with nephrotoxic drugs, diuretics. Monitor for CNS side effects.
  - Civamide: 100 μL of 0.025% into each nostril daily. Only studied in episodic CH in one trial of 28 patients. Most common side effects were nasal burning, lacrimation, pharyngitis, and rhinorrhea (not available in the United States).
  - Capsaicin: 0.025% ipsilateral nostril for 7 days showed benefit in one small RCT.
  - Warfarin: for refractory chronic CH. One crossover RCT showed reduction in attack frequency during treatment period compared to placebo period. Patients were treated to an INR goal of 1.5 to 1.9. NNT = 2.6 (1)[B]. Weigh risk of bleeding complications against benefit.

**ADDITIONAL THERAPIES**
Transitional prophylaxis:
- Used to reduce attack frequency until longer term preventive treatment becomes effective. Longer term maintenance agents are started concurrently.
- Steroids: Several open studies suggested benefit but no rigorous trials to prove efficacy. Studies support 60 to 80 mg/day (initial dose) prednisone with a
taper no longer than 18 days to avoid side effects; adverse effects for short-term use: insomnia, psychosis, hyponatremia, edema, hyperglycemia, peptic ulcer (4)[C]

- Suboccipital steroid injection: 3.75 mg of cortivazol injected into the suboccipital area on the ipsilateral side of the headache; single injection or series of three injections, given 48 to 72 hours apart, reduces attack frequency during cluster period when used as add-on therapy to verapamil; NNT = 2.5 (5)[B]

- Dihydroergotamine (DHE): 1 mg injected SC/IM BID-TID for up to a week. Controlled studies are lacking (4)[C].

**ALERT**

Ergotamines are contraindicated in patients with CV disease and cannot be used with triptans; black box warning against using concomitantly with 3A4 inhibitors, such as protease inhibitors and macrolide antibiotics

**Pregnancy Considerations**

- Collaboration between headache specialist, obstetrician, pediatrician, and lactation specialist is recommended.
- Patient should be informed of limited data on treatment efficacy versus safety.
- For acute treatment, oxygen is most appropriate first-line therapy. Intranasal lidocaine (pregnancy Category B) can be used as second-line therapy and has no adverse effects with breastfeeding (6)[C].
- For transitional prophylaxis, steroids (pregnancy Category C/D) can be used, but systemic use should be avoided in 1st trimester (6)[C].
- As preventive therapy, verapamil (pregnancy Category C) remains the preferred option. Use of SC or intranasal sumatriptan and zolmitriptan (pregnancy Category C) should be limited as much as possible. Avoid ergotamines (pregnancy Category X) (6)[C].

**ISSUES FOR REFERRAL**

Consider a neurology or headache center referral for refractory or complicated patients.

**SURGERY/OTHER PROCEDURES**

- No evidence for Botox or hyperbaric oxygen treatment
- Surgery may be considered only for patients who are refractory to, or have contraindications to, medical therapy.
• Various techniques focus on stimulation or ablation of segments of trigeminal nerve root and sphenopalatine ganglion. Other techniques are aimed at decreasing pain and inflammation surrounding the greater occipital nerve.
• Neurostimulation
  – Multicenter RCT showed efficacy of sphenopalatine ganglion stimulation (SPG) compared to sham treatment.
  – Bilateral occipital nerve stimulation (ONS) has been shown to reduce severity and attack frequency in chronic CH patients.
  – Deep brain stimulation (DBS) of the hypothalamus has shown a positive response rate but carries risks of stroke, hemorrhage, and death.
  – One double-blind, sham-controlled study of noninvasive vagal nerve stimulation used as adjunctive treatment in acute CH did not show any significant difference between groups. Another RCT noted sustained reductions in chronic CH when used in conjunction with standard therapy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Intractable, severe pain
• Suicidal ideation

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
• Anticipate cluster bouts and initiate early prophylaxis.
• Monitor for depression and suicidal ideation, especially in those with chronic CH.
• Watch for adverse medication responses and side effects, such as unmasking of underlying cardiovascular disorder, when using medications to treat CH.

PROGNOSIS
• Unpredictable but often chronic course
• With increasing age, attack frequency often decreases.
• Possibility of transformation of episodic cluster to chronic cluster

COMPLICATIONS
• Depression and suicide
• Side effects of medication, including unmasking of coronary artery disease

SEE ALSO

Algorithm: *Headache, Chronic*

CODES
ICD10
- G44.009 Cluster headache syndrome, unspecified, not intractable
- G44.019 Episodic cluster headache, not intractable
- G44.029 Chronic cluster headache, not intractable

CLINICAL PEARLS
- Cluster headaches are uncommon but very disabling.
- Patients are often agitated and restless during the acute attack.
- High-flow oxygen and triptans, not narcotics, are first-line therapy for acute attacks.
- Among triptans, injected forms are more effective than nasal sprays, which are more effective than oral tablets.
- Abortive, transitional, and prophylactic treatment must all be considered.
HEADACHE, MIGRAINE

Benjamin N. Schneider, MD

BASICS

DESCRIPTION

Recurrent headache disorder manifesting in attacks lasting 4 to 72 hours. Typical characteristics are unilateral location, pulsating quality, moderate or severe intensity, aggravation by physical activity, and association with nausea and/or photophobia and phonophobia (1).

- Most frequent subtypes of migraine (1):
  - Without aura (common migraine): defining >80% of attacks, often associated with nausea, vomiting, photophobia, and/or phonophobia
  - With aura (classic migraine): visual or other types of fully reversible neurologic phenomenon lasting 5 to 60 minutes
  - Chronic (transformed) migraine: chronic headache pattern evolving from episodic migraine. Migraine-like attacks are superimposed on a daily or near-daily headache pattern (e.g., tension headaches) >15 headache days/month for at least 3 months.
  - Menstrual-related (molimina) migraine: associated with onset of menstrual period

- Rare but important subtypes (1):
  - Status migrainosus: debilitating migraine lasting >72 hours
  - With brainstem aura (basilar migraine): brainstem symptoms—dysarthria, vertigo, tinnitus, or ataxia, which are fully reversible, lasting 5 to 60 minutes
  - Hemiplegic migraine: aura consisting of fully reversible hemiplegia and/or hemiparesis
  - Recurrent painful ophthalmoplegic neuropathy (ophthalmoplegic migraine): neuralgia accompanied by paresis of an ocular cranial nerve with ipsilateral headache
  - Retinal: repeated attacks of monocular visual disturbance, including scintillations, scotomata, or blindness, associated with migraine headache

EPIDEMIOLOGY

Female > male (3:1)
Prevalence

- Affects >28 million Americans
- Adults: women 18%; men 6%

ETIOLOGY AND PATHOPHYSIOLOGY

Trigeminovascular hypothesis: Hyperexcitable trigeminal sensory neurons in brainstem are stimulated and release neuropeptides, such as substance P and calcitonin gene-related peptide (CGRP), leading to vasodilation and neurogenic inflammation.

Genetics

- >80% of patients have a positive family history.
- Familial hemiplegic migraine has been shown to be linked to chromosomes 1, 2, and 19 (1).

RISK FACTORS

- Family history of migraine
- Female gender
- Stress
- Menstrual cycle, hormones
- Sleep pattern disruption
- Diet: skipped meals (40–56%), alcohol (29–35%), chocolate (19–22%), cheese (9–18%), caffeine overuse (14%), monosodium glutamate (MSG) (12%), and artificial sweeteners (e.g., aspartame, sucralose)
- Medications: estrogens, vasodilators

GENERAL PREVENTION

- Avoid precipitants of attacks.
- Lifestyle modifications are the cornerstone of prevention: sleep hygiene, stress management, healthy diet, and regular exercise.
- Biofeedback, education, and psychological intervention
- Prophylactic medication if attacks are frequent, severely debilitating, or not controlled by acute interventions

COMMONLY ASSOCIATED CONDITIONS

- Depression, psychiatric disorders
- Sleep disturbance (e.g., sleep apnea)
- Cerebral vascular disease
- Peripheral vascular disease
- Seizure disorders
- Irritable bowel syndrome
- Obesity
- Medication overuse headache (MOH)

**DIAGNOSIS**

Migraine is a clinical diagnosis; thorough history and neuro examination are usually all that are necessary.

**HISTORY**

- Screening mnemonic “POUND”: Pulsating, duration of 4 to 72 hours, Unilateral, Nausea, Disabling
  - + Likelihood ratio (LR) = 24 for migraine diagnosis if 4 of 5 criteria present
  - + LR = 0.41 for migraine diagnosis if ≤2 criteria present (2)
- Headache usually begins with mild pain escalating into unilateral (30–40% bilateral) throbbing (40% nonthrobbing) pain lasting 4 to 72 hours.
- Intensified by movement and associated with systemic manifestations: nausea (87%), vomiting (56%), diarrhea (16%), photophobia (82%), phonophobia (78%), muscle tenderness (65%), light-headedness (72%), and vertigo (33%)
- May be preceded by aura
  - Visual disruptions are most common—scotoma, hemianopsia, fortification spectra, geometric visual patterns, and occasionally hallucinations.
  - Somatosensory disruption in face or arms
  - Speech difficulties
- Obtain headache profile: number of headaches per month, number of days per month headaches limit daily activities, and frequency and amount of all headache medications used.
- Migraine disability assessment (MiDAS) is a useful tool to assess level of disability and correlates well with headache diaries.
- Identify possible triggers (e.g., stress, sleep disturbance, food, caffeine, alcohol).

**PHYSICAL EXAM**

Neurologic exam should be performed including funduscoppy; abnormalities consistent with other causes for severe headaches MIGHT include the following:
Gait abnormalities and other new cerebellar findings
- Loss of gross and/or fine motor function
- Altered mental status including possible hallucinations (visual, auditory, olfactory)
- Short-term memory loss
- Papilledema

**DIFFERENTIAL DIAGNOSIS**
- Other primary headache syndromes
- Secondary headaches: tumor, infection, vascular pathology, prescription, or illicit drug use (MOH).
- If focal neurologic signs/symptoms are present, consider transient ischemic attack (TIA) or stroke.
- Psychiatric disease
- Rarely, atypical forms of epilepsy

**DIAGNOSTIC TESTS & INTERPRETATION**

Neuroimaging is appropriate ONLY with suspicious symptomatology and/or an abnormality on physical examination (3). Other red flags include the following:
- New onset in patient >50 years of age
- Change in established headache pattern
- Atypical pattern or unremitting/progressive neurologic symptoms
- Prolonged or bizarre aura
- Data are insufficient to make evidence-based recommendations regarding relative sensitivity of MRI compared with CT in the evaluation of migraine or other nonacute headache.
- EEG is NOT indicated unless evaluating loss of consciousness or altered mental status.

**Pediatric Considerations**

NSAIDs and triptans appear to be effective for the acute treatment of children and adolescents with migraine. Triptans may have better efficacy than NSAIDs but also have higher rates of side effects. Not all triptans are approved for use in children (4).

**Pregnancy Considerations**
- Frequency may decrease in 2nd and 3rd trimesters.
- Nonpharmacologic methods are preferred.
No treatment drug has FDA approval in pregnancy
- Acetaminophen (category C) triptans, antiemetics, and short-acting opioids can be considered for acute headaches during pregnancy.
- Ergotamines are contraindicated (category X).
- Avoid herbal remedies.
- Sumatriptan, naratriptan, and opiates are pregnancy category C—risk cannot be ruled out, but early data suggest no increase in birth defects.
- Sumatriptan by injection is ideal for breastfeeding women with disabling migraines.
- Propranolol (category C) is effective for prophylaxis during pregnancy and lactation.

**TREATMENT**

**GENERAL MEASURES**
- Most patients manage attacks with self-care.
- Cold compresses to area of pain
- Withdrawal from stressful surroundings
- Sleep is desirable.
- See also “General Prevention.”

**MEDICATION**

- **First-line abortive treatments**
  - Mild to moderate attacks:
    - Acetaminophen is effective and when combined with metoclopramide has relief rates similar to triptans (5)[A].
    - NSAIDs are inexpensive and effective in up to 60% of cases (5)[B].
    - Aspirin-acetaminophen–caffeine (Excedrin Migraine) is an inexpensive, OTC treatment with efficacy higher than its components (5)[B].
  - Moderate to severe attacks:
    - Triptans when OTC agents fail for moderate attacks OR first line for severe attacks (6)[B]
      - All triptans have similar efficacy/tolerability, but patients often respond better to one triptan over another (5)[C].
    - Suggested initial doses
      - Sumatriptan 100 mg PO; 6 mg SQ; 20 mg intranasal. SQ is most rapid.
      - Eletriptan 40 mg PO
- Rizatriptan 10 mg PO
- Zolmitriptan 2.5 mg PO; 5 mg intranasal
- Naratriptan 2.5 mg PO
- Frovatriptan 2.5 mg PO
  - 44–77% of patients taking triptans report complete pain relief within 2 hours.
  - Frovatriptan and naratriptan have slow onset but long half-lives—best for people with long migraine duration/recurrence.
- Combination triptan and NSAID: Sumatriptan 85 mg/naproxen 500 mg PO at onset of headache show improved efficacy over either alone.
- Antiemetics: Dopamine antagonists are excellent adjunctive medications (5)[B].

**Contraindications to treatments**
- Avoid triptans and ergots in coronary artery or peripheral vascular disease, uncontrolled hypertension, and complicated migraine (e.g., brainstem or hemiplegic migraine).
- Do not combine triptans or use with ergots or MAOIs.
- Avoid opioids or butalbital in patients with frequent migraines.

**Precautions**
- Frequent use of acute-treatment drugs can result in MOH.
- Triptan’s adverse reactions are common and include chest pressure, flushing, weakness, dizziness, feeling of warmth, and paresthesias.

**Second-line abortive treatment**
- Dihydroergotamine: drug of choice in status migrainosus and triptan resistance
- Opiate use can contribute to MOH with use as few as 8 days per month.

**First-line preventative treatment**
- Should not be limited to pharmacologic agents; trigger reduction, biofeedback, relaxation techniques, and CBT have evidence of efficacy.
- Lifestyle modifications should be recommended for all migraine sufferers.
- ~38% of migraineurs need preventative therapy, but only 3–13% use it. Trial and error is needed to determine optimal therapy.

The American Migraine Prevalence and Prevention Study suggests prophylactic treatment when:
- Quality of life is severely impaired.
- ≥6 headache days/month, ≥4 headache days/month of moderate severity, or ≥2 headache days/month of severe impairment
- Migraines do not respond to abortive treatment.
- Frequent, very long, or uncomfortable auras occur.
Prevention of episodic migraine, divalproex, valproate, topiramate, metoprolol, and timolol are effective in reducing frequency/severity.
- NSAIDs appear effective for prevention in people with predictable triggers (menses, etc.) but pose a risk for MOH.
- For treatment/prevention of chronic migraine, botulinum toxin A (Botox) significantly reduces frequency of headache days.

ISSUES FOR REFERRAL
- Obscure diagnosis, concomitant medical conditions, significant psychopathology
- Unresponsive to usual treatment
- Analgesic-dependent headache patterns

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Riboflavin (vitamin B₂): 400 mg/day [6][B]
- Magnesium: 400 mg/day [6][B]
- MIG-99 (Feverfew): 6.25 mg TID [6][B]
- Histamine SC: 1 to 10 ng twice weekly [6][B]
- Melatonin: 3 mg nightly
- Acupuncture is as effective as prophylactic drug treatment and has fewer adverse effects.
- Butterbur use is controversial. Although effective, recent safety concerns in Europe limit its use.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission is rarely necessary unless diagnosis is not clear or in the case of status migrainosus.
- Hydration and antiemetics are central to management. Various IV dihydroergotamine protocols can be found.
- Discharge criteria judgment based on patient’s overall clinical status and patient’s ability to tolerate PO medications

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Early intervention is key at the onset of an attack.
- Preventative treatment to decrease frequency and severity of attacks, make acute treatments more efficacious, and minimize adverse drug reactions.
- Prophylactic medications can be recommended to any patient but should be offered if attacks are frequent, severely debilitating, or not controlled by acute interventions.

Patient Monitoring
- Like many chronic conditions, patients suffering from migraine headaches tend to benefit from regular office visits. Quarterly or even more frequent appointments may be necessary when headaches are suboptimally controlled.
- Monitor frequency of attacks, pain behaviors, and medication usage via headache diary.
- Encourage lifestyle modifications. Counsel patients and manage expectations.
- Regular lab monitoring is not recommended but given that migraine (especially with aura) is a risk factor for stroke, lipid assessment and other harm reduction such as tobacco cessation are reasonable.

PATIENT EDUCATION
Patient education is central to the treatment of migraines.
- Trigger identification and modification can significantly improve headache frequency.
- Setting expectations is also critical, especially with regard to prophylactic medications where success is often defined as a reduction of 50% in severity or frequency of headaches.

PROGNOSIS
- With increasing age, there may be a reduction in severity, frequency, and disability of attacks.
- Most attacks subside within 72 hours.

COMPLICATIONS
- Status migrainosus (>72 hours)
- MOH: headache 10 or more days/month for >3 months due to regular overuse of an acute or symptomatic headache medication; likelihood with butalbital > opiates > triptans > NSAIDs
- Cerebral ischemic events (rare)
REFERENCES

SEE ALSO

Algorithm: Headache, Chronic

CODES

ICD10

- G43.909 Migraine, unsp, not intractable, without status migrainosus
- G43.109 Migraine with aura, not intractable, w/o status migrainosus
- G43.409 Hemiplegic migraine, not intractable, w/o status migrainosus

CLINICAL PEARLS

- Migraine is a chronic headache disorder of unclear etiology often characterized by unilateral, throbbing headaches that may be associated with
additional neurologic symptoms.

- Accurate diagnosis of migraine is crucial.
- Consider nonspecific analgesics for mild attacks; migraine-specific treatments for more severe attacks
- Avoid opiates and barbiturates as well as frequent (>8/month) use of triptans or NSAIDs to avoid creating an MOH.
- All patients should be counseled on lifestyle modifications and trigger identification.
- In those with frequent or highly debilitating migraines, prophylactic treatment should be encouraged.
HEADACHE, TENSION
Kaelen C. Duncan, PharmD • Brandi Hoag, DO

BASICS

DESCRIPTION
- Typically characterized by bilateral mild to moderate pain and pressure; may be associated with pericranial tenderness at the base of the occiput
- Two types
  - Episodic tension–type headache (ETTH) divided into
    - Infrequent: <1 day per month
    - Frequent: ≥1 but <15 days per month
  - Chronic tension–type headache (CTTH): ≥15 days per month for >3 months
- Synonym(s): muscle contraction headache; stress headache

EPIDEMIOLOGY
Most common type of primary headache

Prevalence
- Global prevalence in adults is 42% (1).
- Lifetime prevalence is 79%.
- More prevalent among women
- Prevalence of CTTH is 3%.
- Prevalence of ETTH decreases with age, whereas the prevalence of CTTH increases with age.

ETIOLOGY AND PATHOPHYSIOLOGY
- Debatable: peripheral and/or central mechanisms
- Activation of peripheral nociceptors leads to muscle tenderness in ETTH.
- Central sensitization is associated with CTTH:
  - Nitric oxide may play an important role in central sensitization.
  - Debatable: low-platelet serotonin
- Peripheral: may provoke the central mechanism leading from ETTH to CTTH
- Stress is the most frequently reported precipitating factor.

Genetics
An increased genetic risk has been suggested by studies, particularly for CTTH.

**RISK FACTORS**
Associated with triggers/precipitating factors
- Stress (mental or physical)
- Change in sleep regimen
- Skipping meals
- Certain foods (caffeine, alcohol, chocolate)
- Dehydration
- Physical exertion
- Environmental factors (sun glare, odors, smoke, noise, lighting)
- Poor or sustained posture
- Female hormonal changes
- Medications (e.g., nitrates, SSRIs, antihypertensives)
- Overuse of abortive headache medication

**GENERAL PREVENTION**
- Identify and avoid triggers/precipitating factors.
- Minimize emotional stress.
- Encourage relaxation techniques:
  - Biofeedback, relaxation therapy, and physical therapy
  - Consider counseling/psychotherapy.

**COMMONLY ASSOCIATED CONDITIONS**
- 83% of patients with migraine headaches also suffer from tension-type headaches.
- Debatable: increased prevalence of comorbid anxiety and depression

**DIAGNOSIS**
**HISTORY**
- Obtain a thorough headache history to rule out other headache disorders, including severity, symptoms, onset, location, and radiation of pain; quality of pain; concurrent medical conditions and medications; and recent trauma or other procedures.
- Diagnosis is based on clinical symptoms.
  - Diagnostic criteria provided by the International Headache Society:
Headache lasting 30 minutes to 7 days
- At least two of the following:
  - Bilateral location
  - Pressing/tightening (nonpulsating) quality
  - Mild or moderate intensity
  - Not aggravated by routine physical activity
- Not associated with nausea or vomiting (chronic type may be associated with nausea)
- No more than one of the following: photophobia or phonophobia
  - Headache not due to another disorder
  - Fronto-occipital or generalized pain (dull, pressing, or bandlike)
- Associated symptoms:
  - Fatigue
  - Irritability
  - Difficulty concentrating
  - Muscular tightness, tenderness, or stiffness in neck, occipital, and frontal regions

**PHYSICAL EXAM**
- General physical exam: vital signs, funduscopic and cardiovascular assessment, palpation of the head and neck
- Neurologic exam: mental status, pupillary responses, motor-strength testing, deep tendon reflexes, sensation, cerebellar function, gait testing, signs of meningeal irritation

**DIFFERENTIAL DIAGNOSIS**
- Migraine headache
- Cluster headache
- Head trauma
- Subarachnoid hemorrhage
- Subdural hematoma
- Unruptured vascular malformation
- Ischemic cerebrovascular disease
- Temporal arteritis
- Arterial hypertension (HTN)
- Cerebral venous thrombosis
- Benign intracranial HTN
- Intracranial neoplasm, infection, or meningitis
- Low CSF pressure
- Medication (nonprescription analgesic dependency, nitrates)
- Caffeine dependency
- Metabolic disorders (hypoxia, hypercapnia, hypoglycemia)
- Toxic effects from drugs or fumes
- Temporomandibular joint syndrome
- Eyes: glaucoma, refractive errors
- Sinusitis or middle ear infection
- Cervical spondylosis
- Severe anemia or polycythemia
- Uremia and hepatic disorders
- Paget disease of bone

**DIAGNOSTIC TESTS & INTERPRETATION**
Labs and neuroimaging (CT or MRI) are only necessary when a secondary cause is suspected:
- Atypical pattern of headache (does not fit specific category such as migraine, cluster, or tension)
- Rapid increase in frequency
- Focal neurologic findings
- New onset after age 40 years
- Sudden onset or worsening with exertion
- CT scan, with and without contrast, is as sensitive as MRI and is the test of choice.
- Use MRI when lesions of the posterior fossa or an aneurysm is suspected.

**TREATMENT**
- NSAIDs, acetaminophen (APAP), and aspirin (ASA) are effective for short-term pain relief of ETTH (2)[B].
- Amitriptyline should be considered first-line for prophylaxis of CTTH (2)[B].

**GENERAL MEASURES**
Relief measures: relaxation routines; rest in quiet, dark room; hot bath or shower; massage of back of neck and temples

**MEDICATION**
Choice of simple analgesic is based on patient-specific parameters:
• NSAIDs may be more effective than APAP for ETTH (2)[C]:
  – Ibuprofen and naproxen may be preferred due to better GI tolerability.
• APAP should be considered for patients taking warfarin, unable to tolerate NSAIDs, or allergic to ASA or NSAIDs.

**First Line**

• For acute attack (ETTH): NSAIDs, APAP, or ASA:
  – NSAIDs:
    o Ibuprofen (Motrin, Advil): 400 to 800 mg; may repeat q8h PRN (max 3.2 g/day)
    o Naproxen (Naprosyn): 375 to 500 mg or naproxen sodium (Aleve, Anaprox) 440 to 550 mg; may repeat q8–12h PRN (max 1,250 mg base/day)
    o Ketoprofen (Orudis): 12.5 to 50.0 mg; may repeat q6–8h PRN (max 300 mg/day)
    o Diclofenac (Voltaren, Cataflam): 50 to 100 mg; may repeat q8h PRN (max 150 mg/day)
  – Contraindications: ASA or NSAID allergy or bronchospasm, renal disease, bleeding disorders, increased risk of cardiovascular events (myocardial infarction [MI], stroke, new onset or worsening of HTN)
  – Drug interactions: antihypertensives, anticoagulants, antiplatelet drugs, ASA, lithium, methotrexate
  – Adverse effects: epigastric distress, peptic ulcer
  – APAP (Tylenol): 1,000 mg; may repeat q6h PRN (max 4 g/day):
    o Adverse effects (rare): rash, pancytopenia, liver damage
    o Precaution: hepatic impairment, consumption of ≥3/day alcoholic beverages
  • Aspirin: 500 to 1,000 mg; may repeat q6h PRN (max 4 g/day):
    – Contraindication: ASA or NSAID allergy or bronchospasm, bleeding disorders
    – Drug interactions: anticoagulants, antiplatelet drugs, ACE inhibitors, β-blockers, corticosteroids, NSAIDs, sulfonylureas
    – Adverse effects: GI irritation/bleeding, thrombocytopenia
• Prophylaxis for CTTH: tricyclic antidepressants (TCAs) (amitriptyline [Elavil]) 10 to 75 mg/day:
  – Not FDA approved for CTTH
  – Contraindications: acute recovery phase of MI, use of monamine oxidase inhibitors (MAOIs) within 14 days
  – Drug interactions: clonidine, MAOIs, quinolone antibiotics, SSRIs,
sympathomimetics, azole antifungals, valproic acid
– Adverse effects: drowsiness, dry mouth, tachycardia, heart block, blurred vision, urinary retention, seizure

**Second Line**

- For acute attack (ETTH):
  - Caffeine combinations: 130-mg caffeine with 500-mg APAP and/or 500-mg ASA q6h PRN (2)[C]
  - Narcotic analgesics (rarely indicated; consider secondary causes of headache or secondary gain such as drug-seeking behavior for personal use or diversion/sale)
  - Ketorolac: 60 mg IM, single dose
- For CTTH prophylaxis:
  - Mirtazapine: 15 to 30 mg/day (not FDA approved for CTTH) (2)[B]
  - Venlafaxine XR (Effexor XR): 37.5 to 300 mg/day (not FDA approved for CTTH) (2)[B]

**ALERT**

Use of abortive agents >2 days/week may lead to medication-overuse headaches; must withdraw acute treatment to diagnose

**Pediatric Considerations**

ASA and antidepressants are contraindicated.

**ADDITIONAL THERAPIES**

- The combination of stress management therapy and a TCA (amitriptyline) may be most effective for CTTH.
- Maprotiline: 75 mg/day (not FDA approved for CTTH) (2)[C]
- Topiramate: 100 mg/day (limited clinical evidence for prevention of CTTH; not FDA approved for CTTH)
- Alternative TCAs (although limited evidence of benefit, all are widely used for prophylaxis) (3)[B]
  - Desipramine (Norpramin): 50 to 100 mg/day
  - Imipramine (Tofranil): 50 to 100 mg/day
  - Nortriptyline (Pamelor): 25 to 50 mg/day
  - Protriptyline (Vivactil): 25 mg/day
- Drugs with conflicting clinical evidence for CTTH (not FDA approved for CTTH):
– Tizanidine: 2 to 6 mg TID
– Memantine: 20 to 40 mg/day

Botulinum toxin type A is not likely to be effective for ETTH or CTTH.

COMPLEMENTARY & ALTERNATIVE MEDICINE

– Electromyographic (EMG) biofeedback may be effective and is enhanced when combined with relaxation therapy (2,4)[C].
– Cognitive-behavioral therapy may be helpful (2,4)[C].
– Physical therapy, including positioning, ergonomic instruction, massage, transcutaneous electrical nerve simulation, and application of heat/cold may help.
– Alternative agents (not FDA approved for TTH)
  – Tiger Balm or peppermint oil applied topically to the forehead may be effective for ETTH.

– Limited evidence for use of acupuncture and physical therapy (4)[B]
– Chiropractic spinal manipulation cannot be recommended for the management of ETTH; recommendations cannot be made for CTTH (5)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Outpatient treatment

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

– Regulate sleep schedule.
– Regular exercise

DIET

– Identify and avoid dietary triggers.
– Regulate meal schedule.

PATIENT EDUCATION

For additional information, contact:

– National Headache Foundation: http://www.headaches.org
PROGNOSIS

- Usually follows a chronic course when life stressors are not changed
- Most cases are intermittent.

COMPLICATIONS

- Lost days of work and productivity (more with CTTH)
- Cost to health system
- Dependence/addiction to narcotic analgesics
- GI bleeding from NSAID use

REFERENCES

SEE ALSO

Algorithm: Headache, Chronic

CODES

ICD10

- G44.209 Tension-type headache, unspecified, not intractable
- G44.219 Episodic tension-type headache, not intractable
- G44.229 Chronic tension-type headache, not intractable
CLINICAL PEARLS

- Tension-type headache may be difficult to distinguish from migraine without aura. A tension-type headache is typically described as bilateral, mild to moderate, and dull pain, whereas a migraine is typically pulsating, unilateral, and associated with nausea, vomiting, and photophobia or phonophobia.
- Evidence suggests that NSAIDs may be more effective than APAP for ETTH. Consider APAP for patients who cannot tolerate or have a contraindication to NSAIDs. Initial dose of APAP should be 1,000 mg (500 mg may not be as effective).
- CTTH is difficult to treat, and these patients are more likely to develop medication-overuse headache. Clinical evidence supports the use of amitriptyline plus stress management therapy for CTTH.
- Medication-overuse headaches must be avoided by limiting use of abortive agents to no > 2 days/week.
- A headache diary may be useful to identify triggers, response to treatment, and medication-overuse headaches.
HEARING LOSS
Susan L. Steffans, DO

BASICS

DESCRIPTION
- Decrease in the ability to perceive and comprehend sound. It can be partial, complete, unilateral, or bilateral.
- Types of hearing loss include conductive hearing loss (CHL or air–bone gap), sensorineural hearing loss (SNHL), or mixed hearing loss.
- System(s) affected: auditory; outer and middle ear (CHL) or inner ear, auditory nerve, and/or brainstem (SNHL)

EPIDEMIOLOGY
- All ages affected; common in children (CHL) and elderly (SNHL)
- Usually more severe at an earlier age in men

Incidence
- Increases with age
- Sudden sensorineural hearing loss (SSHL) occurs in 5 to 20 per 100,000 persons/year.

Prevalence
WHO estimates that 538 million people affected worldwide.

Geriatric Considerations
- ~80% of people aged >85 years have hearing loss.
- Hearing aids are underused.
- Loss of communication is a source of emotional stress and a physical risk for the elderly.

Pediatric Considerations
- Congenital hearing loss
  - 1 to 6/1,000 infants have hearing loss.
  - Mandatory screening in >97% of newborns with otoacoustic emission (OAE) and auditory brainstem response (ABR) testing
● Audiologic testing after major intracranial infection (meningitis)
● Significant hearing loss at birth and infancy can lead to speech, language, and cognitive delays. Early diagnosis and treatment improves outcome.

**Pregnancy Considerations**
● Otosclerosis can worsen during pregnancy.
● Maternal infections cause permanent pediatric hearing loss.

**ETIOLOGY AND PATHOPHYSIOLOGY**
● CHL: Hearing loss can result from middle ear effusion, obstruction of canal (cerumen/foreign body, osteomas/exostoses, cholesteatoma, tumor), loss of continuity (ossicular discontinuity), stiffening of the components (myringosclerosis, tympanosclerosis, and otosclerosis), and loss of the pressure differential across the tympanic membrane (TM) (perforation).
● SNHL: damage along the pathway from oval window, cochlea, auditory nerve, and brainstem. Examples include vascular/metabolic insult, mass effect, infection and inflammation, and acoustic trauma.
  – Noise-induced hearing loss is caused by acoustic insult that affects outer hair cells in the organ of Corti, causing them to be less stiff. Over time, severe damage occurs with fusion and loss of stereocilia; eventually may progress to inner hair cells and auditory nerve as well
● Large vestibular aqueduct or superior canal dehiscence: Third mobile window shunts acoustic energy away from cochlea.

**Genetics**
● Connexin 26 (13q11–13q12): most common cause of nonsyndromic genetic hearing loss
● Mitochondrial disorders (may predispose to aminoglycoside ototoxicity)
● Otosclerosis: familial
● Most common congenital syndromes
  – Hemifacial microsomia
  – Stickler syndrome
  – Congenital cytomegalovirus
  – Usher syndrome
  – Branchio-oto-renal syndrome
  – Pendred syndrome
  – CHARGE association
  – Neurofibromatosis type 2
− Waardenburg syndrome

RISK FACTORS

● Conductive
  − Eustachian tube dysfunction
    ○ Chronic sinusitis; allergy
    ○ Adenoid hypertrophy; nasopharyngeal mass
    ○ Cigarette smoking
  − Sleep apnea with continuous positive airway pressure (CPAP) use
  − Neuromuscular disease
  − Family history/heredity
  − Prematurity and low birth weight
  − Craniofacial abnormalities (e.g., cleft palate, Down syndrome)
  − Third mobile window (superior canal dehiscence or large vestibular aqueduct)

● Sensorineural
  − Aging/older age
  − Loud noise/acoustic trauma
  − Dizziness/vertigo: especially Ménière disease or history of labyrinthitis
  − Medications (aminoglycosides, loop diuretics, aspirin, quinine, chemotherapeutic agents, especially cisplatin)
  − Bacterial meningitis
  − Head trauma
  − Atherosclerosis
  − Vestibular schwannoma/skull base neoplasm
  − Previous ear surgery

● Sensorineural, pediatric specific
  − Perinatal asphyxia
  − Mechanical ventilation lasting ≥5 days
  − Congenital infections (toxoplasmosis, other agents, rubella, cytomegalovirus, herpes simplex [TORCH] syndrome)
  − Toxemia of pregnancy
  − Maternal diabetes
  − Rh incompatibility
  − Prematurity or birth weight <1,500 g
  − Severe hyperbilirubinemia; exchange transfusions
  − Anomalous temporal bone (Mondini or large vestibular aqueduct)
  − Infectious diseases: chickenpox, measles, encephalitis, influenza, mumps, bacterial meningitis
GENERAL PREVENTION

- Limit noise exposure; use hearing protection.
- Avoid ear canal instrumentation (e.g., cotton swabs).
- Limit ototoxic medications.

DIAGNOSIS

HISTORY

- The U.S. Preventive Services Task Force concludes that the current evidence is insufficient to assess the balance of benefits and harms of screening for hearing loss in asymptomatic adults aged 50 years or older.
- Social problems and comments from friends and family members are often the first presentation of presbycusis (age-related hearing loss), as patients are often not aware of the degree of hearing loss they experience and how it affects their life; insidious onset and progression
- Difficulty hearing
  - Rapid versus gradual decline: Rapid loss (<3 days) is a medical emergency. Urgent ENT referral and steroid therapy is recommended.
  - Difficulty with discrimination of sounds, hearing in crowds, or turning up the volume of television sets
  - Frequently having to ask speakers to repeat
  - Friends/family complain of hearing loss
- Tinnitus, bilateral or unilateral
- Otalgia
- Otorrhea, clear or purulent
- Dizziness or vertigo
- Aural fullness
- Autophony (hearing own voice louder or echoing)
- History of ear infections or ear surgeries
- History of trauma or noise exposure
- Family history of hearing loss
- History of recent viral infection

PHYSICAL EXAM

- Whispered voice test: A whisper heard from ~2 feet away is a good screen for intact hearing. Patients with SNHL have difficulty with this because their hearing loss is usually in the high frequency range.
• A simple 512-Hz tuning fork test lateralizes to unaffected ear in sudden SNHL (emergency) and lateralizes to the affected ear in CHL (not an emergency).

• 512-Hz tuning fork tests:
  – Sensorineural loss
    o Placed on the forehead: lateralizes to unaffected ear (Weber test)
    o Base of tuning fork placed on the mastoid and then fork end placed next to ear; heard louder next to ear (Rinne test)
  – Conductive loss
    o Placed on the forehead or teeth lateralizes to affected or symptomatic ear
    o Placed on the mastoid and then next to ear; heard louder behind the ear on the side of conductive deficit

• Otoscopy: Assess for deformity, canal patency, and otorrhea; TM integrity/retraction/mobility with insufflation, canal, or middle ear mass.

• Facial symmetry

• Cranial nerve exam

• Nasopharyngoscopy: adenoid hypertrophy or nasopharyngeal mass (mandatory in adult patient with new unilateral serous effusion)

• Pediatric: Survey for syndromic anomalies.

**DIFFERENTIAL DIAGNOSIS**

• Conductive
  – Cerumen impaction/foreign body
  – Perforation of TM
  – Middle ear fluid (serous otitis media)
  – Acute otitis media/adhesive otitis media
  – Ossicular erosion (infection, cholesteatoma)
  – Myringosclerosis/tympanosclerosis
  – Temporal bone fracture
  – Otosclerosis
  – Glomus tumor

• Sensorineural
  – Presbycusis (age-related hearing loss)
  – Noise-induced (recreational, occupational)
  – Ménière disease
  – Ototoxicity (aspirin, aminoglycosides)
  – Viral labyrinthitis
  – Cerebellopontine angle (CPA) tumor
  – Large vestibular aqueduct syndrome
  – Syndromic hearing loss
– Congenital cochlear malformation
– Syphilis
– Cytomegalovirus; rubella
– Temporal bone fracture
– Metabolic (hyper-/hypothyroidism)
– Paget disease
– Perilymphatic (inner ear) fistula

**DIAGNOSTIC TESTS & INTERPRETATION**

Often, labs are not needed. If indicated

- MRI of the brain and brainstem with gadolinium to evaluate SNHL in congenital, early onset, and asymmetric hearing loss
- Fine-cut CT temporal bones without contrast may help in the evaluation of CHL.
- Newborn screening with OAE and/or ABR
- Any pediatric patient with SNHL: Consider genetic testing for connexin 26, mitochondrial studies.
- TORCH screening (congenital infection)
- Rapid plasma reagin (RPR) or Venereal Disease Research Laboratory (VDRL) confirmed by fluorescent treponemal antibody absorption (FTA-ABS)
- Lyme titer in endemic areas
- Antinuclear antibodies and sedimentation rate as a screen for autoimmune disease
- Pendred syndrome (goiter, mental retardation + SNHL): perchlorate test, thyroid function tests
- Alport syndrome (nephritis + SNHL): urinalysis, renal function tests
- Jervell and Lange-Nielsen syndrome (syncope, family history of sudden death + profound SNHL): ECG

**Diagnostic Procedures/Other**

- Audiometry: pure tone (air and bone), speech testing, and impedance (middle ear pressure) testing
- Tympanometry: Type B or C tympanograms indicate fluid or retraction, respectively. Negative middle ear peak pressures were seen even with normal (type A) tympanograms.
- Other tests
  - ABR
  - OAEs: “echo” of the cochlea
– Behavioral (visual reinforcement) audiometry; used in children 6 months to 5 years old

- Myringotomy and tubes can be considered for persistent fluid with hearing loss.

**Test Interpretation**

Varies depending on etiology

---

### TREATMENT

#### MEDICATION

- Depends on cause
- Any sudden SNHL (usually unilateral) is a medical emergency; obtain audiologic testing and start steroid therapy.

- Treatment should begin ASAP, ideally within 1 to 2 weeks of onset with high-dose oral steroids: 1 mg/kg or 60 to 100 mg/day prednisone or 12 to 16 mg/day dexamethasone for 7 to 14 days, followed by a taper. For patients who cannot tolerate systematic steroids, intratympanic steroids are equally effective (1)[A].

- Newer studies are suggesting benefit of combined therapy (oral systemic steroid and intratympanic steroid injections) for first-line treatment of sudden SNHL (2)[A].

- Clinical practical guidelines for sudden hearing loss include the following (3)[C]:
  - Distinguishing SNHL from CHL; testing for bilateral sudden hearing loss in patients with unilateral sudden hearing loss; obtaining an MRI, ABR, or audiometric follow-up to evaluate for retrocochlear pathology; offer intratympanic steroid perfusion for refractory cases after initial management fails to treat idiopathic sudden SNHL (ISSNHL) and follow-up within 6 months of diagnosis.
  - May offer corticosteroids as initial therapy to patients with ISSNHL and hyperbaric oxygen within 3 months of ISSNHL diagnosis
  - Recommend against prescribing antivirals, thrombolitics, vasodilators, vasoactive substances, or antioxidants to patients with ISSNHL.
  - Also recommend against routine laboratory tests in patients with ISSNHL.

---

### ISSUES FOR REFERRAL
• Required for failure of newborn screen, but 32% lost to follow-up.
  – Collaborating with Women, Infants, and Children (WIC) program to provide targeted follow-up improved loss to follow-up rates, decreased age at hearing confirmation by 1 month, and addressed reported care barriers (4)[B].

• Audiology: If hearing loss is suspected, refer to audiology for formal evaluation. Audiologists also provide hearing aid options and maintenance.
• Genetics: if congenital syndrome or familial hearing loss is suspected
• Speech therapist: if speech delay or speech impediment is present
• Endocrinology: Pendred syndrome, other associated endocrine disorder (hypothyroidism)
• Cardiology: Jervell and Lange-Nielsen syndrome
• Ophthalmology: Usher syndrome
• Neurology and neurosurgery: CPA lesion, intracranial complication of middle ear disease

ADDITIONAL THERAPIES
Aural rehabilitation: interdisciplinary approach involving audiologists, speech language pathologists, otologist, family physician, and other members of health care team as needed

SURGERY/OTHER PROCEDURES
• CHL often has surgical options for repair.
  – Tympanostomy and tube placement
  – Tympanoplasty
  – Mastoidectomy
  – Ossicular chain reconstruction
  – Stapedectomy/stapedotomy
  – Canaloplasty
• Those with profound bilateral SNHL may qualify for cochlear implantation.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Audiogram and clinical exam are the primary means of monitoring patient.
Patients with hearing assistive devices benefit from audiology involvement.

**DIET**
Salt restriction to 2 g/day is helpful for patients with Ménière disease.

**PATIENT EDUCATION**
- To prevent damage that leads to noise-induced hearing loss, practice noise exposure moderation.
  - Avoid excessive noise.
  - Avoid prolonged noise exposure.
  - Utilize protective devices.

**PROGNOSIS**
- SNHL is usually permanent and may be progressive. However, amplification devices (e.g., hearing aids) may help improve functionality.
- ISSNHL may recover spontaneously in 32–70% of cases, but urgent referral and treatment is recommended to maximize recovery. No factors have been proven to predict recovery (5).

**COMPLICATIONS**
Acute middle ear problems may become chronic (perforations, cholesteatoma).

**REFERENCES**
CODES

ICD10

- H91.90 Unspecified hearing loss, unspecified ear
- H90.2 Conductive hearing loss, unspecified
- H90.5 Unspecified sensorineural hearing loss

CLINICAL PEARLS

- In sudden hearing loss, if a 512-Hz tuning fork test (Weber test) lateralizes to the *unaffected* ear, suspect sensorineural causes (emergent evaluation needed), but if it lateralizes to the *affected* ear, the diagnosis is CHL (not an emergency).
- ~80% of people aged >85 years have hearing loss, encourage screening and treatment, especially in patients with early dementia.
- Best way to prevent noise-induced hearing loss is to protect against noise exposure.
HEART FAILURE, ACUTELY DECOMPENSATED

Seth Baruffi, MD, FACEP • Gregory A. Parson, DO • Muhammad Durrani, DO, MS

BASICS

DESCRIPTION
Acute decompensated heart failure (ADHF) is a rapid-onset cardiac pump function impairment, structurally or functionally, resulting in inefficient perfusion, yielding symptoms due to excessive fluid accumulation and due to reduction in cardiac output. ADHF can be a new diagnosis or worsening of preexisting chronic HF.

EPIDEMIOLOGY

Incidence

- HF hospitalization places a major strain on health care resources, and medicare spends more to diagnose and treat HF than any other medical condition. HF is the most common cause of admission and readmission in the United States. In 2012, the total cost of HF was $30.7 billion. By 2030, total cost will increase 127% to $69.7 billion. In the United States, there are 915,000 new cases annually. HF is the primary cause of >55,000 deaths each year and a contributing factor in >280,000 deaths.
- >1 million hospital discharges/year, unchanged from 2000 to 2010, and about half of people who have HF die within 5 years of diagnosis. One in nine deaths has HF mentioned on the death certificate.

Prevalence

- ~6.5 million people over the age of 20 years in the United States carry an HF diagnosis; prevalence is expected to increase 46% from 2012 to 2030 resulting in >8 million cases in patients >18 years of age.
- HF is primarily a disease of the elderly; 75% of hospital admissions for HF are in persons >65 years of age.
- African Americans have the highest risk of developing HF, followed by Hispanics, Whites, and Chinese Americans, which reflects differences in
prevalence of hypertension (HTN), DM, and socioeconomic status.

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Two potential pathophysiologic conditions lead to the clinical findings of ADHF, namely systolic and/or diastolic heart dysfunction.
  - Systolic dysfunction: an *inotropic* abnormality, due to myocardial infarction (MI) or dilated or ischemic cardiomyopathy (CM), resulting in diminished systolic emptying (ejection fraction <45%)
  - Diastolic dysfunction: a *compliance* abnormality, due to hypertensive CM, in which ventricular relaxation is impaired (ejection fraction >45%)
  - In attempt to adopt a more pragmatic approach, one that has been accepted by both the European and American HF guidelines, the terms HF with reduced, mid-range, or preserved LVEF (HFrEF, heart failure with mid-range ejection fraction [HFmrEF] and HFpEF, respectively) have been adopted recently.

- ADHF can be caused by the following conditions:
  - Myocardial disease:
    - Exacerbation of chronic HF heralded by noncompliance, infection; any of the following as cause of new HF or exacerbation: coronary artery disease (CAD), MI (especially new-onset ADHF), toxic damage, immune-mediated and inflammatory damage, infiltrative diseases, metabolic derangements, and genetic abnormalities
  - Abnormal loading conditions
    - HTN, valvular and myocardial structural defects, pericardial and endomyocardial pathologies, high output states, volume overload
  - Arrhythmias
    - Arrhythmia: atrial fibrillation, tachyarrhythmias, high-grade heart block, bradyarrhythmias

**Genetics**

Familial CM is a predisposition to development of HF (rare).

**RISK FACTORS**

- CAD and MI: RR 8.1
- Diabetes mellitus: RR 1.9
- Cigarette smoking: RR 1.6
- Valvular heart disease: RR: 1.5
- HTN, systemic or pulmonary: RR 1.4
• Dietary sodium intake: RR 1.4
• Obesity: RR 1.3

GENERAL PREVENTION
Mortality declines have been attributed to treating HF risk factors (see above), and implementation of ACE inhibitors, β-blockers, coronary revascularization, implantable cardioverter-defibrillators, and cardiac resynchronization strategies in patients.

• B-type natriuretic peptide (BNP) screening, in conjunction with guideline-directed management/therapies, is recommended to aid in prevention of new onset HF and in development of left ventricular (LV) dysfunction in existing HF.

COMMONLY ASSOCIATED CONDITIONS
• Dysrhythmia followed by pump failure is the leading cause of death in ADHF. Most patients have >5 comorbidities (especially CAD, chronic kidney disease, and diabetes) and take >5 medications.
• Cardiogenic shock

DIAGNOSIS
Clinical diagnosis, no gold standard: No single historical, physical exam (PE), ECG, or radiographic finding can rule out HF.

HISTORY
• Patients typically have a history of HF, MI, uncontrolled HTN, and other risk factors.
• Dyspnea on exertion and orthopnea are the only symptoms with high sensitivity but suffer from low specificity.
• Other symptoms include deteriorating exercise capacity, fatigue, general weakness, chest pain/discomfort if acute coronary syndrome (ACS) is present, paroxysmal nocturnal dyspnea, nocturnal nonproductive cough, wheezing (especially nocturnal) in absence of history of asthma or infection (cardiac asthma).
• Edema, abdominal bloating (ascites), anasarca, cyanosis, weight gain (>2 kg/week)
**PHYSICAL EXAM**
- $S_3$ was the PE finding with highest likelihood ratio (LR) with positive LR ranging from 1.6 to 13.0. No PE finding has sensitivity >70%.
- Peripheral pitting edema, cool extremities, cyanosis, hepatomegaly, hepatojugular reflux, cardiac murmur, hypotension, laterally displaced apical impulse
- Lung exam: rales (crackles) and sometimes wheezing, Cheyne–Stokes respirations

**DIFFERENTIAL DIAGNOSIS**
Rule out life-threatening diagnoses first: pulmonary embolism, MI, tamponade, pneumothorax, ARDS, sepsis, COPD, pneumonia, constrictive pericarditis, high-output states (anemia, hyperthyroidism).

**DIAGNOSTIC TESTS & INTERPRETATION**
Laboratory data are adjunctive and indicative of complications.

**Initial Tests (lab, imaging)**
- First, assess BP and other vital signs and rule out hemodynamic instability and cardiogenic shock state.
- Cardiac troponins, ECG to evaluate for ACS. Note that elevated troponins are detected in the majority of HF patients, often without obvious myocardial ischemia (1)[C].
- BUN, creatinine, electrolytes, liver function tests, TSH, glucose, and CBC (1)[C]
- Routine ABG is not needed (1)[C].
- Transthoracic echocardiogram: recommended immediately in hemodynamically unstable ADHF patients and within 48 hours when cardiac structure and function are either not known or may have changed since previous studies (1)[C]
- BNP and/or N-type pro-BNP (BT-BNP): Measurement of BNP or NT-proBNP is recommended in all patients with acute dyspnea and suspected ADHF to help in the differentiation of ADHF from noncardiac causes (1)[A].
  - BNP <100 essentially will rule out HF with negative LR of 0.2 and sensitivity of 93.5% (2)[A]. BNP >500 have specificity of 89.8% (2)[A]. BNP 100 to 400 may indicate HF or may be due to a variety of cardiac and noncardiac conditions (1)[A].
  - BNP has a relative increase in women, is lower with obesity, and higher
with renal dysfunction (1)[A].

- NT-proBNP values >450 pg/mL for people below age 50 years, >900 pg/mL ages 50 to 75 years, and >1,800 pg/mL for people >75 years are highly suggestive of HF (sensitivity 90%, specificity of 84%) (3)[B].

- Chest x-ray: to look for pulmonary congestion and to detect other cardiac or noncardiac diseases that may cause or contribute to the patient’s symptoms: increased heart size, vascular redistribution (cephalization) with “butterfly” pattern of pulmonary edema, interstitial and alveolar edema, Kerley B lines, pleural effusions (1)[C]

- Lung ultrasound (LUS): emerging as a diagnostic tool for ADHF with a positive LUS defined by presence of >3 B lines in two bilateral lung zones yielding a specificity of 92.7% and LR of 7.4 (2)[A]

**Follow-Up Tests & Special Considerations**
Please see “Heart Failure, Chronic” topic.

**Diagnostic Procedures/Other**
Cardiac catheterization may be considered when CAD is suspected. Pulmonary artery catheterization may be performed to guide therapy in severe cases with cardiogenic shock.

**Test Interpretation**
Cardiac pathology depends on the etiology of HF. Please refer to “Heart Failure, Chronic” topic.

**TREATMENT**
Goal of treatment is to improve hemodynamics and organ perfusion, alleviate symptoms, limit cardiac and renal damage, restore oxygenation, and minimize hospital length of stay, as well as identify the etiology or precipitating factors. See “Heart Failure, Chronic” chapter as well.

**MEDICATION**

**ALERT**
Contemporary therapies for ADHF remain suboptimal, and many therapies do not favorably impact morbidity or mortality. Diuretics are used initially in fluid overload ADHF, with nitrates added if needed. Once ADHF is stabilized,
recent guideline suggests an ACE inhibitor, ARB, or ARNI and β-blocker be started in patients with reduced systolic function. Use of new agent ivabradine has also been touted in select patients. Avoid NSAIDS and COX-2 inhibitors. There are no class IA drug recommendations for ADHF.

**First Line**

- IV loop diuretics recommended for all patients with ADHF and symptoms of fluid overload in hemodynamically stable patients (contraindicated if systolic blood pressure [SBP] <90 mm Hg, severe hyponatremia, acidosis) (1)[C]; be cautious of electrolyte abnormalities if kidney disease is present. Diuresis should be instituted early in ADHF, continuous infusion is no better than bolus, and high dose is not significantly better than low dose (1)[B].
  - Furosemide (Lasix): New-onset ADHF patients should get boluses of 20 to 40 mg IV (1)[B].
  - If on furosemide (Lasix) chronically, initial IV dose should be equal or exceed chronic oral daily dose (1 to 2.5 for home dose) (1)[B]. Monitor for appropriate urine output.
- Thiazides in combination with loop diuretics may be useful if ineffective diuresis (hydrochlorothiazide [HCTZ] 25 mg PO). Thiazides and spironolactone or eplerenone (25 to 50 mg PO) may be used in combination with loop diuretics if excessive volume overload (1)[C].
- Metolazone (Zaroxolyn): 2.5 to 20.0 mg/day PO, can be added as second diuretic in cases of ineffective diuresis
- Vasodilators: Consider in ADHF with SBP >90 mm Hg and patients with hypertensive ADHF should get IV vasodilators as initial therapy to reduce congestion (1)[B]. Use in chronic HF is not effective (3)[B].
  - IV nitroglycerin may be of short-term benefit to decrease preload, afterload, and systemic resistance (IV 10 to 20 μg/min, increase up to 200 μg/min) (1)[B].
  - IV nitroprusside: Administer with caution, start with 0.3 μg/kg/min and increase up to 5.0 μg/kg/min (1)[B].
- Bilevel positive airway pressure (BIPAP)/NPPV: NPPV decreases early mortality in ADHF. See additional therapies section.

**Second Line**

- Tolvaptan (an oral vasopressin antagonist) for severe hypervolemic hyponatremia refractory to water restriction and medical therapy
- Inotropes: reserved for patients with severe systolic dysfunction occurring
most often in hypotensive ADHF. Withdraw as hemodynamics improve due to increased short- and medium-term mortality. ECG monitoring is required as they can induce ischemia and arrhythmias.

- Phosphodiesterase inhibitors (milrinone, enoximone) decrease pulmonary resistance; may be used for patients on β-blockers but may increase medium-term mortality in CAD patients
- Dobutamine infusion 2 to 20 μg/kg/min requires close BP monitoring; avoid in cardiogenic shock or with tachyarrhythmias.
- Low-dose dopamine infusion may be considered (3 to 5 μg/kg/min).
- Levosimendan (calcium sensitizer) improves hemodynamic parameters but not survival compared to placebo while improving hemodynamic parameters and survival compared to dobutamine.

**Vasopressors:** Consider in patients with cardiogenic shock despite treatment with another inotrope (1)[B].
- Norepinephrine 0.2 to 1.0 μg/kg/min compared with dopamine has fewer side effects and lower mortality (1)[C].
- Epinephrine restricted to patients with persistent hypotension despite other agents (1)[C]
- Nesiritide, a BNP analog, is not recommended secondary to higher rates of hypotension, no benefit on death, or rehospitalization rates.
- Ultrafiltration renal replacement therapy: Routine use of ultrafiltration is not recommended and should be used only in patients with refractory volume overload (1)[C].

**ADDITIONAL THERAPIES**
- Oxygen: Begin treatment early; ideally, arterial oxygen saturation >92% (90% if COPD)
- Cochrane review shows that one death can be avoided for every 14 ADHF patient treated with NPPV and one death for every nine ADHF patients treated with CPAP. Avoid mechanical ventilation for patients with right HF.
- Treat anemia with transfusion: conservative trigger Hgb <8; target Hgb 10. IV iron replacement may help with New York Heart Association (NYHA) II and III patients. Avoid erythropoietin-stimulating agents.
- For patients with new-onset arrhythmias, consider pacing and/or antiarrhythmics.
- Please refer to “Heart Failure, Chronic” for maintenance treatments.

**SURGERY/OTHER PROCEDURES**
Heart valve surgery if defective heart valve is responsible
PCI/CABG for patients with CAD/MI if applicable

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria considerations:
  - Evidence of severely decompensated HF, including hypotension, worsening renal function, altered mental status, dyspnea at rest, decreased oxygenation, arrhythmias, electrolyte disturbances, associated comorbid conditions, newly diagnosed HF
  - Consider observation unit stay for stable patients with preexisting HF and the following:
    - No acute interventions needed for comorbid condition, SBP>120 mm Hg, RR <32 bpm, BUN <40 mg/dL, creatinine <3.0 mg/dL, no evidence of ischemia or elevated troponins, and BNP <1,000, NT-proBNP <5,000 (2)
      - Clinical impression that patient could be discharged in the next 24 hours

- Inpatient: Continuous pulse oxygen; daily weights; monitor input and output; fluid restriction; 2-g sodium diet; echocardiogram if necessary; monitor for worsening HF; assess treatment response.
- 1.5 to 2.0 L/day fluid restriction may be useful to reduce congestive symptoms.
- Discharge criteria: improved symptoms, SBP normalized at 100 to 120 mm Hg, good urine output, serum sodium >135 mEq/L, HF outpatient education

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Rapid follow-up and a multidisciplinary care to reduce hospitalization and mortality (1)[A]

DIET
Reduce sodium (2 g); maintain cardiac or diabetic diet if these comorbidities are present.
PATIENT EDUCATION
- Monitoring and self-care; record daily weight; know how/when to utilize health care systems to increase diuretic dose with weight gain or dyspnea.
- Medications: Understand indications, dose, effects, and side effects of drugs.
- Adherence: Value treatment plan maintenance.
- Alcohol, smoking, and drugs: abstinence recommended in alcohol-induced CM; smoking and illicit drug cessation
- Exercise: Understand the benefits of exercise.

PROGNOSIS
- The ADHERE risk tree stratifies ADHF patients for inpatient mortality using SBP, BUN, and creatinine.
- \( S_3 \) on PE correlates with poor prognosis.
- After diagnosis, 1-year survival \(~75\%\), 5-year survival \(<50\%\), 10-year survival \(<25\%\)
- Consider predischarge BNP to establish postdischarge prognosis in hospitalized patients (3)[C].

COMPLICATIONS
Arrhythmia, pulmonary edema, hyponatremia, death

REFERENCES

CODES
ICD10
- I50.9 Heart failure, unspecified
- I50.21 Acute systolic (congestive) heart failure
- I50.31 Acute diastolic (congestive) heart failure

**CLINICAL PEARLS**

- BNP in ADHF is best reserved for situations in which diagnosis of ADHF is unclear.
- Look for underlying cause of each episode of ADHF.
- IV diuretics are used initially in fluid-overload acute HF, with nitrates added if needed, especially if patient is hypertensive.
- Using early noninvasive ventilation for the treatment of pulmonary edema can bridge care while awaiting the effects of diuretics and can decrease morbidity and mortality associated with intubation.
HEART FAILURE, CHRONIC

Jeffrey Shih, MD

BASICS

DESCRIPTION

- Heart failure (HF) is the condition resulting from inability of the heart to fill and/or pump blood sufficiently to meet tissue metabolic needs. Alternatively, HF may occur when adequate cardiac output can be achieved only at the expense of elevated filling pressures. It is the principal complication of heart disease.
- HF is the preferred term over congestive heart failure because patients are not always congested (fluid overloaded).
- HF may involve the left heart, the right heart, or be biventricular. The New York Heart Association (NYHA) classification is a subjective grading scale used for classifying patients with HF: NYHA I: asymptomatic; NYHA II: symptomatic with moderate exertion; NYHA III: symptomatic with mild exertion and may limit activities of daily living; NYHA IV: symptomatic at rest. For acute HF, see “Heart Failure, Acutely Decompensated.”

EPIDEMIOLOGY

The annual direct and indirect cost of HF in the United States is ~$34.4 billion.

Incidence

In the United States, 550,000 new cases diagnosed annually with >250,000 deaths per year

Prevalence

- ~5.7 million people in the United States have HF; <1% in those age <50 years, increasing to 10% of those age >80 years
- Primarily a disease of the elderly; 75% of hospital admissions for HF are for persons >65 years of age.

ETIOLOGY AND PATHOPHYSIOLOGY

Two physiologic components explain most of the clinical findings of HF and result in classifications of patients in four general categories:
- HF with reduced ejection fraction (HFrEF) or systolic HF: an *inotropic* abnormality, often due to myocardial infarction (MI) or dilated cardiomyopathy (CM), resulting in diminished systolic emptying (ejection fraction [EF] ≤40%)
- HF with preserved ejection fraction (HFpEF) or diastolic HF: a *compliance* abnormality, often due to hypertensive CM, in which the ventricular relaxation is impaired (EF ≥50%)
- Borderline HFpEF (EF 41–49%): mild systolic dysfunction but clinically behaves like HFpEF
- Improved HFpEF (EF >40%): previously HFrEF but with improvement in systolic function
- Patients with systolic dysfunction may also have diastolic dysfunction.
- Most common etiologies: coronary artery disease (CAD)/MI and hypertension (HTN)
- Myocarditis and CM: alcoholic, viral, long-standing HTN, drugs (e.g., chemotherapeutic agents), muscular dystrophy, infiltrative (e.g., amyloidosis, sarcoidosis), postpartum state, infectious (e.g., Chagas disease, HIV), hypertrophic CM (HCM), inherited familial dilated CM, left ventricular (LV) noncompaction
- Valvular and vascular abnormalities: any valvular stenosis or regurgitation, rheumatic heart; renal artery stenosis, usually bilateral, may cause recurrent “flash” pulmonary edema, especially in setting of severe chronic HTN.
- Chronic lung disease and pulmonary HTN (cor pulmonale)
- Iatrogenic volume overload (requires extreme overload in patients with normal hearts and kidneys)
- Arrhythmias (atrial fibrillation and other tachyarrhythmias, high-grade heart block)
- Miscellaneous: high-output states: hyperthyroidism, anemia; cardiac depressants (β-blocker overdose), stress induced
- Idiopathic: 20–50% of idiopathic dilated cardiomyopathies are familial.
- HF is progressive—manifested by the remodeling (altered heart geometry) process.

**Genetics**

Multiple genetic abnormalities responsible for a variety of phenotypes have been identified (HCM, arrhythmogenic right ventricular [RV] dysplasia, LV noncompaction, dilated CM). Consider genetic screening for first-degree relatives of HCM and arrhythmogenic RV dysplasia.
RISK FACTORS
For development of HF: CAD/MI, HTN (80% of cases of HF in the United States caused by either CAD or HTN), valvular heart disease, diabetes mellitus, cardiotoxic medications (e.g., anthracyclines, tyrosine-kinase inhibitors, TNF-α inhibitors), obesity, older age

GENERAL PREVENTION
Control HTN and other risk factors. Thiazide diuretics and angiotensin-converting enzyme inhibitors (ACE-I) are superior to other agents in preventing development of HF.

COMMONLY ASSOCIATED CONDITIONS
Sudden cardiac death and progressive pump failure are the leading causes of death. Most patients have >5 comorbid medical conditions and take >5 medications.

DIAGNOSIS

HISTORY
- Dyspnea on exertion: cardinal sign of left-sided HF. Deteriorating exercise capacity: easy fatigued, general weakness
- Nocturnal nonproductive cough, orthopnea, and paroxysmal nocturnal dyspnea; sometimes frothy or pink sputum. Wheezing, especially nocturnal, in absence of history of asthma or infection (cardiac asthma); Cheyne-Stokes respirations
- Anorexia and/or fullness or dull pain in right upper quadrant (hepatic congestion). Nausea and poor appetite may indicate advanced HF

PHYSICAL EXAM
- Increased filling pressures: rales and sometimes wheezing, peripheral edema, S₃ gallop, hepatomegaly, jugular venous distention, hepatojugular reflux, ascites
- Remodeling: enlarged or displaced point of maximal impulse
- Poor cardiac output: hypotension, pulsus alternans, tachycardia, narrow pulse pressure, cool extremities, cyanosis

DIFFERENTIAL DIAGNOSIS
Simple dependent edema, pulmonary embolism, exertional asthma, cardiac ischemia, asthma/COPD, constrictive pericarditis, nephrotic syndrome, cirrhosis, venous occlusive disease with subsequent peripheral edema, high-output states: anemia, sepsis, hyperthyroidism, lymphedema, tamponade

**DIAGNOSTIC TESTS & INTERPRETATION**

Diagnosis should be primarily clinical, with laboratory data as adjunctive and indicative of complications.

**Initial Tests (lab, imaging)**

- β-Type natriuretic peptide (BNP) and N-terminal pro-BNP (NT-BNP) are helpful in the acute setting to differentiate the cause of dyspnea (BNP <100 essentially rules out HF) (1)[A]. A BNP level in those with risk factors for developing HF or with structural heart disease but no symptoms of HF can help predict the development of symptomatic HF (2)[A]. Other, non-HF conditions, such as pulmonary embolism, renal failure, and acute coronary syndromes, may cause elevated BNP. Obesity may lower BNP levels. The use of BNP-guided therapy in chronic HF and acutely decompensated HF is not well-established although a predischarge BNP can predict risk of readmission and survival (2)[A].

- Lab findings include respiratory alkalosis, mild azotemia, decreased ESR, proteinuria (usually <1 g/day), elevated creatinine (cardiorenal syndrome), dilutional hyponatremia (poor prognosis), hyperuricemia, and hyperbilirubinemia.

- Chest x-ray (changes lag clinical symptoms by up to 6 hours): increased heart size, vascular redistribution (cephalization) with “butterfly” pattern of pulmonary edema, interstitial and alveolar edema, Kerley B lines, and pleural effusions. Findings of pulmonary edema may be absent in long-standing HF.

**Diagnostic Procedures/Other**

Determination of left ventricular ejection fraction (LVEF) is critical to proper diagnosis and management:

- Echocardiogram is the most useful test to determine LVEF, RV function, diastolic dysfunction, ventricular size, wall thickness, and valvular abnormalities; may be repeated if change suspected in underlying cardiac status

- Nuclear imaging to estimate ventricular sizes; assess for ischemia or infarction, ATTR-wild type amyloidosis, and systolic function.
Cardiac MRI can be considered in select circumstances: suspicion of cardiac sarcoidosis, arrhythmogenic RV CM, acute myocarditis, amyloidosis, and hemochromatosis.

Cardiac catheterization is important for excluding CAD as an etiology in the setting of risk factors.

Endomyocardial biopsy should not be performed routinely, only in special circumstances (e.g., suspected giant cell myocarditis) that may change therapy (1)[C].

Test Interpretation
Cardiac pathology depends on underlying etiology.

TREATMENT

GENERAL MEASURES
Correct and treat risk factors for HF. The treatment of chronic HF is focused on improving hemodynamics, relieving symptoms, and blocking the neurohormonal response to improve survival.

MEDICATION
Diuretics are used initially in fluid overload acute HF. The addition of ACE-I and aldosterone antagonists can be added at any time. Once acute HF is stabilized, a β-blocker should be started. Avoid nonsteroidal anti-inflammatory drugs (NSAIDs), which markedly worsen HF. Avoid the use of diltiazem and verapamil in patients with systolic dysfunction as they may increase mortality and have negative inotropic effects.

First Line
- ACE-I: used to decrease afterload. Shown to increase survival, improve symptoms, and overall exercise capacity in patients in all NYHA classifications; benefit greatest for patients with systolic dysfunction and post-MI. Number needed to treat (NNT) ~25 per year for mortality. All ACE-Is considered equally effective. Initiate at low doses and titrate as tolerated to target doses.
- Angiotensin receptor blockers (ARBs) are indicated for those who are intolerant to ACE-Is. Avoid combination of ACE-I and ARB.
- β-Blockers: used in systolic or diastolic HF (Note: Initiate in
hemodynamically stable/compensated patients at low dose and titrate upward slowly.); NNT = 25 for mortality. Mortality decreased in systolic HF. Evidence for titration to heart rate (HR) rather than specific dose (1)[A].

- Carvedilol: 3.125 mg PO BID to a target of 25 mg PO BID; metoprolol succinate extended release: 12.5 mg/day PO to a target of 200 mg/day PO; or bisoprolol: 1.25 to 10.00 mg once daily (currently not FDA approved for the treatment of HF)

- Sacubitril/valsartan (Entresto) is an angiotensin receptor nephrilysin inhibitor (ARNI) shown to reduce the risk of CV death and HF hospitalizations in patients with HFrEF. In patients with HFrEF and NYHA class II and III symptoms who tolerate an ACE-I or ARB, and CrCl >30, replacement by an ARNI is recommended to further reduce morbidity and mortality (NNT to prevent one CV death > 3.5 years: 31). ACE-Is or ARBs should be discontinued at least 36 hours prior to starting ARNIs. The most common adverse effects include hypotension, angioedema, and renal insufficiency (3) [A]. The medication is expensive (approx. $400 to $500/month).

- Diuretics are helpful to manage volume overload/reduce preload.
  - Furosemide (Lasix): 20 to 320 mg/day IV/IM/PO divided dose; bumetanide (Bumex): 0.5 mg to 10.0 mg/day IV/PO divided dose; torsemide (Demadex): 10 to 200 mg/day PO divided dose (1)[C]
  - Metolazone (Zaroxolyn): 2.5 to 20.0 mg/day PO divided dose; hydrochlorothiazide: 12.5 to 100.0 mg/day PO divided dose; chlorothiazide (Diuril): 250 to 2,000 mg/day IV/PO divided dose

- Spironolactone, eplerenone (improve mortality when added to standard therapy in NYHA class II to IV + EF <35%): spironolactone 12.5 to 25.0 mg/day PO; maximum 50 mg/day PO; eplerenone 25 to 50 mg/day; caution regarding hyperkalemia and chronic kidney disease (CKD) (1)[A]

- Digoxin reduces symptoms but has not clearly shown any positive effect on mortality: In patients with preserved renal function (CrCl >50 mL/min), the recommended dose is 0.125 mg/day. Levels lower than used for atrial fibrillation are effective and safer (1)[B].

- The combination of hydralazine (75 mg/day divided BID or TID) and isosorbide dinitrate (40 mg QID) is effective for African Americans (1)[A] or if unable to take ACE-I or an ARB (1)[B].

- Ivabradine (Corlanor) can be considered in patients with NYHA II and III HF, EF ≤35%, on maximally tolerated β-blockers with HRs >70 to reduce hospitalization from worsening HF (2)[B]. Ivabradine is contraindicated in ADHF, hypotension (<90/50 mm Hg), severe hepatic impairment, pacemaker-dependence, bradyarrhythmias, or strong CYP3A4 inhibitors. It should not be
administered to patients that are currently in atrial fibrillation and should be discontinued if atrial fibrillation develops (3)[A].

- Intravenous iron replacement might improve functional status and quality of life in patients with NYHA II and III HF and iron deficiency (ferritin <100 ng/mL or 100 to 300 ng/mL if transferrin saturation <20%) (1)[B].
- In diastolic HF, no medical therapy has improved survival (1)[A]. ARBs and spironolactone can be used to potentially reduce hospitalizations (1,2)[A].

ADDITIONAL THERAPIES
Device therapy including implantable cardioverter defibrillators (ICD) and cardiac resynchronization therapy (CRT) shown to improve outcomes

- CRT is recommended for patients in sinus rhythm with a QRS width ≥150 ms due to left bundle branch block (LBBB) and LVEF ≤35% and persistent mild to moderate HF (NYHA II and III) despite optimal medical therapy. CRT may be considered for ambulatory NYHA class IV patients in sinus rhythm with a QRS width ≥150 ms, LBBB, and LVEF ≤35% (1)[A].
- CRT may be considered for patients with LVEF ≤35%, sinus rhythm, QRS width ≥150 ms, non-LBBB pattern, and NYHA III or ambulatory NYHA IV symptoms (1)[A].
- CRT may also be considered for patients with a QRS width between 120 and 150 ms, LBBB, LVEF ≤35%, and persistent mild to severe HF (NYHA II to IV) despite optimal medical therapy (1)[B].
- ICDs are recommended for primary prevention in patients with nonischemic CM and ischemic CM who are at least 40 days post-MI; LVEF ≤35%, NYHA class II or III HF (1)[A], or LVEF ≤30%, NYHA I HF (1)[B]; and on optimal medical therapy and >1 year estimated survival; generally not indicated in American Heart Association (AHA) stage D (end-stage) HF
- CRT is recommended in patients with reduced LVEF and chronic RV pacing or with bradyarrhythmias and an anticipated need for a pacemaker (4)[A].

SURGERY/OTHER PROCEDURES

- Heart valve surgery if defective heart valve is responsible; mitral valve repair especially helpful if mitral regurgitation is the primary issue and not functional
- Advanced therapies such as cardiac transplantation and LV assist device (LVAD) implantation can be considered in patients with HF refractory to conventional medical/device therapies without other disqualifying medical and psychosocial conditions. Cardiac transplantation is generally considered
for patients ≤70 years old with a predicted 1-year survival worse than that afforded by transplantation. Consideration can be made for patients >70 years with few comorbid conditions. Indications for LVAD implantation are generally similar to cardiac transplantation but are evolving.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- See “Heart Failure, Acutely Decompensated.”
- Admit patients with hemodynamic/respiratory compromise, hypoxia/hypoxemia, change in mental status, acute renal insufficiency, significant volume overload, and significant electrolyte abnormalities (e.g., hyponatremia).
- Discharge criteria: subjective improvement, euvolemia on clinical assessment, resting HR <100 bpm, systolic BP >80 mm Hg, HF outpatient education performed

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Critical patient education performed at all outpatient and inpatient physician visits
- Rapid office follow-up (7 days) after hospitalization

Patient Monitoring
Home health monitoring by specially trained nurses have both been shown to decrease frequency of hospitalizations. Readmissions remain problematic.

DIET
Reduce sodium load (<1.5 to 2.0 g/day). Optimal level is unknown.

PATIENT EDUCATION
AHA: www.americanheart.org

PROGNOSIS
After diagnosis: 1-year survival ~75%, 5-year survival <50%, and 10-year survival <25%
COMPLICATIONS
Sudden death (arrhythmic), acute pulmonary edema, death, progressive pump failure

REFERENCES

SEE ALSO
Algorithm: Congestive Heart Failure: Differential Diagnosis

CODES
ICD10
- I50.9 Heart failure, unspecified
- I50.1 Left ventricular failure
- I50.22 Chronic systolic (congestive) heart failure
CLINICAL PEARLS

- Have patients weigh themselves daily and report weight gains of >2 lb in a day or 5 lb above dry weight.
- $\beta$-Blockers, ACE-I, and aldosterone antagonists are the core medications for management of chronic HF.
- Consider referral for biventricular pacing in patients with LBBB and ICD in those with low EF.
HEAT ILLNESS: HEAT EXHAUSTION AND HEAT STROKE

Sean C. Robinson, MD • Brian Frank, MD

BASICS

DESCRIPTION

- A continuum of increasingly severe heat illnesses caused by dehydration, electrolyte losses, and failure of the body’s thermoregulatory mechanisms when exposed to elevated environmental temperatures
  - Heat exhaustion is a mild to moderate form of heat illness displaying dehydration type symptoms with a normal to elevated temperature <104°F (1).
  - Heat stroke is characterized by an elevated core temperature >104°F with central nervous system abnormalities and is a true medical emergency (1,2).
- System(s) affected: endocrine/metabolic, nervous, hepatic, hematologic
- Synonym(s): heat illness; heat injury; hyperthermia; heat collapse; heat prostration

Geriatric Considerations
Elderly persons are more susceptible.

Pediatric Considerations
Children are more susceptible.

Pregnancy Considerations
Pregnant women may be more susceptible to volume depletion with heat stress.

EPIDEMIOLOGY

- Predominant age: more likely in children or elderly
- Predominant sex: male = female

Incidence

- Depends on intensity of heat; estimate of 20/100,000 persons per season (3)
- Concern for increasing incidence of disease if ambient environmental
temperatures continue to rise.

**Prevalence**
- Depends on predisposing conditions in combination with environmental factors
- Roughly 600 deaths per year in the United States

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Direct cellular toxicity of heat, imbalance between inflammatory and anti-inflammatory cytokines, and vascular endothelial damage causing end-organ dysfunction
- Interplay between failure of heat-dissipating mechanisms, an overwhelming heat stress, and an exaggerated acute-phase inflammatory response

**RISK FACTORS**
- Poor acclimatization to heat or poor physical conditioning
- Salt or water depletion
- Obesity
- Acute febrile or GI illnesses
- Chronic illnesses: uncontrolled diabetes mellitus or hypertension, cardiac disease
- Alcohol and other substance abuse
- High heat and humidity, poor air circulation in environment
- Heavy, restrictive clothing
- Nutritional supplementation that includes ephedra (2)
- Medications (α-adrenergics, anticholinergics, antihistamines, antipsychotics, benzodiazepines, β-blockers, calcium channel blockers, clopidogrel, diuretics, laxatives, neuroleptics, phenothiazines, thyroid agonists, tricyclic antidepressants) (1)

**GENERAL PREVENTION**
- The most important factor in preventing heat illness is activity modification and adequate fluid replacement.
- Allow acclimatization to hot weather through proper conditioning and activity modification.
- Dress appropriately with loose-fitting, open-weaved, light-colored clothing.
- Avoid dehydration by consuming a proper volume of fluids during activity or exercise.
Never leave children (or pets) unattended in cars during hot weather.
Try to gain access to air-conditioned environments during hot weather.

PROGNOSIS
- If mental function is not altered and serum enzymes are not elevated, the prognosis is good and recovery within 24 to 48 hours is typical.
- The mortality rate for heat stroke (10–80%) is directly related to the duration and intensity of hyperthermia as well as to the speed and effectiveness of diagnosis and treatment (3).

COMPLICATIONS
- May involve failure of any major organ system
- Cardiac arrhythmias or infarction
- Pulmonary edema, acute respiratory distress syndrome
- Coma, seizures
- Acute renal failure
- Rhabdomyolysis
- Disseminated intravascular coagulopathy (DIC)
- Hepatocellular necrosis

DIAGNOSIS
- Heat exhaustion: Symptoms are milder than in heat stroke, with no severe CNS derangements:
  - Fatigue, lethargy, weakness, dizziness, nausea, vomiting, myalgias, headache, profuse sweating, tachycardia, hypotension, thirst, hyperventilation
  - Core temperature usually elevated but can be normal, if elevated <104°F (40°C)
- Heat stroke: divided into two categories, classic and exertional; marked by mental status changes and elevated core temperature
  - Classic: caused by environmental exposure, primarily in elderly or chronically ill patients, and may develop gradually over days
    - Delirium
    - Confusion
    - Coma
    - Core temperature >104°F (>40°C)
    - Hot, flushed, dry skin
– Exertional: typically younger, very active patients; rapid onset
  o Exhaustion
  o Confusion, disorientation
  o Delirium
  o Coma
  o Hot, flushed skin, typically with sweating
  o Core temperature >104°F (>40°C) (1,2)

**DIFFERENTIAL DIAGNOSIS**
- Febrile illnesses, sepsis
- Drug-induced fluid loss
- Cardiac arrhythmia or infarction
- Acute cocaine intoxication
- Neuroleptic malignant syndrome
- Malignant hyperthermia (an autosomal inherited disorder of skeletal and cardiac muscle in which patients have abnormal muscle metabolism on exposure to halothane or skeletal muscle reactants)

**DIAGNOSTIC TESTS & INTERPRETATION**
Used primarily to detect end-organ damage

*Initial Tests (lab, imaging)*
- Creatinine, BUN, electrolytes (sodium in particular)
- Liver enzymes, muscle enzymes (creatine phosphokinase)
- CBC
- Urinalysis: Increased urine specific gravity
- Results of these studies may indicate hypernatremia, hyperchloremia, and hemoconcentration.
- Drugs that may alter lab results: diuretics

*Diagnostic Procedures/Other*
Rectal temperature (don’t rely on oral temperature) (1,2)

**TREATMENT**

**GENERAL MEASURES**
- Immediate body immersion in ice water to cool core temperature is
recommended for heat stroke. Monitor hemodynamics and airway status (1,3) [C].

- Fluid and electrolyte replacement with normal saline gradually; avoid hypotonic fluids (1,2)[C].
- Consider CVP monitoring.
- Cooling techniques to consider for heat exhaustion:
  - Evaporative cooling: spraying water over the patient and facilitating evaporation and convection with the use of fans (1,3)[C]
  - Immersing the hands and forearms in cold water (3)[C]
  - Use of ice or cold packs on the neck, groin, and axillae (1,2)[C]
- No clear superiority of any one method for heat exhaustion that is not heat stroke (1)

MEDICATION

First Line
- No medications are required in the initial management. Use isotonic saline solution to rehydrate (1,3)[C].
- Do not use antipyretics to lower core temperature in heat illness.

Second Line
- For severely ill, consider immunomodulators such as corticosteroids (patients in ICU setting).
- Iced gastric, bladder, or peritoneal lavage (3)[C]
- In DIC, consider appropriate replacement therapy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Important to cool patient immediately (prior to transport even) if you suspect heat stroke
- Rapid cooling: Remove clothing, wet patient down, and apply ice packs.
- Emergency treatment; best in a hospital setting

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Rest with legs elevated (3)[C].
**Patient Monitoring**
- Rectal temperature monitoring: Cooling may be discontinued when the core temperature drops to 102°F (38.9°C) and stabilizes.
- Heat stroke patients may require airway management, hemodynamic monitoring, and careful fluid and electrolyte administration and monitoring.
- Consider CVP monitoring.

**DIET**
- Cool or cold clear liquids only (noncarbonated)
- Avoid caffeine.
- Unrestricted sodium

**PATIENT EDUCATION**
- The key to prevention is proper hydration.
- Stress the importance of proper conditioning and acclimatization.
- Instruct patients to recognize heat stress signs and symptoms.
- Maintain as much skin exposure as possible in hot, humid conditions while using proper sunblock protection.

**REFERENCES**

**ADDITIONAL READING**
CODES

ICD10
- T67.5XXA Heat exhaustion, unspecified, initial encounter
- T67.0XXA Heatstroke and sunstroke, initial encounter
- T67.3XXA Heat exhaustion, anhydrotic, initial encounter

CLINICAL PEARLS
- Exertional heat stroke is a life-threatening medical emergency that requires immediate whole body cooling (cold/ice water immersion preferred).
- The diagnosis of heat stroke includes an elevated core temperature and signs of CNS dysfunction (e.g., irritability, ataxia, confusion, seizures, or coma).
- Start the cooling process immediately when heat exhaustion is recognized, beginning with wetting the skin with a cool mist and giving oral rehydration solutions if the patient is alert and oriented.
- If in the field (e.g., sporting events, wilderness), cooling should be priority prior to transport.
- Do not rely on oral temperature—a rectal temperature is always preferred.
HEMATICRUA

Tracy O. Middleton, DO, FACOFP

BASICS

DESCRIPTION

- Gross (visible) or microscopic (nonvisible) blood in the urine
- Symptomatic or asymptomatic

EPIDEMIOLOGY

Prevalence

- Microscopic hematuria in school-aged children: 0.4–4%
- Microscopic hematuria in asymptomatic adults varies from 0.9% to 17%, depending on population.

ETIOLOGY AND PATHOPHYSIOLOGY

- Trauma
  - Exercise-induced (resolves within 24 hours of ceasing activity)
  - Abdominal trauma or pelvic fracture with renal, bladder, or ureteral injury
  - Iatrogenic from abdominal or pelvic surgery; chronic indwelling catheters
  - Foreign body, physical/sexual abuse
- Neoplasms
  - Urologic malignancies
  - Benign tumors
  - Endometriosis of the urinary tract (suspect in females with cyclic hematuria)
- Inflammatory/infectious causes
  - UTI: most common cause of hematuria in adults
  - Renal diseases: radiation nephritis and cystitis, acute/chronic tubulointerstitial nephritis (due to drugs, infections, systemic disease)
  - Glomerular disease
    - Goodpasture syndrome (antiglomerular basement membrane disease; autoimmune; associated pulmonary hemorrhage)
    - IgA nephropathy
    - Lupus nephritis
    - Henoch-Schönlein purpura
• Membranoproliferative, poststreptococcal, or rapidly progressive glomerulonephritis (GN)
  • Wegener granulomatosis
  – Endocarditis/visceral abscesses
  – Other infections: schistosomiasis, TB, syphilis
• Metabolic causes
  – Stones (85% have hematuria)
    • Hypercalciuria: a common cause of both gross and microscopic hematuria in children
    • Hyperuricosuria
• Congenital/familial causes
  – Cystic disease: polycystic, solitary renal cyst
  – Benign familial hematuria or thin basement membrane nephropathy (autosomal dominant)
  – Alport syndrome (X-linked in 85%; hematuria, proteinuria, hearing loss, corneal abnormalities)
  – Fabry disease (X-linked recessive inborn error of metabolism; vascular kidney disease)
  – Nail–patella syndrome (autosomal dominant; nail and patella hypoplasia; hematuria in 33%)
  – Renal tubular acidosis type 1 (autosomal dominant or autoimmune)
• Hematologic causes
  – Bleeding dyscrasias (e.g., hemophilia)
  – Sickle cell anemia/trait (renal papillary necrosis)
• Vascular causes
  – Hemangioma
  – Arteriovenous malformations (rare)
  – Nutcracker syndrome: compression of left renal vein and subsequent renal parenchymal congestion
  – Renal artery/vein thrombosis
  – Arterial emboli to kidney
• Chemical causes
  – Aminoglycosides, cyclosporine, analgesics, oral contraceptives, Chinese herbs
• Obstruction
  – Strictures or posterior urethral valves
  – Hydronephrosis from any cause
  – Benign prostatic hyperplasia: Rule out 25 RBCs/hpf—other causes of hematuria.
Other causes: loin pain hematuria (most often in young women on oral contraceptives)

RISK FACTORS
- Smoking
- Occupational exposures (dyes, rubber, or tire manufacturing)
- Analgesic abuse (e.g., phenacetin)
- Medications (e.g., cyclophosphamide)
- Pelvic irradiation
- Chronic infection, especially with calculi
- Recent upper respiratory tract infection
- Positive family history of renal diseases (stones, GN)
- Underlying primary renal disorder
- Chronic indwelling foreign body

DIAGNOSIS

HISTORY
Considerations
- Burning, urgency, frequency: UTI
- Dark cola-colored urine: glomerular origin
- Clots: extraglomerular bleeding
- Arthritis/arthralgias/rash: lupus, vasculitis, Henoch-Schönlein purpura
- Flank pain: stones, infarction, pyelonephritis
- Recent upper respiratory infection (URI): poststreptococcal GN, membranoproliferative GN
- Concurrent URI: IgA nephropathy
- Excessive vitamin use: stones
- Marathon runner: traumatic, rhabdomyolysis
- Travel: schistosomiasis, TB
- Painless hematuria and/or weight loss: malignancy
- Family history: Alport disease (hereditary nephritis), sickle cell, polycystic, IgA nephropathy, thin basement membrane disease, von Willebrand
- In patients with microscopic hematuria, any episode of visible blood in the urine, even if transient, is associated with an OR of 7.2 for the prevalence of urologic cancers.
PHYSICAL EXAM
Considerations
- Elevated BP, edema, and weight gain: glomerular disease
- Fever: infection
- Palpable kidney: neoplasm, polycystic
- Genitalia: look for meatal erosion, lesions

DIAGNOSTIC TESTS & INTERPRETATION
- A hematuria risk index may assist in stratifying patients at risk for urothelial malignancies who require more intensive testing. High-risk indicators are gross hematuria, age >50 years, male gender, and smoking.
- American Urological Association (AUA) suggests upper urinary tract imaging in all adults with unexplained hematuria (1)[C].
- ACOG and the American Urogynecologic Society both recommend that asymptomatic, low-risk, never smoking women aged 35 to 50 years undergo evaluation only if they have >25 RBCs/hpf (2)[C].

Initial Tests (lab, imaging)
- Urine dipstick (sensitivity 91–100%; specificity 65–99%)
  - False negatives are rare but can be caused by high-dose vitamin C.
  - False positives: oxidizers (povidone, bacterial peroxidases, bleach), myoglobin, alkaline urine (>9), semen, food coloring, food (beets, blackberries)
  - Phenazopyridine may discolor the dipstick, making interpretation difficult.
  - Any proteinuria >2+ raises concern for glomerular disease.
- Microscopic urinalysis should always be done to confirm dipstick findings and quantify RBCs.
  - AUA defines clinically significant microscopic hematuria as ≥3 RBCs/HPF on a properly collected urinary specimen when there is not an obvious benign cause (1)[C].
  - Positive dipstick, but a negative microscopic exam should be followed by three repeat tests. If any one is positive, proceed with a workup (1)[C].
  - Exclude factitious or nonurinary causes, such as menstruation, mild trauma, exercise, poor collection technique, or chemical/drug causes, through cessation of activity/cause and a repeat urinalysis in 48 hours.
  - RBC casts are pathognomonic for glomerular origin; dysmorphic cells are also suggestive.
- Voided urine cytology (sensitivity 0–100%; specificity 62.5–100%)
– No longer recommended by AUA for routine evaluation of hematuria (1)[C]; also not recommended by ACP (3)[C]
– May be considered in those with risk factors for urinary malignancy

- Renal function tests (eGFR, BUN, creatinine) to differentiate intrinsic renal disease and to evaluate for risks for imaging contrast dye or certain medications
  – Indicators of renal disease are: significant (>500 mg/day) proteinuria, red cell casts, dysmorphic RBCs, increased creatinine, and albumin:creatinine ratio ≥30 mg/mmol (1)[C]
- Urine culture if suspected infection/pyuria
- PT/INR for patients on warfarin or suspected of abusing warfarin
- Multidetector CT urography (MDCTU); sensitivity 95%, specificity 92% (4)[C]
  – The initial imaging of choice in nonpregnant adults with unexplained hematuria (4)[C]
  – Highly specific and relatively sensitive for the diagnosis of upper urinary tract neoplasms, especially when >1 cm (4)[C]
  – Higher radiation dose; weigh risk of disease versus risk of radiation exposure.
  – Does not obviate the need for cystoscopy, particularly in high-risk patients (4)[C]
  – Presence of calculi on noncontrast does not exclude another diagnosis or need for contrast phase.
  – Visualization of ureters is discontinuous.
  – Less cost-efficient

- CT
  – Perform unenhanced helical CT for suspected stone disease in children if US is negative (5)[C].
  – Perform CT abdomen and pelvis with contrast in children with traumatic hematuria (5)[C].

- Renal US
  – Best for differentiating cystic from solid masses
  – Sensitive for hydronephrosis
  – No radiation or iodinated contrast exposure
  – Cost-efficient
  – Poor sensitivity for renal masses <3 cm
  – Point of care US in the emergency room may help avoid CT in patients with suspected stones.
  – US can be used first line in patients with contraindications to CTU or at low

mebooksfree.com
risk of malignancy (4)[C].

- Main disadvantage is inability to thoroughly evaluate the urothelium for transitional cell cancer.

- Magnetic resonance urography (MRU)
  - High sensitivity/specificity for renal parenchyma; less useful for collecting system or stones
  - Can be used in patients with contraindications to MDCTU (1,4)[C]

- IV urography (IVU)
  - Limited sensitivity for small renal masses and for differentiating cystic from solid masses
  - Addition of US or CT often necessary to evaluate renal parenchyma, so IVU is rarely used.
  - Potential reactions to IV iodine contrast media

- MRI
  - Similar to CT in sensitivity for renal masses
  - No radiation exposure
  - Least cost-efficient
  - Limited ability to reliably detect urinary tract calcifications (4)[C]
  - Can be combined with retrograde pyelogram (RPG) for patients who cannot tolerate MDCTU or MRU (1)[C]

**Diagnostic Procedures/Other**

- Flexible cystoscopy (sensitivity 62%; specificity 43–98%)
  - Best for evaluation of bladder pathology, especially small urothelial lesions; negative predictive value for bladder tumors is 99%.
  - AUA recommends all patients with hematuria who are ≥35 years of age and all patients with risk factors for bladder cancer regardless of age to receive cystoscopy in addition to imaging (1)[C].

- Renal biopsy
  - Not routine but may be necessary to diagnose GN or in the face of increasing renal insufficiency

- RPG
  - Reserved for patients in which findings on MDCTU are equivocal or in addition to US or noncontrast studies in patients who are contraindicated for contrast or MRI (1,4)[C]
  - Sensitive for small lesions of supravesicular collecting system
  - Requires cystoscopy

- Ureteroscopy/pyeloscopy
  - For visualization of suspected supravesical collecting system lesions
– Biopsy, excision, fulguration, or extraction of lesions/stones possible
– Requires anesthesia
– Requires cystoscopy
– Risk of injury to collecting system

**Follow-Up Tests & Special Considerations**

- Other tests depend on suspected etiology: STD testing, antineutrophil cytoplasmic antibody (ANCA), C3, C4, antistreptolysin O (ASO) titer, hemoglobin electrophoresis.
- Consider genetic testing in patients suspected of having familial hematuria.
- Insufficient evidence to recommend routine use of urinary tumor markers; not recommended by ACP (3)[C].
- Malignancies are detected in up to 5% of patients with microscopic hematuria and up to 40% of patients with gross hematuria.
- Summary positive predictive value of visible hematuria for bladder/renal cancer in age >15 years is 5.1%; risk increases with age and male gender.

**Pregnancy Considerations**

Renal US is initial imaging choice for pregnant patients (4)[C]. MRU or RPG combined with either MRI or US are alternatives (1)[C].

**Pediatric Considerations**

- Consider GN, Wilms tumor, child abuse, and hypercalciuria.
- Isolated asymptomatic microscopic hematuria may not need full workup; these patients rarely need cystoscopy; observe for development of hypertension, gross hematuria, or proteinuria (6)[C].
- In patients with asymptomatic microscopic hematuria, most common diagnoses on renal biopsy are hypercalciuria (30–35%), hyperuricemia (5–20%), and glomerulonephritides, such as IgAN and thin basement membrane disease.
- Gross or symptomatic hematuria needs a full workup.
  - If eumorphic RBCs, consider US (rule out stones, congenital abnormalities) and urinary Ca:Cr ratio. Urine Ca:Cr ratio >0.2 is suggestive of hypercalciuria in children >6 years of age (6)[C].
- If dysmorphic RBCs, consider renal consult.
- Renal US identifies most congenital and malignant conditions; CT is reserved for cases of suspected trauma (with contrast) or stones (without contrast) (5,6) [C].
TREATMENT

MEDICATION
None indicated for undiagnosed hematuria

ISSUES FOR REFERRAL
- Prompt nephrology referral for proteinuria, red cell casts, elevated serum creatinine, and albumin:creatinine ratio ≥30 mg/mmol (1)[C]
- Urology referral for stones, vascular/anatomic anomalies, or nutcracker syndrome

SURGERY/OTHER PROCEDURES
Gross hematuria: Clots may require continuous bladder irrigation with a large-bore Foley catheter (two- or three-way catheter may be helpful) to prevent clot retention.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Some experts still recommend periodic urinalysis; recent literature suggests that, after thorough initial negative investigations (imaging, cystoscopy), no follow-up is indicated for the asymptomatic patient with microscopic hematuria unless symptoms or frank hematuria develop. AUA recommends annual urinalyses in these patients, until two consecutive are negative and the consideration for a repeat workup at 3 to 5 years if hematuria is persistent (1)[C].

DIET
Increased fluids for stones or clots

PROGNOSIS
- Generally excellent for common causes of hematuria
- Poorer for malignant tumors and certain types of nephritis
- Persistent asymptomatic microscopic hematuria is associated with an increased risk of end-stage renal disease in patients aged 16 to 25 years.
REFERENCES

SEE ALSO

Algorithm: Hematuria

CODES

ICD10

- R31.9 Hematuria, unspecified
- R31.1 Benign essential microscopic hematuria
- R31.0 Gross hematuria

CLINICAL PEARLS

- Screening asymptomatic patients for microscopic hematuria is an “I” recommendation from the USPSTF.
- Asymptomatic hematuria and hematuria persisting after treatment of UTIs must be evaluated.
- Patients with bladder cancer can have intermittent microscopic hematuria; a thorough evaluation in high-risk patients is needed after just one episode.
- Routine use of anticoagulants should not cause hematuria unless there is an underlying urologic abnormality.
- Signs of underlying renal disease indicate the need for a nephrologic workup, but a urologic evaluation is still needed in the presence of persistent hematuria (1)[C].
HEMOCHROMATOSIS

Alethea Y. Turner, DO

BASICS

DESCRIPTION

Hereditary hemochromatosis (HHC) is a hereditary multisystem disorder that results in iron overload and subsequent deposition into various tissues.

- HHC includes at least four types of iron overload conditions which involve gene mutations that alter iron metabolism.
- There is no mechanism to excrete excess iron, so the surplus is stored in tissue, including the liver, pancreas, and heart, eventually resulting in severe damage to the affected organ(s).
- Patients are often asymptomatic but early clinical features often include fatigue, malaise, arthralgia, and decreased libido.
- Late effects may include diabetes, liver cirrhosis, hypermelanotic pigmentation of the skin, porphyria cutanea tarda, cardiomyopathy, and cardiac arrhythmias.
- Cirrhosis may ultimately result in hepatocellular carcinoma.
- Synonym(s): bronze diabetes; Troisier-Hanot-Chauffard syndrome

EPIDEMIOLOGY

Incidence

- Predominant age: Metabolic abnormality is congenital, but symptoms typically present between the 3rd and 5th decades for HHC types 1, 3, and 4; type 2 juvenile hemochromatosis typically presents between the 1st and 3rd decades of life and neonatal presentation is exceedingly rare.
- Predominant sex: Gene frequency is equal between male and female, although clinical signs are more frequent in men.

Prevalence

- Prevalence in the United States for carrying an HFE gene mutation (type 1 HHC) is 5.4% for the C282Y gene and 13.5% for the H63D gene; prevalence for homozygosity is 0.3% for C282Y and 1.9% for H63D (1).
- Type 1 accounts for >90% of HHC cases in the United States and primarily
occurs in people of northern European descent; ~1 in 200 white adults in the United States are C282Y homozygous (1,2).

**Pediatric Considerations**
Juvenile (type 2) HHC is rare but can present in young patients (between 1st and 3rd decades of life) with hypogonadism and cardiomyopathy.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- HHC type 1 is caused by mutations in the HFE gene (most commonly C282Y and/or H63D), type 2 by mutations in either the HJV or HAMP gene, type 3 by mutations in the TFR2 gene, and type 4 by mutations in the SLC11A3 gene.
- Types 1 to 3 involve a deficiency in an iron-regulating hormone named hepcidin, which causes increased intestinal absorption of iron through excessive expression of ferroportin (a transmembrane protein that transports iron out of the cell and into the bloodstream).
- Type 4 is caused by an insensitivity of ferroportin to hepcidin (4a) or an inactivity of ferroportin itself (4b); the latter leads to iron accumulation within mesenchymal tissue.
- Other rare types of HHC exist as a result of different gene mutations.
- Increased plasma iron and transferrin saturation leads to elevated levels of unbound iron which are then absorbed into various tissue, eventually causing organ dysfunction.

**Genetics**
- Genetically heterogeneous disorder of iron overload; types 1, 2, and 3 are autosomal recessive; type 4 is autosomal dominant.
- Penetrance is incomplete; expressivity is variable; ~13.5% disease penetrance of C282Y homozygosity (CI 13.5%) (3)
- Factors contributing to variable expressivity include different mutations in the same gene, mitigating or exacerbating genes, and environmental factors.

**RISK FACTORS**
- Family history
- White men between the ages of 30 and 50 years (particularly for HFE-related HHC)
- Alcohol consumption, as it increases the absorption of iron and synergistically damages the liver along with the oxidative effects of iron.
- Loss of blood, such as that which occurs during menstruation and pregnancy,
delays the onset of symptoms in women.

GENERAL PREVENTION
First degree relatives of those with HHC should be screened; typically, with fasting transferrin saturation and ferritin levels

ALERT
Screening of the general population is not recommended as only a small subset of patients with HHC will develop symptoms or advanced disease (2,4)[B].

COMMONLY ASSOCIATED CONDITIONS
See “Complications.”

DIAGNOSIS

HISTORY
- Fatigue
- Weakness
- Arthralgias
- Abdominal pain
- Loss of libido or impotency
- Symptoms of diabetes
- Skin pigmentation or blistering
- Dyspnea on exertion

PHYSICAL EXAM
- Hepatomegaly and/or splenomegaly
- Increased skin pigmentation
- Hepatic tenderness
- Peripheral edema
- Jaundice
- Gynecomastia
- Ascites
- Testicular atrophy
- Hepatic tenderness

DIFFERENTIAL DIAGNOSIS
Inflammatory syndromes
Various causes of hepatitis
Biliary or alcoholic cirrhosis
Repeated transfusions
Sideroblastic anemia
Beta thalassemia major

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
There is currently no evidence to support a concrete relationship between symptoms and the degree of iron overload (1).

- Serum ferritin (SF): >300 μg/L for men and postmenopausal women and 200 μg/L for premenopausal women; may be elevated for a number of other reasons including but not limited to inflammation (consider checking inflammatory markers); if elevated with suspicion of hemochromatosis, obtain fasting transferrin saturation.
- Fasting transferrin saturation (serum iron concentration ÷ total iron-binding capacity × 100) is the earliest biochemical marker to be increased in HHC: >45% is suspicious for HHC but warrants further evaluation as it can be elevated in other disease processes including chronic anemias (5).
- Confirmatory testing should be done through HFE mutation analysis (2).

Follow-Up Tests & Special Considerations
- After the diagnosis is established, check the following to determine need for phlebotomy
  - ALT and AST
- Assess for complications of HHC and order testing as deemed appropriate; for instance:
  - HbA1c to rule out diabetes
  - ECG to evaluate an arrhythmia
  - Echocardiogram if concerned for cardiomyopathy
  - Total testosterone if symptoms of hypogonadism are present
- Consider screening for osteoporosis in patients >50 years with additional risk factors (i.e., alcohol or tobacco use) (2).
- Test for viral hepatitis if transaminitis exists to rule out concomitant disease.
- Monitor for liver lesions with an abdominal ultrasound every 6 months if severe liver fibrosis or cirrhosis is present (2).
**Diagnostic Procedures/Other**

- Liver biopsy or hepatic MRI should be done to measure liver iron content if hepatomegaly is present, SF is >1000 μg/L, and/or ALT/AST are elevated.
- Consider liver biopsy in these cases to determine the degree of liver damage and prognosis (2,4)[C]; SF <1000 μg/L, normal AST, and the absence of hepatomegaly have a negative predictive value of 95% for severe fibrosis or cirrhosis (3).

**Test Interpretation**

- MRI signal intensity of liver to muscle should be <0.88 in the setting of high iron content (~87% sensitive, 90% specific) (3).
- Liver biopsy will reveal increased hepatic parenchymal iron stores and evidence of any fibrosis or cirrhosis.

---

**TREATMENT**

**GENERAL MEASURES**

Due to a lack in evidence-based data, there is debate regarding when treatment should be initiated (particularly in asymptomatic patients), what the target serum indices and frequency of phlebotomy should be. American and European Liver Associations recommend initiating treatment when SF is above the normal limit (see “Initial Tests (lab, imaging)”). If HCC diagnosis is confirmed, there is no liver involvement, SF remains normal and the patient is asymptomatic, it is reasonable to monitor SF at least annually (2)[C].

- Phlebotomy (~500 mL per session) is the mainstay of therapy and is performed once or twice weekly in the initial treatment phase and may take up to 2 to 3 years to deplete iron stores (1,4)[C].
- When the patient finally becomes iron deficient, a lifelong maintenance program of ~2 to 6 phlebotomies a year is required to keep iron storage normal or below normal (3,4)[C].
- Erythrocytapheresis is an alternative to phlebotomy as it involves removing only red cells from the blood; however it is expensive, not widely available, and there is no evidence to support a benefit over phlebotomy (1,3).

**MEDICATION**

- If phlebotomy is not feasible or if it is contraindicated (anemia or severe heart disease), a 2nd tier option is chelation therapy with parenteral deferoxamine.
(contraindicated in severe renal disease) or oral deferasirox (contraindicated in severe hepatic impairment) (2); monitor patients for auditory or visual changes annually if on chelation therapy.

- Hepatitis A and hepatitis B immunizations should be provided if there is no evidence of previous exposure (2)[C].
- Pneumococcal vaccination (PPSV23) should be given if cirrhosis is present (2).

**ALERT**
Caution is advised for prescribing androgens in the setting of hypogonadism secondary to risk of hepatotoxicity (2).

**ISSUES FOR REFERRAL**
- Refer to a gastroenterologist if liver biopsy is indicated and for the management of concomitant liver disease.
- Refer to a cardiologist if cardiac involvement is suspected.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Need for hospitalization is typically rare and necessary only for the management of severe complications including need for organ transplant.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Measure hematocrit before each phlebotomy; skip phlebotomy if hemoglobin is <11 g/dL (2).
- In the initial phases of treatment, check SF every 3 months (3,4).
- Once iron stores are depleted, phlebotomy every 1 to 6 months (adjusted based on patient’s need) should be performed to maintain SF between 50 and 100 μg/L; consider targeting SF to <50 μg/L (3).
- During maintenance therapy, measure transferrin saturation and SF yearly.

**DIET**
- Avoid consumption of iron-fortified foods, oysters, uncooked shellfish,
vitamin C and iron-containing supplements (2)[C].
- Natural sources of vitamin C and iron are considered safe (2,4).
- Black tea chelates iron and may be drank with meals (2)[C].

PATIENT EDUCATION
- Adequate hydration prior to phlebotomy is recommended (2).
- Blood collected through phlebotomy may be donated (3,4).
- http://www.hemochromatosis.org/

PROGNOSIS
- Patients diagnosed and treated before the development of cirrhosis or diabetes have a normal life expectancy (2).
- Life expectancy is reduced in patients with cirrhosis and/or diabetes (4).
- Cirrhosis is associated with an increased risk of hepatocellular carcinoma (annual incidence of 3–4%) and mortality (4).
- Cirrhosis is irreversible; arthralgias and symptoms of hypogonadism may not improve with phlebotomies, but other symptoms and complications may be averted with successful management (2,4).

COMPLICATIONS
Complications develop as a result of untreated HHC.
- Arthritis, chondrocalcinosis
- Diabetes mellitus
- Hypogonadism
- Arrhythmia
- Congestive heart failure
- Cirrhosis (prevalence of 20–45% in C282Y homozygotes with SF > 1000 μg/L) (4)
- Hepatocellular carcinoma
- Osteoporosis
- Infection from Listeria monocytogenes, Yersinia enterocolitica, or Vibrio vulnificus is rare, but those with iron overload are at increased risk (4).

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- E83.110 Hereditary hemochromatosis
- E83.118 Other hemochromatosis
- E83.111 Hemochromatosis due to repeated red blood cell transfusions

**CLINICAL PEARLS**

- Screening of the general population for hemochromatosis is not recommended, but testing is recommended if there is clinical suspicion or family history. An elevated transferrin saturation is the earliest abnormality in hemochromatosis. Ferritin is a sensitive measure of iron overload but can be elevated in a variety of infectious and inflammatory conditions without iron overload being present.
- Genetic testing is recommended to confirm type 1 hemochromatosis, which is the most common type.
- Patients with hemochromatosis who have hepatomegaly, transaminitis, and/or serum transferrin >1000 μg/L should be evaluated for liver iron content via MRI or liver biopsy; liver biopsy is necessary to determine degree of liver damage and clarify prognosis.
- Initiate once or twice weekly phlebotomy when SF levels are elevated,
particularly when symptoms or clinical findings are present.

- Goal is to achieve and then maintain SF levels 50 to 100 μg/L, and possibly even <50 μg/L; maintenance phlebotomy is less frequent and patient specific.
HEMOPHILIA

Katie L. Westerfield, DO, IBCLC, FAAFP • Bryan Malave, MD

BASICS

DESCRIPTION

- Deficiency of factor VIII (hemophilia A) or factor IX (hemophilia B) coagulation proteins leading to bleeding tendencies in affected individuals. The majority of cases are due to inherited genetic mutations in factor VIII or factor IX coagulation proteins. However, an estimated 30% of all hemophilia cases result from spontaneous mutations.
- Hemophilia A and B are clinically indistinguishable, but can be differentiated by assays that detect levels of factors VIII and IX, respectively.
- Disease severity correlates with the relative levels of coagulation factors present in serum analysis:
  - Severe: frequent spontaneous bleeding (factor activity <1%)
  - Moderate: bleeding with mild to moderate trauma (factor activity 1–5%)
  - Mild: bleeding with major trauma, tooth extraction, or surgery (factor activity 5–40%)
- Frequency of bleeding is similar when levels of severity are comparable in hemophilia A and B.

EPIDEMIOLOGY

- Worldwide, an estimated 400,000 people are affected with hemophilia; estimated frequency of 1 in 10,000 births (1)
- Hemophilia A represents 80–85% of the total hemophilia population; hemophilia B comprises the remaining 15–20%.

ETIOLOGY AND PATHOPHYSIOLOGY

- Damage to vascular endothelium leads to exposure of subendothelial tissue factors, which interact with platelets, plasma proteins, and coagulation factors to produce a localized platelet plug contributing to hemostasis. Complexes involving factors VIII and IX participate in the intrinsic coagulation pathway to activate factor X, FXa. Downstream interactions involving FXa culminate in the conversion of prothrombin to thrombin, mediating platelet activation,
and fibrin deposition necessary for stabilization of the platelet plug.

- Deficiencies of factor VIII or factor IX result in decreased production of FXa, leading to an unstable platelet plug and impaired hemostasis.

**Genetics**

- Exhibits an X-chromosome linked inheritance pattern. Males are almost exclusively affected; females are asymptomatic carriers, unless their factor activity is <40% of normal.
- Carriers with symptomatically low clotting factor levels are treated similarly to patients with the trait:
  - May bleed at the time of surgery
- Males within the same family share similar deficiencies and level of severity owing to the same genetic defect.

**GENERAL PREVENTION**

- Patients should carry medical ID tags listing their bleeding disorder or factor deficiency, inhibitor status, type of treatment products used, and initial treatment doses for mild, moderate, or severe bleeding.
- Immediate family members of affected patients should have factor VIII and IX levels checked prior to invasive procedures, childbirth, and if bleeding tendencies occur.
- Genetic testing should be offered to at-risk female family members to facilitate genetic counseling.

**DIAGNOSIS**

- History and initial presentation
  - 2/3 of presenting hemophilic patients have a positive family history. All male infants born to known carriers should have factor level testing.
  - Prolonged bleeding with circumcision, dental work, surgery, or injury
  - Excessive or easy bruising in early childhood
  - Spontaneous bleeding, especially in joints, muscle, or soft tissue
  - Typical presentation times: mild (36 months), moderate (8 months), severe (1 month)

  - **Pregnancy Considerations**: Treat all males born to a carrier as if they have hemophilia. Test at birth. Avoid vacuum/forceps deliveries (2)[B].
  - Cord blood can be used for testing (3)[A].
- Life-threatening bleeds
Intracranial hemorrhage: generally resulting from trauma; incidence of 1:10; fatal in 30% of cases
Hematomas of bowel wall can cause obstruction or intussusception and pain mimicking appendicitis.
Neck or throat bleeds: can lead to airway obstruction

Serious bleeds
Hemarthrosis, most commonly of ankles, elbows, and knees
  - Infants may present with irritability or decreased use of limb.
  - Adults may have prodromal stiffness, acute pain, and swelling of joint.
  - Arthropathy results from repeated bleeding into joints, damaging cartilage, and subchondral bone:
    - Can result in fixed joints, muscle wasting, and significantly impaired mobility
Muscular hematomas most commonly occur in quadriceps, iliopsoas, and forearm:
  - May result in compartment syndrome and ischemic nerve damage, such as femoral nerve neuropathy due to undetected retroperitoneal hemorrhage
  - Mucous membrane bleeding, such as in the genitourinary tract, leading to hematuria
  - Pseudotumor syndrome: untreated hemorrhage causing a hematoma, which calcifies (named because it can be mistaken for cancer)

DIFFERENTIAL DIAGNOSIS
- Von Willebrand disease
- Vitamin K deficiency, anticoagulant (warfarin, rivaroxaban, argatroban, heparin, enoxaparin) therapy (factor IX is vitamin K–dependent)
- Other factor deficiencies, afibrinogenemia, dysfibrinogenemia, fibrinolytic defects, platelet disorders
- Child abuse

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- CBC with platelet count, PT, aPTT, platelet function (preferred) or bleed time, vWF, factor VIII:C assay, factor IX assay; prolonged aPTT: corrected when mixed with pooled normal plasma in absence of inhibitors
- PT, platelet count, and platelet function are normal.
- Diagnosis based on factor VIII:C or IX activity
– Normal factor levels: 50 to 150 IU/dL
– Mild: 5 to 40 IU/dL
– Moderate: 1 to 5 IU/dL
– Severe: <1 IU/Dl

**Follow-Up Tests & Special Considerations**
Inhibitors to factor VIII and IX (see “Complications”):
- Should be periodically measured using the Nijmegen or Bethesda assay, which quantifies the alloantibody titer
- Screen before invasive procedures and at regular intervals.

**Diagnostic Procedures/Other**
Prenatal diagnosis: genetic testing of a sample of chorionic villus or fluid obtained at amniocentesis; not recommended (2)[B]

**Test Interpretation**
In affected joints: synovial hemosiderosis, articular cartilage degeneration, thickening of periarticular tissues, bony hypertrophy

**TREATMENT**

**GENERAL MEASURES**
- Avoid aspirin or other NSAIDs.
- Treat early; acute bleeds should be treated as quickly as possible, preferable within 2 hours (1)[A].
- For surgical prophylaxis
  - If major surgery is undertaken, factor levels should be maintained at >50% for at least 2 to 3 weeks after the procedure:
    - Fibrin glue products may be beneficial for oozing.
  - Dental extractions: Antifibrinolytics (Amicar, tranexamic acid) may be used.
  - Minor procedures: may use desmopressin (DDAVP)
- Hepatitis A and B vaccinations are recommended.
- Encourage physical activity for normal neuromuscular development: Patients should avoid high-impact contact sports; restrict activities in proportion to degree of factor deficiency. Organized sports should be encouraged as opposed to unstructured activities (1)[B].
MEDICATION

First Line

- Principles of therapy
  - Primary prophylaxis: administration of specific factor replacement therapy in the absence of bleeding to maintain adequate baseline plasma levels sufficient for hemostasis in all categories of severity (1)[A]
    - Lower frequency of acute bleeds and episodes of life-threatening hemorrhage compared to on-demand therapy
    - Standard of care for children with severe hemophilia A to prevent joint bleeds and joint degeneration
    - Dosing, frequency, duration of therapeutic regimens tailored to individual patient needs in clinical practice
  - On-demand therapy: treatment administered in response to occurrence of bleeding
    - Amount and duration of factor replacement depends on location and severity of bleeding:
      - Mild bleeds correct to a factor level of >30% major hemorrhages and large muscle bleeds require correction to levels between 50% and 100%
      - Life-threatening bleeds require levels between 80% and 100%, sustained with bolus dosing or continuous infusion.
- Specific agents:
  - Hemophilia A: Replacement with factor VIII concentrates is the treatment of choice: two sources for the factor available:
    - Purified plasma-derived factor VIII: Donor pool is screened, and the plasma-derived factor is treated to inactivate viruses (HIV, hepatitis B, and hepatitis C). Theoretical risks still exist.
    - Recombinant factor VIII
      - Dosing: 1 IU of factor VIII (the amount in 1 mL of plasma)/kg body weight administered will raise the plasma level of the recipient by 2%
      - Most FVIII products have short half-lives, requiring frequent injections; novel recombinant factor VIII; rFVIIIFc, dosed prophylactically 1 to 2 times per week (4)[B]
  - Hemophilia B: Replacement with factor IX concentrates is the treatment of choice:
    - Plasma-derived factor IX and recombinant factor IX (preferred) are commercially available.
    - Dosing: 1 IU/kg body weight administered will raise plasma factor IX
levels 1%.

- Hemophilia patients with inhibitors (neutralizing alloantibodies to factors VIII or IX)
  - Inhibitor formation should be suspected when replacement with the deficient factor fails to correct coagulopathy.
  - Low-titer (<5 BU/mL) patients: Replace with high doses of the deficient factor to overcome the circulating inhibitor concentration.
  - High-titer patients: Treat using products that bypass the factor neutralized by the alloantibody or emergently with high doses of the specific deficient factor:
    - Two bypassing agents are available; both are efficacious at providing 80% of bleeding episodes:
      - Anti-inhibitor coagulation complex (AICC)
      - Recombinant activated factor VII (rFVIIa)
  - Immune tolerance induction (ITI): protocols to promote immune tolerance through repeated exposure to high-dose factor VIII therapy over 12 to 18 months, with or without immunosuppressive therapy (corticosteroids, cyclophosphamide, rituximab). Success rates are 60–80%.
    - Home therapy allows immediate access to clotting factor, resulting in decreased pain, dysfunction, and long term disability (2)[B].

**Second Line**

- Cryoprecipitate and fresh frozen plasma (FFP) can be used in instances where the specific factor concentrate is unavailable for emergent hemostasis.
  - FFP: contains all coagulation factors but generally difficult to attain high levels of factors VIII or IX
    - Starting dose: 15 to 20 mL/kg
  - Cryoprecipitate: derived from precipitates of cooled FFP; contains significant levels of factor VIII (up to 100 IU/bag) but not factor IX:
    - Dosing: 1 mL cryoprecipitate has ~3 to 5 IU factor VIII.
- Desmopressin (DDAVP): synthetic vasopressin; stimulates endogenous release of factor VIII (and vWF) from endothelial stores; used in mild to moderate hemophilia
  - IV or SC: 0.3 μg/kg infused 30 minutes prior to procedure; may repeat if needed
  - Intranasal (150 μg/spray): adult dose, 1 spray to each nostril (300 μg total). Alternate dose if <50 kg: 150 μg once.
  - Adverse effect: hyponatremic seizures, especially in children; restrict fluids and watch sodium levels and urine output.
Antifibrinolytic agents: inhibit plasminogen activation, thereby stabilizing the clot
  – Effective in controlling mucosal bleeding, such as bleeding in oral cavity, epistaxis, and menorrhagia; can also be used prophylactically (e.g., prior to tooth extractions)
    o Tranexamic acid (25 mg/kg PO q6–8h or 10 mg/kg IV q6–8h)
    o Aminocaproic acid (Amicar) is less frequently used.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Regular evaluations every 6 to 12 months, including a musculoskeletal evaluation, an inhibitor screen, liver tests, and tests for antibodies to hepatitis viruses and HIV

PATIENT EDUCATION
- National Hemophilia Foundation: http://www.hemophilia.org/
- World Federation of Hemophilia: http://www.wfh.org/

PROGNOSIS
- Survival is normal for those with mild disease; mortality is increased 2- to 6-fold in those with moderate to severe disease.
- Intracranial hemorrhage is a leading cause of death in hemophilia.
- Hemophilic arthropathy is the main cause of morbidity in patients with severe hemophilia.

COMPLICATIONS
- Hemophilic arthropathy: Symptoms include pain, limitation of motion, and contractures.
- Theoretical transmission of bloodborne infections, such as hepatitis A, B, C, and D and HIV; this risk has been greatly reduced with current testing of blood products.
- Development of inhibitor autoantibodies
  – More common in hemophilia A (20–30% of patients compared to 5% in hemophilia B) and in patients with severe disease requiring multiple
transfusions

- Risk factors for inhibitor development:
  - Specific genetic defect (family history); null mutations have higher inhibitor incidence.
  - Very low or no circulating factor, therefore requiring multiple transfusions
  - Age of first exogenous factor exposure; previous studies report a higher incidence of developing antibodies in those exposed to exogenous factor at <6 months of age, but new studies show this may be due to severity of disease.
  - Concurrent inflammation/infection when administering factor (e.g., surgical prophylaxis)
  - Duration of factor exposure

- No increased risk of bleeding, but when bleeding occurs, it is more difficult to achieve hemostasis due to decreased response to factor replacement.

REFERENCES

ADDITIONAL READING

2012;379(9824):1447–1456.

**CODES**

**ICD10**
- D66 Hereditary factor VIII deficiency
- D67 Hereditary factor IX deficiency
- Z14.01 Asymptomatic hemophilia A carrier

**CLINICAL PEARLS**
- Deficiency of factor VIII (hemophilia A) or factor IX (hemophilia B) coagulation proteins leading to bleeding tendencies in affected individuals
- Deficiencies of factor VIII or factor IX result in decreased production of FXa, leading to an unstable platelet plug and impaired hemostasis.
- The majority is due to inherited genetic mutations in factor VIII or factor IX coagulation proteins.
- An estimated 30% of all hemophilia cases result from spontaneous mutations.
- Exhibits an X-chromosome linked inheritance pattern. Males are almost exclusively affected.
- Diagnosis based on factor VIII:C or IX activity
- Survival is normal for those with mild disease; mortality is increased 2- to 6-fold in those with moderate to severe disease.
HEMORRHOIDS
Juan Qiu, MD, PhD

BASICS
DESCRIPTION

- Varicosities of the hemorrhoidal venous plexus
- External hemorrhoids
  - Located below the dentate line (painful)
  - Covered by squamous epithelium
- Internal hemorrhoids
  - Located above the dentate line (painless)
  - Both types of hemorrhoids often coexist.
  - Classification of internal hemorrhoids:
    o 1st-degree: Hemorrhoids do not prolapse.
    o 2nd-degree: prolapse through the anus on straining but reduce spontaneously
    o 3rd-degree: protrude and require digital reduction
    o 4th-degree: cannot be reduced
- Hemorrhoids often progress from itching and bleeding to protrusion with easy reduction, then difficult reduction, and finally, rectal prolapse. Thrombosis may occur at any stage of protrusion. External hemorrhoids cause pain; internal hemorrhoids generally do not (1).

Geriatric Considerations
Hemorrhoids are more common in elderly, as is rectal prolapse.

Pediatric Considerations
Uncommon in infants and children; when discovered, look for underlying cause (e.g., vena caval or mesenteric obstruction, cirrhosis, portal hypertension [HTN]).
Occasionally, as in adults, hemorrhoids may result from chronic constipation, fecal impaction, and straining at stool; surgery rarely required in children

Pregnancy Considerations
Common in pregnancy
- Usually resolves after pregnancy
- No treatment required, unless extremely painful

**EPIDEMIOLOGY**
- Predominant age: adults; peak from 45 to 65 years
- Predominant sex: male = female

**Incidence**
Common

**Prevalence**
~4–5% in general population in the United States

**ETIOLOGY AND PATHOPHYSIOLOGY**
- There are three primary hemorrhoidal cushions—typically located in left lateral, right anterior, and right posterior positions. Hemorrhoidal cushions augment anal closing pressure and protect the anal sphincter during stool passage. During Valsalva, increased intra-abdominal pressure raises pressure within the hemorrhoidal cushions. Mechanisms implicated in symptomatic hemorrhoidal disease include:
  - Dilated veins of hemorrhoidal plexus
  - Tight internal anal sphincter
  - Abnormal distention of the arteriovenous anastomosis
  - Prolapse of the cushions and the surrounding connective tissues

**Genetics**
No known genetic pattern

**RISK FACTORS**
- Pregnancy
- Pelvic space-occupying lesions
- Liver disease; portal HTN
- Constipation
- Occupations that require prolonged sitting
- Loss of perianal muscle tone due to old age, rectal surgery, birth trauma/episiotomy, anal intercourse
- Obesity
- Chronic diarrhea
GENERAL PREVENTION
- Avoid constipation by consuming high-fiber diet (>30 g/day) and ensuring proper hydration.
- Maintain appropriate weight.
- Avoid prolonged sitting or straining on the toilet.

COMMONLY ASSOCIATED CONDITIONS
- Liver disease; portal HTN
- Pregnancy
- Constipation

DIAGNOSIS
Diagnosis is typically straightforward through history and inspection of the perineum, rectal exam, and anoscopy.

HISTORY
- Internal/external hemorrhoids
  - Classically, bright red blood per rectum
    - May range from scant blood on toilet paper to copious blood in the toilet bowl
  - Constipation or diarrhea
  - Straining with defecation
- Small or minimal external hemorrhoids
  - Episodic bleeding on stool or toilet paper, pruritus and pain
- More extensive internal hemorrhoids
  - Feeling of incomplete evacuation
  - Thrombosed hemorrhoids present as an acute painful mass (1)

PHYSICAL EXAM
- Anorectal exam including anoscopy (1)
- Inspection following straining at stool
- For protruding hemorrhoids: mass, more prominent bleeding; if not reducible, increased risk of strangulation and/or thrombosis with acute pain
- Abdominal exam to exclude mass
- Peripheral stigmata of cirrhosis and portal HTN (caput, telangiectasias, palmar erythema)
DIFFERENTIAL DIAGNOSIS
- Rectal or anal neoplasia
- Condyloma
- Skin tag
- Inflammatory bowel disease
- Anal fistula, fissure, or abscess

DIAGNOSTIC TESTS & INTERPRETATION

**Diagnostic Procedures/Other**
Sigmoidoscopy or colonoscopy depending on risk factors for malignancy in patients with rectal bleeding

TREATMENT

**Prevention**
- Fiber supplements
- Stool softeners
- Anal hygiene

**GENERAL MEASURES**
- Hemorrhoids are a recurrent disease, even after surgical excision. Preventive measures should be continued indefinitely.
- For mild symptoms or prevention
  - Avoid prolonged sitting during bowel movements.
  - Avoid straining.
  - Avoid constipation by eating a high-fiber diet or by taking fiber supplements; if necessary, take regular stool softeners.
- Regular exercise
- For pain, sitz baths warm water or hypertonic Epsom salts (1 cup per 2 quarts of water)
- Pruritus or mild discomfort after stooling responds well to topical hydrocortisone ointment, anesthetic ointments or sprays, and warm sitz baths.
- Constipation relief, anal hygiene, local ointments, and sitz baths are effective through the stage of easy reduction (stage 2). More severe stages often require ligation or surgery.
MEDICATION

First Line
- Dietary modification with adequate fluid (generally ≥2 L water/day) and fiber (≥30 g/day) is primary first-line, nonoperative therapy for symptomatic hemorrhoids.
  - Pain
    - Hydrocortisone ointment (0.5–1.0%)
    - Analgesic sprays or ointments: benzocaine and dibucaine (Nupercainal).
      Use sprays with caution, as they may contain alcohol that can cause burning sensation when applied.
  - Pruritus: hydrocortisone (Anusol-HC, Cortifoam)
  - Bleeding
    - Astringent suppositories (Preparation H)
    - Hydrocortisone (Anusol-HC, Cortifoam)

Second Line
Treatment for special cases
- Thrombosed external hemorrhoids: common complication of hemorrhoidal disease. With conservative treatment, thrombus absorbs over several weeks, and pain improves in 2 to 3 days (1,2)[A].
- With severe acute pain, prompt excision should be performed under local anesthetics and the wound left open without packing. Use sitz baths, topical anesthetics, and mild pain relievers for the first 7 to 10 days after excision (1,2)[A].
- Strangulated hemorrhoid: from irreducible 3rd- or 4th-degree hemorrhoid. If untreated, it can progress to ulceration and thrombosis. Treatment requires urgent or emergent hemorrhoidectomy.
- Acute hemorrhoidal bleeding associated with portal HTN can be life-threatening. Treatment should be suture of the bleeding site with incorporation of the mucosa, submucosa, and internal sphincter. Coagulopathy should be corrected.

SURGERY/OTHER PROCEDURES
- Indications: failure of medical and nonoperative therapy, symptomatic stage 3 or stage 4 symptoms in presence of a concomitant anorectal condition requiring surgery, or patient preference (1,2)[A]
- Incision of thrombosed hemorrhoid: for severe pain
Severe protruding hemorrhoids

- Rubber band ligation (internal hemorrhoids only) (1,2)[A]
- Sclerotherapy: for symptomatic prolapsed stage I or II hemorrhoids; care must be taken not to inject near periprostatic parasympathetic nerves; not for advanced disease or if evidence of infection, inflammation, and ulceration is present
  - Cryotherapy is no longer recommended due to high rate of complications.
- Prolapsed rectum
  - Requires surgical correction
- Surgical resection
  - Gold standard: Conventional hemorrhoidectomy should be considered for grade III hemorrhoids not responding to banding; mixed internal and external; grade IV hemorrhoids; or when complicated by fissures, fistula, or extensive skin tags (1–3)[A].

Newer techniques reduce surgical time, early postoperative pain, urinary retention, and time to return to normal activity.

- Transanal hemorrhoidal dearterialization (THD): fewer complications and can be used in cases of recurrent diseases (2)[A]
- Stapled hemorrhoidopexy: less painful than traditional surgery but higher incidence of skin tags and recurrent prolapse (2)[A]
- LigaSure hemorrhoidectomy: reduces operating time, is superior in patient tolerance, and is equally effective as conventional hemorrhoidectomy in long-term symptom control (4)[B],(5,6)[A]

COMPLEMENTARY & ALTERNATIVE MEDICINE
Aloe vera cream on the surgical site after hemorrhoidectomy reduces postoperative pain and decreases healing time and analgesic requirements.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

- Encourage physical fitness, weight management, and dietary compliance.
- Avoid prolonged sitting and straining on the toilet.

Patient Monitoring
As needed, depending on treatment
DIET
High-fiber with a target of 30 g of insoluble fiber/day through sources such as wheat bran cereals, oatmeal, peanuts, artichokes, beans, corn, peas, spinach, potatoes, apples, apricots, blackberries, raspberries, prunes, pears, bananas; adequate fluids (6 to 8 glasses of water/day); avoid excessive caffeine.

PATIENT EDUCATION
High-fiber diet: Top Fiber-Rich Foods List:

PROGNOSIS
- Spontaneous resolution
- Recurrence

COMPLICATIONS
- Thrombosis
- Ulceration
- Anemia (rare)
- Incontinence
- Pelvic sepsis following hemorrhoidectomy

CODES

ICD10

- K64.9 Unspecified hemorrhoids
- K64.0 First degree hemorrhoids
- K64.1 Second degree hemorrhoids

CLINICAL PEARLS

- Hemorrhoids are very common. Internal hemorrhoids are typically painless. External hemorrhoids are typically painful.
- Anal hygiene and symptomatic pain relief are the treatments of choice for stage 1 and 2 hemorrhoids. Sitz baths with warm water or hypertonic Epsom salts (1 cup per 2 quarts of water) are effective for pain relief.
- All patients should be encouraged to eat a high-fiber diet with 30 g of insoluble fiber per day.
- More advanced hemorrhoidal disease requires intervention with ligation or surgery.
HENOECH-SCHÖNLEIN PURPURA
Shani I. Muhammad, MD

BASICS

DESCRIPTION

- Henoch-Schönlein purpura (HSP) is a nonthrombocytopenic, predominantly IgA-mediated, small vessel vasculitis that affects multiple organ systems and occurs in both children and adults.
- HSP is often self-limited, with the greatest morbidity and mortality attributable to long-term renal damage.
- Characterized by a tetrad of purpuric skin lesions, arthralgia, abdominal pain, and nephropathies.

EPIDEMIOLOGY

Incidence

- Annual incidence: 135/1 million children and 3.4 to 14.3/1 million adults
- Mean age of patients affected is 6 years; 90% <10 years of age but has been reported in patients age 6 months to 75 years old.
- Gender: Male-to-female ratio is 1.2:1.
- Race/ethnicity: most common in Caucasians and Asians, less common among African Americans.

Prevalence

- Annual prevalence: 10 to 22/100,000 persons
- Year-round occurrence; more common in late fall to early spring.

ETIOLOGY AND PATHOPHYSIOLOGY

- Autoimmune disorder in which IgA production is increased in response to trigger(s), IgA1 immune complexes then activate the complement pathway, leading to production of inflammatory cytokines and chemokines.
- Immune complex deposition results in small vessel inflammation; fibrosis; and necrosis within skin, intestinal mucosa, joints, and kidneys.
- No single etiologic agent has been identified.
- Known triggers include infection, drugs, vaccinations, and insect bites.
- Infectious antigens include (but are not limited to) group A Streptococcus.
Paroxysmal cold hemoglobinuria (may be present in up to 30% of HSP-associated nephritis), parvovirus B19, Bartonella henselae, Helicobacter pylori, Haemophilus parainfluenzae, coxsackievirus, adenovirus, hepatitis A and B viruses, Mycoplasma, Epstein-Barr virus, varicella, Campylobacter, methicillin-resistant Staphylococcus aureus.

- Drugs: acetaminophen, quinolones, etanercept, codeine, clarithromycin
- Vaccinations: MMR (measles, mumps, rubella), pneumococcal, meningococcal, influenza, hepatitis B

**Genetics**

Associated with α₁-antitrypsin deficiency, familial Mediterranean fever, HLA-DRB1*01, HLA-B35

**COMMONLY ASSOCIATED CONDITIONS**

- Malignancy (rare): Greatest association is with solid tumors, including lymphoma, prostate cancer, and non–small cell lung cancer, but also associated with multiple myeloma.
- Studies suggest a possible relationship with H. pylori infection (1)[A].

**DIAGNOSIS**

Palpable purpura and at least one of the following:

- Diffuse abdominal pain
- Biopsy with predominant IgA deposition
- Arthralgia or arthritis
- Renal involvement (hematuria or proteinuria)
- Direct immunofluorescence showing IgA deposition (2)[A]

**HISTORY**

- History of exposure to known trigger, including recent infection (particularly upper respiratory infection), vaccination, foods, or offending drug (3)
- Rash (most common presenting symptom): purpuric, palpable; distribution often symmetric on lower extremities and buttocks; may present on upper extremities, trunk, and face; typical duration 3 to 10 days; no definitive temporal association with other symptoms
- Fatigue
- Low-grade fever
- Nausea/vomiting
- Abdominal pain (diffuse, colicky, may be transient or constant)
- Hematochezia/melena
- Polyarthritis (often symmetric involvement of knees and ankles)
- Gross hematuria
- Rare symptoms: periorbital or scrotal swelling, headache, neuropathy, hemoptysis

**PHYSICAL EXAM**
- Rash (96% of cases, 74% primary presenting symptom):
  - May start as urticaria, develops into nonblanching purpura, with or without petechiae and ecchymoses, may also be bullous
  - Distribution usually symmetric, most commonly involving the lower extremities but may involve the face and trunk
- Abdominal tenderness (66% of cases, 12% primary presenting symptom):
  - Evidence of GI hemorrhage (28% of cases)
- Joint tenderness (64% of cases, 15% primary presenting symptom):
  - Mainly affects knees or ankles; may have associated warmth and limited range of motion, less commonly effusion; erythema is absent.
  - Mostly nonmigratory, transient, and nondeforming
- Orchitis (5%):
  - Presents as scrotal swelling and tenderness, may have associated torsion
- Renal disease (<1% primary presenting symptom):
  - Hypertension may be present.
- Rarely, patients present with CNS or pulmonary involvement, which may manifest as signs of cerebral hemorrhage or diffuse interstitial pneumonia, respectively.

**DIFFERENTIAL DIAGNOSIS**
- Infection:
  - Meningococcemia
  - Rocky Mountain spotted fever
  - Bacterial endocarditis
  - Rheumatic fever
- Immune-mediated:
  - Polyarteritis nodosa
  - Wegener granulomatosis
  - Systemic lupus erythematosus
  - Kawasaki disease
Other:
- Inflammatory bowel disease
- Idiopathic thrombocytopenic purpura
- Juvenile rheumatoid arthritis
- Leukemia
- Acute surgical abdomen
- Child abuse

**DIAGNOSTIC TESTS & INTERPRETATION**

- No single lab test confirms the diagnosis of HSP.
- Labs directed toward excluding other illnesses and assessing degree of renal involvement

**Initial Tests (lab, imaging)**

The following are generally accepted as initial labs for HSP:

- **CBC:**
  - Leukocytosis and thrombocytosis may occur. Thrombocytopenia indicates an alternative cause of purpura.
  - Hemoglobin is variable, depending on whether GI hemorrhage occurs.

- **Basic serum chemistry panel (electrolytes, BUN, creatinine):**
  - Electrolyte imbalances or elevated creatinine indicate renal dysfunction.

- **Urinalysis:**
  - Gross or microscopic hematuria, proteinuria, and red cell casts indicate renal dysfunction.

- **PT and PTT:**
  - Normal in HSP

- **Imaging** is not part of the routine workup for HSP but may be performed to rule out alternative etiologies or for evaluation of suspected complications, particularly in cases of GI and renal involvement. Initial imaging modalities to consider include the following:
  - Abdominal radiographs, with or without barium enema: Evaluate for free abdominal air suggestive of bowel perforation.
  - Abdominal ultrasound: sensitive for the detection of intramural bleeding in HSP and may also show thickened bowel wall, reduced peristalsis, intussusception

- Renal ultrasound: evaluates for hydronephrosis in cases of renal failure

**Follow-Up Tests & Special Considerations**
The following labs are also useful in diagnosing HSP:

- **Blood culture:**
  - To rule out sepsis/bacteremia when diagnosis is unclear
- **Acute phase reactants:**
  - Expect mild elevation.
- **IgA level:**
  - Often elevated, although nonspecific, nonsensitive
- **Visfatin levels (4)**
- **Degree of elevation correlates with disease severity and likelihood of renal involvement (4).**
- **Complement levels:**
  - Normal; sometimes decreased
- **Antinuclear antibody/antineutrophil cytoplasmic antibody:**
  - Negative
- **Antistreptolysin-O titer:**
  - Evaluates for preceding streptococcal infection
- **Stool guaiac if suspected GI hemorrhage**
- **CT arteriography may be necessary to identify the location of bleeding in patients with GI hemorrhage.**

**Diagnostic Procedures/Other**

- **Renal biopsy:** Obtain if diagnosis is uncertain or if nephrotic range proteinuria shows mesangial IgA deposition, mesangial proliferation, or, in severe cases, crescentic glomerulonephritis.
- **Skin biopsy of purpura: IgA deposition in the dermis on immunofluorescence (2)[A]**
- **Endoscopy may be considered in cases of GI hemorrhage given symptomatic overlap of HSP with inflammatory bowel disease.**
- **Barium enema may be therapeutic in some instances of intussusception, although surgical correction is commonly needed.**

## TREATMENT

### GENERAL MEASURES

Rest and elevation of affected areas may limit purpura.

### MEDICATION
In the absence of renal dysfunction or complication, HSP is usually self-limited and best managed with supportive care.

NSAIDs effective for symptomatic joint pain. Caution is advised in cases of GI hemorrhage; avoid use in cases of renal involvement and consider acetaminophen as an alternative.

Steroids given early in disease course using oral prednisone 1 to 2 mg/kg/day for 1 to 2 weeks decrease both duration of abdominal pain and severity of joint pain and may have benefit in preventing GI bleeding and causes of surgical abdomen, including intussusception.

Steroids have benefit in treatment of severe and/or bullous purpura.

Steroids given early in disease are effective for the acute treatment of crescentic nephritis and may prevent chronic renal disease in such patients.

Early steroids have no effect on prevention or development of renal involvement after 1 year.

High-dose IV pulse steroids (500 mg to 1 g) may be considered in cases of mesenteric vasculitis and severe renal impairment. Evidence is very limited to support use of cyclophosphamide, plasmapheresis, and intravenous immunoglobulin (IVIG) for severe renal and GI involvement, as well as colchicine for severe skin lesions.

Mycophenolate mofetil (MMF) could be valuable in the treatment of complicated HSP (4,5)[A].

ISSUES FOR REFERRAL

Consider nephrology referral for renal biopsy if nephrotic range proteinuria at any time or proteinuria >100 mg/mmol for 3 months after diagnosis.

Dermatology referral for skin biopsy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Admission criteria/initial stabilization
  – Insufficient oral intake
  – Renal insufficiency
  – Severe abdominal pain
  – Severe GI bleeding
  – Altered mental status
  – Mobility restriction due to arthritis
  – HTN
  – Nephrotic syndrome
IV fluids: Hydration should be maintained.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Patients should be seen weekly during the acute illness. Visits should include history and physical exam to include BP measurement and urinalysis.
- Because ~100% of patients who develop renal involvement will do so within 6 months of HSP diagnosis, all patients should be followed at least monthly with BP and urinalysis for a duration of no <6 months.
- Women with a history of HSP should be monitored for proteinuria and HTN during pregnancy.
- Consider workup for occult malignancy in patients with adult-onset HSP.

**PATIENT EDUCATION**

**PROGNOSIS**
- Long-term prognosis heavily dependent on presence and severity of nephritis
- HSP is self-limited in 94% of children and 89% of adults.
- Most cases of HSP resolve within 4 weeks of diagnosis. Recurrence rate within 6 months of diagnosis is 33%.
- Factors associated with poorer prognosis include age >8 years, fever at presentation, purpura above the waist, elevated ESR or IgA concentration, and increasing severity of renal histology grade.
- Chronic renal disease occurs in up to 20% of children with nephritic and nephrotic syndrome compared with 50% of adults who had any renal involvement. Risk of long-term renal failure is ≤5%.
- Risk factors that may result in renal failure include old age, HTN, elevated serum creatinine, and nephrotic and mixed nephritic–nephrotic syndrome at...
the onset of disease (4)[A].

**COMPLICATIONS**
- Nephrotic/nephritic syndrome and renal failure
- HTN
- Hemorrhagic cystitis
- Ureteral obstruction
- Intestinal infarction, perforation, obstruction, stricture
- GI hemorrhage
- Intussusception
- Alveolar hemorrhage
- CNS complications, including cerebral hemorrhage and seizure
- Anterior uveitis
- Myocarditis
- Orchitis
- Testicular torsion

**ADDITIONAL READING**

CODES

ICD10

D69.0 Allergic purpura

CLINICAL PEARLS

mebooksfree.com
HSP is a systemic small vessel vasculitis characterized by clinical tetrad of palpable purpura, abdominal pain, arthralgia, and renal dysfunction.

The main form of treatment is supportive care, but oral corticosteroids are beneficial in certain circumstances.

In all patients with HSP, regardless of renal involvement at presentation, it is reasonable to check BP and urinalysis at weekly to monthly intervals for no <6 months after diagnosis to monitor for developing renal dysfunction.
HEPARIN-INDUCED THROMBOCYTOPENIA

Tipsuda Junsanto-Bahri, MD • Maria A. Pino, PhD

BASICS

DESCRIPTION

- Unexplained decrease in platelet count in a patient treated with heparin
  - Minimum platelet count falls between 30% and 50% from baseline.
- Antibody-mediated prothrombotic disorder initiated by heparin administration
- Unlike other thrombocytopenias, heparin-induced thrombocytopenia (HIT) is an idiosyncratic reaction that produces thrombosis rather than bleeding.
- Two types: nonimmune heparin-associated thrombocytopenia (previously called HIT type I) and heparin-induced thrombocytopenia/thrombosis (HITT) (immune induced; previously called HIT type II)
  - Nonimmune heparin-associated thrombocytopenia (HIT): more common, onset 1 to 4 days after starting heparin, mild thrombocytopenia (>100,000), few complications
  - Immune HITT: less common, onset 5 to 14 days after primary exposure to heparin, thrombocytopenia often <100,000 but usually >20,000; high risk of thrombosis and mortality
    o Presentation of thrombocytopenia can be immediate with recent heparin exposure (within past 100 days).

EPIDEMIOLOGY

Incidence

- 0.1–5% of heparin-treated patients will experience thrombocytopenia, regardless of dose, schedule, or route of administration.
- 25–50% of these patients will develop HITT (1)[A].

ETIOLOGY AND PATHOPHYSIOLOGY

- Nonimmune heparin-associated thrombocytopenia: potentially a result of direct platelet membrane binding with heparin
- HITT: Heparin can cause an increase in the blood concentration of platelet factor 4 (PF4), a chemokine. PF4 will form a complex with heparin.
• Heparin/PF4 complex can, in turn, stimulate the production of specific antiheparin/PF4 complex antibodies. These antibodies cause platelet activation and a prothrombotic state. Ultimately, this hypercoagulable state leads to thromboembolic complications in many patients.

• Sources of heparin
  – Heparin flushes (e.g., for arterial lines or heparin locks)
  – Heparin-bonded catheters
  – Low-molecular-weight heparin (LMWH) (enoxaparin, dalteparin)

**RISK FACTORS**

• Postsurgical > medical > obstetric
  – Post-cardiopulmonary bypass (CPB) is the most significant risk factor.
• Bovine unfractionated heparin (UFH) > porcine UFH > LMWH
• Female > male
• Heparin duration >5 days

**GENERAL PREVENTION**

• Inquire about recent heparin exposure and any history of HIT.
• Use of LMWH (vs. unfractionated), for a shorter duration, can reduce the risk of developing HIT.
• Properly document past HIT reactions in patient’s medical record. Develop a HIT recognition and treatment protocol.
• No form of heparin should be administered once the diagnosis of HIT is confirmed.

**COMMONLY ASSOCIATED CONDITIONS**

• Venous thrombosis: deep venous thrombosis (DVT), pulmonary embolism (PE), adrenal vein thrombosis with hemorrhagic infarction; seen more frequently among medical and postoperative orthopedic surgery patients
• Arterial thrombosis: myocardial infarction, stroke, mesenteric infarction, limb ischemia; seen more frequently among vascular and cardiac surgery patients
• Skin lesions (skin necrosis at site of injection)
• Acute systemic reactions

**DIAGNOSIS**

• Nonimmune heparin-associated thrombocytopenia (HIT): asymptomatic drop in platelet count
HITT: thrombocytopenia or thrombosis with the presence of heparin-dependent antibodies
– The foundation for diagnosis is based on both clinical and serologic findings.

HISTORY
– Duration of current heparin therapy
– Previous exposure to heparin, including heparin flushes and heparin-coated catheters
– In patients being treated with heparin for thrombosis, in which thrombosis recurs during therapy, consider HITT as a potential cause.
– Clinical scoring systems:
  – Pretest probability for HIT can be calculated using the commonly used “4 Ts” methodology:
    o Thrombocytopenia of new onset
    o Timing of thrombocytopenia (5 to 10 days after exposure)
    o Thrombosis of new onset
    o Thrombocytopenia by other causes is ruled out.
  – The HIT Expert Probability score is an effective pretest probability tool (2) [B].
  – The post-CPB scoring system

PHYSICAL EXAM
– Signs of venous or arterial thrombosis
– Skin necrosis (begins with erythema, progresses to ecchymosis and necrosis)
– Ischemic changes (signs of limb, renal, splenic, mesenteric ischemia)
– Bleeding (less common)
– Acute systemic reactions after IV bolus of heparin (e.g., signs of anaphylaxis)

DIFFERENTIAL DIAGNOSIS
Other potential causes of thrombocytopenia include (list is not all inclusive)
– Sepsis and other infections
– Drug reactions
– Autoimmune
– Transfusion reactions
– Physical destruction (e.g., during CPB)

DIAGNOSTIC TESTS & INTERPRETATION
• Serial platelet counts in patients receiving heparin who have a >1% risk of HITT: Check platelets at baseline and then every 2 to 3 days from days 4 to 14 of heparin therapy:
  – Withhold platelet monitoring for patients receiving heparin with risk of HITT <1%.
• Confirmatory lab tests needed for a clinical diagnosis can be divided into two major categories:
  – Antigen assay to detect presence of anti-PF4 antibodies:
    o ELISA: up to 99% sensitive, poor specificity; has a high negative predictive value for HIT
  – Functional assay to detect evidence of platelet activation in the presence of heparin:
    o Serotonin release assay (SRA), gold standard for diagnosis: high specificity and high sensitivity
    o Heparin-induced platelet activation (HIPA): high specificity and low sensitivity
• Antigenic assay should be the initial test.
  – Either a functional assay or an antigenic assay alone may not be adequate for clinical diagnosis; their use in combination is usually recommended.
• The diagnostic interpretation of these laboratory tests must be made in the context of the clinical estimation of the pretest probability because HIT is a clinicopathologic syndrome. Patients may form heparin-dependent antibodies and still not develop HIT.

**TREATMENT**

Treatment is by prompt withdrawal of heparin and replacement with a suitable alternative anticoagulant.

**GENERAL MEASURES**

• Discontinue all heparin products, including flushes and heparin-coated catheters.
• All patients with a diagnosis of HIT should receive alternative anticoagulation as they are of high thrombotic risk.
• Nonimmune heparin-associated thrombocytopenia generally resolves when heparin is stopped.

**ALERT**
Platelet transfusions can increase thrombosis. Give platelet transfusions only if bleeding or during an invasive procedure with a high risk of bleeding.

Warfarin should not be administered until platelet recovery. If warfarin has been administered, vitamin K should be given due to depletion of proteins S and C and increased risk for venous limb gangrene.

– Among patients with HIT, 7.1% received platelet transfusion. Of these patients, 20.6% experienced thrombotic complications (3)[A].

Adverse reaction to heparin should be clearly documented in the patient’s medical record with instruction to avoid all heparin products.

For patients with a documented history of HIT, under special circumstances only (such as the need for CPB), the use of heparin for a short duration may be acceptable if the absence of heparin/PF4 complex antibodies can be documented. Patients who develop antibodies to the heparin/PF4 complex have a significantly higher rate of postoperative thrombotic events than patients who lack these antibodies (1,4)[A].

MEDICATION

Most patients require anticoagulation because of

– Preexisting thrombosis or
– Risk of thrombosis during 30 days after HIT diagnosis (consider anticoagulation for 30 days)

Dosing of anticoagulant depends on indication (prophylaxis vs. treatment):

– In cases with a clinically low suspicion/pretest probability of HIT and laboratory confirmation is pending, it may be appropriate to continue antithrombotic prophylaxis using nonheparin anticoagulants.

– In cases with high suspicion/pretest probability of HITT and laboratory confirmation is pending, it is appropriate to begin anticoagulation treatment with a nonheparin product (1,4)[A].

Direct thrombin inhibitors (DTIs) (argatroban and bivalirudin)

– Reduce relative risk of thrombosis by 30% and are associated with a 5–10% risk of bleeding
– Can produce misleading elevation in international normalized ratio (INR) (most likely an in vitro reaction)

  o Argatroban > bivalirudin (4)[A]

  Argatroban

  o Currently approved for treatment of HITT or in patients undergoing percutaneous coronary intervention when heparin is contraindicated
  o Initial dose, 2 µg/kg/min by continuous IV infusion; decrease dose (0.5 to
1.2 μg/kg/min) for patients with reduced hepatic function or with critical illness.
- Dose adjustments based to achieve activated partial thromboplastin time (aPTT) 1.5 to 3 times the baseline
- Dose adjustment required for patients with hepatic dysfunction
  - Bivalirudin
    - Off-label use for HIT, complicated by thrombosis
    - Reduced risk of bleeding in patients undergoing percutaneous artery interventions (PCIs) and other cardiac procedures
    - Initial dose of 0.15 to 0.20 mg/kg/hr; adjust aPTT 1.5 to 2.5 times the baseline.

- Factor Xa inhibitors
  - Reports of factor Xa treatment are theorized to be useful.
  - Rivaroxaban has been frequently studied and provide further evidence for HIT management.
    - Not associated with HIT (5)[B],(6)[A]
  - Fondaparinux has not been recommended due to lack of evidence and further investigation is needed.

- Warfarin transition
  - Must anticoagulate with an immediate-acting agent before starting warfarin
  - Begin warfarin after platelet count is >150,000.
    - Discontinue other anticoagulant and continue only warfarin after INR is therapeutic (2 to 3) for at least 5 days. This management differs from the normal heparin-to-warfarin transition in other conditions requiring anticoagulation (1,4)[A].

- LMWH
  - Although LMWH has a lower risk of initiating a HIT reaction, it should not be used when antibodies are already present, which cross-react with LMWH and induce thrombosis and thrombocytopenia.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Avoid heparin flushes.
- Avoid platelet transfusion.
- Clearly document reaction in all medical records to control the future use of heparin.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- The transition period of anticoagulation with a DTI and warfarin in patients with HIT can be problematic.
- The INR while administering both a DTI and warfarin should be therapeutic (2 to 3) for at least 5 days before discontinuing the DTI.
- Warfarin therapy should not be commenced until the platelet count has stabilized within a normal range.
- Warfarin therapy should continue for a minimum of 3 months.
- DTIs can prolong INR; therefore, if INR is <4 while on both warfarin and a DTI, temporarily hold the DTI for 4 to 6 hours and recheck INR; this second INR will represent only the anticoagulant effect of warfarin.
- Monitor use of concurrent drugs with warfarin.

Patient Monitoring

- Serial platelet counts
- Monitor PTT or INR as determined by the anticoagulation agent.

PATIENT EDUCATION

- Patient should inform all health care providers of any previous adverse reaction to heparin.
- HIT information available at http://medlibrary.org/medwiki/Heparin-induced_thrombocytopenia

PROGNOSIS

- Thrombosis in HIT has 20–30% mortality, with additional morbidity from stroke and limb ischemia.
- Platelet counts normalize within weeks after stopping heparin.
- Risk of delayed thrombosis, especially in the first 30 days

REFERENCES

8(12):2642–2650.

**ADDITIONAL READING**

**CODES**

**ICD10**

D75.82 Heparin induced thrombocytopenia (HIT)

**CLINICAL PEARLS**

- Heparin exposure through virtually any preparation (including LMWH), any dose, or any route can cause HIT, a life-threatening condition which is associated with severe and extensive thromboembolism.
- LMWH, warfarin, and platelet transfusion are contraindicated in HIT,
although LMWH is less likely to cause HIT. Once HIT is present, the antibodies will cross-react and continue to cause a HIT reaction. 

- If a patient is suspected of HIT (with or without confirmatory testing), immediately discontinue all forms of heparin.
- Patients will require anticoagulation either because of preexisting thrombosis or the risk of thrombosis in first 30 days after HIT.
- A DTI should be used until a patient’s INR is therapeutic (2 to 3) on warfarin for at least 5 days.
- The key to avoiding sequelae from HIT is awareness, vigilance, and a high degree of suspicion.
HEPATIC ENCEPHALOPATHY

Walter M. Kim, MD, PhD • Jyoti Ramakrishna, MD

**BASICS**

**DESCRIPTION**
- Reversible altered mental and neuromotor functioning occurring in association with acute or chronic liver disease and/or portal systemic shunting
- The prominent features are confusion, impaired arousability, and a “flapping tremor” (asterixis).
- System(s) affected: gastrointestinal; nervous
- Synonym(s): portosystemic encephalopathy (PSE); hepatic coma; liver coma

**EPIDEMIOLOGY**

Predominant sex: male = female (reflects prevalence of underlying liver disease)

**Prevalence**
- Overt hepatic encephalopathy (HE) occurs in 30–45% of cirrhotic patients.
- Occurs in all cases of fulminant hepatic failure
- Present in ~50% of patients requiring liver transplantation
- Parallels the age predominance of fulminant liver disease: peaks in the 40s; cirrhosis peaks in the late 50s; may occur at any age

**ETIOLOGY AND PATHOPHYSIOLOGY**
- There is no defined pathophysiology for the development of HE. Three classifications have been proposed (1):
  - Type A: resulting from acute liver failure
  - Type B: resulting from portosystemic bypass or shunting
  - Type C: resulting from cirrhosis
- Several metabolic factors implicated in HE based on the failure of the liver to detoxify noxious CNS agents (e.g., ammonia, mercaptan, fatty acids)
- Increased aromatic and reduced branched chain amino acids in blood may act as false neurotransmitters, possibly interacting with the γ-aminobutyric acid (GABA) receptor and causing clinical symptoms.
- HE presents most commonly in long-standing cirrhosis with spontaneous shunting of intestinal blood through collateral vessels or surgical portacaval
Asterixis is the inability to maintain a particular posture due to metabolic encephalopathy. Abnormal diencephalic function leads to the characteristic liver flap noted when the arms and wrists are held in extension. Asterixis is also present in patients with uremia, barbiturate toxicity, and some cases of pulmonary disease. As such, asterixis is not pathognomonic for HE.

**Genetics**

- Unknown
- Conditions that predispose an individual to developing chronic liver disease such as cystic fibrosis, \( \alpha_1 \)-antitrypsin deficiency, hemochromatosis, and Wilson disease can contribute to the development of HE.

**RISK FACTORS**

In patients with underlying liver disease, precipitating factors include:

- Infection (overt or occult, including spontaneous bacterial peritonitis [SBP])
- Gastrointestinal hemorrhage
- Use of sedative or opiate drugs
- Fluid or electrolyte disturbance (\( \text{Na}^+, \text{K}^+, \text{Mg}^{2+} \) most commonly)
- Transjugular intrahepatic portosystemic shunt (TIPS—a radiologically inserted shunt to lower portal pressure)

**GENERAL PREVENTION**

- Recognize early signs and seek prompt treatment.
- Avoid nonessential medications, particularly opiates, benzodiazepines, and sedatives.
- Consider lactulose therapy as secondary prophylaxis for recurrence of HE (2) [B].

**COMMONLY ASSOCIATED CONDITIONS**

- May occur as a complication of acute fatty liver of pregnancy
- Occurs rarely in patients with a portacaval shunt but normal liver function

**DIAGNOSIS**

**HISTORY**

- Preexisting liver disease
Confusion; altered mental status
- Impaired arousability
- Constipation

**PHYSICAL EXAM**
- Age 10 to 60 years
  - Five grades of confusion and degree of obtundation (West Haven classification) (1):
    - Minimal: psychometric or neuropsychological alterations without mental status changes
    - Grade I: lack of awareness, anxiety, shortened attention span, impairment of arithmetic, altered sleep rhythm
    - Grade II: asterixis, lethargy, disorientation to time, personality change, inappropriate behavior
    - Grade III: somnolence, confusion, gross disorientation, bizarre behavior
    - Grade IV: coma
  - Prominent signs of underlying liver disease (50%); jaundice is most common, ascites is second most common.
  - GI bleeding with hematemesis or melena (20%)
  - Systemic infection, urinary tract infection, or pulmonary infection (20%)
- Age >60 years
  - Signs of underlying liver disease diminish (25%).
  - Confusion more prominent
  - Precipitating GI hemorrhage or infection is less often identified.
  - Progression is slower.
- Age <10 years
  - Signs of underlying liver disease are prominent; fulminant hepatic failure or advanced cirrhosis
  - Progression is very rapid, often over hours.
  - Wilson disease can imitate HE.
- Vital signs:
  - Bradycardia
  - Increased blood pressure suggestive of increased intracranial pressure
- Jaundice, ascites, and other correlates of liver disease
- CNS exam: Assess short-term memory and presence of asterixis (“liver flap”—a flapping of the wrist when arms are held in extension with the wrist fully extended).

**DIFFERENTIAL DIAGNOSIS**
Metabolic encephalopathy related to anoxia, hypoglycemia, hypokalemia, hypo- or hypercalcemia, or uremia
- Head trauma, concussion, subdural hematoma
- Transient ischemic attack (TIA), ischemic stroke
- Alcohol intoxication
- Alcohol withdrawal syndrome
- Confusion due to medications or illicit drugs
- Meningitis, encephalitis
- Wilson disease
- Reye syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**
- Clinical findings diagnostic in 80% of cases
- Response to treatment often confirms the diagnosis.
- EEG (limited utility): symmetric slowing of basic (α) rhythm (also common with other metabolic encephalopathies)
- Visual evoked potential: specific in grades II to IV
- Number connection test (NCT), line drawing test, critical flicker frequency (CFF) test, digit symbol test (DST), continuous reaction time (CRT) test, inhibitory control test (ICT), and other psychometric tests may be used to assess for minimal HE.

**Initial Tests (lab, imaging)**
- Liver function tests, including aspartate aminotransferase (AST), alanine aminotransferase (ALT), and serum albumin
- Prothrombin time (PT) and international normalized ratio (INR) often elevated
- Serum ammonia level is elevated in 90% of patients with HE; levels affected by infusion of amino acid solutions, opiate administration (constipation), uremia, tissue breakdown, burns, trauma, or infection
- CBC: anemia and leukocytosis
- Complete metabolic profile to identify hypokalemia, hyperbilirubinemia, altered calcium concentration, hypomagnesemia, and hypoglycemia
- BUN: Creatinine >20 mg/dL suggests dehydration or GI bleeding.
- Diagnostic paracentesis to rule out SBP
- Blood, urine, sputum, and ascitic fluid cultures to identify infection, if clinically indicated
- Consider arterial blood gas measurement.
- Toxicology screen
- Head CT to identify frontal cortical atrophy and mild general edema
- MRI may demonstrate increased T1 signal in globus pallidus.

**Test Interpretation**
- Brain edema is seen in 100% of fatal cases.
- Glial hypertrophy in chronic encephalopathy

## TREATMENT
### GENERAL MEASURES
- Identify and treat precipitating causes: GI bleeding, infection, electrolyte imbalance.
- Eliminate offending medications.
- Grade I or higher: Ensure adequate fluid and caloric ≥1,000 kcal (4.19 MJ) intake; avoid hypoglycemia.
- Consider enema for patients without diarrhea.
- If clumsiness and poor judgment are prominent, institute fall precautions.
- Avoid sedatives, benzodiazepines, opiates, diphenoxylate, and atropine.

## MEDICATION
### First Line
- Lactulose syrup (nonabsorbable disaccharide with laxative action that decreases colonic transit time and bacterial digestion that acidifies the colon to promote ammonia excretion): 30 to 45 mL PO up to every hour for goal of 3 to 6 bowel movements per day. Decrease to 15 to 30 mL BID when ≥3 bowel movements per day (3)[A].
- Lactulose enema (for patients who cannot tolerate oral lactulose or have suspected ileus): 300 mL lactulose plus 700 mL tap water, retained for 1 hour
- If worsening occurs acutely or there is no improvement in 2 days, add antibiotics:
  - Rifaximin: 400 mg PO TID or 550 mg PO BID (nonabsorbable antibiotic); highly effective in reversing minimal HE (4)[B]
- Contraindications:
  - Total ileus
  - Hypersensitivity reaction
- Precautions:
  - Hypokalemia
– Electrolyte imbalance
– Dehydration and renal failure

**Second Line**
- Neomycin: 1 to 2 g/day PO divided q6–8h, if renal function is within normal limits
- Polyethylene glycol may be effective as an alternative to lactulose in management of acute HE (5)[B].
- Metronidazole is an alternative antibiotic.
- Flumazenil may be of benefit in select patients.

**ISSUES FOR REFERRAL**
Refer early to a transplant center.

**SURGERY/OTHER PROCEDURES**
- Artificial liver perfusion devices are useful in fulminant hepatic failure as a bridge to transplantation.
- Consider liver transplant in grade II to IV patients.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Probiotics and prebiotics have been associated with improvement of HE through modulation of gut flora (1)[C].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Monitor clinical status closely in grades I and II when diagnosis is clear and watch for progression.
- Evaluate patients with grades II to IV HE in fulminant hepatic failure for liver transplantation

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Activity as tolerated once resolved
**Patient Monitoring**

- Trail-making test (a pencil/paper connect-the-dots according to numbers) helps to monitor HE patients. Periodic evaluation helps determine maintenance treatment and diet. Run test daily at first and then at each visit when changes in drugs and diet are made.
- Patients with changed findings on the trail-making test should be seen twice weekly.
- Stable patients should be seen monthly.
- NCT or line drawing test at each office visit can also help with patient monitoring.
- In cirrhosis, evaluate for transplantation and periodically monitor Model for End-Stage Liver Disease (MELD) score.

**Diet**

- Regular protein diet (1.2 to 1.5 g/kg/day); vegetable protein diets are better tolerated than animal protein diets in patients with advanced cirrhosis; special IV/enteral formulations with increased branched chain amino acids are available.
- Grades III to IV patients need parenteral nutrition or jejunal feeds.

**Patient Education**

American Association for the Study of Liver Diseases, 1729 King Street, Suite 200, Alexandria, VA 22314; 703-299-9766; [www.aasld.org](http://www.aasld.org)

**Prognosis**

- With adequate aggressive treatment, acute HE resolves.
- Chronic liver disease
  - HE recurs.
  - With each recurrence, HE is more difficult to treat—the degree of improvement with treatment is reduced and the mortality rate approaches 80%.

**Complications**

- Recurrence
- With many recurrences, permanent basal ganglion injury (non-Wilsonian hepatolenticular degeneration)
- Hepatorenal syndrome
REFERENCES

ADDITIONAL READING

SEE ALSO

Algorithm: Delirium
CODES

ICD10
- K72.90 Hepatic failure, unspecified without coma
- K72.91 Hepatic failure, unspecified with coma

CLINICAL PEARLS
- HE includes a spectrum of neuropsychiatric findings occurring in patients with significant alterations in hepatic function.
- Lactulose is a cornerstone of therapy for HE.
- Asterixis ("liver flap") is the classic physical finding associated with HE.
HEPATITIS A
Daniel J. Stein, MD, MPH • Stephen K. Lane, MD, FAAFP

BASICS
DESCRIPTION
One of the world’s most common infections, the hepatitis A virus (HAV) primarily involves the liver.

EPIDEMIOLOGY
Pediatric Considerations
- Often, milder or asymptomatic in children; severity increases with age.
- Infections asymptomatic in 70% of children age <6 years
- <50% of 13- to 17-year-olds in the United States are vaccinated.

Pregnancy Considerations
- Increased risk of complications including preterm labor
- Vertical transmission has been reported; fecal–oral transmission during birth is possible.
- Breastfeeding is not contraindicated.

Incidence
- 1.4 million cases globally each year
- Since routine use of hepatitis A vaccine (1995), the incidence of HAV has decreased by 95%.
- Approximately 2,500 HAV infections in 2014, lowest ever in the United States
- Incidence in the United States: 0.4/100,000
- No difference based on sex
- As many as 1/2 of current HAV infections in the United States are acquired during travel to endemic countries.
- Incubation period averages 28 days but can be as long as 50 days.

Prevalence
Serologic evidence of prior HAV infection is present in ~1/3 of U.S. population.
Anti-HAV prevalence relates to age, ranging from 9% in children ages 6 to 11 years to 75% of those >70 years; relates inversely to income

**ETIOLOGY AND PATHOPHYSIOLOGY**

- HAV is a single-stranded linear RNA enterovirus of the *Picornaviridae* family.
- Infection is limited to hepatocytes and macrophages.
- HAV is excreted into the bile and then stool, providing major route of spread.
- Primary transmission is fecal–oral.
- Humans are the only natural host.
- Incubation is 2 to 6 weeks (mean 4 weeks).
- Greatest infectivity is the 2 weeks before and 1 week after onset of clinical illness.
- Infection occurs primarily after consuming food or water contaminated with HAV or via direct contact.
- Outbreaks occur through exposure to a common food or water source.
- Virus is stable in water and on surfaces but is easily killed with high heat or cleaning agents.
- Shellfish (clams and oysters) may be contaminated if harvested from waters contaminated with HAV.
- Blood-borne transmission is rare.
- HAV is not a chronic disease but can last for months.

**Genetics**

Autoimmune hepatitis is rarely associated with human leukocyte antigen class II; DR3 and DR4 after active infection with HAV

**RISK FACTORS**

- Travel to developing countries accounts for >50% of cases in North America and Europe.
- Employment in health care
- Household exposure
- Intimate exposure, especially men who have sex with men
- Injection of illicit drugs
- Child care centers, schools
- Institutionalized individuals
- Clotting factor disorders, such as hemophilia
- Blood exposure/transfusion (rare)
- No identifiable risk factor in 50%
GENERAL PREVENTION

- Proper sanitation and personal hygiene (hand washing), especially for food handlers, health care, and daycare workers
- Active immunization: HAV vaccines: Havrix and Vaqta; Twinrix-combination HAV and HBV
- Vaccine lasts ~25 years or more.
- Vaccine is recommended for (1)[C], (2)[A]:
  - All children aged 12 to 23 months, with catch-up administration until 18 years old
  - All travelers to countries with high endemic rate of hepatitis A
  - Men who have sex with men
  - Illicit IV drug users
  - Anyone with chronic liver disease (including pre- and post-liver transplant)
  - Individuals with a clotting factor disorder
  - Household members and close contacts of children adopted from countries with a high HAV prevalence (prior to arrival)
  - Anyone exposed during an outbreak
- Routine vaccination is no longer routinely recommended for food service, child care, or health care workers (1)[C].
- HIV-infected patients who are negative for HAV IgG should receive HAV vaccine series, preferably early in course of HIV infection.
  - If CD4 count is <200 cells/mm$^3$ or the patient has symptomatic HIV disease, defer vaccination until several months after initiation of antiretroviral (ARV) therapy to maximize antibody response to the vaccine.
- HAV is not killed by freezing.
- HAV is killed by
  - Heating to 185°F for 60 seconds
  - Chlorine
  - Iodine

DIAGNOSIS

HISTORY

- Onset is often abrupt. Common symptoms include nausea, emesis and diarrhea, and headache.
- Symptom severity increases with age.
- Pediatric cases (<6 years) frequently asymptomatic
Other symptoms:
- Fever, malaise, fatigue, myalgias, anorexia
- Dark urine (bilirubinuria)
- Right upper abdominal pain
- Pruritus (can suggest cholestasis)

PHYSICAL EXAM
- Fever (variable)
- Jaundice and icterus present in >70% of adults and older children
- Hepatomegaly is also common; splenomegaly is less common.
- Right upper quadrant abdominal tenderness
- Rare: lymphadenopathy (cervical), arthritis, or rash
- Asterixis suggests acute hepatic failure.

DIFFERENTIAL DIAGNOSIS
- Hepatitis B, C, D, E. Not clinically distinguishable from other forms of viral hepatitis; diagnosis may be suspected with typical symptoms during an outbreak.
- Drug-induced hepatitis; toxin-induced hepatitis
- Alcoholic hepatitis; autoimmune hepatitis
- Hemochromatosis (adults) or Wilson disease
- Malaria
- Epstein-Barr virus (EBV), cytomegalovirus (CMV)
- Primary or secondary hepatic malignancy
- Ischemic hepatitis or Budd-Chiari syndrome
- Nonhepatobiliary disease (elevated AST/ALT): celiac disease, congestive heart failure, thyroid disease
- Bacterial infections (Q fever, leptospirosis, syphilis, Rocky Mountain spotted fever)
- Parasites (liver flukes or toxocariasis)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Anti-HAV IgM: positive at time of onset of symptoms sensitivity and specificity >95%; primary test used to diagnose acute infection
- Anti-HAV IgG: appears soon after IgM and generally persists from years to lifetime
- AST/ALT elevated ~500 to 5,000: ALT usually > AST
Alkaline phosphatase: mildly elevated
Bilirubin: Conjugated and unconjugated fractions usually increased. Bilirubin rises typically follow rise in ALT/AST, consistent with hepatocellular injury pattern.
Prothrombin time and partial thromboplastin time usually remain normal or near normal.
  – Significant rises should raise concern for acute hepatic failure or coexisting chronic liver disease.
CBC: mild leukocytosis; aplasia and pancytopenia
  – Thrombocytopenia may predict illness severity.
  – Autoimmune hemolytic anemia (rare)
Albumin, electrolytes, and glucose to evaluate for hepatic and renal function (rare renal failure)
Urinalysis (not clinically necessary): bilirubinuria
Consider ultrasound (US) to rule out biliary obstruction only if lab pattern is cholestatic.

Follow-Up Tests & Special Considerations
Illness usually resolves within 4 weeks of symptom onset. Repeat labs are not indicated unless symptoms persist or new symptoms develop.

Diagnostic Procedures/Other
Liver biopsy is usually not necessary. US can evaluate other causes (e.g., thrombosis or concurrent cirrhosis).

Test Interpretation
  ● Positive serum markers in hepatitis A
    – Acute disease: anti-HAV IgM only
    – Recent disease (last 6 months): anti-HAV IgM and IgG positive
    – Previous disease: anti-HAV IgM negative and IgG positive
  ● If liver biopsy obtained, shows portal inflammation; immunofluorescent stains for HAV antigen positive

TREATMENT
GENERAL MEASURES
  ● Maintain appropriate nutrition/hydration.
Avoid alcohol.
Universal precautions to prevent spread
Monitor coagulation defects, fluid, electrolytes, acid–base imbalance, hypoglycemia, and renal function.
Report cases to local public health department.
Laboratory evaluation including coagulation factors is important to rule out fulminant hepatic failure.
Referral to liver transplant center for fulminant failure (rare)

MEDICATION
Preexposure vaccination per recommended guidelines. Both hepatitis A vaccines in the United States (Havrix, Vaqta) require two doses.
The ACIP recommends administering the 1st dose as soon as possible in travelers to endemic areas (1)[C].
  – For healthy individuals <40 years, vaccinate up to the day or departure (1)[C].
  – Give immunoglobulin (0.02 mL/kg) to those >40 years or with chronic medical conditions if <2 weeks from planned departure (1)[C].
Give postexposure prophylaxis to persons who have not previously received HAV vaccine within 2 weeks of exposure to HAV (3)[A],(4)[C].
  – Administer hepatitis A vaccine to healthy persons between the ages of 1 and 40 years (5)[A].
  – Administer immunoglobulin (0.02 mL/kg) to persons <1 or >40 years of age or to patients with significant comorbidities (immunosuppression, liver disease) who are at risk for poor immune response (3)[A],(4)[C].
Use immunoglobulin for passive preexposure prophylaxis in those not eligible for the vaccine (3)[A],(4)[C].
  – 0.02 mL/kg provides 1 to 2 months of coverage; 0.06 mL/kg provides 3 to 5 months of coverage.
  – Long-term prophylaxis should be with 0.06 mL/kg every 5 months for sustained risk (e.g., travelers).
  – Use immunoglobulin alone in children <1 year old and unvaccinated pregnant women who will be traveling.
  – Do not give immunoglobulin with the MMR or varicella vaccines.

First Line
No antiviral medications indicated; spontaneous resolution occurs in almost all patients.
Caution with acetaminophen. If used, limit to 2 g/day or less.
Avoid hepatotoxic agents.

**Second Line**
- Antiemetics (e.g., ondansetron)
- IV fluids
- Pruritus: diphenhydramine 50 mg PO IM q6h; consider cholestryamine 4 g BID if cholestasis.

**ISSUES FOR REFERRAL**
- Dictated by severity of illness
- Hepatic failure, refer to a high-volume liver transplant program.

**SURGERY/OTHER PROCEDURES**
Liver transplant in fulminant hepatic failure—rare

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Avoid potentially hepatotoxic botanicals including barberry, comfrey, golden ragwort, groundsel, huang qin, kava kava, pennyroyal, sassafras, senna, valerian, wall germander, and wood sage.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Treatment is usually outpatient unless signs of liver failure; dictated by severity of illness
- Treat dehydration and electrolyte imbalances.
- Enteric isolation. Private rooms, gowns, and masks are not necessary. Frequent hand washing. Use gloves when handling potentially contaminated material.
- 1:100 bleach dilution can be used to clean surfaces.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Return to work/school 10 to 14 days after onset of symptoms with diligence to
hygiene (patients remain infectious for up to 4 weeks from symptom onset).

**Patient Monitoring**
Monitor coagulation defects, fluid and electrolytes, acid–base imbalance, hypoglycemia, and renal function.

**DIET**
- Adequate balanced nutrition
- Avoid alcohol.

**PATIENT EDUCATION**
- Segregate food handlers with HAV.
- HAV immunity persists after infection.
- CDC hepatitis A FAQs link: [http://www.cdc.gov/hepatitis/hav/afaq.htm](http://www.cdc.gov/hepatitis/hav/afaq.htm)

**PROGNOSIS**
- Excellent; mortality is 0.3%.
- Risk increased with underlying chronic liver disease and in the elderly (1.8% mortality age >50 years).

**COMPLICATIONS**
- Coagulopathy, encephalopathy, and renal failure
- Relapsing HAV: usually milder than the initial case
- Positive anti-HAV IgM; total duration typically <9 months
- Prolonged cholestasis: characterized by protracted periods of jaundice and pruritus (>3 months); resolves without intervention (supportive care only)
- Autoimmune hepatitis: can be seen after HAV infection; good response to steroids
- Hepatic failure: rare (1–2%)
- Postviral encephalitis, Guillain-Barré syndrome, pancreatitis, aplastic or hemolytic anemia, agranulocytosis, thrombocytopenic purpura, pancytopenia, arthritis, vasculitis, and cryoglobulinemia (all rare)

**REFERENCES**

- Hepatitis B; Hepatitis C
- Algorithms: Cirrhosis; Jaundice

CODES

ICD10

B15.9 Hepatitis A without hepatic coma

CLINICAL PEARLS

- HAV vaccine is indicated for all children, travelers (particularly to endemic areas), those at elevated risk of disease, and patients with liver impairment.
- Check HAV IgG in all HIV-positive patients; provide HAV vaccine if results are negative.
- HAV disease severity directly correlates with age; children are often asymptomatic.
- Treatment of acute HAV is supportive.
- Eligible patients should receive postexposure prophylaxis within 14 days of exposure.
HEPATITIS B

Jason Chao, MD, MS • Navpreet K. Singh, MD

BASICS

DESCRIPTION
Systemic viral infection associated with acute and chronic liver disease and hepatocellular carcinoma (HCC)

EPIDEMIOLOGY

Incidence
- Predominant age: can infect patients of all ages
- Predominant sex: fulminant hepatitis B virus (HBV): male > female (2:1)
- In the United States, ~3,000 cases of acute HBV in 2014
- African Americans have the highest rate of acute HBV infection in the United States.
- Overall rate of new infections is down 82% since 1991 (due to national immunization strategy).
- Vaccine coverage for the birth dose ~72% in United States

Prevalence
- In the United States, 800,000 to 1.4 million with chronic HBV.
- Asia and the Pacific Islands have the largest populations at risk for HBV.
- Chronic HBV worldwide: 350 to 400 million persons
  - 1 million deaths annually
    - Second most important carcinogen (behind tobacco)
    - Of chronic carriers with active disease, 25% die due to complications of cirrhosis or HCC.
    - Of chronic carriers, 75% are Asian.

ETIOLOGY AND PATHOPHYSIOLOGY
HBV is a DNA virus of the Hepadnaviridae family highly infectious via blood and secretions

Genetics
Family history of HBV and/or HCC
RISK FACTORS

- Screen the following high-risk groups for HBV with HBsAg/sAb. Vaccinate if seronegative (1)[A]:
  - Persons born in endemic areas (45% of world)
  - Hemodialysis patients
  - IV drug users (IVDUs), past or present
  - Men who have sex with men (MSM)
  - HIV- and HCV-positive patients
  - Household members of HBsAg carriers
  - Sexual contacts of HBsAg carriers
  - Inmates of correctional facilities
  - Patients with chronically elevated AST/ALT levels

- Additional risk factors:
  - Needle stick/occupational exposure
  - Recipients of blood/products; organ transplant recipients
  - Intranasal drug use
  - Body piercing/tattoos
  - Survivors of sexual assault

Pediatric Considerations

- Shorter acute course; fewer complications
- 90% of vertical/perinatal infections become chronic

Pregnancy Considerations

- Screen all prenatal patients for HBsAg (1)[A].

- Consider treating patients with high viral load at 28 weeks or hx of previous HBV (+) infant with oral nucleos(t)ide medication beginning at 32 weeks to reduce perinatal transmission (2)[C].

- Infants born to HBV-infected mothers require HB immune globulin (HBIg) (0.5 mL) and HBV vaccine within 12 hours of birth.

- Breastfeeding is safe if HBIg and HBV vaccines are administered and the areolar complex is without fissures or open sores. Oral nucleos(t)ide medications are not recommended during lactation.

- HIV coinfection increases risk of vertical transmission.

- Continue medications if pregnancy occurs while on an oral antiviral therapy to prevent acute flare.

GENERAL PREVENTION
Most effective: HBV vaccination series (3 doses)

- Vaccinate
  - All infants at birth and during well-child care visits
  - All at-risk patients (see “Risk Factors”)
  - Health care and public safety workers
  - Sexual contacts of HBsAg carriers
  - Household contacts of HBsAg carriers
- Proper hygiene/sanitation by health care workers, IVDU, and tattoo/piercing artists
  - Barrier precautions, needle disposal, sterilize equipment, cover open cuts
- Do not share personal items exposed to blood (e.g., nail clipper, razor, toothbrush).
- Safe sexual practices (condoms)
- HBsAg carriers cannot donate blood or tissue.
- Postexposure (e.g., needle stick): HBIg 0.06 mL/kg in <24 hours in addition to vaccination

COMMONLY ASSOCIATED CONDITIONS
HIV, hepatitis C coinfection

DIAGNOSIS

HISTORY

- Exposure: detailed family and social history
- Acute HBV
  - Fever, malaise, fatigue, arthralgias, myalgias
  - Anorexia, nausea, vomiting
  - Jaundice, scleral icterus
  - Dark urine, pale stools
  - Right upper quadrant (RUQ) abdominal pain
- Chronic HBV: typically asymptomatic

PHYSICAL EXAM
Acute disease: ill; jaundice/scleral icterus; RUQ tenderness; hepatomegaly

DIFFERENTIAL DIAGNOSIS

- Epstein-Barr virus (EBV); cytomegalovirus (CMV); hepatitis A, C, or E
Drug-induced, alcoholic, or autoimmune hepatitis
Wilson disease or rheumatologic/immunologic disorders

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- AST/ALT: markedly elevated in acute HBV (particularly ALT), hundreds to several thousand IU/mL. Transaminases may be normal or mildly elevated in chronic HBV:
  - Transaminases elevate before bilirubin.
- Bilirubin (conjugated/unconjugated): normal to markedly elevated in acute HBV
  - Last test to normalize as acute infection resolves
- Alkaline phosphatase: mild elevation
- HBCAb IgM may be the only early finding (“window period,” before HBsAg turns positive).
- For acute hepatitis:
  - PT, albumin, electrolytes, glucose, and CBC
  - If severe acute HBV, check for superinfection with hepatitis D (HDV Ag and HDV Ab).
  - Hepatitis B serologic markers
- Hepatitis B e-antigen (HBeAg+) indicates high replication/infectivity; confirmed with high HBV DNA ($\geq 10^5$ copies/mL); benefit from medical therapy.
- HBV precore mutants have undetectable HBeAg despite active viral replication (confirm with HBV DNA level) as well as antibody to e-antigen (HBeAb+).
- Screen for HDV, HIV, HCV, and immunity to hepatitis A virus (HAV Ab total/IgG).
- Ultrasound to document ascites, organomegaly, signs of portal hypertension, hepatic or portal obstruction, and to screen for HCC
- Contrast CT or MRI if ultrasound is abnormal or if $\alpha$-fetoprotein (AFP) is elevated.

Follow-Up Tests & Special Considerations
HBsAg+ persistence >6 months defines chronic HBV:
- Measure HBV DNA level and ALT every 3 to 6 months.
- If age >40 years and ALT borderline or mildly elevated, consider liver biopsy.
- Measure baseline AFP.
Follow HBeAg for elimination (every 6 to 12 months).
Lifetime monitoring for progression, need for treatment, and screening for HCC

**Diagnostic Procedures/Other**
- Liver biopsy
- Noninvasive tests (Hepascore, Fibrotest) or measurement of elastography (Fibroscan) to assess for hepatic fibrosis

**Test Interpretation**
Liver biopsy in chronic HBV may show interface hepatitis and inflammation, necrosis, cholestasis, fibrosis, cirrhosis, or chronic active hepatitis.

**TREATMENT**

**GENERAL MEASURES**
- Vaccinate for HAV if seronegative.
- Monitor CBC, coagulation, electrolytes, glucose, renal function, and phosphate.
- Monitor ALT and HBV DNA; increased ALT and reduced DNA implies response to therapy.
- Screen for HCC if HBsAg+

**MEDICATION**

**First Line**
- Acute HBV
  - Supportive care; spontaneously resolves in 95% of immunocompetent adults
  - Antiviral therapy not indicated except for fulminant liver failure or immunosuppressed

**Chronic Hepatitis B Therapy**

</tr>
</tbody>
</table>

*ALT elevated if >2 × ULN; ULN for male = 30 IU/mL and for female = 19 IU/mL

- **Chronic HBV:** Treatment is based on HBeAg status:
  - FDA-approved drugs: lamivudine 100 mg, adefovir 10 mg, entecavir 0.5 to 1 mg, telbivudine 600 mg, or tenofovir 300 mg, all given PO every day (dose based on renal function); pegylated interferon (peg-IFN) α2a, α2b SC weekly (3)[A]
  - Entecavir, tenofovir, and peg-IFN are preferred first-line agents (3)[A].
  - Extended oral regimens are indicated (3)[A]:
    - If HBeAg+, treat 6 to 12 months post disappearance of HBeAg and gain of HBeAb, and monitor after cessation.
    - If HBeAg−, treat indefinitely or until HBsAg clearance and HBsAb development.
  - Change/add drug based on resistance:
    - Confirm medication adherence prior to assuming drug resistance.
    - Adherence to therapy lowers rate of resistance.
  - Adjust dosing for renal function.
  - Peg-IFN preferred to standard interferon:
    - Weekly peg-IFN (Pegasys) injections for 48 weeks
    - Most efficacious for genotype A
    - Contraindicated if decompensated cirrhosis
  - Goals of therapy: undetectable HBV DNA, normal ALT, loss of HBeAg, gain of HBeAb; loss of HBsAg and gain of HBsAb
  - Precautions:
    - Oral drugs: renal insufficiency
    - Peg-IFN: coagulopathy, myelosuppression, depression/suicidal ideation

**Second Line**
Emtricitabine suppresses viral load; not FDA-approved

**ISSUES FOR REFERRAL**
- Refer all persistent HBsAg+ patients for potential antiviral therapy.
- Immediate referral for liver transplant if fulminant acute hepatitis, end-stage
liver disease, or HCC

SURGERY/OTHER PROCEDURES
Liver transplantation, operative resection, radiofrequency ablation for HCC

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Worsening course (marked increase in bilirubin, transaminases, or symptoms)
- Hepatic failure (high PT, encephalopathy)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Serial ALT and HBV DNA:
  - High ALT + low HBV DNA associated with favorable response to therapy
- Serologic markers: See table.
- CBC for WBC and platelets if on interferon therapy
- Monitor HBV DNA q3–6mo during therapy:
  - Undetectable DNA at week 24 of oral drug therapy associated with low resistance at year 2
- Monitor for complications (ascites, encephalopathy, variceal bleed) in cirrhosis.
- Vaccinate household contacts and sexual partners.
- Ultrasound q6–12mo to screen for HCC starting at age 40 in men and age 50 in women (3)[B]

DIET
Avoid alcohol.

PATIENT EDUCATION
- Acute HBV
  - Review transmission precautions.
- Chronic HBV
  - Alcohol and tobacco use accelerate progression.
  - Emphasize medication compliance to prevent flare.
- Patient education materials:

COMPLICATIONS
- Hepatic necrosis; cirrhosis; hepatic failure
- HCC (all chronic HBV patients are at risk)
- Severe flare of chronic HBV with corticosteroids and other immunosuppressants: Avoid if possible.
- Reactivation of infection if immunosuppressed (e.g., chemotherapy):
  Premedicate prophylactically if HBsAg+ or if HBcAb+ and receiving systemic chemotherapy (1)[A].

ADDITIONAL READING
SEE ALSO
- Cirrhosis of the Liver; Hepatitis A; Hepatitis C
- Algorithm: Cirrhosis; Jaundice

CODES

ICD10
- B19.10 Unspecified viral hepatitis B without hepatic coma
- B16.9 Acute hepatitis B w/o delta-agent and without hepatic coma
- B18.1 Chronic viral hepatitis B without delta-agent

CLINICAL PEARLS
- Screen for HBV infection in all patients born in countries with endemic disease using HBsAg.
- Patients with chronic HBV need lifetime monitoring for disease progression and HCC.
- HBV is the second most common worldwide carcinogen (behind tobacco).
HEPATITIS C

Christopher Lin-Brande, MD • Jason C. McCarthy, MD

BASICS

DESCRIPTION
Systemic viral infection (acute and chronic) primarily involving liver

EPIDEMIOLOGY
- Highest incidence ages 20 to 39 years; highest prevalence between 40 and 59 years of age
- Males and non-Hispanic blacks (1)

Geriatric Considerations
Patients >60 years are less responsive to therapy; important to initiate treatment early

Pregnancy Considerations
- Routine HCV testing is not indicated.
- Vertical transmission 6/100 births; risk doubles with HIV coinfection.
- Breastfeeding is safe if no cracks or fissures on the breast.

Pediatric Considerations
- Prevalence: 0.3%
- Test children born to HCV-positive mothers with HCV Ab at 18 months or HCV RNA at 1 to 2 months.
- More likely to clear spontaneously; slower rate of progression

Incidence
Incidence has been rising since 2010. In 2014, there were 2,194 cases of acute HCV reported to the CDC, with an estimated 30,500 total new cases in the United States.

Prevalence
- 2.7 to 3.9 million in the United States have chronic HCV (Ab+).
- Prevalence highest if born 1945 to 1965 (2.6%) (1)
HCV-related deaths are more common than HIV-related deaths.

HCV is the most common cause of chronic liver disease and transplantation in the United States.

Six known genotypes (GT) with 50 subtypes. GT 1 is the predominant form in the United States (75%). GT predicts response to treatment.

**ETIOLOGY AND PATHOPHYSIOLOGY**

Single-stranded RNA virus of *Flaviviridae* family

**RISK FACTORS**

- **Exposure risks**
  - Chronic hemodialysis
  - Blood/blood product transfusion or organ transplantation before July 1992
  - Hemophilia treatment before 1987
  - Household or health care–related exposure to HCV-infected body fluids (1.8% risk)
  - Children born to HCV-positive mothers

- **Risk behaviors and/or medical conditions**
  - Prior history of injection drug use
  - Intranasal illicit drug use
  - History of incarceration
  - Tattooing in unregulated settings
  - Current sexual partners of HCV-positive persons
  - HIV and hepatitis B infection

**GENERAL PREVENTION**

- **Primary prevention**
  - Do not share razors/toothbrushes/nail clippers.
  - Use and dispose needles properly through harm reduction programs.
  - Practice safe sex.
  - Cover cuts and sores.

- **Secondary prevention**
  - No vaccine or postexposure prophylaxis available
  - Substance abuse treatment
  - Reinforce use of barrier contraception for HIV-seropositive coinfected with HCV.
  - Assess for degree of liver fibrosis/cirrhosis.
COMMONLY ASSOCIATED CONDITIONS
Diabetes, metabolic syndrome, iron overload, depression, substance abuse/recovery, autoimmune and hematologic disease, HIV, and hepatitis B coinfection

DIAGNOSIS

HISTORY
- Determine exposure risk: *detailed* social history including alcohol and IV drug use, psychiatric and medical comorbidities, coinfections.
- Chronic HCV: Most cases are mildly symptomatic (nonspecific fatigue) or asymptomatic (elevated alanine/aspartate aminotransferase [ALT, AST]).
- Acute HCV: *If* symptoms develop (rare)
  - Onset typically 4 to 12 weeks postexposure
  - Jaundice, dark urine, steatorrhea, nausea, abdominal pain (right upper quadrant [RUQ]), fatigue, low-grade fevers, myalgias, arthralgias

PHYSICAL EXAM
- Typically normal unless advanced fibrosis/cirrhosis
- May have RUQ tenderness/hepatomegaly
- Spider angioma, caput medusa, palmar erythema, jaundice, gynecomastia, Terry nails
- Arthralgias/myalgias, neuropathy, glomerulonephritis, livedo reticularis, lichen planus, pruritus, sicca syndrome, cold agglutinin disease

DIFFERENTIAL DIAGNOSIS
Hepatitis A or B; Epstein-Barr virus (EBV), cytomegalovirus (CMV); alcoholic hepatitis; nonalcoholic steatohepatitis (NASH); hemochromatosis; Wilson disease, α1-antitrypsin deficiency; ischemic, drug-induced, or autoimmune hepatitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (*lab, imaging*)
- Screen adults born between 1945 and 1965, those with exposure risks, current and former IV drug users, HIV-positive individuals, men who have sex with men (MSM), and patients with persistently elevated ALT.
- CDC algorithm
  - HCV Ab
    - If nonreactive, no further action unless recent exposure is suspected (test with HCV RNA)
    - If reactive, test HCV RNA.
  - HCV RNA
    - If not detected, no current HCV infection; no further action
- HCV Ab detected 3 to 12 weeks after infection
- HCV RNA detected 1 to 2 weeks after infection
- RNA detectability precedes ALT elevation.
- AST/ALT: often normal but elevations may persist in chronic HCV; ALT usually is 1 to 2 times upper limit of normal; AST may be normal/elevated. If present, AST elevations are typically less than ALT.
  - Acute hepatitis C can elevate transaminases and bilirubin (direct and indirect).
- AST/ALT ratio ≥1 associated with cirrhosis
  - If AST/ALT ratio >2, rule out alcohol abuse.
- Persistent HCV RNA >6 months = chronic HCV

**Follow-Up Tests & Special Considerations**
- CBC metabolic panel, TSH (if using PEG), vitamin D (may predict response)
- Hepatic function panel, coagulation factors
- HCV GT and resistance testing
- IL28B testing: (CC homozygote more likely to clear)
- HBV and HIV coinfection
- Vaccinate if seronegative for hepatitis A/B.
- Pneumococcal polysaccharide vaccine (PPSV23)

**Diagnostic Procedures/Other**
Evaluate for advanced hepatic fibrosis.
- Indirect markers include multiple clinical prediction models: AST-to-platelet ratio index (APRI), Fibrosis-4 score, FibroIndex, Forns index, HepaScore/FibroScore, FibroSure that are based on factors such as age, gender, AST, ALT, platelets, bilirubin estimate fibrosis
- Liver imaging: ultrasound (US), CT scan, MRI, transient US elastography, MR elastography
- Liver biopsy (gold standard)
  - Indications: discordant indirect marker results, concurrent non-HCV liver
disease, elastography not available
– Not necessary if diagnosis of hepatocellular carcinoma (HCC) is definitive based on imaging

**Test Interpretation**
- Biopsy measures grade (degree of inflammation) and stage (amount of existing fibrosis).
- Scoring systems: Batts and Ludwig, METAVIR, International Association for the Study of the Liver (IASL)

**TREATMENT**

**GENERAL MEASURES**
- Report acute HCV to health department.
- Treat all patients with virologic evidence of HCV.
- Pretreatment counseling includes a thorough behavioral health and substance abuse history.
- Optimize therapy of comorbidities prior to treatment.
- Discuss treatment plan and likelihood of success based on individual factors such as BMI, GT, race, stage of fibrosis, and viral load.
- Goal is sustained virologic response (SVR): undetectable HCV RNA after 12 to 24 weeks of treatment.
- HCV cascade: Only 50% of patients with chronic HCV are diagnosed; 25% are HCV RNA confirmed, 15% are prescribed treatment, and 10% achieve SVR (2).

**MEDICATION**

**First Line**
- Acute HCV: OK to delay treatment for 12 to 16 weeks after suspected inoculation to allow for spontaneous clearance. Regimen is the same as for chronic HCV.
- Chronic HCV treatment with traditional agents, pegylated interferon (PEG-IFN) and ribavirin (RBV), is often poorly tolerated.
- New oral-only agents more tolerable (but expensive)
- PEG and RBV less preferred now due to side effects

**ISSUES FOR REFERRAL**
● Involve a consultant experienced with HCV.
● Refer to liver transplant program if fulminant acute hepatitis, complication of end-stage disease, or diagnosis of HCC.

COMPLEMENTARY & ALTERNATIVE MEDICINE
No evidence for effective complementary therapy in HCV/cirrhosis/HCC

Discontinued: boceprevir (Victrelis) and telaprevir (Incivek)

C-P: Child-Pugh classification

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Treat early to prevent fibrosis. If cirrhosis is present, treatment may not prevent decompensation.
- Monitor serial viral load only if on antiviral therapy.
- Some experts recommend abdominal US every 6 months to monitor for HCC.
- Screen for varices with endoscopy if cirrhosis present.

Patient Monitoring
- Serial ALT/AST, renal function, and CBCs
- For 12-week course, follow up 4 weeks after starting therapy and 12 weeks after completing therapy.
  - 4-week HCV RNA: If detectable, recheck at week 6. If RNA has increased >10 times, stop therapy.
  - SVR12: Undetectable HCV RNA 12 weeks after completing therapy generally translates to long-term cure (goal of therapy).
SVR decreases risk of portal hypertension, hepatic decompensation, and HCC. Monitor for decompensation (low albumin, ascites, encephalopathy, GI bleed).

**DIET**
- Low-fat, high-fiber diet and exercise to treat obesity/fatty liver
- Extra protein and fluids while on IFN therapy

**PATIENT EDUCATION**
- Avoid alcohol, tobacco, and illicit drugs (including marijuana); refer to rehabilitation/12-step program and monitor for relapse as appropriate.
- Caution with nutritional supplements and herbal medications (may contain hepatotoxins)
- [http://www.cdc.gov/knowmorehepatitis/](http://www.cdc.gov/knowmorehepatitis/)

**PROGNOSIS**
- For every 100 persons infected with HCV
  - 75 to 85 will develop chronic infection.
  - 60 to 70 will develop chronic liver disease.
  - 10 to 20 will develop cirrhosis over 20 to 30 years (more rapid if older age at infection, male gender, alcohol/substance abuse, HIV/HBV coinfection, or diabetes/insulin resistance).
    - 1–5% annual risk of HCC
    - 3–6% annual risk of hepatic decompensation
- Chronic HCV is *curable* in ~70% of cases; in noncirrhotic GT 2 or 3, cure rate is ~90%.

**COMPLICATIONS**
- Fibrosis and cirrhosis typically develop within the first 5 to 10 years of infection.
- Acute/subacute hepatic necrosis, liver failure, HCC, transplant and complications, death
- Risk factors for cirrhosis: age, white race, hypertension, alcohol use, anemia; risk for decompensation: diabetes, hypertension, anemia

**REFERENCES**

SEE ALSO

- Cirrhosis of the Liver; Hepatitis A; Hepatitis B; HIV/AIDS
- Algorithm: Jaundice
- [http://www.hepatitisc.uw.edu/](http://www.hepatitisc.uw.edu/)

CODES

**ICD10**

- B19.20 Unspecified viral hepatitis C without hepatic coma
- B17.10 Acute hepatitis C without hepatic coma
- B18.2 Chronic viral hepatitis C

CLINICAL PEARLS

- 1 of every 10 patients with hepatitis C has no identifiable risk factors.
- 15–25% of HCV-infected persons spontaneously resolve the infection without specific treatment.
- Look for coinfections (HBV/HIV) and comorbid substance abuse in patients infected with HCV.
HERNIA

Yuhamy Curbelo-Peña, MD • Yulibeth Curbelo, MD • Adrian Medina-Gallardo, MD, PhD

BASICS

DESCRIPTION

Areas of weakness or disruption of the abdominal wall through which intracavity structures pass

- **Types**
  - **Inguinal**
    - **Direct:** acquired; herniation through defect in transversalis fascia of abdominal wall medial to inferior epigastric vessels; increased frequency with age as fascia weakens
    - **Indirect:** congenital; herniation lateral to the inferior epigastric vessels through internal inguinal ring into inguinal canal. A “complete hernia” descends into the scrotum, an “incomplete hernia” remains in the inguinal canal.
  - **Pantaloon:** combination of direct and indirect inguinal hernia with protrusion of abdominal wall on both sides of the epigastric vessels
  - **Femoral:** herniation descending through the femoral canal deep to the inguinal ligament; has a narrow neck and is especially prone to incarceration and strangulation
  - **Incisional or ventral:** herniation through a defect in the anterior abdominal wall at the site of a prior surgical incision
  - **Congenital:** herniation through defect in abdominal wall fascia due to collagen deficiency disease
  - **Umbilical:** defect at umbilical ring
  - **Epigastric:** protrusion through the middle line above the level of the umbilicus
  - **Spigelian hernia:** herniation through Spigelian line (lateral border of the rectus abdominis) for a lateral ventral hernia result
  - **Sports hernia (not a true hernia):** strain or tear of soft tissue of groin or lower abdomen
  - **Others:** obturator, sciatic, perineal

- **Definitions**
Reducible: Extruded sac and its contents can be returned to intra-abdominal position spontaneously or with gentle manipulation.

Irreducible/incarcerated: Extruded sac and its contents cannot be returned to original intra-abdominal position.

Strangulated: Blood supply to hernia sac contents is compromised.

Richter: Partial circumference of the bowel is incarcerated or strangulated. Partial wall damage may occur, increasing potential for bowel rupture and peritonitis.

Sliding: wall of a viscus forms part of the wall of the inguinal hernia sac (i.e., R-cecum, L-sigmoid colon)

**Geriatric Considerations**

Abdominal wall hernias increase with advancing age, with significant increase in risk during surgical repair.

**Pregnancy Considerations**

- Increased intra-abdominal pressure and hormone imbalances with pregnancy may contribute to increased risk of abdominal wall hernias.
- Umbilical hernias are associated with multiple, prolonged deliveries.

**EPIEMIOLOGY**

**Incidence**

- 75–80% groin hernias: inguinal and femoral
- 2–20% incisional/ventral, depending on whether a prior surgery was associated with infection or contamination
- 3–10% umbilical, considered congenital
- Groin
  - 6–27% lifetime risk in adult men
  - Two-peaks: most inguinal hernias present before 1 year of age or after 55 years of age
  - ~50% of children <2 years of age have a patent processus vaginalis, decreasing to 40% after age 2 years. Only between 25% and 50% are clinically significant.
  - Inguinal hernia in <5% of newborns male-to-female ratio 10:1
  - Increased incidence in premature infants
  - Increased incidence in patients with abdominal aortic aneurysms
  - Femoral <10% of all groin hernias, 40% present as a surgical emergency
- Incisional/ventral: ~10–23% of abdominal surgeries complicated by an
Incisional hernia, most common in upper midline incisions
- Incidence ratio: male = female
- Umbilical: 10–20% of newborns; most close by 5 years of age

**Prevalence**
- Groin and inguinal hernias are more prevalent in men.
- Femoral and umbilical hernias are more prevalent in women.
- Most inguinal hernias are indirect in men and women.
- Incisional/ventral hernias (IVH) are more prevalent in smokers and obese individuals.

**ETIOLOGY AND PATHOPHYSIOLOGY**
Loss of tissue strength and elasticity (especially with aging or congenital defect in abdominal fascia) results in a fascial defect of the abdominal wall. Most pediatric hernias are congenital (e.g., patent processus vaginalis). Most adult hernias are a result of acquired weakness in the tissues of the anterior abdominal wall.

**Genetics**
No known genetic pattern

**RISK FACTORS**
- Increased abdominal pressure, coughing, heavy lifting, constipation, pregnancy, ascites, prostatism, obesity, advancing age (loss of tissue turgor), smoking, steroid use, low birth weight, prematurity
- Age: Femoral and scrotal hernias, along with recurrent groin hernias, are associated with increased risk for acute hernia surgery.

**COMMONLY ASSOCIATED CONDITIONS**
Obesity, chronic obstructive pulmonary disease, multiple abdominal surgeries, pregnancy, advanced age, Ehlers-Danlos syndrome, Marfan syndrome, polycystic kidney disease (PKD), osteogenesis imperfecta, Down syndrome, abdominal aortic aneurysm

**DIAGNOSIS**

**HISTORY**
May observe protrusion through abdominal wall during increased intra-abdominal pressure (Valsalva maneuver or cough)

- Pain, nausea, vomiting, bloating; relieved with reclining; may signal complication (e.g., strangulation)

**PHYSICAL EXAM**

- Examine initially with patient standing. During palpation, the patient should be instructed to cough, strain, or perform Valsalva maneuver to determine the extent of intracavitary content movement. Repeat exam with patient in supine position.
- Inguinal (superior to inguinal ligament)
  - Direct inguinal hernia: Finger in inguinal canal finds defect of the transversalis fascia as a deep (posterior to anterior) bulge palpated with increased intra-abdominal pressure.
  - Indirect inguinal hernia: Finger in inguinal canal finds a persistent process vaginalis as a bulge (lateral to medial) that may extend down into scrotum.
- Femoral (inferior to inguinal ligament): bulge in upper middle thigh; neck of the sac will protrude lateral to and below a finger placed on the pubic tubercle.
- Umbilical: palpable protrusion at umbilicus
- Incisional/ventral: palpable protrusion at site of prior abdominal incision or midline superior to the umbilicus
- Epigastric: palpable protrusion that occurs off midline above umbilicus

**DIFFERENTIAL DIAGNOSIS**

Lymphadenopathy, hydrocele, lipoma, varices, cryptorchidism, abscess, tumor, sports hernia (athletic pubalgia), pelvic fractures, adductor tears, omphalomesenteric duct, urachal cyst

**DIAGNOSTIC TESTS & INTERPRETATION**

Imaging rarely required; reserve for suspected abdominal hernia or unclear diagnosis; plain radiographs to rule out obstruction

- Ultrasound (US) can assess inguinal hernias.
- CT or tangential radiography for incisional and abdominal wall hernias and postsurgical patients with complaints of abdominal pain
- Herniography is no longer recommended.

**Follow-Up Tests & Special Considerations**

Diagnostic laparoscopy may be beneficial for occult hernias poorly appreciated
on exam or with imaging.

TREATMENT

- Elective surgical repair is associated with significantly lower morbidity and mortality.
- Acute setting
  - Pain management for symptomatic hernias
  - Strangulated hernias should be surgically repaired early to prevent complications such as necrosis and viscus perforation.
  - Manual reduction of incarcerated hernias improves outcomes by allowing for elective repair after swelling and inflammation subside.
  - Complication rate is significantly greater with emergent pediatric inguinal hernia repairs when compared with elective procedures.
  - Acute hernia repair carries a higher morbidity and lower survival rate.
  - Laparoscopic repair of IVH is safe, has fewer complications, and shorter hospital stays and possibly a shorter surgical time. Postoperative pain and recurrence rates are similar to open repair.
  - For patients undergoing repair, operative times are shorter for laparoscopic totally extraperitoneal repair then with open mesh repair and with no difference in complication rates (1)[B].
  - Mesh is recommended for hernia repairs.

MEDICATION

- Antibiotics: Prophylaxis does not reduce wound infections after groin hernia repairs.
- Pain: Local anesthetic during surgical repair results in significant reduction of postoperative pain. Tension-free procedures, such as Lichtenstein, may be performed under local anesthesia.

ADDITIONAL THERAPIES

Geriatric Considerations
Use of a truss (external supportive device) for direct inguinal hernias is common; no data regarding efficacy

ISSUES FOR REFERRAL
Warn patients of symptoms or signs of incarceration or strangulation (acute abdominal pain, fever, bloody bowel movements), which mandate immediate evaluation.

**SURGERY/OTHER PROCEDURES**

All inguinal hernias should be surgically repaired. Watchful waiting in asymptomatic patients is safe if the patient has significant comorbidities that may compromise emergent repair.

- Incarceration and strangulation are absolute indications for hernia repair.
- Contraindications: patients who are not surgical candidates based on cardiovascular risk factors
  - Avoid elective repair in pregnant patients or those with active infections.
- Special considerations
  - Umbilical hernias <0.5 cm usually obliterate and can be observed.
  - Umbilical hernias in children age 2 to 4 years may also be observed, as they typically close spontaneously.
  - Operative times and complication rates are similar when comparing single-incision laparoscopic inguinal hernia repair versus traditional multiport laparoscopic repair (2)[B].
  - “Watchful waiting” is recommended in pregnancy. Elective postpartum repair has similar outcomes and no increased risk of incarceration or strangulation before or during delivery.
  - Women have lower recurrence rates using laparoscopic methods compared with Lichtenstein open method.
  - Ascites is not a strict contraindication for surgical repair.

- **Gold standard**
  - Inguinal hernia
    - Open: Lichtenstein with mesh (37%) or mesh plug (34%): decreased recurrence rates
    - Laparoscopic (14%) with mesh: decreased hospital stay and postoperative pain
      - Requires general anesthesia
      - Transabdominal preperitoneal (TAPP) versus total extraperitoneal (TEP)
    - Pediatric: Laparoscopic percutaneous repair is an efficient, safe, and effective alternative to open repair. It is associated with reduced operative times and no increase in complication or recurrence rates. Avoid mesh in pediatric patients (3)[B].
Incisional/ventral
  - Laparoscopic repair is effective for most patients with primary or recurrent ventral hernias; there is <10% recurrence rate.

Umbilical
  - Pediatric: open excision with suture closure
  - Adult: Open repair with mesh or plug may reduce hernia recurrence.

Newer techniques
  - Prolene hernia system
  - Biologic wound closure system: reduced recurrence in contaminated procedures

Complications
  - Recurrence
  - Seromas
  - Postoperative pain, temporary or chronic: less with laparoscopic versus open technique
  - Wound infection
  - Injury to cord structures in inguinal herniorrhaphy; with nerve injury, most symptoms will resolve.

ONGOING CARE

PATIENT EDUCATION
  - Cleveland clinic: http://my.clevelandclinic.org/disorders/hernia/hic_hernia.aspx
  - Umbilical hernias: Boston Children’s Hospital: http://www.childrenshospital.org/az/Site1018/mainpageS1018P0.html

PROGNOSIS
  - Groin (pediatric): low recurrence rates (<3%) with surgery; may spontaneously resolve in infants
  - Groin (adult): ≥1% per year risk of bowel strangulation without surgical treatment; 0–10% postoperative recurrence rates, depending on surgeon’s experience level and method
  - Incisional/ventral: 3–5% postoperative occurrence: 2–17% postrepair recurrence, increased to 20–46% in larger hernias
  - Umbilical (pediatric)
    - High rate of spontaneous resolution
– Hernia less likely to close further in older children and in children with larger defects
• Umbilical (adult): up to 11% postoperative recurrence
• Epigastric: most ultimately become incarcerated and/or strangulated without surgical treatment. Recurrence is high due to frequency of missed defects during repair.

REFERENCES

ADDITIONAL READING

SEE ALSO
Algorithms: Abdominal Pain, Lower; Intestinal Obstruction; Pelvic Pain

CODES
**ICD10**
• K46.9 Unspecified abdominal hernia without obstruction or gangrene
• K40.90 Unil inguinal hernia, w/o obst or gangr, not spcf as recur
• K41.90 Unil femoral hernia, w/o obst or gangrene, not spcf as recur
**CLINICAL PEARLS**

- Inguinal hernias are either direct or indirect:
  - Direct inguinal: acquired; herniation through defect in transversalis fascia of abdominal wall medial to inferior epigastric vessels
  - Indirect inguinal: congenital; herniation lateral to the inferior epigastric vessels; a “complete hernia” descends into the scrotum; an “incomplete hernia” remains within the inguinal canal.
- Pantaloon: combined direct and indirect inguinal hernia
- Femoral: descends through the femoral canal deep to the inguinal ligament
- Incisional or ventral: iatrogenic, herniation through a defect at site of a prior surgical incision
- Umbilical: Defect occurs at umbilical ring tissue.
HERPES EYE INFECTIONS

Stephanie L. Conway, PharmD, RPh • Gerald Gleich, MD

BASICS

DESCRIPTION

- Eye infection (blepharitis, conjunctivitis, keratitis, stromal keratitis, uveitis, retinitis, glaucoma, or optic neuritis) caused by herpes simplex virus (HSV) types 1 or 2 or varicella-zoster virus (VZV, also known as human herpesvirus type 3 [HHV3])
- Categories
  - HSV: can affect many parts of the eye but most often affects the cornea (herpes keratoconjunctivitis); HSV1 > HSV2; can be further divided into primary and recurrent
  - VZV: When VZV is reactivated and affects the ophthalmic division of the 5th cranial nerve, this is known as herpes zoster ophthalmicus (HZO), a type of shingles.
- System(s) affected: eye, skin, central nervous system (CNS) (neonatal)

EPIDEMIOLOGY

- Predominant age: HSV—mean age of onset 37.4 years but can occur at any age, including primary infection in newborns; VZV usually advancing age (>50 years)
- Predominant sex: HSV—male = female; HZO—female > male

Incidence

- HSV keratitis: In the United States, approximated at 18.2 per 100,000 person-years. Incidence is 1.5 million per year worldwide (1).
- VZV: 1 million new cases of shingles per year in the United States; 25–40% develop ophthalmic complications. Temporary keratitis is most common.

Prevalence

- Ocular HSV prevalence estimated at 500,000 in the United States (1)
- VZV: Prevalence of herpes zoster infection is 20–30%. Ocular involvement in 50% if not treated with antivirals (2); overall lifetime prevalence of HZO: 1%
ETIOLOGY AND PATHOPHYSIOLOGY

- HSV and VZV are herpesviridae dsDNA viruses.
- HSV: primary infection from direct contact with infected person via saliva, genital contact, or birth canal exposure (neonates)
  - Primary infection may lead to severe disease in neonates, including eye, skin, CNS, and disseminated disease.
  - Recurrent infection is more common overall cause of herpetic eye infections.
- VZV: Primary infection from direct contact with infected person may cause varicella (“chickenpox”) and/or lead to a latent state within trigeminal ganglia.
  - Reactivation of the virus may affect any dermatome (resulting in herpes zoster or “shingles”), including the ophthalmic branch (HZO).

RISK FACTORS

- HSV: personal history of HSV or close contact with HSV-infected person
  - General risk factors for reactivation: stress, trauma, fever, UV light exposure, other viral infections
  - Risk factors for HSV keratitis: UV laser eye treatment, some topical ocular medications such as prostaglandin analogues and primary/secondary immunosuppression
- HZO
  - History of varicella infection, advancing age (>50 years), sex (female > male), acute/painful prodrome, trauma, stress, immunosuppression (1,3)

ALERT

Consider primary/secondary immunodeficiency disorders in all zoster patients <40 years of age (e.g., AIDS, malignancy).

GENERAL PREVENTION

- Contact precautions with active lesions (HSV and VZV)
- VZV can be spread to those who have not had chickenpox and are not immunized.
- Varicella vaccination (Zostavax) (VZV only): single 0.65 mL SC dose; no booster. Recommended by the CDC for all persons age 60 years and older. Reduces incidence of herpes zoster by 51% and HZO for 49%; also significantly decreases rates of postherpetic neuralgia (PHN) (4)
- Acyclovir can be used prophylactically to prevent recurrence of ocular HSV.
- HSV immunization currently being researched (1)
ALERT
Zoster vaccination is contraindicated if HIV-positive or other immunocompromised state, pregnancy, or in active untreated tuberculosis (TB).

Pregnancy Considerations
- Pregnant women without history of chickenpox should avoid contact with persons with active zoster.
- Pregnancy increases risk of recurrence of HSV/VZV.
- Live vaccine (Zostavax) is contraindicated during pregnancy.

COMMONLY ASSOCIATED CONDITIONS
Primary and secondary immunocompromised states

DIAGNOSIS

HISTORY
- Varies according to the virus and the ocular structures involved
- History of varicella or herpes simplex infection
- Acute onset, eye pain, headache, photophobia, tearing, ocular redness, decreased or blurry vision (3)[A]
- May present with a prodromal period of fever, malaise, headache, and eye pain before skin eruptions and eye lesions (HZO) (3)[A]

PHYSICAL EXAM
- Varies according to the virus and ocular structures involved
  - HSV most commonly affects the corneal epithelium (1)[A].
  - VZV most commonly affects corneal stroma and uvea (3)[A].
- Typically unilateral in presentation
  - HZO presents as early as 1 to 2 days after unilateral vesicular eruption in a dermatomal pattern (3)[A].
- Decreased visual acuity
- Conjunctival injection near the limbus
- Decreased corneal sensation
- Slit-lamp exam
  - Fluorescein and rose bengal stain: dendritic corneal lesions most often seen in HSV, followed by stromal keratitis, corneal edema, or infiltrate (2)[C]
– Stromal keratitis often seen in HZO, although dendritic lesions may form \(^{(2)}\)[A]

**ALERT**
Unilateral dermatomal vesicular rash most commonly in ophthalmic branch (\(V_1\)) of trigeminal nerve (VZV):

- Hutchinson sign: Vesicular lesion on nose from VZV indicates an increased risk of HZO due to involvement of nasociliary branch of trigeminal nerve, which also innervates the eye \(^{(3)}\)[A].

**DIFFERENTIAL DIAGNOSIS**
- Any other cause of red, painful eye
  - Bacterial, fungal, allergic, or other viral conjunctivitis
  - Acute angle-closure glaucoma
- Corneal abrasion, recurrent corneal erosion, toxic conjunctivitis
- Temporal arteritis
- Trigeminal neuralgia

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- Typically none needed, as diagnosis is primarily based on history and physical exam \(^{(3)}\)[A]

- Other
  - Corneal swab for HSV DNA by polymerase chain reaction (PCR) (PPV = 96%)
  - If vesicle present, can perform a Tzanck smear for VZV or HSV (multinucleated giant cells)
  - Antibody titers to assess exposure only; direct fluorescent antibody (DFA); tissue culture

**ALERT**
Urgent ophthalmology referral necessary for slit-lamp exam, dilated fundus exam, and intraocular pressure measurement

**TREATMENT**

mebooksfree.com
GENERAL MEASURES
- Avoid contact with nonimmune people.
- No contact lenses should be worn during treatment period.
- Cool compresses
- Artificial tears
- Oral pain medications

MEDICATION

**First Line**
- HSV corneal epithelial disease
  - Trifluridine 1%: Apply 1 drop q2h while awake to a max of 9 drops daily until reepithelialization occurs and then 1 drop q4h for another 7 days.
  - Acyclovir: 400 mg PO 5 times per day for 10 days
  - Ganciclovir 0.15% gel: Apply 1 drop in eye q3h while awake, ~5 times daily, until reepithelialization occurs and then 1 drop q8h for 7 days.
  - Vidarabine 3% ointment (Vira-A): Apply 0.5 inch into lower conjunctival sac 5 times daily q3h until reepithelialization occurs.
  - Trifluridine and acyclovir cure about 90% of treated eyes within 2 weeks with no significant differences in effectiveness (5)[A].
  - Evidence conflicting as to whether ganciclovir is as good as or better than acyclovir (5)[A]
  - Epithelial débridement by an ophthalmologist: may accelerate healing in combination with treatment as above (5)[A]
  - Avoid topical steroids.
- Utility of PO antivirals unclear HSV stromal keratitis or uveitis (without epithelial disease): combination of antiviral and steroid treatment; requires ophthalmology evaluation
  - Prednisolone acetate: 1% drops QID with slow taper (6)[A]
  - Consider systemic steroids in severe uveitis (6)[A].
  - Trifluorothymidine: 1% drops QID for prophylaxis while on topical steroids
- HZO
  - Valacyclovir (Valtrex) 1 g PO TID for 7 to 10 days or famciclovir (Famvir) 500 mg PO TID for 7 to 10 days or acyclovir 800 mg PO 5 times a day for 7 to 10 days
  - Valacyclovir and famciclovir result in significant reduction in PHN compared to acyclovir (number needed to treat [NNT] = 3) with equivalent efficacy (7)[A].
– Topical antibiotic ophthalmic ointment to protect ocular surfaces (e.g., bacitracin, polymyxin): 0.5-inch ribbon BID–TID for 7 to 10 days (8)[C]
– If immunocompromised: acyclovir 10 to 15 mg/kg IV q8h for 10 days
– Prednisolone acetate: 1% drops QID with slow taper with an ophthalmologist (8)[C]
• Cycloplegic agent if anterior uveitis present; intraocular pressure-lowering agent if necessary

Second Line
• HSV: acyclovir 2 g/day PO in divided doses over 10 days in patients intolerant of topical antivirals
• Topical idoxuridine, acyclovir, brivudine, although approved internationally, are not approved for use in the United States.
• Concomitant treatment with interferon may also improve outcomes but is not currently available.

ALERT
• HZO: Antiviral therapy is most effective within the first 72 hours of rash onset but should still be initiated >72 hours after onset because of the possible complications of HZO (2)[C].
• Topical antiviral agents
  – Toxic to corneal epithelium, especially after 10 to 14 days of continuous use
• Acyclovir: Reduce dosage in renal insufficiency.
• Topical steroids
  – Should only be prescribed by an ophthalmologist
  – Contraindicated with active corneal epithelial disease, which is best monitored with a slit lamp
  – Can increase intraocular pressure, cause corneal thinning, and, with long-term use, cause cataracts
• Prednisone: caution in immunocompromised patients

ISSUES FOR REFERRAL
Emergent or urgent ophthalmology referral, depending on severity of disease

ADDITIONAL THERAPIES
• Recurrent HSV requires suppressive therapy:
  – Acyclovir 400 mg PO every day or BID or valacyclovir 500 mg PO daily (9)[C]
HZO leading to PHN is very common and can be treated with gabapentin or pregabalin, TCAs, opioids, and/or lidocaine gel.

SURGERY/OTHER PROCEDURES
Corneal transplantation for severe scarring or perforation

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization
  - Severe systemic VZV disease
  - Systemic HSV in neonates—see “Herpes Simplex Virus, Pediatric.”
- Discharge criteria: resolution of systemic disease

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Monitor with slit-lamp exam q1–2d until improvement and then q3–4d until epithelial defect resolves.
- Weekly after epithelial disease resolves until off topical antivirals

PATIENT EDUCATION
Educate patients about the importance of early recognition of recurrent symptoms and need for prompt evaluation and treatment.

PROGNOSIS
- Many cases are self-limited but, depending on the ocular structure involved, can lead to permanent blindness, especially in the setting of recurrent disease.
- Ocular HSV is the number one cause of infectious blindness worldwide (1).
- Recurrent ocular HSV
  - HSV epithelial disease without treatment
  - Without sequelae, 40% resolve.
  - With treatment, 90–95% resolve without complication.

Pediatric Considerations
- Neonatal primary HSV often disseminated with high mortality rate; 37%
- Develop vision worse than 20/200.
- Pediatric cases more likely to be bilateral (26%), recurrent (48% in 15 months), and may cause amblyopia

**COMPLICATIONS**
- Recurrence
- Corneal neovascularization and scarring resulting in poor vision
- Neurotrophic ulcer with perforation
- Secondary bacterial or fungal infection
- Secondary glaucoma in 10%
- PHN in 20–40% with VZV, typically longer lasting in older patients
- Vision loss from optic neuritis or chorioretinitis

**REFERENCES**
SEE ALSO

- Herpes Simplex; Herpes Simplex Virus, Pediatric; Herpes Zoster (Shingles)
- Algorithm: Eye Pain

CODES

ICD10

- B00.50 Herpesviral ocular disease, unspecified
- B02.30 Zoster ocular disease, unspecified
- B00.52 Herpesviral keratitis

CLINICAL PEARLS

- HSV and VZV can lead to a wide array of ocular manifestations, ranging from self-limited disease to potentially vision-threatening disease and complications.
- A slit-lamp exam with fluorescein stain should be performed on all patients with possible HSV keratitis or HZO.
- Topical antiviral treatment is appropriate for HSV, but systemic PO antiviral treatment is necessary for HZO.
- An ophthalmologist should be consulted before prescribing topical steroids. All HZO patients should be referred to an ophthalmologist.
- Hutchinson sign (vesicular lesion on nose from VZV) is a strong indicator of HZO.
- Zostavax is effective at preventing zoster and HZO as well as decreasing the duration of PHN.
BASICS

DESCRIPTION

- Characteristic vesicular rash primarily located in oral and genital regions as the result of infection with
  - Herpes simplex virus (HSV)-1 blisters mostly on lips, in mouth, face, eyes
  - HSV-2 primarily genital herpes, although cross-reactivity is common (HSV-1 can cause genital sores through oral–genital contact)
- Associated with a wide range of sequelae. Complexity and variation of presentation depends on the age and immune status of host, whether the infection is primary or recurrent and the degree of dissemination.
- Viral shedding is typically greatest in the first (primary) infection and lessens with recurrences.
- Meningitis/encephalitis and pneumonia are serious systemic manifestations associated with HSV infection.

EPIDEMIOLOGY

- Predominant age: affects all ages; however, most HSV-1 is acquired in childhood, and most HSV-2 is acquired in young–middle adulthood.
- Predominant sex: male = female

Incidence

- >1 million new cases of HSV per year
- HSV can reactivate, causing recurrent disease.

Prevalence

- Widespread; 1–25% of adults may shed HSV-1 or HSV-2 at any given time. Many are unaware of their infection status.
- Prevalence of antibodies to HSV-1 is 90% by adulthood in the general population. 30% of adults have antibodies to HSV-2.

ETIOLOGY AND PATHOPHYSIOLOGY
HSV-1 and HSV-2 are double-stranded DNA viruses from the family *Herpesviridae*. HSV-1 and HSV-2 are transmitted by contact with infected skin during periods of viral shedding. Transmission also occurs vertically during childbirth. Most often, HSV-1 is associated with oral lesions and HSV-2 with genital lesions.

**RISK FACTORS**
- Immunocompromised state
  - Chemotherapy, malignancy/chronic disease states such as diabetes or AIDS, old age
- Atopic eczema, especially in children
- Prior HSV infection
- Sexual intercourse with infected person (condoms help minimize HSV transmission, but lesions outside condom-protected areas can spread virus)
- Occupational exposure
  - Dental professionals at higher risk for HSV-1 and resulting herpetic whitlow
- Neonatal herpes simplex: Primary infection is life-threatening and usually acquired by vaginal birth to an infected mother; risk is greatest in mothers with primary genital herpes infection; incubation is usually from 5 to 7 days (rarely 4 weeks); cutaneous, mucous membrane, or ocular signs seen in only 70%

**GENERAL PREVENTION**
- If active lesions are present, avoid direct contact with immunocompromised people, elderly, and newborns.
- Hand hygiene
- Kissing, sharing beverages, and sharing utensils/toothbrushes can transmit HSV.
- Genital herpes: Avoid sexual contact if active lesions (herpes simplex is also transmitted when disease appears to be inactive); discuss condom benefits and limits; consider antiviral therapy to reduce viral shedding; encourage safe sex.

**COMMONLY ASSOCIATED CONDITIONS**
- Erythema multiforme: 50% of cases associated with HSV-1 or HSV-2
- Screen all severe, treatment-resistant, or unusual HSV for concurrent HIV infection.
DIAGNOSIS

HISTORY
- Many patients are unaware of a known exposure.
- Prodrome of fatigue, low-grade fever, itching, tingling, or hot skin for several days immediately prior to outbreak of characteristic vesicular rash.
- Herpes labialis is precipitated by sunlight, fever, trauma, menses, and stress; prodrome of pain, burning, and itching commonly occurs 6 to 48 hours before vesicles appear.

PHYSICAL EXAM
- Vesicles are often clustered and become painful ulcerated lesions, often with erythematous base.
- Primary genital herpes: See “Herpes, Genital.”
- Primary herpetic gingivostomatitis and pharyngitis: usually in early childhood; incubation from 2 to 12 days, followed by fever, sore throat, pharyngeal edema, and erythema;
  - Small vesicles develop on pharyngeal and oral mucosa, rapidly ulcerate, and increase in number to involve soft palate, buccal mucosa, tongue, floor of mouth, lips, and cheeks; tender, bleeding gums; cervical adenopathy; fever, general toxicity, poor oral intake, and excess salivation contribute to dehydration; autoinoculation of other sites may occur; resolves in 10 to 14 days.
- Primary herpes keratoconjunctivitis: unilateral conjunctivitis with regional adenopathy, blepharitis with vesicles on lid marginal keratitis with dendritic lesions, or with punctate opacities; lasts 2 to 3 weeks; systemic involvement prolongs process.
- Eczema herpeticum: diffuse pox-like eruption complicating atopic dermatitis; sudden appearance of lesions in typical atopic areas (upper trunk, neck, head); high fever, localized edema, adenopathy.
- Herpetic whitlow: localized infection of affected finger with intense itching and pain, followed by vesicles that may coalesce with swelling and erythema. Mimics pyogenic paronychia; neuralgia and axillary adenopathy are possible; heals in 2 to 3 weeks.
- Congenital infection through transplacental transfer may present with jaundice, hepatosplenomegaly, disseminated intravascular coagulation (DIC), encephalitis, seizures, temperature instability, chorioretinitis, and conjunctivitis with/without vesicles.
- Recurrent diseases from endogenous reactivation
  - Herpes labialis: recurrent lesions with HSV-1; usually <1 recurrence/6 months, but 5–25% may have >1 attack/month; vesicles often at vermilion border, ulcerate and crust within 48 hours; heal within 8 to 10 days; may have local adenopathy
  - Ocular herpes: may recur as keratitis, blepharitis, or keratoconjunctivitis; dendritic ulcers, decreased corneal sensation, decreased visual acuity; uveitis may cause permanent visual loss.

**DIFFERENTIAL DIAGNOSIS**

- Impetigo: honey-crusted vesicles
- Aphthous stomatitis: grayish, shallow erosions with ring of hyperemia of anterior in mouth and lips
- Herpes zoster: unilateral dermatome distribution
- Syphilitic chancre: painless ulcer
- Folliculitis: may mimic “shave bumps” in genital area
- Herpangina: Vesicles predominate on anterior tonsillar pillars, soft palate, uvula, and oropharynx but not more anteriorly on lips/gums (usually caused by group A coxsackievirus).
- Stevens-Johnson syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

- Screen for other sexually transmitted infections (STIs) in patients with primary genital herpes.
- Viral: HIV, hepatitis B and C, and human papillomavirus (HPV) have crossover.
- Bacterial: Screen for concurrent gonorrhea, chlamydia in new primary genital outbreaks.

**Initial Tests (lab, imaging)**

- Tzanck smear shows multinucleated giant cells often with eosinophilic intranuclear inclusions (scrape material from lesion to slide, fix with ethanol/methanol, stain with Giemsa or Wright stain); varicella (herpes zoster) has identical findings.
- HSV culture: swab and plate on viral-specific media. Sample may need to be refrigerated; can take up to 6 days to be positive; highly specific, hence, reliable if positive but has 20% false-negative rate
- HSV type-specific antibody tests distinguish between HSV-1 and HSV-2.
Polymerase chain reaction (PCR), direct fluorescent antibody (DFA), ELISA, and Western blot
– 3 weeks after infection, 50% of those infected test positive; 70%, 6 weeks after infection; by 16 weeks, nearly all infected test positive.

Diagnostic Procedures/Other
Biopsy is occasionally needed to confirm diagnosis.

Test Interpretation
- Intraepithelial edema (ballooning degeneration) and intracellular edema
- Brain biopsy (in encephalitis) shows hemorrhagic necrosis of gray and white matter with acute and chronic inflammation, thrombosis, and fibrinoid necrosis of parenchymal vessels; intranuclear inclusions in astrocytes, oligodendroglia, and neurons

TREATMENT

GENERAL MEASURES
- Cool dressings moistened with aluminum acetate solution
- Pouring a cup of warm water over genitals while urinating or by sitting in a warm bath while urinating (sitz baths) if lesions are causing urinary difficulty
- Children with gingivostomatitis who resist oral intake due to pain or extensive skin disease (eczema herpeticum) may require IV hydration.

MEDICATION

First Line
- Begin promptly, preferably in prodromal phase.
- Acyclovir (generic)
  - Mucocutaneous (or genital) HSV
    - Primary/first infection: 400 mg TID or 200 mg 5 times per day for 7 to 10 days
    - If severe, start with IV q8h dosing for the first few days, then complete 10-day course PO route.
    - Recurrence: 400 mg PO TID for 5 days or 800 mg BID for 5 days or 800 mg TID for 2 days
  - Suppression: 400 mg BID daily (1)[B]
    - Keratitis HSV: 400 mg PO 5 times per day; topical treatment is preferred as
First line.

- Pediatric dosing: neonatal herpes simplex or encephalitis: 60 mg/kg/day IV divided q8h for 14 to 21 days (2)[B]
  - Older (>3 months of age) immunocompetent is weight-based dosing (40 to 80 mg/kg/day [max 1,000 mg/day] divided q8h for 5 to 7 days).
- Safe in pregnancy and lactation—Category B
- Recurrent herpes labialis: 800 to 1,600 mg/day for prevention (3,4)[B]
- Penciclovir (Denavir): 1% cream. Apply to oral lesions q2h during waking hours for 4 days (5)[B].

- Valacyclovir (Valtrex)
  - Primary genital herpes: 1 g PO BID for 7 to 10 days. Recurrent genital herpes: 500 mg PO BID for 3 days; suppression: 500 to 1,000 mg PO daily (depending on frequency of outbreaks); labialis HSV (cold sores/oral lesions): 2,000 mg PO q12h for 1 day (3,4,6)[B]
  - 500-mg daily dose if suppression is needed/desired
- Recurrent herpes labialis: 500 mg/day for 4 months for prevention (3)[B]
- Famciclovir (Famvir)
  - Primary genital herpes: 250 mg PO TID for 7 to 10 days
  - Recurrence: 125 mg PO BID for 5 days or 1,000 mg PO BID for 1 day
  - Suppression: 250 mg PO BID

Precautions
- Renal dosing for all oral antivirals
- Significant possible interactions: Probenecid with IV acyclovir and possibly probenecid with valacyclovir may reduce renal clearance and elevate antiviral drug levels.

Second Line

- Foscarnet
  - Drug of choice for acyclovir resistance in immunocompromised persons with systemic HSV
  - 40 mg/kg IV q8h (assume valacyclovir and famciclovir resistance also if acyclovir resistance occurs)

- Other topicals
  - Ophthalmic preparations for herpes keratoconjunctivitis; acyclovir, vidarabine (Vira-A), ganciclovir, trifluridine
  - Topical acyclovir and penciclovir improve recurrent herpes labialis healing times by ~10% (3)[B].
  - Topical analgesics: Lidocaine 2% or 5% helps reduce pain associated with
vulvar and penile outbreaks.
- Over-the-counter topical antivirals: docosanol

**ISSUES FOR REFERRAL**
Refer recurrent cases of herpes keratoconjunctivitis to an ophthalmologist.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Pregnancy considerations
  - Cesarean section and/or acyclovir are indicated if any active genital lesions (or prodrome) present at time of delivery; consider cesarean delivery if primary genital herpes is suspected within previous 4 weeks (5,6)[B].
  - Daily oral antivirals after 36 weeks of pregnancy in women with history of genital herpes help to prevent outbreak around the time of delivery.
  - Avoid fetal scalp electrodes, forceps, vacuum extractor, and artificial rupture of membranes if mother has history of genital HSV.
  - Risk of viral shedding at delivery from asymptomatic recurrent genital HSV is low (~1.6%).
- Pediatric considerations
  - Neonates with likely exposure (high index of suspicion) at birth or those who exhibit signs of HSV infection should have body fluids cultured and immediately start treatment (IV acyclovir).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- For most routine cases, follow-up is not necessary. Lesions and symptoms resolve rapidly within 10 days. Extensive cases should be rechecked in 1 week; monitor for secondary bacterial infections.
- Consider long-term suppression.

**DIET**
If oral lesions are present, avoid salty, acidic, or sharp foods (e.g., snack chips, orange juice).

**PATIENT EDUCATION**
• Explain the natural history that timing of exposure is difficult to determine and that the virus will remain in the body indefinitely. Acknowledging and discussing psychological impact of the diagnosis helps to reduce stigmatization.
• Emphasize personal hygiene to avoid self-spreading to other body areas (autoinoculation) or exposing others. Frequent hand washing; avoid scratching; cover active, moist lesions.
• Reinforce safe sexual practices.

PROGNOSIS
• Usual duration of primary disease is 5 days to 2 weeks.
• Antiviral treatment shortens duration, reduces complications, and mitigates recurrences (if used for suppression).
• Viral shedding during recurrence is briefer than with primary disease; frequency of recurrence is variable and depends on individual host factors.
• Newborns/immunocompromised individuals are at highest risk for major morbidity/mortality.
• HSV is never eliminated from the body but stays dormant in dorsal root ganglia and can reactivate, causing recurrent symptoms and lesions.

COMPLICATIONS
• Herpes encephalitis: Brain biopsy may be needed for diagnosis.
• Herpes pneumonia

**ADDITIONAL READING**

**SEE ALSO**

- Herpes, Genital
- Algorithm: Genital Ulcers

**CODES**

**ICD10**

- B00.9 Herpesviral infection, unspecified
- A60.00 Herpesviral infection of urogenital system, unspecified
- B00.1 Herpesviral vesicular dermatitis

**CLINICAL PEARLS**

- Up to 25–30% of the U.S. population has serologic evidence of genital herpes (HSV-2), and >80% is seropositive for HSV-1.
- Most individuals are unaware they are infected, allowing for asymptomatic viral transmission.
- Viral suppression for patients with frequent recurrences reduces transmission and decreases outbreak frequency.
HERPES ZOSTER (SHINGLES)
Mark B. Stephens, MD

BASICS

DESCRIPTION
- Results from reactivation of latent varicella-zoster virus (human herpesvirus type 3) infection
- Postherpetic neuralgia (PHN) is defined as pain persisting at least 1 month after rash has healed. The term *zoster-associated pain* is more clinically useful.
- Usually presents as a painful unilateral vesicular eruption with a dermatomal distribution
- System(s) affected: nervous; integumentary; exocrine
- Synonym(s): shingles

EPIDEMIOLOGY
Predominant sex: male = female

Incidence
- Incidence increases with age. 2/3 of cases occur in adults age ≥50 years. Incidence is increasing overall as the U.S. population ages.
- Herpes zoster: 4/1,000 person-years
- PHN: 18% in adult patients with herpes zoster; 33% in patients ≥79 years of age

Prevalence
Nearly 1 million new cases of herpes zoster annually

Pregnancy Considerations
May occur during pregnancy

Geriatric Considerations
- Increased incidence of zoster outbreaks
- Increased incidence of PHN
**Pediatric Considerations**
- Occurs less frequently in children
- Has been reported in newborns infected in utero

**ETIOLOGY AND PATHOPHYSIOLOGY**
Reactivation of varicella-zoster virus from dorsal root/cranial nerve ganglia. Upon reactivation, the virus replicates within neuronal cell bodies, and virions are carried along axons to dermatomal skin zones, causing local inflammation and vesicle formation.

**RISK FACTORS**
- Increasing age
- Immunosuppression (malignancy or chemotherapy)
- HIV infection
- Spinal surgery

**GENERAL PREVENTION**
- Herpes zoster vaccination (Shingrix) is recommended by the CDC for patients ≥50 years (1,2) to prevent shingles and related complications. Shingrix is recommended for adults who previously received Zostavax and is the preferred vaccine.
- Patients with active zoster may transmit disease-causing varicella virus (chickenpox) to susceptible persons.

**COMMONLY ASSOCIATED CONDITIONS**
Immunocompromised states HIV infection, posttransplantation, immunosuppressive drugs, and malignancy

**DIAGNOSIS**

**HISTORY**
- Prodromal phase (sensory changes over involved dermatome prior to rash)
  - Tingling, paresthesias
  - Itching
  - Boring “knife-like” pain
- Acute phase
  - Constitutional symptoms (e.g., fatigue, malaise, headache, low-grade fever)
are variable.

- Dermatomal rash

**PHYSICAL EXAM**

- Acute phase
  - Rash: initially erythematous and maculopapular; evolves to characteristic grouped vesicles
  - Vesicles become pustular and/or hemorrhagic in 3 to 4 days.
  - Weakness in distribution of rash (1%)
  - Rash crusts and resolves crusts by 14 to 21 days
- Possible sine herpete (zoster without rash) and other chronic disorders associated with varicella-zoster virus without the typical rash
  - Herpes zoster ophthalmicus (HZO). Vesicles on tip of the nose (Hutchinson sign) indicate involvement of the external branch of cranial nerve V; associated with increased incidence of ocular zoster

- Chronic phase
  - PHN (15% overall; increases with age)
  - 1–5% of cases may affect the motor nerves, causing weakness (*zoster motorius*), facial nerve (e.g., Ramsay Hunt syndrome), spinal motor radiculopathies.

**DIFFERENTIAL DIAGNOSIS**

- Rash
  - Herpes simplex virus
  - Coxsackievirus
  - Contact dermatitis
  - Superficial pyoderma

- Pain
  - Cholecystitis
  - Appendicitis
  - Nephrolithiasis
  - Pleuritis
  - Myocardial infarction
  - Diabetic neuropathy

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

Rarely necessary. Clinical appearance is distinct.
Follow-Up Tests & Special Considerations

- Viral culture
- Tzanck smear (does not distinguish from herpes simplex, and false-negative results occur)
- Polymerase chain reaction
- Immunofluorescent antigen staining
- Varicella-zoster–specific IgM

Test Interpretation

- Multinucleated giant cells with intralesional inclusion
- Lymphatic infiltration of sensory ganglia with focal hemorrhage and nerve cell destruction

TREATMENT

GENERAL MEASURES

- Treat to control symptoms and prevent complications.
- Antiviral therapy decreases viral replication, lessens inflammation, nerve damage, and reduces the severity and duration of long-term pain.
- Prompt analgesia may shorten the duration of zoster-associated pain.
- Calamine and colloidal oatmeal may help reduce itching and burning.

MEDICATION

First Line

- Acute treatment
  - Antiviral agents initiated within 72 hours of skin lesions help relieve symptoms, speed resolution, and prevent or mitigate PHN (3) [A].
  - Valacyclovir: 1,000 mg PO TID for 7 days
  - Famciclovir: 500 mg PO TID for 7 days
  - Acyclovir: 800 mg q4h (5 doses daily) for 7 days
- Analgesics (acetaminophen, NSAIDs)
- Corticosteroids given acutely during zoster infection do not prevent PHN but may accelerate resolution of acute neuritis; use generally limited to cases with severe pain or with neurologic signs if not otherwise contraindicated
  - Tricyclic antidepressants (TCAs; amitriptyline 25 mg at bedtime and other low-dose TCAs) relieve pain acutely and may reduce pain duration; dose
may be titrated up to 75 to 150 mg/day as tolerated.
- Lidocaine patch 5% (Lidoderm) applied over painful areas (limit three patches simultaneously or trim a single patch) for up to 12 hours may be effective.
- Gabapentin: 100 to 600 mg TID for pain and other quality-of-life indicators; limited by adverse effects
- Capsaicin cream and other analgesics may be useful adjuncts. Use opioids sparingly.
- Pregabalin: 50 to 100 mg TID reduces pain, but usefulness is limited by side effects
- Prevention of PHN and zoster-associated pain: Nothing has been shown to prevent PHN completely, but treatment may shorten duration and/or reduce severity of symptoms.
  - Antiviral therapy with valacyclovir, famciclovir, or acyclovir given during acute skin eruption may decrease the duration of pain.
  - Low-dose amitriptyline (25 mg at bedtime) started within 72 hours of rash onset and continued for 90 days may reduce PHN incidence/duration.
- Insufficient evidence to suggest that corticosteroids reduce incidence, severity, or duration of PHN
- Precautions
  - Assess renal function prior to using valacyclovir, famciclovir, or acyclovir.
  - Valacyclovir, famciclovir, and acyclovir are pregnancy Category B.

**Second Line**
Numerous therapies have been advocated, but supporting evidence to routinely recommend is lacking.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Cupping therapy (traditional Chinese medicine) shows potential benefit, but evidence is conflicting.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Outpatient treatment, unless disseminated or occurring as complication of serious underlying disease requiring hospitalization
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Refer to ophthalmology if concern that ophthalmic branch of the trigeminal nerve is involved.

Patient Monitoring
Follow duration of symptoms—particularly PHN. Consider hospitalization if symptoms are severe; patients are immunocompromised; >2 dermatomes are involved; serious bacterial superinfection, disseminated zoster, or meningoencephalitis develops.

DIET
No special diet

PATIENT EDUCATION
- The duration of rash is typically 2 to 3 weeks.
- Encourage good hygiene and proper skin care.
- Warn of potential for dissemination (dissemination must be suspected with constitutional illness signs and/or spreading rash).
- Warn of potential PHN.
- Warn of potential risk of transmitting illness (chickenpox) to susceptible persons.
- Seek medical attention if any eye involvement.

PROGNOSIS
- Immunocompetent individuals should experience spontaneous and complete recovery within a few weeks.
- Acute rash typically resolves within 14 to 21 days.
- PHN may occur in patients despite antiviral treatment.

COMPLICATIONS
- PHN
- HZO: 10–20%
- Superinfection of skin lesions
- Meningoencephalitis
- Disseminated zoster
Hepatitis; pneumonitis; myelitis
- Cranial and peripheral nerve palsies
- Acute retinal necrosis

REFERENCES

ADDITIONAL READING

SEE ALSO
- Bell Palsy; Chickenpox (Varicella Zoster); Herpes Eye Infections; Herpes Simplex
- Algorithm: Genital Ulcers

CODES

**ICD10**
- B02.9 Zoster without complications
- B02.29 Other postherpetic nervous system involvement

CLINICAL PEARLS
- Begin antiviral therapy within 72 hours of the onset of rash to be most effective.
- Patients with active herpes zoster can transmit clinically active disease (chickenpox) to susceptible individuals.
- Zoster vaccine is recommended for patients ≥50 years of age.
HERPES, GENITAL
Cecilia M. Kipnis, MD, FAAFP

BASICS
DESCRIPTION
- Chronic, recurrent herpes simplex virus (HSV) type 1 or 2 infection of any area innervated by the sacral ganglia
- HSV-1 causes anogenital and orolabial lesions.
- HSV-2 causes anogenital lesions.
- Primary episode: occurs in the absence of preexisting antibodies to HSV-1 or HSV-2 (may be asymptomatic)
- First episode nonprimary: initial genital eruption; preexisting antibodies are present.
- Reactivation: recurrent episodes
- Synonym(s): herpes genitalis

EPIDEMIOLOGY
- Most commonly infected from age 15 to 30 years; prevalence increases with age due to cumulative likelihood of exposure.
- Predominant sex: female > male
- Predominant race: non-Hispanic blacks

Incidence
>700,000 new cases per year in the United States

Prevalence
- Overall prevalence of HSV-2 is 10–40% in the general population and up to 60–95% in the HIV-positive population (1).
- Up to 90% of seropositive persons lack formal diagnosis.
- >50 million are infected with HSV-2 in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY
- HSV is a double-stranded DNA virus of the Herpetoviridae family (1).
- Spread via genital-to-genital contact, oral-to-genital contact, and via maternal–fetal transmission (2)
Incubation is 4 to 7 days after exposure.
- Risk of transmission highest when lesions are present
- Viral shedding is possible in the absence of lesions, increasing the risk of transmission since precautions may not be followed (abstinence, condom use). Viral shedding occurs intermittently and unpredictably.
- HSV infection increases the risk for HIV.

RISK FACTORS
- Risk increases with age, number of lifetime partners, history of sexually transmitted infections (STIs), history of HIV, sexual encounters before the age of 17 years, and partner with HSV-1 or HSV-2.
- Infection with HSV-1 increases the risk of being infected with HSV-2 by 3-fold.
- Immunosuppression, fever, stress, and trauma increases risk of reactivation.

COMMONLY ASSOCIATED CONDITIONS
Syphilis, HIV, chlamydia, gonorrhea, and other STIs

DIAGNOSIS

HISTORY
- Many patients are asymptomatic (74% of HSV-1 and 63% of HSV-2) or do not recognize clinical manifestations of disease (2).
- If symptoms are present during primary episode, they are often more severe, longer in duration, and associated with constitutional symptoms.
- Common presenting symptoms (primary episode): multiple genital ulcers, dysuria, pruritus, fever, tender inguinal lymphadenopathy, headache, malaise, myalgias, cervicitis/dyspareunia, urethritis (watery discharge)
- First episode, nonprimary: In general, symptoms are less severe than primary episode.
- Common presenting symptoms for recurrent episodes: prodrome of tingling, burning, or shooting pain (2 to 24 hours before lesion appears); single ulcer; lesion can be atypical in appearance; dysuria; pruritus (lasting 4 to 6 days on average)
- Recurrent episodes are more frequent with HSV-2 than with HSV-1, especially the first year after infection. Recurrences are less frequent over time.
- Less common presentations: constipation (from anal involvement causing
tenderness), proctitis, stomatitis, pharyngitis, sacral paresthesias

**PHYSICAL EXAM**
- Lesions occur in “boxer short” distribution and within anus, vagina, and on cervix.
- Lesion may appear as papular, vesicular, pustular, ulcerated, or crusted; can be in various stages
- Inguinal lymphadenopathy
- Extranagenital manifestations include meningitis, recurrent meningitis (Mollaret syndrome), sacral radiculitis/paresthesias, encephalitis, transverse myelitis, and hepatitis

**Pediatric Considerations**
- Neonatal infection occurs in 20 to 50/100,000 live births; 80% of infections result from asymptomatic maternal viral shedding during an undiagnosed primary infection in the 3rd trimester.
- Transmission ranges from 30–50% if the primary episode is near time of delivery. This risk is higher with HSV-1 than with HSV-2. Neonatal disease is associated with high morbidity and mortality.
- Suspect sexual abuse with genital lesions in children.

**DIFFERENTIAL DIAGNOSIS**
- HIV; syphilis; chancroid
- Herpes zoster
- Ulcerative balanitis
- Granuloma inguinale; lymphogranuloma venereum
- Cytomegalovirus; Epstein-Barr virus
- Drug eruption; trauma
- Behçet syndrome
- Neoplasia

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Confirm clinical diagnosis with laboratory testing.
- Viral isolation from lesion (swab or scraping) for culture or PCR
  - Use Dacron or polyester-tipped swabs with plastic shafts (cotton tips/wood shafts inhibit viral growth and/or replication) (1).
  - Culture by unroofing vesicle to obtain fluid sample. Specificity >99%;
sensitivity depends on sample: 52–93% for vesicle, 41–72% for ulcer, 19–30% for crusted lesion (1,3).

- Culture requires timely transport of live virus to the laboratory in appropriate medium at 4°C.
- PCR has the greatest sensitivity (98%) and specificity (>99%) but is also expensive and not readily available. It can increase detection rates by up to 70% (4); used primarily for CSF (1)

- Type-specific serologic assays
  - Seroconversion occurs 10 days to 4 months after infection (3). Antibody testing is not necessary if a positive culture or PCR has been obtained.
  - IgM antibody testing is not useful because HSV IgM is often present with recurrent disease and does not distinguish new from old infection.
  - Western blot (gold standard) and type-specific IgG antibody (glycoprotein G) enzyme-linked immunosorbent assay (ELISA) are used to discriminate between HSV-1 and HSV-2 (3)[B].
  - Western blot is >97–99% sensitive and specific but labor intensive and not readily available (1,3).
  - ELISA 81–100% sensitive; 93–100% specific (1) for HSV-2 but lower for HSV-1 detection. False positives are possible.
  - Screening with type-specific antibody is not generally recommended (3) considered for:
    - Asymptomatic patients with HIV infection
    - Discordant couples (one partner with known HSV, the other without)
    - Recurrent symptoms but no active lesions

## TREATMENT
### GENERAL MEASURES
- Ice packs to perineum, sitz baths, topical anesthetics
- Analgesics, NSAIDs

### MEDICATION
Start antiviral medications within 72 hours of onset of symptoms (including prodrome). After 3 days, antivirals may help if new lesions form or for significant pain.

First Line
• Acyclovir (4)[A]: the most studied antiviral in genital herpes; decreases pain, duration of viral shedding, and time to full resolution
  – Primary episode
    o 400 mg PO TID for 7 to 10 days
    o 200 mg PO 5 times a day for 7 to 10 days
    o Longer if needed for incomplete healing
  – Episodic therapy
    o 200 mg 5 times per day for 5 days
    o 400 mg TID for 5 days
    o 800 mg BID for 5 days
    o 800 mg TID for 2 days
  – Daily suppression
    o 400 mg BID
  – Severe, complicated infections (IV therapy)
    o 5 to 10 mg/kg/dose q8h until clinical improvement; switch to PO therapy to complete a 10-day course.
  – HIV infection: 400 mg PO 3 to 5 times per day until clinical resolution is attained
  – Precautions
    o Modify dose in renal insufficiency.

• Valacyclovir (Valtrex) (4)[A]: prodrug of acyclovir, improved bioavailability, less frequent dosing
  – Primary episode
    o 1 g PO BID for 7 to 10 days
  – Episodic therapy
    o 500 mg PO BID for 3 to 5 days
    o 1 g PO daily for 5 days
  – Daily suppression
    o 500 mg PO daily
    o 1 g PO daily

• Famciclovir (Famvir) (4)[A]
  – Primary episode
    o 250 mg PO TID for 7 to 10 days
  – Episodic therapy
    o 125 mg PO BID for 5 days
    o 1 g PO BID for 1 day
  – Daily suppression: 250 mg PO BID
ISSUES FOR REFERRAL

- For acyclovir-resistant HSV, in consultation with infectious disease specialist (4)[A]:
  - Foscarnet: 40 mg/kg/dose IV q8h until clinical resolution
    - Associated with significant toxicity
  - Cidofovir: 5 mg/kg IV once weekly

Pregnancy Considerations

ACOG Clinical Management Guidelines (4)[A],(5)[C]:

- SCREENING: Pregnant women negative for HSV-1 and HSV-2 antibodies should avoid sexual contact in the 3rd trimester if their partner is antibody positive.
- SUPPRESSIVE THERAPY: Pregnant women with a history of genital herpes should be offered suppression treatment starting at 36 gestational weeks until delivery to decrease reactivation rate and reduce the risk of neonatal infection:
  - Acyclovir 400 mg PO TID
  - Valacyclovir 500 mg PO BID
- Monitor for outbreaks during pregnancy and examine for any lesions at the onset of labor. C-section is recommended if prodromal symptoms or lesions are present at onset of labor.

Pediatric Considerations

- High-risk infants include those with active symptoms or lesions, those delivered vaginally with maternal lesions present, and those born during a primary maternal episode. Monitor closely; obtain diagnostic laboratory specimens (HSV PCR and ocular, nasal, anal, and oral cultures). If symptomatic, require prolonged treatment:
  - Acyclovir 20 mg/kg IV q8h for 14 days if skin or mucosal lesions, 21 days if disseminated or CNS disease (4)[A]
- Low-risk infants who are asymptomatic can be observed while obtaining serum HSV PCR and ocular, nasal, anal, and oral cultures.
- Infants with possible HSV infection should be isolated from other neonates; maternal separation is not necessary and breastfeeding is not contraindicated.

ONGOING CARE
GENERAL PREVENTION
- Use barrier contraception and avoid sexual contact when symptoms/lesions are present.
- Abstinence is the only means of complete protection.

Patient Monitoring
Test for HIV and other STIs.

PATIENT EDUCATION
- Counseling is important for treatment of subsequent outbreaks and reducing risk of transmission:
  - Treatment options include daily suppressive therapy and episodic therapy.
  - Alert partners of history prior to sexual activity.
  - Avoid sexual contact when symptoms or lesions are present.
  - Viral shedding and transmission can occur when symptoms/lesions are NOT present.
    - Shedding increased with HSV-2 and HIV.
  - 100% condom use reduces HSV-2 transmission risk by 30%.
  - Sexual activity between concordant couples (i.e., both partners with the same type of herpes [HSV-1 or HSV-2]) does not increase risk of outbreaks.
  - Ensure maternity care team is aware of HSV history for any pregnancy.
- Herpes Resource Center: http://www.ashasexualhealth.org/stdsstis/herpes/
- Centers for Disease Control and Prevention: http://www.cdc.gov/

PROGNOSIS
- Resolution of signs/symptoms: 3 to 21 days
- Average recurrence rate is 1 to 4 episodes/year (2).
- Antivirals do not eliminate virus from body but can reduce transmission, shedding, and outbreaks.

Pediatric Considerations
Neonatal infection survival rates: localized >95%, CNS 85%, systemic 30%

COMPLICATIONS
Behavioral issues include lowered self-esteem, guilt, anger, depression, fear of rejection, and fear of transmission to partner.

REFERENCES

**ADDITIONAL READING**

- Kimberlin DW, Baley J; and Committee on Infectious Diseases, Committee on Fetus and Newborn. Guidance on management of asymptomatic neonates born to women with active genital herpes lesions. *Pediatrics* 2013;131(2):e635–e646.

**SEE ALSO**

Algorithm: *Genital Ulcers*

**CODES**

**ICD10**

- A60.00 Herpesviral infection of urogenital system, unspecified
A60.04 Herpesviral vulvovaginitis
A60.09 Herpesviral infection of other urogenital tract

CLINICAL PEARLS

- Genital herpes can be caused by HSV-1 and/or HSV-2.
- Many seropositive individuals are unaware that they are infected.
- Most primary episodes are asymptomatic.
- Viral shedding occurs in the absence of lesions.
- Regular (100%) condom use decreases transmission significantly.
HICCUPS

Maria Montanez, MD • Renee F. del Carmen, MD • Nida Hussain, MD

BASICS

DESCRIPTION

- Hiccups are caused by a repetitive sudden involuntary contraction of the inspiratory muscles (predominantly the diaphragm) and terminated by the abrupt closure of the glottis, which stops the inflow of air and produces a characteristic sound.
- Hiccups are classified based on their duration: Hiccup bouts last up to 48 hours; persistent hiccups last >48 hours but <1 month; intractable hiccups last for >1 month.
- System(s) affected: nervous, pulmonary
- Synonym(s): hiccoughs; singultus

Geriatric Considerations

Can be a serious problem, particularly among the elderly

Pregnancy Considerations

- Fetal hiccups are rhythmic fetal movements (confirmed sonographically) that can be confused with contractions.
- Fetal hiccups are a sign of normal neurologic development (1).

EPIDEMIOLOGY

- Predominant age: all ages (including fetus)
- Predominant sex: male > female (4:1)

Prevalence

Self-limited hiccups are extremely common, as are intra- and postoperative hiccups.

ETIOLOGY AND PATHOPHYSIOLOGY

- Results from stimulation of ≥1 limbs of the hiccup reflux arc (vagus and phrenic nerves) with a “hiccup center” located in the upper spinal cord and
brain (2)

- In men, >90% have an organic basis; whereas in women, a psychogenic cause is more common.
- Specific underlying causes include:
  - CNS disorders: vascular lesions (AV malformation), infectious causes (meningitis, encephalitis), structural lesions (intracranial /brainstem mass lesions, multiple sclerosis, hydrocephalus, syringomyelia)
  - Seizure disorder
  - Diaphragmatic irritation (tumors, pericarditis, eventration, splenomegaly, hepatomegaly, peritonitis)
  - Irritation of the tympanic membrane
  - Nerve irritation: pharyngitis, laryngitis, neck tumors
  - Mediastinal and other thoracic lesions (pneumonia, aortic aneurysm, tuberculosis [TB], myocardial infarction [MI], lung cancer, rib exostoses)
  - Esophageal lesions (reflux esophagitis, achalasia, Candida esophagitis, carcinoma, obstruction)
  - Gastrointestinal disorders (gastritis, GERD, PUD, distention, cancer)
  - Hepatic lesions (hepatitis, hepatoma)
  - Pancreatic lesions (pancreatitis, pseudocysts, cancer)
  - Inflammatory bowel disease
  - Cholelithiasis, cholecystitis
  - Prostatic disorders
  - Appendicitis
  - Postoperative, particularly with abdominal procedures
  - Metabolic causes (uremia, hyponatremia, gout, diabetes)
  - Drug-induced (dexamethasone, methylprednisolone, anabolic steroids, benzodiazepines, α-methyldopa, propofol)
  - Psychogenic causes (hysterical neurosis, grief, malingering)
  - Idiopathic

**RISK FACTORS**

- Overeating
- Consuming carbonated beverages
- Excessive alcohol consumption
- Excitement or emotional stress
- Changes in ambient or gastrointestinal temperature

**GENERAL PREVENTION**

- Identify and correct relevant underlying cause(s).
Avoid gastric distention.
Acupuncture shows promise compared to chronic drug therapy for controlling hiccups (3).

**DIAGNOSIS**

- Hiccup attacks usually occur at brief intervals and last seconds or minutes. Persistent bouts lasting >48 hours often imply an underlying physical or metabolic disorder.
- Intractable hiccups may occur continuously for months or years (4).
- Hiccups usually have a frequency of 4 to 60 per minute (4).
- Persistent and intractable hiccups warrant further evaluation.

**HISTORY**

- Severity and duration of hiccup bouts
- Associated medical conditions that could be causative—GI, cardiac, neurologic, or pulmonary disorders
- Recent surgery (especially genitourinary)
- Behavioral health history
- Review of medications
- Alcohol and illicit drug use

**PHYSICAL EXAM**

- Correlate exam with potential etiologies (e.g., rales with pneumonia; organomegaly with splenic or hepatic disease).
- Examine the ear canal for foreign bodies.
- Head and neck masses and lymphadenopathy
- Complete neurologic exam

**DIFFERENTIAL DIAGNOSIS**

Hiccups are rarely be confused with burping (eructation).

**DIAGNOSTIC TESTS & INTERPRETATION**

- In hiccups lasting longer than 48 hours, if an underlying etiology is suspected, consider condition-specific testing as appropriate (e.g., CBC, electrolytes, BUN, creatinine, LFTs, amylase/lipase, metabolic panel, chest x-ray).
- Fluoroscopy can evaluate hemidiaphragm movement.
**Diagnostic Procedures/Other**

- Upper endoscopy; CT scan (or other imaging) of brain, thorax, abdomen, and pelvis to look for underlying causes
- Head MRI with contrast, lumbar puncture
- The extent of the workup is often in proportion to the duration and severity of the hiccups (2).

**TREATMENT**

- Outpatient (usually)
- Inpatient (if elderly, debilitated, or intractable hiccups)
- Many hiccup treatments are purely anecdotal.

**GENERAL MEASURES**

- Evaluate frequent bouts or persistent hiccups.
- Treat underlying cause when identified (2,4)[C].
  - Dilate esophageal stricture or obstruction.
  - Treat ulcers or reflux disease.
  - Remove hair or foreign body from ear canal.
  - Angostura bitters for alcohol-induced hiccups
  - Catheter stimulation of pharynx for operative and postoperative hiccups
  - Antifungal treatment for *Candida* esophagitis
  - Correct electrolyte imbalance.
- Medical measures
  - Relieve gastric distention (gastric lavage, nasogastric aspiration, induced vomiting).
  - Cautious counterirritation of the vagus nerve (supraorbital pressure, carotid sinus massage, digital rectal massage)
  - Respiratory center stimulants (breathing 5% CO₂)
  - Behavioral health modification (hypnosis, meditation, paced respirations)
  - Phrenic nerve block or electrical stimulation (or pacing) of the dominant hemidiaphragm
  - Acupuncture
  - Miscellaneous (cardioversion)

**MEDICATION**
**First Line**
- Physical maneuvers: breath holding, Valsalva maneuver, breathing into a bag, fright, ice water gargles
- Others: swallowing granulated sugar, hard bread, or peanut butter; biting on a lemon, pulling knees to chest or leaning forward to compress chest
- Drug therapy if physical maneuvers have failed or treatment is directed toward a specific cause of hiccups

<table>
<thead>
<tr>
<th>Pharmacologic therapy (5)[B]</th>
</tr>
</thead>
<tbody>
<tr>
<td>- Chlorpromazine (FDA-approved for hiccups): 25 to 50 mg PO/IV TID</td>
</tr>
<tr>
<td>- Metoclopramide: 5 to 10 mg PO QID</td>
</tr>
<tr>
<td>- Baclofen: 5 to 10 mg PO TID (2,4,6)[B]</td>
</tr>
<tr>
<td>- Haloperidol: 2 to 5 mg PO/IM followed by 1 to 2 mg PO TID</td>
</tr>
<tr>
<td>- Phenytoin: 200 to 300 mg PO HS</td>
</tr>
<tr>
<td>- Nifedipine: 10 to 20 mg PO daily to TID</td>
</tr>
<tr>
<td>- Amitriptyline: 10 mg PO TID</td>
</tr>
<tr>
<td>- Viscous lidocaine 2%: 5 mL PO daily to TID</td>
</tr>
</tbody>
</table>

- Gabapentin (Neurontin): 300 mg PO HS; may increase up to 1,800 mg/day PO in divided doses (4)[B]; 1,200 mg/day PO for 3 days and then 400 mg/day PO for 3 days in patients undergoing stroke rehabilitation or in the palliative care setting where chlorpromazine adverse effects are undesirable (4)[B]
- Combination of lansoprazole 15 mg PO daily, clonazepam 0.5 mg PO BID, and dimenhydrinate 25 mg PO BID (5)[B]

- Contraindications: Refer to manufacturer’s literature.
  - Chlorpromazine is not recommended in elderly patient with dementia.
  - Baclofen is not recommended in patients with stroke or other cerebral lesions or in severe renal impairment. Avoid abrupt withdrawal of baclofen.

**Other possible drug therapies (2,5,6)[C]**
- Amantadine, carbidopa and levodopa in Parkinson disease
- Steroid replacement in Addison disease
- Antifungal agent in *Candida* esophagitis
- Ondansetron in carcinomatosis with vomiting
- Nefopam (a nonopioid analgesic with antishivering properties related to antihistamines and antiparkinsonian drugs) is available outside the United States in both IV and oral formulations.
- Olanzapine 10 mg QHS
- Pregabalin 375 mg/day
ISSUES FOR REFERRAL
For acupuncture or phrenic nerve crush, block, or electrostimulation; cardioversion

SURGERY/OTHER PROCEDURES
- Phrenic nerve crush or transaction or electrostimulation of the dominant diaphragmatic leaflet
- Resection of rib exostoses

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Acupuncture is increasingly used to manage persistent or intractable hiccups, especially in cancer patients (3,4)[A].
- Home remedies (2)[C]
  - Swallowing a spoonful of sugar
  - Sucking on hard candy or swallowing peanut butter
  - Holding breath and increasing pressure on diaphragm (Valsalva maneuver)
  - Tongue traction
  - Lifting the uvula with a cold spoon
  - Inducing fright
  - Smelling salts
  - Rebreathing into a paper (not plastic) bag
  - Sipping ice water
  - Rubbing a wet cotton-tipped applicator between hard and soft palate for 1 minute

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Most patients can be managed as outpatients; those with severe intractable hiccups may require rehydration, pain control, IV medications, or surgery.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
Until hiccups cease

**DIET**
Avoid gastric distension from overeating, carbonated beverages, and aerophagia.

**PATIENT EDUCATION**
See “General Measures.”

**PROGNOSIS**
- Hiccups often cease during sleep.
- Most acute benign hiccups resolve spontaneously or with home remedies.
- Intractable hiccups may last for years or decades.
- Hiccups have persisted despite bilateral phrenic nerve transection.

**COMPLICATIONS**
- Inability to eat
- Weight loss
- Exhaustion, debility
- Insomnia
- Cardiac arrhythmias
- Wound dehiscence
- Death (rare)

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- R06.6 Hiccough
- F45.8 Other somatoform disorders

**CLINICAL PEARLS**

- Most hiccups resolve spontaneously.
- An organic cause is more likely in men and individuals with intractable hiccups.
- Rule out foreign body in the ear canal as a trigger.
- Baclofen and gabapentin are the only pharmacologic agents proven to be clinically effective.
- Acupuncture may be effective for persistent hiccups.
BASICS

DESCRIPTION

- Chronic follicular occlusive disease manifested as recurrent inflammatory nodules, abscesses, sinus tracts, and complex scar formation
- Lesions are tender, malodorous, often with exudative drainage.
- Common in intertriginous skin regions: axillae, groin, perianal, perineal, inframammary skin
- System affected: skin
- Synonym(s): acne inversa; Verneuil disease; apocrinitis; hidradenitis axillaris

Geriatric Considerations
Rare after menopause

Pediatric Considerations
Rarely occurs before puberty; occurrence in children is associated with premature adrenarche.

Pregnancy Considerations
No Accutane (isotretinoin) or tetracycline treatment during pregnancy. Disease may ease during pregnancy and rebound after parturition.

EPIDEMIOLOGY
Predominant sex: female > male (3:1)

Incidence
Peak onset during 2nd and 3rd decades of life

Prevalence
0.3–4% (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Not fully understood; previously considered a disorder of apocrine glands
Inflammatory disorder of the hair follicle triggered by follicular plugging within apocrine gland–bearing skin.

Hormonally induced ductal keratinocyte proliferation leads to a failure of follicular epithelial shedding, causing follicular occlusion.

Mechanical stress on skin (intertriginous regions) precipitates follicular rupture and immune response.

Bacterial involvement is a secondary event.

Rupture and reepithelialization cause sinus tracts to form.

Obesity and smoking are major risk factors in disease onset and severity.

**Genetics**

- Familiar occurrences suggest single gene transmission (autosomal dominant), but the condition may also be polygenic.
- Estimated 40% of patients have an affected family member.

**RISK FACTORS**

- Obesity
- Smoking
- Hyperandrogenism, oral contraceptive pills (OCPs)
- Lithium may trigger onset of or exacerbate this condition.

**GENERAL PREVENTION**

- Lose weight if overweight or obese.
- Smoking cessation
- Avoid constrictive clothing/synthetic fabrics, frictional trauma, heat exposure, excessive sweating, shaving, depilation, and deodorants.
- Use of antiseptic soaps

**COMMONLY ASSOCIATED CONDITIONS**

- Acne vulgaris, acne conglobate
- Perifolliculitis capitis abscedens et suffodiens (dissecting cellulitis of scalp)
- Pilonidal disease
- Arthritis and spondyloarthritis (seronegative)
- Obesity (with diabetes, atopy, acanthosis)
- Irritable bowel disease (Crohn disease)
- Squamous cell carcinoma
- PAPASH syndrome (pyogenic arthritis, pyoderma gangrenosum, acne, suppurative hydadenitis)
DIAGNOSIS

HISTORY

- Diagnostic criteria adopted by the 2nd International Conference on Hidradenitis Suppurativa, 2009 (2)[C]
- All three criteria (morphology, location, progression) must be present for diagnosis:
  - Typical lesions: painful nodules, abscesses, draining sinus, bridged scars, and “tombstone” double-ended pseudocomedones in secondary lesions
  - Typical topography: axillae, groins, perineal and perianal region, buttocks, infra- and intermammary folds
  - Chronicity and recurrences, commonly refractory to initial treatments

PHYSICAL EXAM

- Tender nodules (dome-shaped) 0.5 to 3.0 cm in size are present.
  - Location corresponds with the distribution of apocrine-related mammary tissue and terminal hair follicles dependent on low androgen concentrations.
  - Sites ordered by frequency of occurrence: axillary, inguinal, perianal and perineal, mammary and inframammary, buttock, pubic region, chest, scalp, retroauricular, eyelid
  - Large lesions are often fluctuant; comedones may be present.
- Possible malodorous discharge
- Hurley clinical staging system
  - Stage I: abscess formation (singular or multiple) without sinus tracts or scarring
  - Stage II: widely separated, recurrent abscesses with tract formation and scarring
  - Stage III: diffuse, multiple interconnected tracts and abscesses
- Sartorius clinical staging system (points attributed)
  - Anatomic region
  - Quantity and quality of lesions
  - Distance between lesions
  - Presence or absence of normal skin between lesions

DIFFERENTIAL DIAGNOSIS

- Acne vulgaris, conglobate
- Furunculosis/carbuncles
- Infected Bartholin or sebaceous cysts
- Lymphadenopathy/lymphadenitis
- Cutaneous Langerhans cell histiocytosis
- Actinomycosis
- Granuloma inguinale
- Lymphogranuloma venereum
- Apocrine nevus
- Crohn disease with anogenital fistula(s) (may coexist with hidradenitis suppurativa)
- Cutaneous tuberculosis
- Fox-Fordyce disease

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Cultures of skin or aspirates of boils are most commonly negative. When positive, cultures are often polymicrobial and commonly grow *Staphylococcus aureus* and *Staphylococcus epidermidis*.
- Lesion biopsy usually unnecessary. Useful to rule out other disorders such as squamous cell carcinoma.
- May note increased erythrocyte sedimentation rate (ESR), leukocytosis, decreased serum iron, normocytic anemia, or changes in serum electrophoresis pattern

**Follow-Up Tests & Special Considerations**
- Consider biopsy of concerning lesions due to increased risk of squamous cell carcinoma.
- If the patient is female, overweight, and/or hirsute, consider evaluating the following:
  - Dehydroepiandrosterone sulfate
  - Testosterone: total and free
  - Sex hormone-binding globulin
  - Progesterone

**Diagnostic Procedures/Other**
- Incision and drainage, culture and biopsy
- Ultrasound may be useful in planning an excision to identify the full extent of sinus tracts.

**Test Interpretation**
Dermis shows granulomatous inflammation and inflammatory cells, giant cells, sinus tracts, subcutaneous abscesses, and extensive fibrosis.

Hair follicular dilatation and occlusion by keratinized stratified squamous epithelium

**TREATMENT**

Despite the prevalence of this condition, most trials has been small and underpowered. Evidence is therefore generally of poor quality (3)[A]. Treatment goals: Reduce extent of disease, prevent new lesions, remove chronic disease, limit scar formation.

- Conservative treatment includes all items under general prevention, plus use of warm compresses, sitz baths, topical antiseptics for inflamed lesions, and nonopioid analgesics.
- Weight loss and smoking cessation result in marked improvement (1).
- For stages I and II, attempt medical treatment.
- Short medical trial may be appropriate in stage III prior to moving on to surgical therapies.
- Only FDA-approved medication for this condition is adalimumab. Other biologics may be effective. No medications are curative; relapse is almost inevitable, but the disease may be controlled.

**GENERAL MEASURES**

- Education and psychosocial support
- Appropriate hygiene including avoidance of shearing stress to skin (light clothing), daily cleansing with antibacterial soap
- Diet: Avoid dairy and high glycemic loads.
- Symptomatic treatment for acute lesions
- Improve environmental factors that cause follicular blockage (see “General Prevention”).
- Smoking cessation and weight loss

**MEDICATION**

**First Line**

- Stage I disease: Consider either systemic or topical antibiotics.
  - Topical antibiotics (clindamycin has the most evidence) (1,4)[B]
    - Clindamycin 1% solution BID for 12 weeks with or without benzoyl
- Peroxide 5–10% solution
  - Chlorhexidine 4% solution
- Systemic antibiotics (initial 7- to 10-day course)
  - Tetracycline 500 mg BID
  - Doxycycline 100 mg q12h
  - Augmentin 875 mg q8–12h
  - Clindamycin 300 mg BID

**Stages II and III disease**
- Address overlying bacterial infection with broad-spectrum coverage. Base antibiotic selection on disease location, characteristics; best evidence for antibiotic treatment with combinations of clindamycin and rifampicin, or ertapenem followed by combination rifampicin, moxifloxacin, and metronidazole for 6 months
- Minor surgical procedures (punch débridement, local unroofing) to treat individual lesions or sinus tracts

**Other modalities (rarely used)**
- Hormonal therapy: antiandrogenic therapy such as cyproterone acetate (may not be available in the United States), estrogen/norgestrel oral contraceptive, finasteride (5 mg daily)
- Intralesional corticosteroids: accelerates healing, although efficacy not formally evaluated (triamcinolone acetonide 5 to 10 mg/mL)

**Second Line**
- Dapsone 50 to 150 mg daily
- Metformin: significant reduction in Sartorius score
- Oral retinoids (isotretinoin): poor efficacy, limited therapeutic effect
- TNF-α inhibitors:
  - Adalimumab 40 mg weekly (a high dose) produces statistically significant differences versus placebo in treated patients but clinical effect size is small (Cochrane) (1)[A], and long-term safety is unknown (6)[A].
  - Infliximab: A majority of patients in the treatment group had a 50% or greater decrease in disease, improving quality of life (6)[A].
  - Etanercept: no difference versus placebo

**ISSUES FOR REFERRAL**
- Lack of response to treatment, stages II and III disease, or concern for malignancy (squamous cell carcinoma) is a reason to refer for surgical excision or radiation/laser treatment (stage II).
- If significant psychosocial stress exists secondary to disease, refer for stress management or psychiatric evaluation.
- Suspicion of hyperandrogenic states (e.g., polycystic ovary syndrome [PCOS]) should prompt investigation or referral.
- Severe perianal/perivulvar disease or otherwise very extensive disease may prompt referral to plastic surgeon or reconstructive urologist.

**SURGERY/OTHER PROCEDURES**
- Important mode of treatment
- Could be used in conjunction with antibiotics or if first-line therapy fails
- Various surgical approaches have been used for stages II and III disease
  - Incision and drainage: may be necessary to treat as a temporizing method for acute flare-ups
  - Deroofing and marsupialization of the sinus tracts is often beneficial primarily for Hurley stages I and II disease, as healing time is reduced. Recurrences remain common but usually are smaller than original lesions.
  - Wide full-thickness excision with healing by granulation or flap placement is the most definitive treatment and rarely has local recurrence if all sinus tracts are excised. Rates of local recurrence (within 3 to 72 months): axillary (3%), perianal (0%), inguinoperineal (37%), submammary (50%)
- Laser therapy for Hurley stages I and II disease (rarely used)
  - Consider monthly treatments with neodymium-doped yttrium aluminum garnet (Nd:YAG) laser for 3 to 4 months.
  - CO₂ laser ablation with healing by secondary intention
- Cryotherapy and photodynamic therapy have shown variable results; they are not routinely recommended.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Follow-up monthly or sooner to evaluate progress and to assist with symptom management

**DIET**
- Avoid dairy, high glycemic loads.
- Healthy diet that promotes weight loss.
- May benefit from zinc supplementation
PATIENT EDUCATION

- Severity can range from only 2 to 3 papules per year to extensive draining sinus tracts.
- Medications are temporizing measures, rarely curative. Attempts at local surgical “cures” do not affect recurrence at other sites.
- Smoking cessation and weight loss can improve symptoms significantly.
- Hidradenitis Suppurativa Foundation: www.hs-foundation.org

PROGNOSIS

- Individual lesions heal slowly in 10 to 30 days.
- Recurrences may last for several years.
- Relentlessly progressive scarring and sinus tracts are likely with severe disease.
- Radical wide-area excision, with removal of all hair-bearing skin in the affected area, shows the greatest chance for cure.

COMPLICATIONS

- Contracture and stricturing of the skin after extensive abscess rupture, scarring, and healing; or at sites of surgical excisions
- Lymphatic obstruction, lymphedema
- Psychosocial: anxiety, malaise, depression, self-injury
- Anemia, amyloidosis, and hypoproteinemia (due to chronic suppuration)
- Lumbosacral epidural abscess, sacral bacterial osteomyelitis
- Squamous cell carcinoma may develop in indolent sinus tracts.
- Disseminated infection or septicemia (rare)
- Urethral, rectal, or bladder fistula (rare)

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

L73.2 Hidradenitis suppurativa

**CLINICAL PEARLS**

- Chronic inflammatory disease of the skin, often difficult to control with behavior changes and medication alone
• First-line treatment for mild disease is topical and/or systemic antibiotics.
• For patients with refractory or severe disease, wide local excision provides the only chance at a cure. Success rates depend on the location and extent of excision.
HIRSUTISM

Imola K. Osapay, MD • Andrea M. Konkoly, MD

BASICS

DESCRIPTION
- Presence of excessive terminal (coarse, pigmented) hair of body and face, in a male pattern
- May be present in normal adults as an ethnic characteristic or may develop as a result of androgen excess
- Often seen in polycystic ovarian syndrome (PCOS) which is characterized by hirsutism, acne, menstrual irregularities, and obesity
- System(s) affected: dermatologic, endocrine, metabolic, reproductive

EPIDEMIOLOGY

Prevalence
5–10% of adult women

ETIOLOGY AND PATHOPHYSIOLOGY
- Hirsutism is due to increased androgenic (male) hormones, either from increased peripheral binding (idiopathic) or increased production from the ovaries, adrenals, or body fat.
- Exogenous medications can also cause hirsutism.

Genetics
Multifactorial

RISK FACTORS
- Family history
- Ethnicity—increased in Ashkenazi Jews and Mediterranean backgrounds
- Anovulation
- Obesity

GENERAL PREVENTION
Women with late-onset congenital adrenal hyperplasia (CAH) should be counseled that they may be carriers for the severe early-onset childhood disease.
COMMONLY ASSOCIATED CONDITIONS

- PCOS: the most common cause of premenopausal hirsutism (1)
- Insulin resistance, common
- Prolonged amenorrhea and anovulation, common
- Emotional distress and depression, common
- Acne, common
- Central obesity
- Hypothyroidism/hyperthyroidism, rare
- Hyperprolactinemia, rare
- Risk for endometrial hyperplasia or carcinoma, rare
- Virilization (rapid onset, clitoromegaly, balding, deepening voice) (2)
- Cushing syndrome: characterized by moon facies, striae, hypertension, rare
- Vitamin D deficiency

DIAGNOSIS

HISTORY

- Severity, time course, and age of onset of hirsutism
- Weight
- Psychosocial impact on patient
- Menstrual and fertility history, anovulation (defined as ovulatory cycle >35 days)
- Severe acne, especially if treatment resistant
- Presence of virilization
- Medication history: Look for use of valproic acid, testosterone, danazol, glucocorticoids, and athletic performance drugs.
- The presence of galactorrhea

PHYSICAL EXAM

- Increased hair growth in premenopausal women, particularly over the chin, neck, sideburns, lower back, sternum, abdomen, shoulders, buttocks, perineal area, and inner thighs
- Check skin for acne, striae, acanthosis nigricans (velvety black skin in the axillae or neck).
- Virilization: Deep voice, male pattern balding, and clitoromegaly indicate risk of tumor.
- The Ferriman-Gallwey scale (an instrument that rates hair growth in nine
areas on a scale of 0 to 4, with >8 being positive) may be used for diagnosis but underrates patient’s perception of hirsutism and altered by previous cosmetic treatment (1).

**DIFFERENTIAL DIAGNOSIS**

- **PCOS (72–82%)**—irregular menses, elevated androgens, polycystic ovaries on US, infertility, insulin resistance
- **Idiopathic hyperandrogenemia (6–15%)**—hirsutism with normal ovaries on US, elevated androgen levels, no other explainable cause
- **Idiopathic hirsutism (4–7%)**—hirsutism with normal menses, androgen levels, and ovaries on ultrasonography, no other explainable cause
- **Late-onset CAH (2–4%), a genetic enzyme deficiency associated with more severe and earlier onset hirsutism in amenorrheic patients presents in adolescence with severe hirsutism and irregular menses.**
- **Androgen-secreting tumor (0.2%)**—ovaries (benign or malignant) or adrenals (commonly malignant); have rapid onset, virilization, resistance to treatment
- **Ovarian hyperthecosis**—increase in testosterone by theca cells. Gradual onset of hirsutism, frank virilization; mostly affects postmenopausal women
- **Thyroid dysfunction**
- **Hyperprolactinemia if accompanied by galactorrhea or amenorrhea**
- **Rare endocrine disorders**—Cushing, acromegaly

**DIAGNOSTIC TESTS & INTERPRETATION**

- Diagnosis is clinical. Empiric treatment without lab workup is an acceptable option in mild-to-moderate hirsutism (2)[C].
- **PCOS** is diagnosed by having two out of three signs: menstrual dysfunction, clinical or biochemical hyperandrogenemia, polycystic ovaries on US (2)[C].
- **Lab testing** is performed to rule out underlying tumor and pituitary diseases, which are rare.

**Initial Tests (lab, imaging)**

- **Basic workup of moderate hirsutism** is a total testosterone level +/- thyroid screen (TSH) (1)[C].
- **Testosterone:** Random total testosterone level is usually sufficient.
- **Normal upper limit for serum total testosterone in adult women** is approximately 40 to 60 ng/dL (1.4 to 2.1 nmol/L). Patients who have clinical features consistent with PCOS but have normal total testosterone should have repeat testing, preferably an early morning serum free testosterone level
calculated from sex hormone binding globulin (SHBG). A morning free testosterone is 50% more sensitive (1,3).

- If testosterone is >150 (some use 200) ng/dL, consider ovarian or adrenal tumor (2,4). Testosterone is made by both the ovaries and adrenals, so both areas should be imaged. US is best for the ovaries, and CT is best for the adrenals.
- The workup for PCOS recommended by the American Congress of Obstetricians and Gynecologists (ACOG) includes the above plus:
  - Screening for metabolic syndrome with a fasting and 2-hour glucose after 75-g glucose load, lipid panel, waist circumference, and blood pressure (4) [C]
  - Ovarian US to look for polycystic ovaries
  - If the patient is amenorrheic, check prolactin, FSH, LH, TSH, and a pregnancy test (5)[C]. An LH/FSH ratio >2 indicates PCOS.

**Follow-Up Tests & Special Considerations**

- 17α-Hydroxyprogesterone (17α-OHP)
  - Elevations of 17α-OHP (>300) can indicate late-onset CAH.
  - Consider in patients with onset in early adolescence or high-risk group (Ashkenazi Jews) (2)[C].
  - If elevated, order corticotropin stimulation test.
- If prolactin level is high, MRI the pituitary.
- If PCOS is diagnosed, ACOG recommends screening for dyslipidemia and DM type 2 (4)[C].
- New studies show an inverse correlation between vitamin D levels and insulin resistance in women with PCOS. Screening women who are at risk of vitamin D deficiency and supplementation with vitamin D could be considered.
- Dehydroepiandrosterone sulfate (DHEA-S) is no longer recommended routinely but should be checked in virilization (5)[C].
  - Levels >700 may indicate adrenal tumor.

**TREATMENT**

**GENERAL MEASURES**

- Treatment in mild hirsutism depends on patient preference and psychosocial effect.
- If patient desires pregnancy, induction of ovulation may be necessary.
Provide contraception, as needed.
Encourage patient to maintain ideal weight with lifestyle modification. A calorie-restricted diet is recommended in all overweight patients with PCOS. Weight loss has positive effects on fertility, metabolic profile, and may improve hirsutism (5).
Treat accompanying acne.

MEDICATION

First Line

Treatment goal is to decrease new hair growth and improve metabolic disorders.

Oral contraceptives are first line to manage menstrual abnormalities and hirsutism/acne (3)[A]; they will suppress ovarian androgen production and increase SHBG, improve metabolic syndrome, and slow but not reverse hair growth.
- Doses of 20 to 35 μg ethinyl estradiol effectively decrease ovarian androgen production. Those containing the progestins, norgestimate, desogestrel, or drospirenone have more androgen-blocking effects, but desogestrel and drospirenone are associated with more DVTs especially in severely obese patients (3,4)[C].
- They take 6 months to show effect and are continued for years.
- Oral preparations, compared to vaginal or transdermal, are better at controlling hirsutism and acne; by passing through the liver, they induce SHBG production (1).

Progesterone (depot or intermittent oral) can be used if estrogens are contraindicated (4).

Eflornithine (Vaniqa) HCl cream: Apply BID at least 8 hours apart; reduces facial hair in 40% of women (must be used indefinitely to prevent regrowth); only FDA-approved hirsutism treatment

Second Line

Antiandrogenic drugs will further reduce hirsutism to 15–25%. Usually begun 6 months after first-line therapy if results are suboptimal. Must be used in combination with oral contraceptives to prevent menorrhagia and potential fetal toxicity. All should be avoided in pregnancy (2,5)[C].
- Spironolactone, 50 to 200 mg/day: Onset of action is slow; use with oral contraceptives to prevent menorrhagia. Watch for hyperkalemia, especially with drospirenone-containing OCP (Yasmin); avoid use in pregnancy.
– Finasteride: 5 mg/day decreases androgen binding; not approved by FDA. Use with contraception (pregnancy Category X).
– Cyproterone, not available in the United States: 12.5 to 100.0 mg/day for days 5 to 15 of cycle combined with ethinyl estradiol 20 to 50 μg for days 5 to 25 of cycle
– Flutamide is not recommended (2).

Insulin sensitizers (metformin, pioglitazone): mildly effective but less so than oral contraceptives and antiandrogens. Can restore ovulation in 30–50% of patients with PCOS. May be used in patients with impaired glucose tolerance, diabetes, or if oral contraceptives are contraindicated. Metformin is more effective than pioglitazone (2)[A].

Steroids: used in late-onset CAH
– Dexamethasone: 2 mg/day

Cosmetic treatment: includes many methods of hair removal
– Temporary: shaving, chemical depilation, plucking, waxing
– Permanent: Laser epilation and photoepilation are preferred to electrolysis (4)[C].

Pregnancy Considerations
– May have related infertility. Offer intervention, if desired.
– As hormone balance improves, fertility may increase; provide contraception, as needed.
– Several medications used for treatment are contraindicated in pregnancy.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Several herbals including spearmint tea, saw palmetto, licorice, fennel, and soy have been shown in small (<50 people) and short (<12 weeks) studies to decrease hair size or lower androgen levels (5)[C].

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
No special activity

Patient Monitoring
Monitor for known side effects of medications.
DIET
Diet consisting of low-calorie, low-glycemic index foods improve fertility in obese PCOS patients with anovulatory infertility.

PATIENT EDUCATION
- Hormonal treatment stops further hair growth and will improve but not reverse present hair.
  - Treatment takes 6 months to effect and may need to be lifelong.
- Cosmetic measures may be needed for the already present hair (see above).

PROGNOSIS
- Good (with long-term therapy) for halting further hair growth
- Moderate to poor for reversing current hair growth

COMPLICATIONS
- If PCOS is present, dysfunctional uterine bleeding may lead to anemia.
- If PCOS is present, anovulation may increase endometrial hyperplasia and uterine cancer risk.
- Androgenic excess may adversely affect lipid status, cardiac risk, and bone density.
- Poor self-image

REFERENCES
ADDITIONAL READING

SEE ALSO

Acne Vulgaris; Infertility; Polycystic Ovarian Syndrome (PCOS)

CODES

ICD10

- L68.0 Hirsutism
- E28.2 Polycystic ovarian syndrome

CLINICAL PEARLS

- PCOS is the most common cause of hirsutism (diagnosed with two out of three: menstrual dysfunction, clinical or biochemical hyperandrogenemia, polycystic ovaries on US).
- Diagnosis is clinical; total testosterone and TSH for initial testing
- Patients suspected of PCOS should also get prolactin, lipid panel, blood pressure, and pregnancy test.
- Treatment is long term and often lifelong.
- Virilization (clitoromegaly, balding, deepening voice) suspect if testosterone >150 ng/dL, look for adrenal and ovarian tumor.
- Lifestyle modification and OCPs are first-line therapy for hirsutism, menstrual irregularities, and acne.
HIV/AIDS
Carol Hope Hungerford, DO • Pamela R. Hughes, MD

BASICS

DESCRIPTION
- HIV is a retrovirus (subgroup lentivirus) that integrates into CD4 T-lymphocytes, altering cell-mediated immunity and causing cell death, severe immunodeficiency, opportunistic infections, and malignancies if not treated.
- The natural history of untreated HIV infection includes viral transmission, acute retroviral syndrome, recovery and seroconversion, asymptomatic chronic HIV infection, and symptomatic HIV infection or AIDS.
- Without treatment, the average patient progresses to AIDS ~10 years after acquiring the virus.
- HIV-infected persons with CD4 <200 cells/mm³ or with AIDS-defining illnesses are categorized as living with AIDS.

EPIDEMIOLOGY

Incidence
In the United States, HIV incidence has remained stable at ~40,000 infections per year since 2008 (1). There were approximately 1.8 million new cases of HIV worldwide in 2016 (1).

Prevalence
- 1.1 million persons in the United States are living with HIV, ~15% are not aware they are infected (1).
- Worldwide, >30 million people are infected with HIV. More than 75% are in sub-Saharan Africa.
- In 2016, ~1 million people died from AIDS (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- HIV primarily infects CD4+ cells. HIV is a single-stranded, positive-sense, enveloped RNA virus. After entering target cells, viral RNA is transcribed to DNA (through the process of reverse transcription), imported to the host cell nucleus and encoded into the host DNA. The virus can become latent or
produce new viral RNA with proteins that are released to infect other CD4+ cells. Host CD8+ cells are activated as part of the seroconversion response.

- There are two types of HIV. HIV-1 was first described and is more virulent, causing the majority of HIV infections worldwide. HIV-2 is less infective and seen primarily in West Africa.

**RISK FACTORS**

- Sexual activity (70% of transmission): Ulcerative urogenital lesions promote transmission.
- Injection drug use
- Children of HIV-infected women
  - Maternal HIV-1 RNA level predicts transmission.
  - HIV can also be transmitted in breast milk. HIV+ women should not breastfeed their infants unless there is no other alternative. In this case, consider antiretroviral therapy (ART) (2).
- Recipients of blood products prior to 1985
- Occupational exposure (health care workers)

**GENERAL PREVENTION**

- Avoid unprotected, high-risk sex and intravenous drug use, particularly with shared needles.
- Preexposure prophylaxis (PrEP) is recommended by WHO for persons at high risk of acquiring HIV.
- General guidelines for PrEP: (i) exclude acute or chronic HIV infection before initiating therapy, (ii) repeat HIV testing every 3 months during therapy, (iii) renal function testing at baseline and every 6 months
- PrEP should be started within 72 hours of exposure and continued for 28 days with a three-drug regimen (1).

**COMMONLY ASSOCIATED CONDITIONS**

- Syphilis more aggressive in HIV-infected persons
- Tuberculosis (TB) is coepidemic with HIV; test all for TB. Dually infected (TB and HIV) have 100 times greater risk of developing active TB.
- Patients coinfected with hepatitis C or hepatitis B have a more rapid progression to cirrhosis.
- Increased risk for cervical cancer, lymphoma, and skin malignancies
**DIAGNOSIS**

- Acute retroviral syndrome: CD4 lymphocyte count declines with increase in viral load 1 to 4 weeks after transmission; confirmed by high-HIV RNA in the absence of HIV antibody
- Acute retroviral syndrome presents as a mononucleosis-like syndrome:
  - Fever, adenopathy, pharyngitis, rash, myalgias/arthralgias
  - Seroconversion: positive HIV antibody 4 weeks to 6 months after exposure
- Clinical latency (asymptomatic): variable duration (average is 8 to 10 years) accompanied by a gradual decline in CD4 cell counts and relatively stable HIV RNA levels (the viral “set point”). Patients often develop persistent generalized lymphadenopathy (>1 cm in size, at ≥2 extrainguinal sites) and may develop fever, weight loss, myalgias, and gastrointestinal problems if unrecognized.
- Associated conditions:
  - Fever or diarrhea >1 month, bacillary angiomatosis, thrush, persistent candidal vulvovaginitis, cervical dysplasia or carcinoma in situ, oral hairy leukoplakia, herpes zoster, idiopathic thrombocytopenic purpura, pelvic inflammatory disease, peripheral neuropathy or myelopathy
- AIDS: defined by a CD4 cell count <200, a CD4 cell percentage of total lymphocytes <14%, or an AIDS-related opportunistic infections: *Pneumocystis jiroveci (carinii)* pneumonia, cryptococcal meningitis, recurrent bacterial pneumonia, candida esophagitis, CNS toxoplasmosis, TB, non-Hodgkin lymphoma (NHL), progressive multifocal encephalopathy, HIV nephropathy, Kaposi sarcoma, Hodgkin lymphoma, invasive cervical cancer
- Advanced HIV disease: CD4 cell count <50. Most AIDS-related deaths occur at this time. Common late opportunistic infections: cytomegalovirus (CMV) disease (retinitis, colitis) or disseminated *Mycobacterium avium* complex

**HISTORY**

- Complete medical history, including risk exposures, and social/occupational history
- Review of systems: fever, chills, night sweats, weight loss, fatigue, adenopathy, diarrhea, oral sores, odynophagia (esophageal candidiasis), cough, shortness of breath and dyspnea on exertion (early *P. jiroveci* pneumonia), sinusitis, visual changes (CMV retinitis), neurologic symptoms (CNS infection, malignancy, or dementia), skin rash
- Review immunization record.
PHYSICAL EXAM
Focus on weight, skin, retinal exam, oropharynx, lymph nodes, liver, spleen, mental status, neurologic, genital, and rectal examinations.

DIFFERENTIAL DIAGNOSIS
TB, Burkitt lymphoma, candidiasis, coccidioidomycosis, cryptococcus, CMV, mononucleosis, herpes simplex, lymphoma, toxoplasmosis, influenza

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Screening: Rapid oral test is FDA-approved. Two FDA-approved home testing kits are available.
- Fourth-generation HIV testing combines antibody/antigen immunoassay for HIV-1, HIV-2 (3)[A].
  - Can be positive within 2 to 3 weeks of exposure
  - Is considered a confirmatory test
- Obtain HIV RNA if acute HIV infection is suspected using quantitative PCR; can detect infection within 11 to 12 days
- CD4 cell count and percentage (3)[A]
- HIV RNA viral load (3)[A]
- CBC with differential; lipid levels
- Western blot confirmation is no longer recommended.
- Serologies: hepatitis A, B, and C, syphilis, urine screen for STIs
- Cervical cytology
- Purified protein derivative (PPD) or interferon gamma release assay (IGRA) to screen for latent TB infection, chest x-ray if pulmonary symptoms or positive PPD
- HLAB*5701 testing if abacavir planned for treatment (3)[A]
- Genotypic tests for resistance to antiretrovirals for patients with pretreatment HIV RNA >1,000 copies/mL; transmitted resistance to at least one drug seen in 6–16% of patients (3)[A]
- Tropism assay if considering CCR5 antagonist

TREATMENT
- Initiate ART in patients meeting eligibility requirements. Select/change regimens based on resistance testing.
Consider dosing frequency, pill burden, adverse toxic effect profiles, comorbidities, and drug interactions.

Several conditions increase the urgency for therapy including pregnancy, AIDS-defining conditions, acute opportunistic infections, CD4 <200, HIV-associated nephropathy, acute/early infection, HIV/HBV coinfection, HIV/HCV coinfection, rapidly declining CD4 counts (>100 cells/mm³ per year), and high viral loads (>100,000 copies/mL) (3)[A].

In women of child bearing age, consider ART regimen that will decrease viral load and minimize teratogenicity (2)[A].

Genotypic testing is recommended to guide therapy in patients who are naïve to antiretroviral therapy.

Tenofovir/emtricitabine (Truvada) 300 mg/200 mg PO daily is FDA-approved for PrEP in adults at high risk (4)[A].

**GENERAL MEASURES**

- The main goal of ART is to reduce viral load (ideally below limits of detection) and delay immune suppression. Viral load is the most important indicator of response to ART.
- Assess drug resistance before starting ART (3).
- Assess substance abuse, economic factors (unstable housing, food insecurity), social support, mental illness, comorbidities, high-risk behaviors, and factors known to impair adherence and promote transmission.
- Prophylactic antimicrobial agents and vaccines:
  - *P. jiroveci prophylaxis*: trimethoprim/sulfamethoxazole if CD4 <200 cells/mm³, prior *P. jiroveci*, thrush, or unexplained fever for >2 weeks
  - *Mycobacterium tuberculosis*: Treat for latent TB if positive PPD or positive IGRA without prior prophylaxis or treatment, with negative CXR, recent TB contact, or history of inadequately treated TB that healed.
  - *Toxoplasma gondii prophylaxis*: 33% per year risk of infection in untreated patients with CD4 <100 cells/mm³; prophylaxis: TMP-SMX 1 DS tab daily
  - *M. avium complex prophylaxis*: 20–40% risk with CD4 <50 and no ART. Azithromycin 1,200 mg PO weekly is preferred prophylaxis.
  - *Streptococcus pneumoniae*: 50 to 100 times increased risk of invasive infection compared with general population; Prevnar and Pneumovax at least 8 weeks apart, every 5 years
  - Influenza vaccine annually (no live vaccine)
  - Hepatitis A and B vaccines
  - Tdap vaccination every 10 years. Substitute one-time dose of Tdap vaccine
at time of next booster.

**MEDICATION**

- Recommended regimens for ART-naive (3)[A]
  - Integrase strand transfer inhibitor-based regimens:
    - Dolutegravir/abacavir/lamivudine (50 mg/600 mg/300 mg PO daily)—only for patients who are HLA-B*5701 negative
    - Dolutegravir (50 mg PO daily) plus tenofovir disoproxil fumarate/emtricitabine (300 mg/200 mg PO daily)
    - Elvitegravir/cobicistat/tenofovir/emtricitabine (150 mg/150 mg/300 mg/200 mg PO daily)—only for patients with pre-ART CrCl >70 mL/min
    - Raltegravir (400 mg PO BID) plus tenofovir/emtricitabine (300 mg/200 mg PO daily)
  - Protease inhibitor-based regimen:
    - Darunavir and ritonavir (800 mg PO daily and 100 mg PO daily) plus tenofovir/emtricitabine (300 mg/200 mg PO daily)

- Drug failure: Before selecting regimen, review clinical symptoms, history of ART, and adherence. Perform resistance testing.

- ART, especially the protease inhibitors, have interactions with other medications, such as antacids, steroids, contraceptives.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- If HIV RNA is detectable at 2 to 8 weeks, repeat every 4 to 8 weeks until suppressed to less than level of detection and then follow every 3 to 6 months (3).
- Monitor HIV RNA, CD4, and CBC every 3 to 4 months (3). CD4 monitoring may be spaced out after long-term virologic control.
- Annual HIV RNA and CD4 count once viral load undetectable and stable
- Once viral load has been suppressed consistently for >2 years and CD4 cell counts are consistently >500/μL, monitoring CD4 cell counts is optional unless virologic failure occurs or there are intercurrent immunosuppressive treatments or conditions.
- Confirm detectable HIV-1 RNA level (>50 copies/mL) noted during therapy within 4 weeks prior to making management decisions.
- Test fasting lipids and fasting glucose annually; basic metabolic panel, aspartate aminotransferase, alanine aminotransferase, T/D bilirubin every 6 to 12 months (3)
- Cervical cytology annually (regardless of age) until three negative screens and then space to every 3 years
- Pregnancy test women of childbearing age (3)
- Urinalysis every 6 to 12 months or as clinically indicated (3)
- Hepatitis C as clinically indicated (3)

**DIET**
- Encourage good nutrition; avoid raw eggs and unpasteurized dairy products.
- Discuss unknown and potentially harmful effects of supplement use including drug–drug interactions.

**PATIENT EDUCATION**

**PROGNOSIS**
- Untreated HIV infection leading to the diagnosis of AIDS has an associated life expectancy of about 3 years, and if the patient has an opportunistic infection, the life expectancy is about 1 year.
- AIDS-defining opportunistic infections usually do not develop until CD4 <200.
- Adherence failure—not drug resistance—is the most common cause of treatment failure.

**COMPLICATIONS**
- Immunodeficiency
- Opportunistic infections
- Neurologic complications:
  - AIDS dementia complex (ADC), cryptococcal meningitis, CMV encephalitis, progressive multifocal leukoencephalopathy (PML), neurosyphilis, herpes encephalitis, toxoplasma encephalitis, vacuolar myelopathy and psychological and neuropsychiatric disorders (5)
- Respiratory complications such as acute bronchitis, bacterial pneumonia, *Pneumocystis carinii* pneumonia with CD4 <200 cells/mm3 and *M. avium*. 
• Malignancy, including cervical or anal cancer

ADDITIONAL READING

CODES

ICD10
CLINICAL PEARLS

- Acute HIV seroconversion illness mimics mononucleosis and is characterized by fever, sore throat, adenopathy, myalgias, and rash.
- Transmitted drug resistance is increasing. Evaluate patients for resistance before initiating ART.
- Appropriate vaccination and prophylactic antibiotics should be administered to HIV+ patients based on clinical history and CD4 count.
- Discuss prevention strategies, including PrEP, with individuals who are at high risk of HIV infection.
- Consider HIV testing in patients reporting unintended weight loss, fatigue, night sweats, or rash.
HODGKIN LYMPHOMA

Rory M. Shallis, MD • John L. Reagan, MD

BASICS

DESCRIPTION

Historical background:

- Described in 1832 by Thomas Hodgkin in “On some morbid appearance of the absorbent glands and spleen”
- First neoplasm to be (i) defined by cytologic grounds based on presence of Reed-Sternberg (RS) cells, (ii) clinically staged neoplastic disease, and (iii) treated with chemotherapy and/or radiotherapy
- Neoplastic RS cells of monoclonal lymphoid B-cell origin within inflammatory background of lymphocytes (T-helper type 2 and regulatory T cells), eosinophils, histiocytes, and plasma cells
- Two subtypes: classic Hodgkin lymphoma (CHL, 95% of cases) and nodular lymphocyte-predominant Hodgkin lymphoma (NLPHL, 3–8% of cases)
  - NLPHL: B cells, neoplastic luteinizing hormone (LH) cells with multilobulated nuclei, small nucleoli, and popcorn-like appearance
  - CHL histologic subdivisions: nodular sclerosing (60%), mixed cellularity (30%), lymphocyte depleted (<10%), lymphocyte rich (<10%)
  - Frequency of lymph node involvement: cervical > mediastinal > axillary > paraaortic

EPIDEMIOLOGY

- Incidence: 2.6/100,000/year
- Predominance: 8% of lymphoid malignancies
- Typically diagnosed at age 20 to 34 years with median age 39 years at diagnosis given decreasing bimodal age distribution
- 1.3:1 male-to-female ratio

Geriatric Considerations

Poorer prognosis if present at ≥60 years:

- Less likely to tolerate intensive chemotherapy
- Less likely to be included in clinical trial
Pediatric Considerations
Young females (<30 years of age) treated with thoracic radiation are at high risk for breast cancer, and early breast cancer screening is recommended.

Pregnancy Considerations
- Abdominal ultrasonography to detect subdiaphragmatic disease
- Treatment:
  - Delay until after delivery if asymptomatic and early stage.
  - ABVD safely used in 2nd and 3rd trimesters
  - Vinblastine monotherapy to control symptoms
  - 1st trimester: ABVD may or may not cause fetal malformations.

Incidence
Approximately 8,500 new cases in the United States annually

Prevalence
Approximately 220,000 living with Hodgkin lymphoma in the United States in 2015

ETIOLOGY AND PATHOPHYSIOLOGY
- RS cells likely derived from germinal center B cells with mutations in immunoglobulin variable chain
- Seasonal features and higher frequencies with Epstein-Barr virus (EBV) suggest environmental factors.
- T-lymphocyte defects persist even after successful treatment.
- Human leukocyte antigen (HLA) is strongly associated with increased risk.
- EBV positivity associated with increased risk
- Genome-wide association studies identified 19p13.3 at intron 2 of TCF3.

Genetics
- First-degree relative: 3 to 9 times risk
- Siblings of younger patients: 7 times risk
- Weak correlation between familial HL and HLA class I regions containing HLA-A1, HLA-B5, HLA-B8, HLA-B18 alleles

RISK FACTORS
- Immunodeficiency (inherited or acquired)
- Autoimmune disorders
- EBV
- Seasonal factors

**COMMONLY ASSOCIATED CONDITIONS**

In HIV:
- AIDS-defining illness
- Predominantly mixed-cellularity or lymphocyte-depleted histologic subtypes
- At diagnosis: widespread disease, extranodal involvement, systemic symptoms

**DIAGNOSIS**

**HISTORY**
- Asymptomatic lymphadenopathy (cervical/supraclavicular)
- Pel-Ebstein (cyclic) fever
- Constitutional symptoms: night sweats, weight loss, fatigue, anorexia
- Alcohol-induced pain
- Pruritus

**PHYSICAL EXAM**
- Lymphadenopathy 70% (cervical > supraclavicular > axillary)
- Splenomegaly
- Hepatomegaly

**DIFFERENTIAL DIAGNOSIS**
Non-Hodgkin lymphoma, infectious lymphadenopathy, solid tumor metastases, sarcoidosis, autoimmune disease, AIDS/HIV, drug reaction

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- CBC with differential
- Comprehensive metabolic panel
- LFT, LDH
- ESR
- HIV, EBV, HCV
- Pregnancy test for women of childbearing age
Echocardiogram (in anticipation of treatment with anthracycline)

- Pulmonary function tests (diffusion capacity of the lung for CO in anticipation of treatment with bleomycin)
- Chest x-ray
- Computed tomography (CT) with contrast of chest, abdomen, and pelvis
- Positron emission tomography (PET): for initial staging, midtreatment decision making, and end-of-treatment evaluation

**Follow-Up Tests & Special Considerations**

- Fertility considerations:
  - Semen cryopreservation if chemotherapy or pelvic radiation therapy
  - In vitro fertilization or ovarian tissue/oocyte cryopreservation
- Radiation therapy (RT) considerations:
  - Splenic RT: pneumococcal, *Haemophilus influenzae*, meningococcal vaccine

**Diagnostic Procedures/Other**

- Excisional lymph node biopsy
- Immunohistochemistry
- Bone marrow biopsy if cytopenia with negative PET
- Liver biopsy (in selected cases)

**Test Interpretation**

RS cell characteristics include the following:

- Diameter: 20 to 50 μm
- Abundant acidophilic cytoplasm
- Bi- or polylobulated nucleus
- Acidophilic nucleoli
- CD30+, CD15+, CD45−, CD3−, CD20+ in 40% of cases
- RS cells necessary but not sufficient for diagnosis (needs inflammatory background)

**TREATMENT**

- Ann Arbor staging with Cotswold modification
  - Stage I: single lymph node or of a single extralymphatic organ or site
  - Stage II: ≥2 lymph node regions on the same side of diaphragm alone or
with involvement of extralymphatic organ or tissue
- Stage III: node groups on both sides of the diaphragm
- Stage IV: dissemination involving extranodal organs (except the spleen, which is considered lymphoid tissue)
- Subclasses: A = no systemic symptoms; B = systemic symptoms (fever, night sweats, weight loss >10% body weight); X = bulky disease (>1/3 intrathoracic, diameter, or >10-cm nodal mass)
- Classified into three groups: early stage (I or II) favorable, early stage unfavorable (I or II with presence of either B symptoms, large mediastinal adenopathy, three or more nodal sites of disease, extranodal involvement, or an ESR ≥50), or advanced stage (III or IV)

- Goal: Aim for cure.
- All subsequent treatment and follow-up care recommendations based on National Comprehensive Cancer Network (NCCN) consensus. Please refer to NCCN Practice Guidelines in Oncology for Hodgkin lymphoma.

MEDICATION
Hodgkin lymphoma

First Line
- Early stage disease: combined modality treatment or chemotherapy
- Advanced stage disease: chemotherapy
- PET/CT used after cycle 2 (PET-2) to guide either escalation or de-escalation of therapy (1)
- ABVD (doxorubicin, bleomycin, vinblastine, dacarbazine):
  - Highly emetic, severe phlebitis
  - Doxorubicin: risk of cardiotoxicity; monitor LVEF.
  - Bleomycin: risk of pulmonary toxicity, death; test dose may be administered prior to first cycle.
  - Dacarbazine cannot be omitted without loss of efficacy.
- Stage I/II favorable: ABVD × 2 then 20 Gy involved site radiation therapy (ISRT) (2); can also use Stanford V × 8 weeks +/− 30 Gy ISRT pending PET/CT response (3)
- Stage I/II unfavorable: ABVD × 2 then PET-2. If PET-2 negative, then ABVD × 2 + ISRT or AVD [dropped bleomycin (4)] × 4. If PET-2 positive, then ABVD × 2 + ISRT or escalated BEACOPP + ISRT; can also use Stanford V × 12 weeks + 30 to 36 Gy.
- Stage III/IV: ABVD × 2 is preferred then AVD [dropped bleomycin (4)] × 4 if PET-2 negative. If PET-2 positive, then ABVD × 2 + ISRT or escalated
BEACOPP × 4 +/- ISRT; can also use Stanford V × 12 + ISRT unless refractory or BEACOPP × 6 +/- ISRT pending PET/CT response.

**Second Line**
- Reserved for patients with relapse or disease refractory to first-line treatment
- Standard is for chemotherapy agents not used for initial treatment and then high-dose therapy with autologous stem cell transplant (HDT/ASCT) +/- ISRT.
  - HDT/ASCT shows improved EFS/PFS compared with conventional chemotherapy but not overall survival; can achieve disease-free survival in 30–40% of patients after auto SCT
  - Allogeneic SCT to be considered if failed autologous SCT (used in trials only)
- Brentuximab vedotin (anti-CD30 chimeric antibody conjugated to synthetic antimicrotubule agent monomethyl auristatin E) FDA approved for use as maintenance therapy × 1 year in relapsed HL after HDT/ASCT or failed two prior lines of multiagent chemotherapy. Strongly encouraged if Deauville of 4 on restaging PET after HDT/ASCT or in patients at high risk for relapse. Improves PFS in those at risk for relapse or progression after transplantation (5). Initial phase II study data showed 73% response rate and 34% CR. 3-year follow-up data confirmed responses with OS and PFS rates of 75% and 58%, respectively (6).
  - Side effects include peripheral neuropathy, nausea, fatigue, neutropenia, diarrhea.
  - May also be used prior to HDT/ASCT to avoid toxicity with HDT
- Nivolumab (anti-PD1) may be used for patients who have failed HCT/ASCT and brentuximab vedotin therapy
- Pembrolizumab (another anti-PD1) may be used for patients with relapsed/refractory CHL who have failed brentuximab vedotin. Recent phase I study showed a CR and partial response (PR) of 16% and 48%, respectively (7).
- Third-line novel agents undergoing studies: NF-κB inhibitors (bortezomib), mammalian target of rapamycin (mTOR) inhibitors (everolimus), immunomodulators (lenalidomide), cell signaling targets histone deacetylase (HDAC) inhibitors (vorinostat, panobinostat, mocetinostat)
- Median survival <3 years if fail second-line therapy, including SCT
- Nodular lymphocyte predominant Hodgkin
  - Treated with either rituximab + ABVD or rituximab + CHOP (CD20 positive)
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- During therapy: CBC, nutrition, and hydration
- Restage with PET after 2 to 4 cycles of chemotherapy: sensitive prognostic indicator
- Posttreatment monitoring:
  - History and physical: q3–6mo for first 2 years, then q6–12mo for next 3 to 5 years, then annually
  - Laboratory studies
    - CBC, platelets, BMP, ESR (if elevated at time of diagnosis), as indicated clinically
    - Thyroid-stimulating hormone (TSH) annually if radiation to neck
  - Imaging:
    - CT is appropriate 6, 12, and 24 months posttreatment as well as when clinically indicated.
    - Annual breast mammogram beginning 8 to 10 years after therapy or at age 40 years (whichever first) if chest or axillary irradiation (annual breast MRI as well if initially radiated between ages 10 and 30 years) according to the American Cancer Society
    - Surveillance PET should not be done routinely due to risk of false-positive findings.
- Annual influenza vaccine

PATIENT EDUCATION

- Reproductive impact
- Risks of secondary malignancy
- Oral and dental care during therapy
- Leukemia & Lymphoma Society (http://www.lls.org/)

PROGNOSIS

- Cure rate for CHL: 80%
- Relapse or progression of disease rate: 5–20%
- Overall survival rates:
  - 1-year survival: 92%
  - 5-year survival: 86% (92% if localized)
- 10-year survival: 80%
- **International prognostic score for advanced disease:**
  - Age >45 years
  - Male gender
  - Albumin <4 g/dL
  - Hemoglobin <10.5 g/dL
  - Lymphocytopenia: <600 lymphocyte cells/dL or lymphocytes <8% of WBC
  - WBC ≥15,000 cells/dL
  - Stage IV disease
- **Main cause of death**
  - Initial 5 years: Hodgkin lymphoma
  - After 5 to 10 years: leukemia, myelodysplastic syndrome
  - After 20 years: second primary malignancy, cardiovascular disease

**REFERENCES**

CODES

ICD10

- C81.90 Hodgkin lymphoma, unspecified, unspecified site
- C81.91 Hodgkin lymphoma, esp, lymph nodes of head, face, and neck
- C81.92 Hodgkin lymphoma, unspecified, intrathoracic lymph nodes

CLINICAL PEARLS

- Neoplastic disease of lymphatics
- RS cells of monoclonal lymphoid B-cell origin within inflammatory background of lymphocytes
- Two subtypes: CHL 95% of cases and NLPHL 5% of cases
- Cure rate for CHL: 80%
- 5-year survival: ~86%
- Relapse or progression of disease rate: 5–20%
- Immunotherapy with CD30 and PD-1 blockade currently underway and promising
HOMELESSNESS

Dana Sprute, MD, MPH, FAAFP • Minying Gu, MD

BASICS

DESCRIPTION
Defined as (i) an individual who lacks a fixed, regular, and adequate nighttime residence; and (ii) an individual who has a primary nighttime residence that is (a) a supervised publicly or privately operated shelter designed to provide temporary living accommodations (including welfare hotels, congregate shelters, and transitional housing for the mentally ill); (b) an institution that provides a temporary residence for individuals intended to be institutionalized; and (c) a public or private place not designed for, or ordinarily used as, a regular sleeping accommodation for human beings.

EPIDEMIOLOGY

Prevalence
In 2016, on any given night in January, there are 549,928 homeless individuals in the United States: 35% are homeless families; 15.6% are chronically homeless; and 22% are children (1).

- From 2015 to 2016, overall homelessness decreased by 2.6% largely due to increases in available housing locations. Risk for becoming homeless remains high in certain populations (see “Risk Factors”) (1).
- Although many homeless individuals reside in temporary housing or shelters, 32% live unsheltered (1).
- Homelessness continues to decrease due to increases in targeted federal funding for rapid rehousing/permanent housing; 2016 fiscal year $5.5 billion (1,2)

RISK FACTORS
- Economic factors
  - Poverty
    - 2017 federal poverty definition: $24,600 annual income for four-person household in the lower 48 states and District of Columbia, slightly higher in Alaska and Hawaii (3).
In 2015, 14.7% of the U.S. population fell below federal poverty definition (United States. Census Bureau).

- **Unemployment**: U.S. rate 4.4% in June 2017 (U.S. Bureau of Labor Statistics)
- **Lack of affordable health care**: In 2015, 13% of people in United States were without health insurance. This has decreased to 11.5% by the beginning of 2016 (4).
- **Young adults** (ages 19 to 34 years) are disproportionately uninsured (27%) compared with the average for all ages (13%); the uninsured rate for ages 19 to 25 years decreased by 12% between 2009 and 2016, following Affordable Care Act provision allowing individuals in this age group to stay on parental insurance plans (4).
- The number of uninsured nonelderly Americans has dropped 43% since October 2013 (4).
- **Lack of affordable housing**: Housing is considered affordable if ≤30% of household income is devoted to housing costs.
- An estimated 12 million households are “severely housing cost burdened” (≥50% of income is spent on housing).

- Additional at-risk populations: intimate partner violence (IPV), victims of violence; youth (particularly those aging out of foster care); veterans; rural; addiction; psychiatric illness; disabled due to chronic medical disease, psychiatric illness, or substance use disorder; reentry after incarceration/prison
  - IPV: 12% of overall homeless population, and as many as 1 in 5 families, will have reported experiencing IPV; IPV leads directly to homelessness in many cases (2).
  - Youth: In 2016, Department of Housing and Urban Development (HUD) estimates 35,686 unaccompanied individual homeless youths (up to age 24 years), and another 9,800 persons in families where the parent is a youth (1). Approximately 550,000 youths in a year will experience homelessness lasting longer than a week (2).
  - Veterans: 9% of homeless adults; homelessness rate decreased between 2009 and 2016 (1).
  - Addiction disorders: 46% of homeless individuals report alcohol and/or drug use as a major factor contributing to homelessness (2).
  - Psychiatric illness: 45% of homeless report indicators of a mental health issue in the past year; 25% of homeless adults suffer from chronic mental illness (2).
  - Reentry after incarceration: Up to 50,000 people each year enter homeless shelters from jails or prisons (2).
Fundamental issues in homelessness and health care that require ongoing consideration:

- Unstable housing, limited access to nutritious food and water, lack of transportation
- Higher risk for abuse and violence
- Physical/cognitive impairments, behavioral health problems
- Developmental discrepancies for children: speech delay, chronic ear infection, insufficient opportunity to practice gross and fine motor skills
- Higher risk for communicable disease
- Lack of health insurance/resources, discontinuous/inaccessible health care, lack of a medical home, barriers to disability assistance
- Cultural/linguistic barriers: racial and ethnic groups overrepresented in homeless population
- Limited education/literacy
- Lack of social supports: Alienation from family and friends precipitates homelessness.
- Criminalization of homelessness: frequent arrests for loitering, sleeping in public places

GENERAL PREVENTION

- Policy and funding for community programs to provide emergency/rapid housing, housing stabilization, and case management services
- Increased Medicaid eligibility for homeless and expanded home and community-based services and case management to the homeless population (5)
- HUD: increasing permanent supportive housing units, increasing services for veterans and those with disabilities (5)
- Social Justice policy recommendations: permanent affordable housing, foreclosure and homelessness prevention, increased funds for HUD McKinney-Vento programs (emergency, transitional, and permanent housing) and National Housing Trust Fund, rural homeless assistance, universal health care, universal livable income, employment/workforce services, prevention of hate crimes against the homeless, decriminalization of homelessness

COMMONLY ASSOCIATED CONDITIONS

- Hunger
- Worsening of chronic medical conditions: lack of healthy food, places to store medications, or medical equipment; lack of restful sleep; decreased health literacy
- Infectious diseases
  - Tuberculosis (TB), HIV/AIDS, STI
  - Skin/nail infections and infestation (lice and scabies)
  - Liver disease (e.g., hepatitis B or C, or alcohol-related)
- Cognitive impairment: traumatic brain injury (TBI), cerebrovascular accident (CVA), substance use
- Dental problems
- Exposure-related conditions (frostbite, heatstroke)
- Psychiatric illness
- Trauma: increased risk of assault, victims of hate crimes

DIAGNOSIS

HISTORY
- Living conditions: location, access to food, restrooms, place to store medicines, safety
- Prior homelessness: causes and circumstances
- Individual/family history of reactive airway disease (RAD), chronic otitis media, anemia, diabetes, cardiovascular disease (CVD), TB, HIV/STIs, hospitalizations
- Family members, especially dependent children
- Medications: Include OTC medication, dietary supplements, medication “borrowed” from others.
- Prior providers: oral health, primary and specialty care, current medical home
- Mental health: stress, anxiety, appetite, sleep, concentration, mood, speech, memory, thought process and content, auditory/visual hallucinations, suicidal/homicidal ideation, insight, judgment, impulse control, social interactions; symptoms of brain injury (headaches, seizures, memory loss, irritability, dizziness, insomnia, poor organizational/decision-making skills)
- Alcohol/nicotine/drug use: amount, frequency, duration
- Gender identity/orientation, behaviors, rape, pregnancies, hepatitis, HIV, other STIs
- History of or current abuse: emotional, physical, sexual; patient safety
- Legal problems/violence: history of incarceration
- Activities: routines (treatment feasibility); level of strenuous activity
- Work: previous types of jobs, length held, veteran status, occupational injuries/toxic exposures; vocational skills, interest
• Education: highest level; ever in special education; assess ability to read/language skills/English fluency.
• Nutrition/hydration: diet, food resources, preparation skills, liquid intake
• Cultural heritage/affiliations: family, friends, faith community, other sources of support
• Strengths: coping skills, job skills, resourcefulness, abilities, interests

PHYSICAL EXAM
• Comprehensive exam: height/weight, BMI, especially abdominal, cardiopulmonary, dermatologic, oral, feet, neurologic, mental status
• Focused exams: for patients uncomfortable with full-body, unclothed exam at first visit
• Dental assessment: age-appropriate teeth, obvious caries, dental/referred pain, diabetes, CVD

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Mental health: Patient Health Questionnaire (PHQ-9, PHQ-2), MHS-III, MDQ, GAD-7
• Cognitive assessment: Mini-Mental State Examination (MMSE), Traumatic Brain Injury Questionnaire (TBIQ), Repeatable Battery for the Assessment of Neuropsychological Status (RBANS)
• Developmental assessment: Ages & Stages Questionnaires, Parents’ Evaluation of Developmental Status (PEDS), Denver II, or other screening tool
• Interpersonal violence: IPV, sexual assault, TBI
• Forensic evaluation: if indicated by history
• Baseline labs: as needed to address suspected medical concerns
• TB screening: PPD
• STI screening: HIV, chlamydia, gonorrhea, syphilis, hepatitis B, hepatitis C, trichomonas
• Substance abuse: SSI-AOD (Simple Screening Instrument for Alcohol and Other Drugs), urine drug screen

Follow-Up Tests & Special Considerations
• Reproductive health care and STIs: Obtain detailed sexual history (sexual identity, orientation, behaviors/sexual practices, number of partners). Consider patient exploitation, especially if mental illness/developmental disability
suspected. Communicate willingness to initiate contraception first visit without exam. Genital exam recommended, but be sensitive to patient needs, if possible sexual abuse history. If pelvic exam is refused, consider empiric treatment for STI (and possibility of multiple orifice infection). Dispense medications on site; facilitate partner treatment.

- **Pediatric care:** complete exam every visit, use each visit to identify/address problems and provide vaccinations as homeless families may not see a medical provider unless child is sick. Vision and hearing screening at every visit. Facilitate referrals as able.

### TREATMENT

- **Establish rapport:** Many patients will have had negative health care experiences.
- **Enlist community resources:** mental health and substance abuse programs, free clinics, case management
- **Health care maintenance:** vaccinations (hepatitis A and B, Pneumovax, Tdap, influenza) cancer and chronic disease screening for adults; Early Periodic Screening, Diagnosis, and Treatment Program (EPSDT) screening and vaccinations for children
- **Care plan**
  - Basic needs: Food, clothing and housing may be higher priorities than health care.
  - Patient goals and priorities: immediate/long-term health needs. Address patient concerns first.
  - Action plan: simple language, pocket card
  - After hours: extended clinic hours and access
  - Safety plan: violence and abuse; mandatory reporting requirements
  - Emergency plan: location of nearest emergency department (ED), preparation for evacuation
  - Adherence plan: use of interpreter; identification of potential barriers.

### MEDICATION

- **Simple regimen:** low pill count, once-daily dosing
- **Dispensing:** small amounts on-site to promote follow-up, decrease loss/theft/misuse. Determine resources for written prescriptions.
- **Storage of medications:** If no access, avoid medications requiring refrigeration.
• Patient assistance: free/low-cost drugs depending on available local options
• Aids to adherence: harm reduction, outreach/case management, directly observed therapy
• Side effects: Primary reason for medication nonadherence are drugs causing diarrhea, polyuria, nausea, and/or disorientation
• Analgesia/symptomatic treatment: Consider pain contract, single provider for pain medication refills.
• Dietary supplements: multivitamins with minerals, nutritional supplements
• Managed care: generics, if possible; assistance getting prescription filled
• Lab monitoring: Monitor patients on antipsychotic medications for metabolic disorders using available laboratory resources.

ADDITONAL THERAPIES
• Associated problems/complications
  – Fragmented care: multiple providers. Use electronic medical record (EMR) as possible; list prescribed medication on wallet-sized card.
  – Masked symptoms/misdiagnosis: for example, weight loss, dementia, edema, lactic acidosis
  – Focus on immediate concerns, not possible future consequences.
  – Integrated treatment for concurrent mental illness/substance use disorders
  – Support for parent of child abused by others and for abused parent
• Follow-up
  – Reliable phone/e-mail contact for patient/friend/family/case manager
  – Frequent follow-up, incentives, nonjudgmental care regardless of adherence
  – Anticipate/accommodate unscheduled clinic visits.
  – Provide car fare, tokens, and help with transportation services.
  – Monitor school attendance and address health/developmental problems with family/school.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Homeless likely to benefit from admission if living conditions are suboptimal to treat medical, psychiatric, and substance use disorders.
• Discharge criteria
  – Bed rest, extended periods of elevation, rest, or icing are not feasible in most instances.
  – Plans requiring multiple return visits likely to fail if no transportation.
  – Admission to inpatient rehabilitation if appropriate and possible
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Patients with a history of nonadherence need additional support (e.g., case manager, outreach) to succeed in ongoing care after hospital discharge.
- Limited telephone access to schedule appointments; may be unable to receive telephone messages with test results or rescheduled appointment times. Some social service agencies will provide phone, mail, e-mail, Internet, and laundry services.
- Arrange appointments prior to discharge.
- Document the best way to contact the individual.
- Work with experienced health care agency designed to address physical/mental health services and substance use treatment.

PATIENT EDUCATION

- https://www.nhchc.org/
- http://www.endhomelessness.org/pages/mentalphysical_health

PROGNOSIS

Mortality rates for homeless adults are 3 to 4 times higher compared with general U.S. population (6)[C].

REFERENCES

**CODES**

**ICD10**
- Z59.0 Homelessness
- Z59.1 Inadequate housing
- Z59.8 Other problems related to housing and economic circumstances

**CLINICAL PEARLS**
- Permanent supportive housing is an important step toward ending homelessness, in accordance with a Housing First approach.
- Assistance in gaining access to benefits or providing help to support basic needs decreases stress, improves therapeutic relationship, and allows individuals to focus on physical and mental health.
HORDEOLUM (STYE)
Konstantinos E. Deligiannidis, MD, MPH, FAAFP

BASICS

DESCRIPTION
- An acute inflammation or infection of the eyelid margin involving the sebaceous gland of an eyelash (external hordeolum) or a meibomian gland (internal hordeolum)
- System(s) affected: skin/exocrine
- Synonym(s): internal hordeolum; external hordeolum; zeisian sty; meibomian styte; styte

EPIDEMIOLOGY
- Predominant age: none
- Predominant sex: male = female

Incidence
Unknown: Although external hordeolum is common, internal hordeolum is rare.

ETIOLOGY AND PATHOPHYSIOLOGY
- Bacterial infection of sweat or sebaceous glands, causing an acute inflammatory reaction
- In an internal hordeolum, the meibomian gland may become obstructed, leading to a pustule on the conjunctival surface as opposed to the margin of the eyelid.
- Most commonly caused by *Staphylococcus aureus* (~90–95% of all cases) or by *Staphylococcus epidermidis*
- Seborrhea can predispose to infections of the eyelid.

Genetics
No known genetic pattern

RISK FACTORS
- Poor eyelid hygiene
- Previous hordeolum
- Contact lens wearers
- Application of makeup
- Seborrheic dermatitis
- Predisposing blepharitis (low-grade infections of the eyelid margin)
- Ocular rosacea

**GENERAL PREVENTION**
Eyelid hygiene

**COMMONLY ASSOCIATED CONDITIONS**
- Acne
- Seborrhea
- An association may exist between hordeolum during childhood and developing rosacea in adulthood.

**DIAGNOSIS**

**HISTORY**
- Localized inflammation (vs. involvement of the entire eyelid or surrounding skin)
- Foreign body sensation in the eye
- Prior episodes are common.

**PHYSICAL EXAM**
- Localized inflammation of the eyelashes or a small pustule at the margin of the eyelid
- Localized swelling and tenderness on the internal or external aspect of the eyelid with an opening to either side
- To determine if an internal hordeolum is obstructed, the eyelid should be gently everted to examine for a pustule on the tarsal conjunctiva.
- Itching or scaling of the eyelids; collection of discharge, redness, and irritation leading to localized tenderness and pain
- The size of the swelling usually correlates to the severity of the hordeolum.

**DIFFERENTIAL DIAGNOSIS**
- Chalazion
- Blepharitis
• Eyelid neoplasms
• Periorbital cellulitis
• Dacryocystitis
• Squamous cell carcinoma

**DIAGNOSTIC TESTS & INTERPRETATION**
Culture of the eyelid margins usually is not necessary.

**Diagnostic Procedures/Other**
History and eye exam

**Test Interpretation**
Bacterial contamination and white cells in eyelid discharge

**TREATMENT**

**GENERAL MEASURES**
• The hordeolum should not be expressed.
• Warm compresses to the area of inflammation can help increase blood supply and encourage spontaneous drainage.
• Good personal hygiene with attention to cleansing the eyelids on a daily basis helps to prevent recurrent infections.

**MEDICATION**

**First Line**
• A Cochrane review found no evidence for or against nonsurgical treatment of internal hordeolum. External hordeola were not considered (1)[A].
• Usually, a hordeolum spontaneously drains, aided by warm compresses to the area.
• Also, lid scrubs, digital massage, and alternative medicine have been used to reduce healing time and relieving symptoms.
• Application of an antibiotic ointment (e.g., erythromycin) to the margin of the eyelid after proper cleansing (except in children age <12 years, in whom there is a risk of blurred vision and amblyopia) helps reduce bacterial proliferation. There is little evidence that any topical therapy is effective. Erythromycin ophthalmic ointment may be applied up to 6 times per day for 7 to 10 days or
an antibiotic ointment containing bacitracin (2,3)[C].

- Treat underlying dry eye with artificial tears.

**Second Line**

- Occasionally, the use of an aminoglycoside ophthalmic ointment, such as gentamicin or tobramycin, may be necessary if condition is refractory to simpler treatment (case reports).
- Oral dicloxacillin or cephalaxin for 2 weeks if refractory to topical antibiotics

**ISSUES FOR REFERRAL**

Consider referral if unresponsive to oral antibiotics.

**SURGERY/OTHER PROCEDURES**

- If the infection becomes localized to a single gland, incision, drainage, or curettage sometimes is necessary. This is an in-office procedure with a local anesthetic: Exercise caution because ocular perforation has been reported with the injection of an anesthetic to an infected lid.
- Use of combined antibiotic ointment (neomycin sulfate, polymyxin B sulfate, and gramicidin) after surgery was not shown to have any statistically significant benefit compared with artificial tears.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Broncasma berna is a polyvalent antigen vaccine that may be useful in the treatment of recurrent hordeolum.

  A Cochrane review found low-quality evidence that acupuncture (with or without antibiotics and/or warm compresses) may increase the chance of improvement of hordeolum compared to antibiotics and/or warm compresses (4)[A].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Outpatient

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS
No restrictions

Patient Monitoring
The patient should be seen within several weeks to assess the effectiveness of therapy or should at least call the physician’s office with a progress report.

DIET
No special diet

PATIENT EDUCATION
- The patient should be instructed in proper cleansing of the eyelids using a solution of tap water and baby shampoo or a commercially prepared hypoallergenic cleanser.
- The stye should not be squeezed or incised.

PROGNOSIS
- Usually responds well to good hygiene and warm compresses
- Inflammation usually improves within a week.
- Hordeolum tends to recur in some patients, usually due to incomplete elimination of bacteria.

COMPLICATIONS
An internal hordeolum, if untreated, may lead to chalazion, infections of adjacent glands, or generalized cellulitis of the lid.

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**
- H00.019 Hordeolum externum unspecified eye, unspecified eyelid
- H00.029 Hordeolum internum unspecified eye, unspecified eyelid
- H00.039 Abscess of eyelid unspecified eye, unspecified eyelid

**CLINICAL PEARLS**
- A hordeolum should not be expressed.
- Warm compresses to the area of inflammation can encourage spontaneous drainage.
- Application of an antibiotic ointment (e.g., erythromycin) to the margin of the eyelid after proper cleansing helps reduce bacterial proliferation but may have no effect on the healing of the stye.
- Good personal hygiene with attention to cleansing the eyelids on a daily basis can prevent recurrent infections.
**HORNER SYNDROME**

_Jairo L. Tejada-Tejada, MD • Jose L. Perez-Lara, MD • Manjeet Dhallu, MD_

---

**BASICS**

**DESCRIPTION**

- Horner syndrome is a constellation of neurological signs and symptoms manifested as a classic triad of ipsilateral miosis, eyelid ptosis, and anhidrosis of the ipsilateral midface and/or neck (with iris heterochromia in children).
- It is caused by the interruption or lesion along the sympathetic nerve supply to the head, neck, and eye.
- Oculosympathetic pathway anatomy:
  - First-order neuron: Sympathetic nerve fibers originate in the hypothalamus, descend through the brainstem, and synapse at the ciliospinal center (of Budge) located at approximately the C8–T2 levels of the spinal cord.
  - Second-order neuron: exits the spinal column at the T1 level primarily, arches over the apex of the lung and under the subclavian artery, ascending to the superior cervical ganglion at the level of the carotid bifurcation and angle of the jaw
  - Third-order neuron: ascends along the adventitia of the internal carotid artery, through the cavernous sinus in proximity to cranial nerve (CN) VI, and joins CN VI to innervate the iris dilator muscle and Müller muscle in the eye
- System(s) affected: nervous, skin/exocrine
- Synonym(s): Bernard-Horner syndrome; Bernard syndrome; Horner syndrome; cervical sympathetic syndrome; oculosympathetic syndrome; oculosympathetic paralysis; oculosympathetic deficiency; oculosympathetic paresis

**EPIDEMIOLOGY**

- Predominant age: none
- Predominant sex: male = female

**Incidence**

Unknown
Prevalence
Unknown

ETIOLOGY AND PATHOPHYSIOLOGY

- The constellation of signs and symptoms will be produced when sympathetic innervation is lesioned anywhere along the track producing ipsilateral Horner syndrome.
- Syndrome characteristics based on lesion locations:
  - Central or preganglionic lesion (complete syndrome):
    - First-order Horner syndrome (central): lesion located in the sympathetic tracts in the brainstem or cervicothoracic spinal cord; most common cause (MCC) lateral medullary infarction which present Horner syndrome as part of Wallenberg syndrome
    - Second-order Horner syndrome (preganglionic): due to trauma or surgery involving spinal cord, thoracic outlet or lung apex
  - Peripheral postganglionic lesion (incomplete syndrome, given by anhidrosis): third-order Horner syndrome; lesions usually located in internal carotid artery (e.g., dissection, thrombosis, cavernous sinus aneurysm, surgical endarterectomy, or stenting)
- Sympathetic fibers innervating sweat glands and vasodilatory muscles branch off before the cervical sympathetic ganglion traveling along the external carotid artery, so distal lesions will not result in anhidrosis; idiopathic (40%), congenital, or acquired
- Best classified by which order neuron is affected as mentioned above and by age (pediatric vs. adult)
- Etiology adult:
  - First-order neuron (13%)—central mostly located in hypothalamus/brainstem (lateral medulla)/spinal cord (cervical-thoracic):
    - Arnold-Chiari malformation
    - Basal meningitis (e.g., syphilis)
    - Tumors
    - Cerebral vascular accident: lateral medullary (Wallenberg) syndrome
    - Cervical cord trauma
    - Demyelinating disease (multiple sclerosis)
    - Intrapontine hemorrhage
    - Neck trauma
    - Pituitary tumor
    - Syringomyelia
- Unintended subdural placement of lumbar epidural catheter
  - Second-order neuron (44%)—preganglionic: pulmonary or thoracic upper lesions
    - Aneurysm/dissection of aorta
    - Central venous catheterization
    - Chest tubes
    - 1st rib fracture
    - Lymphadenopathy (Hodgkin, leukemia, tuberculosis, mediastinal tumors, sarcoid)
    - Mandibular tooth abscess
    - Neurofibromatosis types I and II
    - Pancoast tumor or infection of lung apex
    - Proximal common carotid artery dissection
    - Trauma/surgical injury
  - Third-order neuron lesions (43%)—postganglionic lesions located in superior cervical ganglion, internal carotid artery, skull base lesions, cavernous sinus lesions
    - Carotid cavernous fistula or other pathology
    - Carotid endarterectomy or carotid artery stenting
    - Cluster headaches
    - Internal carotid artery dissection
    - Herpes zoster
    - Lesions of the middle ear (acute otitis media)
    - Lyme disease
    - Nasopharyngeal cancer
    - Tonsillectomy
    - Raeder paratrigeminal syndrome

- Etiology children: Common causes are birth-related injuries (in neck and shoulder), neuroblastoma (paraspinal), vascular anomalies, and chest surgical interventions.
- MCC birth-related: associated injury to lower brachial plexus presenting ipsilateral forearm and hand weakness (Klumpke paralysis)
- Drugs: acetophenazine, alseroxylon, bupivacaine, butaperazine, carphenazine, chlorprocaine, deserpidine, diacetylmorphine, diethazine, ethopropazine, etidocaine, guanethidine, influenza virus vaccine, levodopa, lidocaine, mepivacaine, mesoridazine, methdilazine, methotrimeprazine, oral contraceptives, perazine, prilocaine, procaine, prochlorperazine, promazine, propoxycaine, reserpine, thioproperazine, thioridazine, trifluoperazine
Genetics
Rare autosomal dominant inheritance

RISK FACTORS
- Most common: apical bronchogenic carcinoma (Pancoast tumor) in smokers
- Aneurysm of the carotid or subclavian artery
- Injuries to the carotid artery high in the neck
- Dissection of the carotid arteries
- Carotid artery occlusion
  - 15% of patients with carotid artery occlusion develop ipsilateral Horner syndrome.
  - May occur without evidence of cerebral ischemia, neck injuries, or operative procedures
- Cluster headaches
  - 20% have an ipsilateral Horner syndrome.

COMMONLY ASSOCIATED CONDITIONS
- Wallenberg syndrome
- Pancoast tumor
- C8 radiculopathy

DIAGNOSIS

HISTORY
- Symptoms presented from birth? Presentation is acute or progressive?
- Is there any associated headaches or double vision?
- Does the degree of ptosis vary over the course of the day or with fatigue?
- Ask questions regarding anhidrosis or hypohidrosis (difficult to appreciate by patients or clinicians):
  - Ipsilateral side of the body: suggests central lesion
  - Ipsilateral face: suggests preganglionic lesion
  - Medial portion of forehead and side of nose: suggests postganglionic lesion

Pediatric Considerations
In infants and children, loss of facial flushing is appreciated more than anhidrosis (harlequin sign).
ALERT
Horner syndrome in the presence of pain merits urgent evaluation and referral to the emergency room:

- Axial, shoulder, scapula, arm, or hand pain may be related to Pancoast tumor.
- Acute-onset, ipsilateral facial or neck pain: Consider carotid artery dissection until proven otherwise.
- Paratrigeminal syndromes:
  - Raeder paratrigeminal syndrome type I: orbital pain, miosis, ptosis, with associated ipsilateral lesions of CN III to VI; suspect middle cranial fossa mass lesion.
  - Raeder paratrigeminal syndrome type II: episodic retrobulbar or orbital pain, miosis, ptosis with no CN lesions; suspect migraine variant, syphilis, herpes zoster, hypertension.

PHYSICAL EXAM

- Measure pupillary diameter in dim and bright light and reactivity to light and accommodative response (1):
  - Anisocoria is greatest in dark, with affected pupil failing to dilate.
  - Redilation (after light is removed) may lag 15 to 20 seconds on the affected side.
- Examine the upper lids for ptosis (<2 mm).
- Miosis examine if associated with dilated lag
- Examination of the lower lids for “upside-down ptosis”: elevation of lower lid due to Müller muscle weakness
  - Illusion of enophthalmos secondary to narrowing of palpebral fissure
- Ipsilateral impaired flushing may be found.
- Loss of ciliospinal reflex. Pinching the skin on back of the neck normally produces ipsilateral pupil dilation (unreliable).
- Biomicroscopic exam of the papillary margin and iris structure and color
  - In congenital Horner syndrome, long-standing Horner syndrome, or Horner syndrome that occurs in children <2 years: Iris shows reduced pigmentation, blue-gray, and mottling of the affected eye (heterochromia iridis) because formation of iris pigment early in life is under sympathetic control.
- Observe for the presence of nystagmus, facial swelling, lymphadenopathy, or vesicular eruptions.
- Ophthalmoparesis, specifically CN VI palsy with Horner syndrome, is suggestive of cavernous sinus lesion.
Neurologic and chest exams for associated physical findings

DIFFERENTIAL DIAGNOSIS

- Physiologic anisocoria (15–30% population)
- Neurologic diseases versus neuromuscular junctional disease (myasthenia gravis, botulinum toxin)
- Myogenic disease (mitochondrial myopathy, myotonic dystrophy, pseudoptosis)
- 3rd nerve palsy
- Blepharoptosis
- Unilateral use of miotics
- Unilateral use of mydriatics
- Adie tonic pupil
- Iris sphincter muscle damage
- Pharmacologic causes

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

CBC, fluorescent treponemal antibody absorption test, venereal disease research laboratory, purified protein derivative; vanillylmandelic acid, homovanillic acid to rule out neuroblastoma in pediatric patients

- Chest x-ray if patient is a smoker (apical bronchogenic carcinoma)
- Computed tomography (CT)/magnetic resonance imaging (MRI), and/or angiography (MRA) of the brain, chest, and spinal cord
  - If painful, order MRI/MRA to evaluate for carotid artery dissection emergently.
- Ultrasound/duplex may be considered for evaluation of internal carotid artery.

Pediatric Considerations

In a child of any age without contributory history, MRI brain, neck, and chest to exclude a mass lesion (2)[B]

Diagnostic Procedures/Other

- When in doubt of Horner syndrome, confirmation test is required:
  - Topical 0.5% apraclonidine drops (3)[A],(4,5)[B]
  - 4–10% topical cocaine drops:
    - Used to confirm diagnosis of Horner syndrome when subtle symptoms but will not identify location of lesion
If the diagnosis is clear clinically, then confirmatory test is not required as it may interrupt with other test to localize lesions.

- Test interpretation:
  - A normal pupil will dilate. The miotic pupil in Horner syndrome (regardless of location of lesion) will not dilate or will dilate poorly after 45 minutes because of the absence of norepinephrine at the nerve endings of the third-order neuron (3)[A].
  - Positive test is anisocoria of ≥1 mm.

- Mechanism of action:
  - Cocaine blocks the reuptake of norepinephrine at the level of sympathetic neuron. It has no effect in impaired sympathetic innervation regardless of site of lesion.
  - Apraclonidine is a direct $\alpha$-adrenergic agonist, weak $\alpha$-1 (mediates pupil dilation in Horner pupils) with strong $\alpha$-2 receptor agonist (mediates pupil constriction in normal pupil).

- Test to localize level of the lesion:
  - Topical 1% hydroxyamphetamine drops (3)[A]
    - If there is a first- or second-order neuron lesion, dilation will take place.
    - Failure of the pupil to dilate, or poor dilation, indicates a third-order neuron lesion (positive when anisocoria increases by ≥1 mm).
    - No pharmacologic test exists to differentiate between a first- and second-order neuron lesion.
    - Hydroxyamphetamine causes release of endogenous norepinephrine stored in the postganglionic neuron.
    - Alternative test: 1% topical pholedrine drops

- Must wait 24 to 72 hours between the cocaine and hydroxyamphetamine tests

**Pediatric Considerations**

Due to transsynaptic degeneration in children, the hydroxyamphetamine test is not reliable.

**Test Interpretation**

- Brainstem lesion
- Massive hemisphere lesion
- Cervical cord lesion
- Root lesion
- Sympathetic chain lesion
TREATMENT

GENERAL MEASURES
- Horner syndrome itself does not produce any disability or necessarily require treatment.
- Treat the underlying etiology.
- Search for a tumor or other compressive lesion.

MEDICATION
Carotid artery dissection: Pharmacologic treatment options include thrombolysis, antithrombotic therapy with anticoagulation, or antiplatelet therapy. No randomized control trials have compared these treatment options (6)[C].

ISSUES FOR REFERRAL
- Neurologic, neuro-ophthalmic, oculoplastic
- Neurologic or vascular surgery: interventional in cases of suspected carotid artery dissection or aneurysm
- Neurosurgery, surgical oncology, oncology, or radiotherapy consultation depends on the particular etiology.

SURGERY/OTHER PROCEDURES
- Surgical care depends on etiology.
- Consider ptosis repair surgery (oculoplastics).

ONGOING CARE

PROGNOSIS
- Postganglionic: usually benign
- Central and preganglionic: poorer prognosis

COMPLICATIONS
- Chronic pupillary constriction
- Cosmesis

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- G90.2 Horner’s syndrome
- S14.5XXA Injury of cervical sympathetic nerves, initial encounter

mebooksfree.com
CLINICAL PEARLS

- Horner syndrome triad: ipsilateral miosis, eyelid ptosis, and anhidrosis caused by a lesion of the oculosympathetic pathway
- Horner syndrome in the presence of acute-onset, ipsilateral facial or neck pain: Consider carotid artery dissection until proven otherwise.
- Ptosis is mild, usually <2 mm.
- Red flags: If associated with pain, suspect central or preganglionic lesion.
- Confirm the diagnosis clinically with topical cocaine to the affected eye.
- Use hydroxyamphetamine to differentiate which order neuron is affected.
- Order imaging studies based on history and physical and hydroxyamphetamine testing.
HYDROCELE

Jared M. Patton, MD, MS • John E. Laird, MD, FAAFP

BASICS

DESCRIPTION
A collection of fluid between the parietal and visceral layers of the tunica vaginalis within the scrotum

- Communicating hydrocele (patent processus vaginalis)
  - Direct communication with the peritoneal cavity
  - Contains peritoneal fluid
  - Almost always with associated indirect inguinal hernia
  - Decreases in size with recumbent position

- Noncommunicating hydrocele (the processus vaginalis is not patent)
  - No direct connection to the peritoneal cavity
  - Fluid contained is from the mesothelial lining.
  - Can be isolated to the cord with the distal and proximal portions of the processus vaginalis closed

- Acute hydrocele: fluid collection resulting from an acute process within the tunica vaginalis, typically involving only the scrotum

- System(s) affected: urogenital

Pediatric Considerations
In a communicating hydrocele, consider contralateral inguinal exploration to rule out an occult indirect hernia.

EPIDEMIOLOGY
Predominant age: childhood

Incidence
Estimated at 0.7–4.7% of male infants

Prevalence
- 1,000/100,000
- Estimated at 1% of adult men
ETIOLOGY AND PATHOPHYSIOLOGY
- Incomplete closure of the processus vaginalis trapping peritoneal fluid anywhere along the length of the tunica vaginalis
- Failure of closure of the processus vaginalis maintaining a communication to the peritoneal cavity
- Imbalance of the secretion and reabsorption of fluid from the lining of the tunica vaginalis
- Infection
- Tumors
- Trauma
- Ipsilateral renal transplantation

RISK FACTORS
- Ventriculoperitoneal shunt
- Exstrophy of the bladder
- Cloacal exstrophy
- Ehlers-Danlos syndrome
- Peritoneal dialysis

COMMONLY ASSOCIATED CONDITIONS
- Testicular tumors
- Scrotal trauma
- Ventriculoperitoneal shunt
- Nephrotic syndrome
- Renal failure with peritoneal dialysis

DIAGNOSIS

HISTORY
- Acute, subacute, or chronic swelling of the scrotum or inguinal canal
- Frequent changes in size of the hydrocele with position change or activity (indicative of communicating)
- Usually painless unless acute onset
- Sensation of heaviness or pressure in the scrotum
- Pain radiating to the flank/back

PHYSICAL EXAM
Swelling in the scrotum or inguinal canal  
Scrotal mass, usually fluctuant  
Fluctuation in size with change of position (communicating hydrocele)  
Scrotal mass that transilluminates

**DIFFERENTIAL DIAGNOSIS**
- Indirect inguinal hernia  
- Orchitis  
- Epididymitis  
- Varicocele  
- Traumatic testicular injury  
- Testicular torsion or torsion of appendix testes  
- Testicular neoplasm

**DIAGNOSTIC TESTS & INTERPRETATION**
- Inguinoscrotal ultrasound (US): can demonstrate the presence of bowel (e.g., distinguish incarcerated hernia from a hydrocele of the cord) as well as the presence of testicular torsion  
- Testicular MRI when US is unable to distinguish etiology  
- Doppler US or testicular nuclear scan can distinguish testicular torsion.

**Diagnostic Procedures/Other**

**ALERT**  
Aspiration of a hydrocele for diagnosis is not indicated and may lead to severe complications if herniated bowel is present.

**Test Interpretation**  
Patent processus vaginalis on imaging in communicating hydroceles

**TREATMENT**

**ISSUES FOR REFERRAL**  
- Urology referral for symptomatic adults or if underlying diagnosis is unclear  
- Pediatric urology/surgery referral for children with symptomatic noncommunicating hydrocele  
- Children with communicating hydroceles can be expectantly managed until at
least 2 years of age to allow time for spontaneous resolution unless there is a concern for inguinal hernia (1)[C].

- New onset hydrocele in late childhood and preadolescent patients typically resembles the adult type hydrocele pathology (2)[B].

**SURGERY/OTHER PROCEDURES**

- Children: Surgical treatment is generally deferred until 2 years of age as many hydroceles will spontaneously resolve. Some evidence shows that delaying longer than 2 years may be appropriate and decreases unnecessary surgery (1)[C].
  - When surgery is indicated, children with communicating hydroceles may undergo either open or laparoscopic approach.
    - Open inguinal approach involves ligation of the processus vaginalis and excision, distal splitting, or drainage of hydrocele sac (in a hydrocele of cord, the sac can be completely removed).
    - Open scrotal approach involves ligation and removal of the processus vaginalis. The benefit of this approach is improved cosmesis and decreased operative time (3)[B].
  - Laparoscopic repair offers the benefit of contralateral exploration.

- Adults: No therapy is needed unless the hydrocele causes discomfort or unless there is a significant underlying cause such as a tumor.
  - If resection is indicated, a scrotal approach with resection of hydrocele sac has the highest complication rate but lowest recurrence rate (4)[C].
  - Aspiration of the hydrocele with instillation of a sclerosing agent has been successfully used in adults (5)[A].
  - Hydrocelectomy may be performed endoscopically via a transscrotal approach; it involves cauterization of the entire parietal surface of the tunica vaginalis.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Open inguinal or scrotal approach is typically performed as an outpatient.
- Laparoscopic approach may require 24-hour admission for postoperative monitoring.
- Sclerotherapy is a same-day office procedure.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Depending on method of treatment, initial follow-up is generally in the first 4 to 6 weeks.
- With sclerotherapy follow-up for confirmation of resolution or to proceed with retreatment
- Postoperative follow-up at 2 to 4 weeks and subsequent 2- to 3-month intervals until resolution of any postoperative complications

COMPLICATIONS

- Complication rate for a scrotal approach may reach 30%.
- Postoperative traumatic hydrocele is common and usually resolves spontaneously.
- Injury to vas deferens or spermatic vessels
- Suture granuloma
- Hematoma
- Wound infection
- Recurrence

REFERENCES

CODES

ICD10
- N43.3 Hydrocele, unspecified
- N43.2 Other hydrocele
- P83.5 Congenital hydrocele

CLINICAL PEARLS
- A hydrocele can usually be diagnosed by physical exam and transillumination. If there is any concern for other underlying process, a formal US is recommended.
- Aspirating a hydrocele is not indicated as the primary treatment due to high recurrence rate.
- Attempted aspiration of an unconfirmed hydrocele could lead to bowel injury in an undiagnosed inguinal hernia.
- Laparoscopic repair in children offers the benefit of contralateral exploration and repair.
- Expectant management of children with hydrocele until >2 years of age is acceptable to allow sufficient time for spontaneous resolution.
HYDROCEPHALUS, NORMAL PRESSURE

Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION

- Normal pressure hydrocephalus (NPH) is a clinical triad of gait instability, incontinence, and dementia (mnemonic: wet, wobbly, wacky); originally described by Hakim in 1957
- Two forms of the disorder: idiopathic and obstructive (the latter usually due to physical insult—posttrauma, meningitis, or subarachnoid hemorrhage)
- Absence of papilledema on clinical exam and normal CSF pressures at lumbar puncture

ALERT

Idiopathic NPH (iNPH) primarily affects persons >60 years; extremely rare before 40 years

EPIDEMIOLOGY

Incidence

- Varies from 1.1–5.5% in various surrogate analysis of shunt data. Arriving at accurate data is hampered by uncertain diagnosis.
- iNPH form primarily affects elderly, at least >40 years of age.
- Secondary form can occur at any age.
- Male = female

Prevalence

- Ranges from 0.2% in the 70 to 79 years age group and increases to 5.9% in those 80 years and older. It is estimated that approximately 700,000 are affected in the United States (compared with 400,000 with MS) (1).
- Estimated to be a contributing factor in 6% of all cases of dementia

ETIOLOGY AND PATHOPHYSIOLOGY

- Idiopathic form is a communicating hydrocephalus, a disorder of decreased CSF absorption (not overproduction). In iNPH, the leading theory suggests that poor venous compliance impairs the subarachnoid granulations’ ability to...
maintain baseline removal of CSF. In secondary NPH, scarring is likely.

- The result is a pressure gradient between the subarachnoid space and ventricular system.
- CSF production decreases in the face of an increased pressure set point (but still in excess of the amount of CSF absorbed).
- Elevated pressure distends ventricles and compresses the brain parenchyma.
- As a result of compression, ischemic changes occur in the parenchymal vasculature with subsequent tissue damage and loss.
- Some believe that the idiopathic form is a result of persistently insufficient removal of CSF by immature subarachnoid granulations from childhood.
- Secondary NPH may result from the following:
  - Head trauma (most common)
  - Subarachnoid hemorrhage
  - Resolved acute meningitis
  - Chronic meningitis (tuberculosis, syphilis)
  - Paget disease of the skull

RISK FACTORS

- Idiopathic risk is unknown (case reports suggest a possible genetic link but unsubstantiated).
- Secondary form is due to head trauma, subarachnoid hemorrhage, meningitis, or encephalitis.

DIAGNOSIS

Detailed history and careful examination is the key to early diagnosis.

HISTORY

- Insidious and usually progressive; gait instability usually manifests initially, followed by changes in mentation, and eventually, urinary incontinence.
- Behavioral changes noted in many cases: Depression, mania, and psychotic features in many cases precede the physical findings and respond poorly to usual treatment (1).
- Difficulty with initiation of movement: Feet appear “glued to the floor.” Gait is wide-based, shuffling, and turning appears “en bloc.”
- Inattention, forgetfulness, and lack of spontaneity often are seen with the subcortical dementia of NPH.
- Urinary urgency initially, followed by lack of inhibition and then frank
● incontinence
● A minimum duration of at least 3 to 6 months of symptoms and progression over time
● A remote trauma or infection suggests secondary versus the idiopathic form.
● A lack of psychiatric, neurologic, or other medical conditions to explain the symptoms (including structural reasons for CSF flow restriction) (2)
● Because memory impairment may be present, it is important to include a knowledgeable informant who is familiar with the patient’s premorbid state.
● Frontal lobe function is affected disproportionately to the memory impairment (objective testing may lead to an early diagnosis).

PHYSICAL EXAM
● Decreased step height and length
● Reduced speed of walking (cadence)
● Widened standing base
● Swaying of trunk during walking
● Decreased fine motor speed and accuracy
● Recall impaired for recent events
● Impaired ability to do multistep tasks or interpret abstractions

DIFFERENTIAL DIAGNOSIS
● Alzheimer disease (may be a comorbid condition in as many as 75%)
● Parkinson disease
● Chronic alcoholism
● Intracranial infection
● Multi-infarct dementia
● Subdural hematoma
● Carcinomatous meningitis
● Collagen vascular disorders
● Depression
● Syphilis
● B₁₂ deficiency
● Urologic disorders
● Other hydrocephalus disorders

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
● Thyroid-stimulating hormone (TSH)
- Syphilis serology
- CBC
- Serum B<sub>12</sub>, folate
- Metabolic profile
- Blood alcohol, analysis for drugs of abuse
- Urinalysis
- CSF analysis, including an opening pressure <245 mm H<sub>2</sub>O (a value greater than this rules out iNPH by definition)
- Imaging is essential.
- Either CT or MRI (preferred imaging study) shows the ventriculomegaly (particularly lateral and 3rd ventricles) with preservation of the cerebral parenchyma (as opposed to ventricular enlargement seen in other forms of dementia where brain atrophy is present). A narrow subarachnoid space (“tight convexity”) was recently shown to correlate to probable or definite iNPH (3)[A].
- MRI can allow detection of other features, such as signs of altered brain water content and callosal angles. However, these supportive findings are not independently diagnostic of NPH.

**Diagnostic Procedures/Other**

CSF removal aids in the definitive diagnosis as well as predicting response to surgical treatment.

- High-volume (30 to 70 mL) CSF removal via spinal tap (“tap test”)
- Comparison of gait analysis before and after CSF removal should be performed within 24 hours (a ≥20% improvement indicates a positive test) especially when combined with coexisting executive function improvement. Testing should be done with a quantifiable gait scale (Berg Balance Scale, Timed Get UP and Go Test, etc.) (4)[B].

**TREATMENT**

**MEDICATION**

- No medication is significantly helpful.
- Use of carbonic anhydrase inhibitors (acetazolamide) with repeat lumbar punctures has provided mild and transient relief but is only supported by anecdotal evidence.
- Use of levodopa to rule out Parkinson disease may be helpful (NPH will
display little, if any, significant improvement to dopamine agonist).

**ISSUES FOR REFERRAL**
- Neurology or neurosurgical consultation is helpful in suspected cases when other reversible medical conditions are ruled out.
- Recent cohort studies have demonstrated clinical improvement after surgical shunts. Perimeters of urinary continence, gait stability, and cognitive scores all improved at 1 year postshunt.

**ADDITIONAL THERAPIES**
Gait training and use of ambulation assist devices, as indicated, but limited efficacy

**SURGERY/OTHER PROCEDURES**
- Current therapy is limited to placement of ventricle-peritoneal or ventricle-atrial shunt from a lateral ventricle tunneled SC and drained into the peritoneal cavity (or right atrium). Recent work demonstrated that use of a lumbar-peritoneal shunt to be noninferior is technically easier and associated with less complications.
- Patients whose symptoms have been present for a shorter period (<2 years) have a greater chance of improvement with shunting. Age has not been shown to negatively affect response to shunting. Improvement has been seen in patients with symptoms present for many years and previously undiagnosed (5)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Usually only for planned surgical treatment

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Assessment and modification of environment for fall risks
- Evaluation for ability to operate a motor vehicle safely (if driving)

*Patient Monitoring*
Repeat neuropsychological testing to evaluate the status of the dementia after treatment.

Improvement in the incontinence and walking speed can also be objectively measured.

PATIENT EDUCATION

Information at: http://www.ninds.nih.gov/disorders/normal_pressure_hydrocephalus/normal_pres

PROGNOSIS

Natural history is progressive deterioration. Patient’s axial skeletal stability worsens with inability to walk, stand, sit, or turn over in bed.

COMPLICATIONS

- In patients treated surgically, cerebral infarcts, hemorrhage, infection, and seizures (in addition to the usual surgical risks): all usual age-related illnesses (as NPH is a condition affecting those age >65 years)
- Shunt malfunction (especially when symptoms recur after successful shunt placement)
- Falls due to gait instability
- UTIs
- Skin breakdown, pressure ulcers, infections as movement dysfunction progresses

CODES

ICD10

- G91.2 (Idiopathic) normal pressure hydrocephalus
- G91.0 Communicating hydrocephalus

CLINICAL PEARLS

- Consider in unexplained dementia or behavioral change.
- Poor prognosis without therapy
HYDRONEPHROSIS
Rohanjit S. Sidhu, MD • Pang-Yen Fan, MD

BASICS
DESCRIPTION
- Hydronephrosis refers to a structural finding—dilatation of the renal calyces and pelvis.
  - May occur with urinary tract infection (UTI), vesicoureteric reflux (VUR), high urine output, or physiologic changes in pregnancy
  - Sometimes accompanied with hydroureter
  - Presentation varies from incidental finding to discovery during workup for UTI or for flank or abdominal pain.
- Hydronephrosis should not be used interchangeably with obstructive uropathy, which refers to the damage to renal parenchyma resulting from urinary tract obstruction (UTO).

EPIDEMIOLOGY
- UTO is more common in men than women and in children than adults (congenital anomalies).
- Acute unilateral obstruction is more common than bilateral.

ETIOLOGY AND PATHOPHYSIOLOGY
- Hydronephrosis develops with increased pressure in the urinary collecting system.
- Increased pressure within the renal collecting system can cause calyceal fornix rupture and urinary extravasation.
- Over time, pressures return to normal, but kidney function declines from intense renal vasoconstriction.
- With concomitant urinary infection, bacteria can enter the renal vasculature, resulting in sepsis.
- UTO: may be acute/chronic, partial/complete, uni-/bilateral
  - Intraluminal obstruction: calculi, sloughed renal papillae, blood clot, fungal ball
  - Intrinsic abnormality of the urinary collecting system: transitional cell carcinomas, benign prostatic hypertrophy, prostate cancer, congenital
ureteropelvic junction (UPJ) obstruction, ureterocele, neurogenic bladder (functional obstruction), urethral stricture or tuberculosis (TB) (can cause ureteral narrowing)

- Extrinsic compression of the urinary collecting system: extraaurinary malignancy (lymphoma, colon, cervix), aortic/iliac aneurysm, retroperitoneal fibrosis, uterine prolapse (15% affected), endometriosis, ovarian vein syndrome, IgG4-related disease
- Transplant hydronephrosis: Consider BK virus.

- UTO in transplanted kidneys is more common than native kidneys, specifically in immediate posttransplant period. It is due to ureteral strictures, lymphoceles (ureteral compression and bladder dysfunction).
- VUR resulting in varying degrees of hydroureteronephrosis
- Physiologic hydronephrosis of pregnancy
- Hydronephrosis due to high urine output (e.g., diabetes insipidus, psychogenic polydipsia)
- Hydronephrosis of infection: due to bacterial toxins inhibiting smooth muscle contraction of the renal pelvis and ureter

**Pediatric Considerations**

- Antenatal hydronephrosis is diagnosed in 1–5% of pregnancies, usually by US, as early as the 12th to 14th week of gestation.
- Children with antenatal hydronephrosis are at greater risk of postnatal pathology.
- Postnatal evaluation begins with US exam; further studies, such as voiding cystourethrogram (VCUG), based on the severity of postnatal hydronephrosis
- In neonates, it is the most common cause of abdominal mass.
- Common etiologies in children are VUR, congenital UPJ obstruction, neurogenic bladder, and posterior urethral valves.
- Pediatric diagnostic algorithm differs from adult due to different differential diagnosis necessitating age-appropriate testing.

**Pregnancy Considerations**

- Physiologic hydronephrosis in pregnancy is more prominent on the right than left and can be seen in up to 80% of pregnant women.
- Dilatation is caused by hormonal effects, external compression from expanding uterus, and intrinsic changes in the ureteral wall.
- Despite high incidence, most cases are asymptomatic.
- If symptomatic and refractory to medical management, ureteric calculus should be considered and urinary infection must be excluded.
DIAGNOSIS

Symptoms vary according to cause, chronicity, location, and degree of obstruction.

HISTORY

- Although often asymptomatic, hydronephrosis can be associated with pain ranging from vague, intermittent discomfort to severe renal colic.
- Nausea and vomiting may be associated with severe pain or infection.
- Fever, chills with coexisting infection
- Polyuria may occur due to impaired urinary concentration in partial obstruction, postobstructive diuresis.
- Anuria, if complete bilateral obstruction or complete obstruction of a solitary kidney
- Symptoms of chronic kidney disease (CKD): anorexia, malaise, weight gain, edema, shortness of breath, mental state changes, tremors from long-standing bilateral obstruction
- Dietl crisis: sudden attack of flank pain due to distension of renal pelvis caused by rapid ingestion of large amount of liquid or kinking of a ureter, producing temporary occlusion of urine flow
- Symptoms of bladder outlet obstruction: weak urine stream, nocturia, straining to void, overflow incontinence, urgency, and frequency
- General medical and surgical history: malignancy (extrinsic compression), radiotherapy (ureteric stricture/fibrosis), surgery (iatrogenic obstruction), trauma (hematoma or fibrosis), gynecologic disease (endometriosis, ovarian masses, uterine prolapse), smoking (urothelial cancer), drugs (methysergide-induced retroperitoneal fibrosis)

PHYSICAL EXAM

- General signs
  - Volume overload (edema, rales, hypertension [HTN]) from renal failure
  - Diaphoresis, tachycardia, tachypnea with pain
  - High-grade fever, if infection
- Abdominal exam: CVA tenderness, palpable bladder, rarely palpable abdominal mass (may be visible, particularly in thin children)
- Pelvic exam: pelvic mass, uterine prolapse, palpable enlarged prostate (cancer or benign), urethral meatal stenosis, phimosis
DIAGNOSTIC TESTS & INTERPRETATION

- Urinalysis with microscopy: hematuria, proteinuria, crystalluria, pyuria
- Midstream urine culture and sensitivity: Exclude UTI.
- Basic metabolic panel: Elevated urea and creatinine may indicate obstructive uropathy. Hyperkalemic nonanion gap metabolic acidosis may indicate type 4 distal RTA due to obstruction.
- CBC: Anemia of CKD, leukocytosis; if infection, check platelet count prior to considering ureteral instrumentation.
- Prostate-specific antigen (PSA): adult males age >50 years or with abnormal digital rectal exam or bladder outlet obstruction signs or symptoms
- Urine cytology: for malignant cells in urothelial malignancies
- US and noncontrast CT scanning are effective in diagnosing presence and cause of obstruction in most cases.
- US: screening test of choice for hydronephrosis
  - Sensitivity 90%, specificity 84.5% compared with IVU. Does not assess function and rarely detects cause and level of obstruction. Degree of hydronephrosis does not correlate with duration or severity of the obstruction.
  - Advantages: detects renal parenchymal disease (decreased renal size, increased cortical echogenicity, cortical thinning, cysts); no exposure to radiation or contrast; safe in pregnancy, contrast allergy, and renal dysfunction
  - False-positive findings 15.5% (for UTO): normal extrarenal pelvis, parapelvic cysts, VUR, excessive diuresis
  - False-negative findings 10%: dehydration, acute obstruction, calyceal dilatation misinterpreted as renal cortical cysts, and retroperitoneal fibrosis
- Noncontrast helical CT (NHCT): test of choice for suspected nephrolithiasis
  - Reported sensitivity 94–96%, specificity 94–100%. Stone is most commonly found at levels of ureteric luminal narrowing: UPJ, pelvic brim, and the vesicoureteric junction.
  - Typical findings in acute obstruction are hydronephrosis with hydroureter proximal to the level of obstruction, perinephric stranding, and renal swelling. If chronic, renal atrophy may be noted.
  - Advantages: no contrast exposure, time-saving, cost-effective, identifies extraurinary pathology
  - Disadvantages: does not assess function or degree of obstruction; higher radiation exposure, although low radiation dose protocols have shown comparable accuracy
- DTPA or MAG-3 radionuclide renal scan (diuretic renal scintigraphy)
  - Indicated only for evaluation of hydronephrosis without apparent obstruction
  - Determines presence of true obstruction as well as total and split (right vs. left) renal function
  - Furosemide is given 20 minutes after the tracer and the T1/2 for the tracer’s washout is measured. T1/2; <10 minutes is unobstructed, >20 minutes is obstructed, and 10 to 20 minutes is equivocal; some experts consider <15 minutes normal.
  - Advantages: no contrast exposure, safe in contrast allergy and renal dysfunction
  - False-positive findings: delayed excretion due to renal failure, massive dilatation causing a water-reservoir effect of delayed excretion without obstruction
  - False-negative findings: dehydration or inadequate diuretic challenge
- Multiphase contrast-enhanced CT
  - Nonenhanced phase detects stones and swelling.
  - Parenchymal phase demonstrates decreased enhancement of renal parenchyma with acute obstruction; can identify extraurinary causes of obstruction and determine the relative glomerular filtration rate (GFR) of each kidney with accuracy equal to radionuclide renal scan
  - Delayed phase allows visualization of the collecting system and soft tissue filling defects (e.g., urothelial cancer).
- Magnetic resonance urography (MRU): indicated when US and NHCT are nondiagnostic
  - Provides anatomic, functional, and prognostic information; sensitivity not superior to US or NHCT for nephrolithiasis (70%) but superior for soft tissue causes including strictures
  - Advantages: no radiation exposure, safe in young children and pregnant women
  - Disadvantages: more expensive and time-consuming (35 minutes vs. 5 minutes) and less available compared with CT. Gadolinium is contraindicated in renal failure especially when GFR is <30 mL/min due to risk of nephrogenic systemic fibrosis.

**Diagnostic Procedures/Other**
Cystoscopy, retrograde pyelogram ± ureteroscopy, and biopsy are occasionally used to determine the cause of obstruction (e.g., small urothelial cancer missed on imaging) or to confirm a normal distal ureter prior to pyeloplasty. In addition,
such procedures are often needed to establish a definitive pathologic diagnosis for mass lesions.

**TREATMENT**

**GENERAL MEASURES**
- Medical treatment: correction of fluid and electrolyte abnormalities, pain control, antibiotics as an adjunct to drainage if infection present
- Relief of obstruction: prompt drainage indicated in the presence of UTI, compromised renal function, or uncontrollable/persistent pain
  - Bladder outlet obstruction: urethral or suprapubic catheter
  - Ureteric obstruction: retrograde (cystoscopic) or antegrade (percutaneous) stenting (2)
- VUR is often managed conservatively with antibiotics; surgical management required in severe cases in children or women of childbearing age
- Medical expulsive therapy (MET) with α-blockers or calcium channel blockers indicated for urethral stones <10 mm in patients with controlled pain, no signs of sepsis, with good renal function (3)[C]

**SURGERY/OTHER PROCEDURES**
- Hydronephrosis due to obstruction
  - Congenital UPJ obstruction: Pyeloplasty (open or laparoscopic) and minimally invasive stricture incision (endopyelotomy) are used with comparable results.
  - Nephrolithiasis: Extracorporeal shock wave lithotripsy (ESWL) is the initial treatment of choice for management of impacted upper urethral stones ≤2 cm. Ureteroscopy with or without intracorporeal lithotripsy has lower retreatment but higher complication rates and longer hospital stay; ureteral stenting pre-ESWL or postureteroscopy associated with no additional benefit and more discomfort and morbidity (4)[A]
  - Transitional cell cancer: nephroureterectomy
  - Idiopathic retroperitoneal fibrosis: ureterolysis (frees ureters from inflammatory mass)
  - Prostate disorders: various treatment modalities, including transurethral resection of the prostate (TURP) and radical prostatectomy
- Nonobstructed hydronephrosis
  - VUR: ureteric reimplantation, endoscopic suburethral injection
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Obstruction coexisting with infection (pyonephrosis) is a true urologic emergency requiring urgent drainage. Typically, this requires placement of percutaneous nephrostomy tube(s), as retrograde (cystoscopic) stenting is often difficult, but both are equally effective.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Serial monitoring of kidney function (electrolytes, BUN, and creatinine) and BP until renal function stabilizes. Frequency of monitoring depends on severity of renal dysfunction.
- Follow-up US after stabilization of renal function to assess for resolution of hydronephrosis. If hydronephrosis persists, consider diuretic radionuclide study to rule out persistent obstruction.

PROGNOSIS
- Recovery of renal function depends on etiology, presence or absence of UTI, and degree and duration of obstruction.
- Significant recovery can occur despite days of complete obstruction, although some irreversible injury may develop within 24 hours. Delays in therapy can lead to irreversible renal damage (5).
- Diagnostic testing is of poor predictive value. Course of incomplete obstruction is highly unpredictable.

COMPLICATIONS
- Urine stasis: increased risk of infection and stones formation
- Obstruction causes progressive atrophy of kidney with irreversible loss of function.
- Spontaneous rupture of a calyx may occur with urine extravasation in the perinephric space.
- Postobstructive diuresis: marked polyuria after relief of obstruction:
  – Caused mostly by fluid and solute overload but may be exacerbated by impaired renal tubular concentrating ability. Urine output may be >500 mL/hr.
Replace urine losses with hypotonic fluid (usually with 0.45% NaCl) and only enough to avoid volume depletion. Replacement of urine output with equal amounts of saline will perpetuate the diuresis.

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- N13.30 Unspecified hydronephrosis
- N13.39 Other hydronephrosis
- Q62.0 Congenital hydronephrosis

**CLINICAL PEARLS**
US and noncontrast CT identify most causes of hydronephrosis.
Relief of obstruction, when present, is the primary treatment.
HYPERCHOLESTEROLEMIA

Elizabeth Kardas, MD • Jeremy Golding, MD, FAAFP

BASICS

DESCRIPTION

- High cholesterol is a significant risk factor for atherosclerotic cardiovascular disease (ASCVD).
- Lipoprotein subtypes:
  - Low-density lipoproteins (LDL): atherogenic; primary target of therapy
  - High-density lipoproteins (HDL): atheroprotective
  - Triglycerides (TG)
- System(s) affected: cardiovascular (CV)

EPIDEMIOLOGY

Age: increases with age

Prevalence

27.9% of men and 27.5% of women in the United States with total cholesterol (TC) >240 mg/dL

ETIOLOGY AND PATHOPHYSIOLOGY

- Pathophysiology
  - Deposition of cholesterol in vascular walls creates fatty streaks which become fibrous plaques.
  - Inflammation causes plaque instability, leading to plaque rupture.
- Etiology
  - Primary: genetic causes (familial dyslipidemia)
  - Secondary: obesity, diet, excessive alcohol intake, hypothyroidism, diabetes, nephrotic syndrome, liver disease, chronic renal failure, medications (thiazide diuretics, carbamazepine, cyclosporine, progestins, anabolic steroids, corticosteroids, protease inhibitors)

Genetics

- Familial hypercholesterolemia (FH)
  - Elevated LDL levels from birth
– Prevalence = 1:500 in the United States
– Predisposed to atherosclerotic disease in early adulthood and high coronary heart disease (CHD) risk in 40s to 50s
– Tendon xanthomas on Achilles and extensor tendons of hands are common.
– Early lipid-lowering drug therapy shown to reduce ASCVD risk.

**Early cholesterol testing of first-degree relatives is beneficial.**

**RISK FACTORS**

Obesity (BMI >30 kg/m²), physical inactivity, heredity, cigarette smoking, excessive alcohol use. Unclear relationship between diet rich in saturated fat and hypercholesterolemia. The relationship of diet to disease is very complex and is not explained by how much cholesterol is present in an individual’s diet. Eggs and whole fat dairy sources are likely *not* significant contributors to atherosclerosis.

**GENERAL PREVENTION**

- Regular physical activity
- Weight control (see “Ongoing Care”)

**COMMONLY ASSOCIATED CONDITIONS**

Hypertension, diabetes mellitus (DM), obesity

**DIAGNOSIS**

Screening recommendations:

- U.S. Preventive Services Task Force (USPSTF) (1)[A]: TC and HDL cholesterol (HDL-C) every 5 years
  - All men age ≥35 years
  - Men aged 20 to 35 years and women aged 20 to 45 years if at increased risk for ASCVD
  - Women 45 ≥years if at increased risk for ASCVD (diabetes, atherosclerosis, FH of premature CAD, tobacco use, hypertension, obesity)
- American Diabetic Association: yearly dyslipidemia screening for patients with diabetes

**Pediatric Considerations**

- National Heart, Lung, and Blood Institute (NHLBI): Recommend lipids
screening on all children between 9 and 11 years. This recommendation and American Academy of Pediatrics recommendation remain controversial because of absence of data showing improved outcomes, and concern about potential harms. Selective screening of children with FH is not controversial.

- USPSTF: Review showed insufficient evidence to recommend for or against screening in those ≤20 years.

HISTORY
- Review possible secondary etiologies.
- Review medications which may alter lipid levels.
- Assess other ASCVD risk factors.

PHYSICAL EXAM
Nonspecific findings; may calculate BMI and examine for xanthomas

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Lipid panel (fasting labs do not significantly affect lab values): TC, LDL, HDL, TG: LDL is usually a calculated value and is accurate if TG <350 mg/dL.
- If elevated LDL or other form of hyperlipidemia, repeat test and conduct clinical/laboratory assessment before initiating lipid-lowering therapy: ALT, diabetes screening
- Consider genetic etiology in very high LDL (>190 mg/dL).

TREATMENT

ALERT
2013 American College of Cardiology/American Heart Association (ACC/AHA) cholesterol guidelines no longer recommend treatment to an LDL goal. ACC/AHA, NICE, and USPSTF guidelines recommend statin therapy based on patients’ risk of an ASCVD event. Efficacy of statin medication for reduction in myocardial infarction and death is likely due to mechanisms other than cholesterol-lowering alone. Risk stratifying patients should be reserved for primary prevention as patients with established cardiovascular disease should be considered high risk (secondary prevention).
- United States: ACC/AHA cholesterol guidelines (2)[C]
  - Four groups benefit from statin therapy:
    - Clinical ASCVD
      - <75 years old: high-intensity statin
      - >75 years old or not candidate for high-intensity statin: moderate-intensity statin
    - Primary elevation of LDL-C >190 mg/dL: high-intensity statin
    - Diabetics (type 1 or 2) ages 40 to 75 years with LDL-C 70 to 189 mg/dL:
      - 10-year ASCVD risk <7.5%: moderate-intensity statin
      - 10-year ASCVD risk >7.5%: high-intensity statin
    - Without above but estimated 10-year ASCVD risk >7.5% based on Pooled Cohort Equations http://tools.acc.org/ASCVD-Risk-Estimator/: moderate- to high-intensity statin
  - Definition of clinical ASCVD:
    - Acute coronary syndrome or history of MI
    - Stable or unstable angina
    - Coronary or other arterial revascularization
    - Stroke or TIA
    - Peripheral arterial disease
  - Significant controversy over threshold calculated risk with which to treat patients:
    - Concern that Pooled Cohort Equations significantly overestimate ASCVD risk
    - Concern for significant overtreatment: one study shows 96% of men and 66% of women >55 years of age on statins based on recommendations
  - Many more patients treated and medications used in the United States than elsewhere in the world without substantial evidence for improved outcomes
- United Kingdom: National Institute for Health and Care Excellence (NICE) cholesterol guidelines (3)[C]
  - 10-year risk to be calculated using QRISK2: http://www.qrisk.org/
  - If 10-year risk of CVD >10% and no history of CVD, startatorvastatin 20 mg.
  - If 10-year risk of CVD >10% in presence of known CVD, startatorvastatin 80 mg.
  - If eGFR <60 or type 1 diabetes, startatorvastatin 20 mg regardless of risk.
  - Check nonfasting lipid panel before treatment initiation and at 3 months of treatment: goal reduction of 40% in non–HDL-C
- US Veterans Administration 2014 Guideline advises moderate-dose statin for 10-year CVD risk >12%, or LDL-C ≥190, or DM with HTN or smoking.
European: European Society of Cardiology/European Atherosclerosis Society (ESC/EAS) cholesterol guidelines (4)[C]
  – Risk stratification to low, moderate, high, and very high risk based on SCORE charts
  – High- and very high-risk patients should be offered drug therapy.

**ALERT**
Elevated serum TG

- If >500, TG lowering becomes primary target until TG <500 to prevent acute pancreatitis, although statin therapy is usually recommended as treatment unless TG’s remain >500 after statin added. Fibrates may be used cautiously with statins (increased risk of rhabdomyolysis).

**MEDICATION**
- Therapeutic lifestyle changes are cornerstone therapies to be attempted before drug therapy (diet and regular exercise; see “Ongoing Care”).
- Check lipid panel 4 to 12 weeks after starting medication to evaluate response/compliance.
  - High-intensity statin: should lower LDL-C >50%
  - Moderate-intensity statin: should lower LDL-C 30–50%
  - Subsequent monitoring not indicating unless question of patient adherence

**First Line**
HMG-CoA reductase inhibitors (statins)
- Categorized based on intensity
  - High intensity
    - Atorvastatin 40 to 80 mg/day
    - Rosuvastatin 20 to 40 mg/day
  - Moderate intensity
    - Atorvastatin 10 to 20 mg/day
    - Rosuvastatin 5 to 10 mg/day
    - Simvastatin 20 to 40 mg/day
    - Pravastatin 40 to 80 mg/day
  - Moderate intensity
    - Lovastatin 40 mg/day
    - Fluvastatin XL 80 mg/day
    - Fluvastatin 40 mg BID
    - Pitavastatin 2 to 4 mg/day
  - Low intensity
Simvastatin 10 mg/day
Pravastatin 10 to 20 mg/day
Lovastatin 20 mg/day
Fluvastatin 20 to 40 mg/day
Pitavastatin 1 mg/day

- To be taken in the evening or at bedtime for best effect as majority of cholesterol synthesis appears to occur at night.
- Effect is greatest in lowering LDL-C; shown to decrease CHD incidence and all-cause mortality (1), although number needed to treat may be high in primary prevention.
- Contraindications: pregnancy, lactation, or active liver disease
- Drug interactions: cyclosporine, macrolide antibiotics, various antifungal agents, HIV protease inhibitors, fibrates/nicotinic acid (to be used with caution)
- Adverse reactions:
  - Mild myalgia is common.
  - Liver transaminase elevations: ALT before therapy to establish baseline; if ALT >3 times upper limit of normal, do not start statin; routine monitoring is not recommended.
  - Association with increased cases of diabetes: 0.1 excess cases of diabetes per 100 persons on moderate-intensity statin and 0.3 excess cases per 100 persons on high-intensity statin
  - Myopathies (considered rare but not well studied):
    -Creatine kinase (CK) baseline reasonable for those at increased risk for adverse muscle events; routine monitoring not recommended
    -Instruct patients to report new onset myalgias or weakness.
    -If myopathy or rhabdomyolysis is suspected, discontinue statin and draw serum CK, creatinine, urine analysis.
    -Can rechallenge statin at lower dose or different type after resolution of symptoms.
  - Statin intolerance
    -Consider use of a different statin.
    -Dose reduction
    -Alternate day therapy

**ALERT**
FDA-alert: Simvastatin should no longer be prescribed at 80 mg/day doses due to increased risk of myopathy. Patients who have been at this drug dosage for >1 year can continue if no signs of myopathy. Dose restrictions to reduce
myopathy risk include the following:

- Do not exceed simvastatin 10 mg/day with amiodarone, verapamil, and diltiazem.
- Do not exceed simvastatin 20 mg/day with amlodipine and ranolazine.

**ALERT**
Avoid grapefruit juice with statins.

**Pregnancy Considerations**
- Statins contraindicated during pregnancy: class X
- Lactation: possibly unsafe

**Second Line**
- Second-line drugs are no longer recommended for primary prevention due to lack of evidence of improved patient outcomes, especially in patients already on statin therapy (2)[C]. However, for secondary prevention in high-risk patients, adjunctive therapy may be indicated to lower LDL even more.
- Ezetimibe
  - Can be taken by itself or in combination with a statin: monotherapy (10 mg/day) or ezetimibe/simvastatin (10/10, 10/20, 10/40)
  - Effect: lowers LDL-C; one recent RCT shows combination therapy with statin has small benefit in reducing CV events and CV-related mortality after acute coronary syndromes.
  - Adverse reactions: generally well tolerated
- Fibrates
  - Types: gemfibrozil 600 mg BID, fenofibrate
  - Effect: most effective in lowering TG with moderate effect in lowering LDL and raising HDL. More recent studies fail to show benefit in most patients.
  - Contraindications: severe hepatic or renal insufficiency
  - Possible interactions: potentiates effects of warfarin and oral hypoglycemic agents
  - Adverse reactions: GI complaints; increased likelihood of gallstones
- Nicotinic acid: raises HDL but no evidence for improved outcomes in recent trials and significant potential harms; should no longer be used in routine practice
- Bile acid sequestrant (e.g., cholestyramine) causes significant GI side effects, no evidence for improved outcomes, rarely used
• Proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitors (e.g., alirocumab, evolocumab)
  – Monoclonal antibody requiring SC injections every 2 to 4 weeks
  – Current evidence shows decreased incidence of CVD in secondary prevention without affecting incidence of all-cause mortality; active research ongoing
  – Very expensive and unclear role in therapy at this time

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

• Omega-3 fatty acids and fish oil intake:
  – Sources—fish oil (salmon), plants (flaxseed, canola oil, soybean oil, nuts)
  – Effect—mainly lowers TG level (dose dependent) but has some benefit in lowering LDL and raising HDL, although overall CV benefit and mortality reduction is uncertain.

• β-Sitosterols and red yeast rice (contains small amount of natural lovastatin-analogue) can reduce TC and LDL. However, there is significant variability across commercial preparations.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Exercise: sustained exercise for 30 minutes, 3 to 4 times per week: increases HDL, lowers TC, and helps control weight

**Patient Monitoring**

• Initially, lipid panel in 4 to 12 weeks after starting therapy; routine monitoring of LDL levels in patients on statin is not necessary.
• Routine monitoring of LFTs is no longer recommended if initial ALT is within normal range.

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Hypothyroidism, Adult

**CODES**

**ICD10**

E78.0 Pure hypercholesterolemia

**CLINICAL PEARLS**

- Hypercholesterolemia is a significant risk factor for ASCVD, but ASCVD is a multifactorial disease with many different risk factors.
- Diet and exercise should be tried before pharmaceutical interventions.
- Statins are considered first-line medications for hypercholesterolemia. Other medications show little evidence of benefit.
HYPEREMESIS GRAVIDARUM

Emma Brooks, MD

BASICS

DESCRIPTION

- Hyperemesis gravidarum is persistent vomiting in a pregnant woman that interferes with fluid and electrolyte balance as well as nutrition:
  - Usually associated with the first 8 to 20 weeks of pregnancy
  - Believed to have biomedical and behavioral aspects
  - Associated with high estrogen and human chorionic gonadotropin (hCG) levels
  - Symptoms usually begin ~2 weeks after first missed period.
- System(s) affected: endocrine/metabolic; gastrointestinal; reproductive
- Synonym(s): morning sickness

Pregnancy Considerations

Common condition during pregnancy, typically in the 1st and 2nd trimesters but may persist into the 3rd trimester.

EPIDEMIOLOGY

Incidence

Hyperemesis gravidarum occurs in 1–2% of pregnancies.

Prevalence

Hyperemesis gravidarum is the most common cause of hospitalization in the first half of pregnancy and the second most common cause of hospitalization of pregnant women.

ETIOLOGY AND PATHOPHYSIOLOGY

- Unknown
- Possible psychological factors
- Hyperthyroidism
- Hyperparathyroidism
- Gestational hormones
- Liver dysfunction
Autonomic nervous system dysfunction
CNS neoplasm
Addison disease

RISK FACTORS
- Obesity
- Nulliparity
- Multiple gestations
- Gestational trophoblastic disease
- Gonadotropin production stimulated
- Altered GI function
- Hyperthyroidism
- Hyperparathyroidism
- Liver dysfunction
- Female fetus
- Helicobacter pylori infection

GENERAL PREVENTION
Anticipatory guidance in 1st and 2nd trimesters regarding dietary habits in hopes of avoiding dehydration and nutritional depletion

Pregnancy Considerations
- 2% of pregnancies have electrolyte disturbances.
- 50% of pregnancies have at least some GI disturbance.

COMMONLY ASSOCIATED CONDITIONS
Hyperthyroidism

DIAGNOSIS

HISTORY
- Hypersensitivity to smell
- Alteration in taste
- Excessive salivation
- Poor appetite
- Nausea
- Vomiting with retching
- Decreased urine output
- Fatigue
- Dizziness with standing

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Urinalysis: may see glucosuria, albuminuria, granular casts, and hematuria (rare); ketosis more common
- Thyroid-stimulating hormone (TSH), T4
- Electrolytes, BUN, creatinine:
  - Electrolyte abnormalities due to nausea and vomiting and subsequent dehydration
  - Acidosis
- Calcium
- Uric acid
- Albumin

No imaging is indicated for the diagnosis of hyperemesis gravidarum unless there is concern for hydatidiform mole or multiple gestation, in which case ultrasound may be obtained.

**Follow-Up Tests & Special Considerations**
- If hypercalcemia, consider checking parathyroid hormone (PTH) for hyperparathyroidism.
- Drugs are unlikely to alter lab results.

**Diagnostic Procedures/Other**
Indicated only if it is necessary to rule out other diagnoses, as listed in the following section

**DIFFERENTIAL DIAGNOSIS**
Other common causes of vomiting must be considered:
- Gastroenteritis
- Gastritis
- Reflux esophagitis
- Peptic ulcer disease
- Cholelithiasis
- Cholecystitis
- Pyelonephritis
- Anxiety
- Hyperparathyroidism
- *H. pylori* infection

**TREATMENT**

Pyridoxine and doxylamine (pregnancy Category A) are first-line treatments for hyperemesis gravidarum (1)[C]. This is followed by metoclopramide or ondansetron (pregnancy Category B) and then prochlorperazine (pregnancy Category C), methylprednisolone (pregnancy Category C), or promethazine (pregnancy Category C).

**GENERAL MEASURES**

- Patient reassurance
- Bed rest
- If dehydrated, IV fluids, either normal saline or 5% dextrose normal saline (with consideration for potential thiamine deficiency). Repeat if there is a recurrence of symptoms following initial improvement.
- For severe cases, consider PO thiamine 25 to 50 mg TID or IV 100 mg in 100 mL of normal saline over 30 minutes once weekly and potential parental nutrition if needed.
- Ondansetron carries an FDA warning regarding concerns for QT prolongation, but this is in the setting of high-dose IV administration and in patients with heart disease. It has unclear risk in the setting of pregnancy. The majority of the current studies appear to show no increased risk of fetal malformation with the use of ondansetron, but this is still an area of controversy.

**MEDICATION**

- Pyridoxine (vitamin B₆) 25 mg PO or IV every 8 hours
- Antihistamines (e.g., diphenhydramine [25 to 50 mg q4–6h] or doxylamine [12.5 mg PO BID]) (2)[C]
- Combination product Diclegis (sustained-release pyridoxine 10 mg and doxylamine 10 mg) dosed (start 2 tabs PO qhs; if symptoms persist, increase to 1 tab in AM and 2 hs; if symptoms still persist, take 1 tab q AM, 1 mid day, and 2 hs; max 4 tablets/day)
- Phenothiazines (e.g., promethazine or prochlorperazine):
  - Precautions: Phenothiazines are associated with prolonged jaundice,
extrapyramidal effects, and hyper- or hyporeflexia in newborns.

- Meclizine 25 mg PO q6h
- Metoclopramide 10 mg PO q6–8h
- Methylprednisolone 16 mg PO/IV q8h for 2 to 3 days and then taper over 2 weeks if initial 3-day treatment is effective; reserved for severe cases with unclear benefit
- Ondansetron 4 to 8 mg PO q8h

**Pregnancy Considerations**
All medications taken during pregnancy should balance the risks and benefits both to the mother and the fetus.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Ginger 350 mg PO TID may help (3)[A].
- Evidence is mixed regarding the impact of acupressure and acupuncture in treating hyperemesis gravidarum. Acupressure bands at the Neiguan point are effective adjuvant treatment in severe hyperemesis (4)[A].
- Medical hypnosis may be a helpful adjunct to the typical medical treatment regimen, but further study is needed.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Typically outpatient therapy
- In some severe cases, parenteral therapy in the hospital or at home may be required.
- Enteral volume and nutrition repletion may be indicated, but early enteral tube feeding does not improve maternal or perinatal outcomes (5)[A].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Activity as tolerated after improvement
- Overall quality of life and future fertility plans can be impacted by severity of nausea and vomiting (6)[B].
**Patient Monitoring**
- In severe cases, follow-up on a daily basis for weight monitoring
- Special attention should be given to monitor for ketosis, hypokalemia, or acid–base disturbances due to hyperemesis.

**DIET**
- NPO for first 24 hours if patient is ill enough to require hospitalization
- For outpatient: a diet rich in carbohydrates and protein, such as fruit, cheese, cottage cheese, eggs, beef, poultry, vegetables, toast, crackers, rice. Limit intake of butter. Patients should avoid spicy meals and high-fat foods. Consider cold foods. Encourage small amounts at a time every 1 to 2 hours.

**PATIENT EDUCATION**
- Attention should be given to psychosocial issues, such as possible ambivalence about the pregnancy.
- Patients should be instructed to take small amounts of fluid frequently to avoid volume depletion.
- Avoid individual foods known to be irritating to the patient.
- Wet-to-dry nutrients (sherbet, broth, gelatin to dry crackers, toast)

**PROGNOSIS**
- Self-limited illness with good prognosis if patient’s weight is maintained at >95% of prepregnancy weight
- With complication of hemorrhagic retinitis, mortality rate of pregnant patient is 50%.

**COMPlications**
- Patients with >5% weight loss are associated with intrauterine growth retardation and fetal anomalies.
- Poor weight gain is associated with slightly increased risk for small for gestational age infant <2,500 g and premature birth <37 weeks (7)[A].
- Hemorrhagic retinitis
- Liver damage
- CNS deterioration, Wernicke encephalopathy secondary to thiamine deficiency, coma

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- O21.9 Vomiting of pregnancy, unspecified
- O21.0 Mild hyperemesis gravidarum
- O21.1 Hyperemesis gravidarum with metabolic disturbance

**CLINICAL PEARLS**

- Do not allow patients to become volume depleted. Once this occurs, it is more difficult to interrupt the process.
- Do not be hesitant to use medications to assist the patient, as this may help avoid volume depletion.
- Consider secondary causes of hyperemesis if it develops after 12 weeks of gestation.
HYPERKALEMIA

Merima Bucaj, DO • Roselyn Jan W. Clemente-Fuentes, MD, FAAFP • Ian J. McDowell, DO

BASICS

DESCRIPTION

- Hyperkalemia is a common electrolyte disorder that may be defined as a plasma potassium (K) concentration >5.5 mEq/L (>5 mmol/L).
- Hyperkalemia depresses cardiac conduction and can lead to fatal arrhythmias.
- Normal K regulation
  - Ingested K enters portal circulation; pancreas releases insulin in response. Insulin facilitates K entry into cells.
  - K in renal circulation causes renin release from juxtaglomerular cells, leading to activation of angiotensin I, which is converted to angiotensin II in lungs. Angiotensin II acts in adrenal zona glomerulosa to stimulate aldosterone secretion. Aldosterone, at the renal collecting ducts, causes K to be excreted and sodium to be retained.
- Four major causes
  - Increased load: either endogenous from tissue release or exogenous from a high intake, usually in association with decreased excretion
  - Decreased excretion: due to decreased glomerular filtration rate or impaired aldosterone secretion
  - Cellular redistribution: shifts from intracellular space (majority of K is intracellular) to extracellular space
  - Pseudohyperkalemia: related to red cell lysis during collection or transport of blood sample, thrombocytosis, or leukocytosis

Geriatric Considerations

Increased risk for hyperkalemia because of decreases in renin and aldosterone as well as comorbid conditions

EPIDEMIOLOGY

Prevalence

- 1–10% of hospitalized patients
2–3% in general population but as high as 50% in patients with chronic kidney disease (1)
• Predominant sex: male = female
• No age-related predilection

ETIOLOGY AND PATHOPHYSIOLOGY

• Pseudohyperkalemia
  – Hemolysis of red cells in phlebotomy tube (spurious result is most common)
  – Thrombolysis
  – Leukocytosis
  – Thrombocytosis
  – Hereditary spherocytosis
  – Infectious mononucleosis
  – Traumatic venipuncture or fist clenching during phlebotomy (spurious result)
  – Familial pseudohyperkalemia
• Transcellular shift (redistribution)
  – Metabolic acidosis
  – Insulin deficiency
  – Hyperglycemia (diabetic ketoacidosis or hyperosmolar hyperglycemic state)
  – Tissue damage (rhabdomyolysis, burns, trauma)
  – Tumor lysis syndrome
  – Cocaine abuse
  – Exercise with heavy sweating
  – Mannitol
• Impaired K excretion
  – Renal insufficiency/failure
  – Addison disease
  – Mineralocorticoid deficiency
  – Primary hyporeninemia, primary hypoaldosteronism
  – Type IV renal tubular acidosis (hyporeninemic hypoaldosteronism)
  – Obstructive uropathy
  – Cirrhosis
  – Congestive heart failure
  – Sickle cell disease
  – Amyloidosis
  – Systemic lupus erythematosus
• Medication-induced
- Excess K supplementation
- Statins
- ACE inhibitors
- Angiotensin receptor blockers
- \(\beta\)-Blockers
- Cyclosporine
- Digoxin toxicity
- Ethinyl estradiol/drospirenone
- Heparin
- Lithium
- NSAIDs
- Penicillin G potassium
- Pentamidine
- Spironolactone
- Succinylcholine
- Tacrolimus
- Trimethoprim, particularly with other medications associated with hyperkalemia (2)

**Genetics**
Associated with some inherited diseases and conditions
- Familial hyperkalemic periodic paralysis
- Congenital adrenal hyperplasia

**RISK FACTORS**
- Impaired renal excretion of K
- Acidemia
- Massive cell breakdown (rhabdomyolysis, burns, trauma)
- Use of K-sparing diuretics
- Excess K supplementation
- Comorbid conditions: chronic kidney disease, diabetes, heart failure, liver disease

**GENERAL PREVENTION**
Low K diet and oral supplement compliance in those at risk
DIAGNOSIS

HISTORY
- Neuromuscular cramps
- Abdominal pain
- Palpitations
- Myalgias
- Numbness
- Muscle weakness or paralysis

PHYSICAL EXAM
- Decreased deep tendon reflexes
- Flaccid paralysis of extremities

DIAGNOSTIC TESTS & INTERPRETATION
- Serum electrolytes
- Renal function: BUN, creatinine
- Urinalysis: K, creatinine, osmoles (to calculate fractional excretion of K and transtubular K gradient; both assess renal handling of K)
- Disorders that may alter lab results
  - Acidemia: K shifts from the intracellular to extracellular space
  - Insulin deficiency
  - Hemolysis of sample
- Cortisol, aldosterone, and renin levels to check for mineralocorticoid deficiency when other causes are ruled out

Diagnostic Procedures/Other
ECG abnormalities usually occur when K ≥7 mEq/L
- Peaked T wave with shortened QT interval in precordial leads (most common, usually earliest ECG change; however, neither sensitive nor specific) (3)
- Lengthening of PR interval
- Loss of P wave
- Widened QRS
- Sine wave at very high K
- Can eventually lead to arrhythmias including bradycardia, ventricular fibrillation and asystole
TREATMENT

MEDICATION

- Stabilize myocardial membranes. Initial treatment with calcium gluconate IV 1,000 mg (10 mL of 10% solution) over 2 to 3 minutes (2)[A]
  - With constant cardiac monitoring
  - Can repeat after 5 minutes if needed
  - Effect begins within minutes, but only lasts 30 to 60 minutes and should be used in conjunction with definitive therapies
  - Can also use calcium chloride (3 times as concentrated; however, central or deep vein administration is necessary to avoid tissue necrosis).

- Drive extracellular K into cells
  - Nebulized albuterol (at 10 to 20 mg/4 mL saline >10 minutes—4 to 8 times bronchodilation dose) and other β-agonists have an additive effect with insulin and glucose (2)[B].
  - Dextrose 50% 1 amp (if plasma glucose <250 mg/dL) and insulin 10 U IV may drive K intracellularly but does not decrease total body K and may result in hypoglycemia (close monitoring advised, especially 1 to 2 hours postinjection) (2)[B].

- Sodium bicarbonate not routinely recommended but some possible benefits in severe metabolic acidosis (4)[C]

- Remove excess K from body.
  - Cation exchange resins definitive treatment but require several doses and best used with rapidly acting transient therapies above and when dialysis not readily available (5)[A]

- Gastrointestinal cation exchangers, patiromer calcium (Veltassa), sodium polystyrene sulfonate (Kayexalate) and zirconium cyclosilicate bind K in the intestinal tract. Patiromer in particular is favored for improved tolerance and decreased side effects in both acute and chronic settings (6)[C].

- Patiromer calcium (Veltassa): 8.4 g PO daily (dose may vary 4.2 to 16.8 g BID in studies)
  - This requires ~7 to 24 hours to lower K. This may be repeated q12h, if necessary (7)[C].

- Sodium polystyrene sulfonate (Kayexalate): 15 g PO or 30 g rectally
  - This requires 1 to 4 hours to lower K. This may be repeated q6h, if necessary.
  - Enema has faster effect than PO (2)[C].

- Hemodialysis is the definitive therapy when other measures are not
effective. This may be required particularly when conditions, such as digitalis toxicity, rhabdomyolysis, end-stage renal disease, severe chronic kidney disease, or acute kidney injury, are present; should watch for postdialysis rebound (2)[A].

- Little clinical evidence for the use of diuretics (loop and thiazides), however, can consider for control of chronic hyperkalemia (2)[B]

**ALERT**

- Sodium polystyrene sulfonate provides a sodium load that may exacerbate fluid overload in patients with cardiac or renal failure.
- Avoid sodium polystyrene sulfonate use in patients who are postoperative or with a bowel obstruction or ileus due to high risk of intestinal necrosis.
- Rapid administration of calcium in patients with suspected digitalis toxicity may result in a fatal dysrhythmia. Calcium should be administered slowly over 20 to 30 minutes in 5% dextrose with extreme caution. Preferred therapy is digoxin-specific antibody fragments.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- If hyperkalemia is severe, treat first, and then do diagnostic investigations.
- Consider early consultation of nephrologist.
- IV calcium to stabilize myocardium (caution in setting of digoxin toxicity, as definitive treatment may cause hypokalemia)
- Insulin (usually 10 U IV, given with 50 mL of 50% glucose [if serum glucose <250 mg/dL] to avoid hypoglycemia); consider repeating if elevation persists.
- Inhaled β₂-agonist (nebulized albuterol)
- Discontinue any medications that may increase K (e.g., K-sparing diuretics, exogenous K).
- Admit for cardiac monitoring if ECG changes are present or if K is >6 mEq/L (6 mmol/L).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Reduction of plasma K should begin within the first hour of treatment
initiation.

- Serum K levels should be rechecked every 2 to 4 hours until the patient has stabilized, and recurrent hyperkalemia is no longer a threat.
- Identification and elimination of possible causes and risk factors for hyperkalemia are essential.

**DIET**
Recommend ≤80 mEq (≤80 mmol) of K per 24 hours. Many foods contain K. Those that are particularly high in K (>6.4 mEq/serving) include bananas, orange juice, other citrus fruits and their juices, figs, molasses, seaweed, dried fruits, nuts, avocados, lima beans, bran, tomatoes, cantaloupe, honeydew melon, peaches, potatoes, and salt substitutes. Multiple herbal medications can also increase K levels, including alfalfa, dandelion, horsetail nettle, milkweed, hawthorn berries, toad skin, oleander, foxglove, and ginseng.

**PATIENT EDUCATION**
Consult with a dietitian about a low-K diet.

**PROGNOSIS**
- Associated with poor prognosis in patients with heart failure and chronic kidney disease
- Associated with poor prognosis in disaster medicine, with trauma, tissue necrosis, K⁺ supplementation, metabolic acidosis, if calcium gluconate administered for treatment of hyperkalemia, if AKI, or if prolonged duration of hyperkalemia (4)

**COMPLICATIONS**
- Life-threatening cardiac arrhythmias
- Hypokalemia
- Potential complications of the use of ion-exchange resins for the treatment of hyperkalemia include volume overload and intestinal necrosis (6)[C].

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

- Addison Disease; Hypokalemia
- Algorithm: Hyperkalemia
CLINICAL PEARLS

- Emergency and urgent management of hyperkalemia takes precedent to a thorough diagnostic workup. Urgent treatment includes stabilization of the myocardium with calcium gluconate to protect against arrhythmias and pharmacologic strategies to move K from the extracellular (vascular) space into cells.
- Calcium and dextrose/insulin are only temporizing measures and do not actually lower total body K levels. Definitive treatment with either dialysis or cation exchange resin (sodium polystyrene sulfonate) necessary.
- To lower a patient’s risk of developing hyperkalemia, have the patient follow a low-K diet, use selective β₁-blockers, such as metoprolol or atenolol, instead of nonselective β-blockers such as carvedilol. Avoid NSAIDs. Concomitant use of kaliuretic loop diuretics may be useful.
HYPERNATREMIA

Japheth E. Mukaya, MD • Pang-Yen Fan, MD

BASICS

DESCRIPTION

- Serum sodium (Na) concentration >145 mEq/L (1)
- Usually represents a state of hypertonicity (1,2)
- Na concentration reflects balance between total body water (TBW) and total body Na. Hypernatremia occurs from deficit of water relative to Na.
- Hypernatremia results from net water loss or, more rarely, from primary Na gain (1).
- May exist with hypo-, hyper-, or euvoleda, although hypovolemia is by far most common type
  - Hypovolemic: occurs with a decrease in TBW and a proportionately smaller decrease in total body Na
  - Euvolemic: no change in TBW with a proportionate increase in total body Na
  - Hypervolemic: increase in TBW and a proportionately greater increase in total body Na

- It has been shown to be an indicator for higher mortality in critically ill patients and patients with chronic kidney disease (CKD) (3)[B].

EPIDEMIOLOGY

Incidence

- More common in elderly and young
- Occurs in 1% of hospitalized elderly patients (4)
- Seen in about 9% of ICU patients (4). Gastroenteritis with diarrhea is the most common cause of hypernatremia in infants.
- Women are at an increased risk due to decreased TBW, as compared with men.

ETIOLOGY AND PATHOPHYSIOLOGY

- Water loss (total body Na normal). Hypernatremia due to water loss occurs only in patients who can’t access water such as infants, elderly, patients with altered mental status and hypodipsia (5). The following conditions lead to

mebooksfree.com
water loss:
- Insensible loss
  - Burns
  - Hyperventilation
  - Excessive sweating such as with fever, infants under radiant heaters, and exercise
- Renal loss
  - Nephrogenic diabetes insipidus (DI) (congenital or due to renal dysfunction, hypercalcemia, hypokalemia, medication-related, particularly lithium)
  - Central DI (due to head trauma, stroke, meningitis) (4)
  - Osmotic diuresis: glucose, urea, and mannitol
  - Post-ATN diuresis
- Gastrointestinal loss
  - Osmotic diarrhea: lactulose, malabsorption, and some types of infectious diarrhea
  - Enterocutaneous fistula
  - Vomiting, NG suction
- Hypothalamic disorders leading to impaired thirst or osmoreceptor function
  - Primary hypodipsia
  - Reset osmostat due to volume expansion in mineralocorticoid excess.
  - Essential hypernatremia with loss of osmoreceptor function
- Excess Na (increase in total body Na) resulting from the following:
  - IV NaCl or NaHCO₃ during cardiopulmonary resuscitation, metabolic acidosis, or hyperkalemia (4)
  - Sea water ingestion
  - Excessive use of NaHCO₃ antacid
  - Incorrect infant formula preparation
  - Intrauterine NaCl for abortion
  - Excessive Na in dialysate solutions
  - Disorders of the adrenal axis (Cushing syndrome, Conn syndrome, congenital adrenal hyperplasia)
  - Tube feeding
- With acute hypernatremia, the rapid decrease in brain volume can cause rupture of the cerebral veins, leading to focal intracerebral and subarachnoid hemorrhages and possibly irreversible neurologic damage (2).

Genetics
Some forms of DI may be hereditary.

RISK FACTORS
- Patients at increased risk include those with an impaired thirst mechanism or restricted access to water as well as those with increased water loss
- Infants/children
- Elderly patients (may also have a diminished thirst response to osmotic stimulation via an unknown mechanism)
- Patients who are intubated/have altered mental status
- Diabetes mellitus
- Prior brain injury
- Surgery
- Diuretic therapy, especially loop diuretics
- Lithium treatment

GENERAL PREVENTION
- Treatment/prevention of underlying cause
- Properly prepare infant formula and never add salt to any commercial infant formula.
- Keep patients well hydrated.

COMMONLY ASSOCIATED CONDITIONS
- Gastroenteritis
- Altered mental status
- Burns
- Hypermetabolic conditions
- Head injury
- Renal dysfunction

DIAGNOSIS
HISTORY
- Excessive thirst, nausea, vomiting, diarrhea, oliguria, polyuria
- Fever, myalgia, muscle weakness
- Neurologic symptoms common: altered mental status, seizure (especially if rapid development of hypernatremia), twitching, lethargy, irritability, coma, anophthalmos
- Severe symptoms are likely to occur with acute increases in plasma Na levels or at concentrations >160 mEq/L.
- Obtain list of current and recent medications.
- Review recent illnesses and activities.

**PHYSICAL EXAM**
- Sinus tachycardia, hypotension, orthostatic hypotension, poor O₂ saturation
- Dry mucous membranes, cool/gray skin
- Neurologic abnormalities: lethargy, weakness, focal deficits (in cases of intracerebral bleeding/lesion), confusion, coma, seizures

**DIFFERENTIAL DIAGNOSIS**
- DI
- Hyperosmotic coma
- Salt ingestion
- Hypertonic dehydration
- Hypothyroidism
- Cushing syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Serum Na, potassium, BUN, creatinine, calcium, and osmolality (serum lithium if appropriate)
- Urine Na and osmolality
  - DI: urine osmolality (usually <300 mOsmol/kg) < serum osmolality, and urine Na usually low normal/slightly low (due to dilution) (5)
  - Partial DI and central DI with volume depletion can give a urine osmolarity of 300 to 800 mOsm/kg.
  - Osmotic diuresis: urine osmolality intermediate, urine Na low/low-normal, total daily osmole excretion high
  - Salt ingestion: increased urine osmolality (>600 mOsmol/kg) and high urine Na
  - Hypertonic dehydration: increased urine osmolality and decreased urine Na
- Serum glucose
- Special tests for DI
  - Water deprivation test: In DI, urine osmolality does not increase as it normally should when hypernatremic.
  - Antidiuretic hormone (ADH) stimulation: distinguishes central versus
nephrogenic DI
  - Urine osmolality does not increase after ADH or desmopressin (DDAVP) in nephrogenic DI.
- Head CT/MRI in DI to rule out craniopharyngioma, other brain tumor or masses, or median cleft syndrome

**Diagnostic Procedures/Other**
History, physical, laboratory studies, family history for central DI

**TREATMENT**

**GENERAL MEASURES**
- The treatment of hypernatremia involves treating the underlying cause and correcting the water deficit.
- Goal for corrected Na is 145 mEq/L (1).
- Speed of correction depends on symptom severity and rate of development of hypernatremia. Avoid rapid correction to prevent development of cerebral edema if chronic hypernatremia (>24 hours):
  - Maximum of 0.5 mEq/L/hr or 10 mEq/L/day
  - May correct at up to 1 mEq/L/hr if acute hypernatremia (<24 hours) (1)
- Treat volume depletion first, then hypernatremia:
  - Restore intravascular volume with IV fluids to normalize serum Na levels.
- Replace water orally if patient is conscious.
- Important formulas in determining rate of fluid administration
  - TBW = coefficient × wt (kg), where coefficient = 0.6 for men and children, 0.5 for women and elderly men, 0.45 for elderly women
  - Calculated free water deficit (liters) = TBW × (PNa / 140 − 1), where PNa = plasma Na+, TBW = total body water
  - Change in serum Na per 1 L infusate = [(infusate Na + infusate K) − serum Na] / (TBW + 1)
  - Example: A 45-year-old male weighing 70 kg is admitted with head injury. Labs show a serum Na of 160.
    - Free water deficit = 70 × 0.6 × (160 / 140 − 1) = 6 L
    - Remember the 6 L should be given over a 48-hour period to avoid over correction.
- Account for ongoing fluid losses during calculation of rate of fluid administration.
• Dialysis can be considered if acute kidney injury is present concomitantly and if conventional treatment has failed (6)[B].

MEDICATION

First Line
• See “General Measures” for overall approach.
• Volume depletion: Use isotonic fluids initially if signs of hemodynamic compromise and then change to hypotonic fluids when stable:
  – Hypotonic fluids (0.45% NaCl or dextrose 5% in water)
    o Important not to decrease serum Na by >10 mEq/L/day to prevent cerebral edema (5)[C]
• Hypervolemia: Give furosemide along with hypotonic fluids. Dose varies depending on desired urine output. Loop diuretics with fluid restriction worsen hypernatremia (5)[C].
• Central DI
  – DDAVP acetate: Use parenteral form for acute symptomatic patients, and use intranasal or oral form for chronic therapy (5).
  – Free water replacement: may use 2.5% dextrose in water if giving large volumes of water in DI to avoid glycosuria
  – May consider sulfonylureas/thiazide diuretics for chronic but not acute treatment
• Nephrogenic DI
  – Treat with diuretics and NSAIDs.
  – Lithium-induced nephrogenic DI: hydrochlorothiazide 25 mg PO BID or indomethacin 50 mg PO TID, or amiloride hydrochloride 5 to 10 mg PO BID
• Precautions
  – Rapid correction of hypernatremia can cause cerebral edema, central pontine myelinolysis, seizures, or death.
  – Hypocalcemia and more rarely acidosis can occur during correction.
  – DI: High rates of dextrose 5% in water can cause hyperglycemia and glucose-induced diuresis.

Second Line
• Consider NSAIDs in nephrogenic DI.
• Modalities requiring further investigations
• Continuous renal replacement therapy (CRRT): Multiple case reports and case series have shown success and safety in using CRRT to treat hypernatremia in
critically ill patients with CHF and severe burns (6).

**ISSUES FOR REFERRAL**
Underlying renal involvement associated with hypernatremia would benefit from a nephrology referral.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Symptomatic patient with serum Na >155 mEq/L requires IV fluid therapy.
- IV fluids: Refer to “Medication” section.
- Bed rest until stable or underlying condition resolved/controlled
- Discharge criteria: Stabilization of serum Na level and symptoms are minimal.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Frequent reexams in an acute setting
- Frequent electrolytes and blood glucose: initially q4–6h
- Urine osmolality and urine output in DI
- Ensure adequate ingestion of calories because patients may ingest so much water that they feel full and do not eat.
- Measure ongoing losses of water and solute and replace as needed.
- Daily weights

**DIET**
- Ensure proper nutrition during acute phase.
- After resolution of acute phase, may want to consider Na-restricted diet for patient
- Low-salt, low-protein diet in nephrogenic DI

**PATIENT EDUCATION**
Patients with nephrogenic DI must avoid salt and drink large amounts of water.

**PROGNOSIS**
Most recover but neurologic impairment can occur.
COMPLICATIONS

- CNS thrombosis/hemorrhage
- Seizures
- Mental retardation
- Hyperactivity
- Chronic hypernatremia: >2 days duration has higher mortality.
- Serum Na >180 mEq/L (>180 mmol/L): often results in residual CNS damage
- More common if rapid development of hypernatremia

REFERENCES

ADDITIONAL READING

SEE ALSO

- Diabetes Insipidus
- Algorithm: Hypernatremia
CLINICAL PEARLS

- Occurs from water deficit in comparison to total body Na stores
- Common causes include dehydration, DI, impaired access to fluids.
- Determine if the patient has hypervolemic, euvolemic, or hypovolemic hypernatremia in the differential diagnosis of etiology; most commonly hypovolemic; other entities rare
- Avoid rapid correction of hypernatremia to prevent development of cerebral edema when hypernatremia is chronic (goal rate is 10 mEq/L in 24 hours).
- Use hypotonic fluids unless patient has hemodynamic compromise, which necessitates use of isotonic fluids.
- Use oral replacement in conscious patients if possible.
- Use the estimated water deficit, desired rate of correction, and estimation of ongoing free water losses to calculate a fluid repletion regimen.
HYPERPARATHYROIDISM

Michael Morkos, MD, MS

BASICS

DESCRIPTION
A dysfunction of the body’s normal regulatory feedback mechanisms resulting in excess production of parathyroid hormone (PTH)

- Primary hyperparathyroidism (HPT): intrinsic parathyroid gland dysfunction resulting in excessive secretion of PTH with a lack of response to feedback inhibition by elevated calcium
- Secondary HPT: excessive secretion of PTH in response to hypocalcemia, which can be caused by vitamin D deficiency or renal failure
- Tertiary HPT: autonomous hyperfunction of the parathyroid gland in the setting of long-standing secondary HPT

EPIDEMIOLOGY

Incidence
- Predominantly postmenopausal females
- Female > male (3:1)

Prevalence
Primary HPT is 1 in 500 to 1 in 1,000 in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

- PTH is synthesized by the four parathyroid glands, which are located behind the four poles of the thyroid gland (locations can vary).
- Ectopic (abnormal locations and most common is the thymus) or supernumerary glands (more than four glands)
- PTH releases calcium from bone by osteoclastic stimulation (increasing bone resorption).
- PTH increases reabsorption of calcium in the distal tubules of the kidneys.
- PTH stimulates conversion of 25-hydroxycholecalciferol (25[OH]-Vit D) to 1,25-dihydroxycholecalciferol (1,25[OH]$_2$-Vit D or active vitamin D) in the kidneys. 1,25(OH)$_2$-Vit D increases calcium and phosphate absorption from
the GI tract and kidneys, and stimulates osteoclastic activity and bone resorption.

- **Primary HPT**: unregulated PTH production and release due to the loss of normal feedback control by extracellular calcium, causing increase in serum calcium
  - Solitary adenoma (80–85%)
  - Diffuse hyperplasia (10–15%) of the four parathyroid glands, either sporadically or in association with multiple endocrine neoplasia (MEN) types I or II
  - Parathyroid carcinoma (<1%), a very rare and severe form
- **Secondary HPT**: adaptive parathyroid gland hyperplasia and hyperfunction
  - Dietary: vitamin D or calcium deficiency
  - Chronic renal disease resulting in the following:
    - Renal parenchymal loss causing hyperphosphatemia
    - Impaired calcitriol production causing hypocalcemia
    - General skeletal and renal resistance to PTH
- **Tertiary HPT**: autonomous oversecretion of PTH following prolonged parathyroid stimulation

**Genetics**

- **MEN types I and II**: Patients with multiple gland hyperplasia in the absence of renal disease should be screened for MEN-I gene mutation.
- **Neonatal severe primary HPT**
- **HPT—jaw tumor syndrome**
- **Familial hypocalciuric hypercalcemia (FHH)**
- **Familial isolated HPT**

**RISK FACTORS**

Chronic kidney disease, increasing age, poor nutrition, radiation, and/or family history

**GENERAL PREVENTION**

Adequate intake of calcium and vitamin D may help prevent secondary HPT.

**COMMONLY ASSOCIATED CONDITIONS**

- Vitamin D deficiency
- Chronic renal failure
- MEN syndromes types I and II
DIAGNOSIS

HISTORY

- History of present illness
  - Almost 80% of patients are asymptomatic
  - Kidney stones (15–20%)
  - Osteitis fibrosa cystica (<5%) characterized by subperiosteal resorption of phalanges, tapering of distal clavicles, bone cysts, brown tumors of long bones, and “salt and pepper” appearance of the skull
  - Symptoms due to hypercalcemia like polyuria, polydipsia, constipation, bone pain, decreased concentration, fatigue, and muscle weakness

- Past medical history
  - The following conditions may be associated with HPT:
    - MEN syndrome (MEN-associated conditions include pancreatic cancer, pituitary adenomas, medullary thyroid cancer, and pheochromocytoma), nephrolithiasis (in 20–30%), nephrocalcinosis, pancreatitis, gastroduodenal ulcer, hyperventilation, short QT interval, left ventricular hypertrophy, osteitis fibrosa cystica, cystic bone lesions, spontaneous fracture, vertebral collapse, osteoporosis, gout, pseudogout, anxiety, depression, psychosis, coma, conjunctivitis, band keratopathy, conjunctival calcium deposits, radiation to the neck

- Medications: hydrochlorothiazide or lithium (decreases parathyroid sensitivity to calcium in small subset of patients)

PHYSICAL EXAM

- Limited usefulness, 70–80% of patients have no obvious symptoms or signs of disease.
- Physical findings related to the underlying cause of HPT may be found.

DIFFERENTIAL DIAGNOSIS

- Increased PTH: ectopic PTH production is rare. In most of the cases, it establishes the diagnosis of primary HPT, but first rule out:
  - FHH
  - Thiazide diuretics and lithium

- Nonparathyroid causes
  - Malignancy: lung (squamous cell) carcinoma, breast carcinoma, multiple myeloma, lymphoma, leukemia, prostate cancer, Paget disease
  - Granulomatous diseases: sarcoidosis, tuberculosis, berylliosis,
histoplasmosis, coccidioidomycosis
- Drugs: vitamin D intoxication, milk-alkali syndrome
- Endocrine: hyperthyroidism, acute adrenal insufficiency

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- The disease is often detected by an incidental finding of hypercalcemia on routine labs. The best modality is to check ionized calcium but it is not done routinely.
- The best next step is to calculate the corrected calcium: [serum calcium in mg/dL + 0.8 × (4 – patient’s albumin in g/dL)]. Some patients will have mild hypercalcemia for years and it won’t be detected as the uncorrected calcium is normal.
- If hypercalcemia is confirmed, follow with intact PTH level (1)[B].
  - PTH-dependent: High or (abnormally) normal PTH suggests primary HPT.
  - PTH-independent: undetectable or low PTH suggests PTH-independent hypercalcemia
- Other findings may include low serum phosphate and high 24-hour urine calcium excretion.
- In secondary HPT, an elevated phosphorus suggests chronic renal failure; a low phosphorus suggests another cause, commonly 25(OH) D deficiency. Both are common causes of elevated PTH levels while having normal corrected calcium levels.

**Follow-Up Tests & Special Considerations**
- A 24-hour urine calcium concentration to creatinine clearance ratio >0.02 suggests primary HPT; a ratio <0.01 may be normal or indicate FHH; an important finding because FHH does not require surgery (1)[C]
- Routine measurement of 25(OH)D levels is recommended in all patients with primary HPT. In case of vitamin D deficiency (<20 ng/mL or <50 nmol/L), defer management decisions until levels are maintained >20 ng/mL (50 nmol/L) (1)[C].

**Diagnostic Procedures/Other**
- Imaging is not required for diagnosis. It is required for surgical planning, especially for minimally invasive parathyroidectomy (MIP) (2)[C].
  - Imaging is also indicated to localize hyperplasia or an ectopic parathyroid gland in repeat surgery.
• Imaging options for presurgical localization
  – Technetium-99m sestamibi with or without single-photon emission computed tomography (SPECT): it has the greatest reported success in localizing single parathyroid adenomas but often inaccurate in multigland disease (3)[B].
  – Neck ultrasound (US): painless, noninvasive, and does not expose the patient to radiation; however, its accuracy is operator-dependent (4)[C].
  – Four-dimensional CT (4D-CT) may be more effective for primary localization than both US and sestamibi-SPECT (4)[B].
  – Positron emission tomography (PET) using C-methionine (MET-PET) is comparable to US and Technetium-99m sestamibi with SPECT in terms of diagnostic use (2)[B].
  – CT and MRI are mostly used to localize ectopic mediastinal glands.

**TREATMENT**

**MEDICATION**

• Primary HPT: Operative management is curative, indications for surgical intervention are mentioned below. For those awaiting or unable to have surgery:
  – Bisphosphonates (alendronate): reduces bone turnover and helps to maintain bone density; avoid in kidney disease (GFR ≤35).
  – Calcimimetics (cinacalcet) (1)[B]: activates calcium-sensing receptor in parathyroid gland thereby inhibiting PTH secretion. FDA-approved for symptomatic patients who are unfit for surgery; no long-term data on its effect on constitutional, neuropsychological symptoms or fractures
  – Selective estrogen receptor modulator therapy (raloxifene): antagonizes PTH-mediated bone resorption
  – Hormone replacement therapy with estrogens is not recommended as first-line treatment; must weigh benefit with risks of known systemic effects
    ▪ Can be used in postmenopausal women who do not undergo or refuse surgery
  – Secondary HPT
    – Calcium replacement
    – Vitamin D analogues (paricalcitol and calcitriol)
    – Phosphorus-binding agents (sevelamer)
    – Calcimimetic (cinacalcet)
Tertiary HPT
- Medical treatment is not curative and generally not indicated.

**SURGERY/OTHER PROCEDURES**

- Operative management is curative for patients with primary HPT in 95–98% of patients.

- Indications for parathyroidectomy
  - Symptomatic primary HPT
    - Nephrolithiasis
    - Fragility fractures
    - Osteitis fibrosa cystica
  - Asymptomatic primary HPT (1)[C]
    - Serum Ca$^+$ level >1 mg/dL above normal
    - Age <50 years
    - Creatinine clearance <60 mL/min
    - 24-hour urine for calcium >400 mg/day (>10 mmol/day) and increased stone risk by biochemical stone risk analysis
    - Presence of nephrolithiasis or nephrocalcinosis by x-ray, US, or CT
    - Bone density loss with a T-score <−2.5 at the lumbar spine, femoral neck, total hip, or distal 1/3 radius

- Tertiary HPT

- Surgical removal of diseased gland or tissue is only proven curative therapy for HPT.

- Surgical options include the following:
  - Bilateral open neck exploratory surgery
  - MIP using preoperative sestamibi scan with SPECT/US/4D-CT, and intraoperative PTH levels (high sensitivity 79–95% to predict location of single parathyroid adenoma) (5), which result in decreased pain, smaller incisions, improved cosmetic results, lower morbidity, and decreased length of hospital stay when compared with open neck exploratory surgery.

- Follow postoperative serum calcium, magnesium, and phosphorus levels; monitor closely for hypocalcemia “hungry bone” syndrome.

- Patients may need IV calcium infusion postoperatively with oral calcitriol and calcium supplementation initially. Hungry pain syndrome can be severe, although less common now.

- Patients also at risk for bleeding and airway compromise

- Monitor renal function closely.
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Critical hypercalcemia requires IV fluid rehydration, IV bisphosphonate therapy, and SC calcitonin (4 U/kg q12h) for severe symptoms.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Asymptomatic patients with primary HPT require serial monitoring of calcium and PTH.

Patient Monitoring

In patients with primary HPT who are asymptomatic, measurement of serum calcium and creatinine annually and bone density scan every 1 to 2 years is sufficient (1)[C].

Diet

- In the presence of hypercalciuria or elevated 1,25(OH)_2D levels, dietary calcium restriction is recommended. Otherwise, daily calcium intake should be maintained at up to 1,000 mg.
- Restrict dietary phosphate in secondary HPT.

PATIENT EDUCATION

- Importance of periodic lab testing
- Signs of severe hypercalcemia

PROGNOSIS

Prognosis after surgery is excellent in primary HPT, with resolution of many of the preoperative symptoms.

COMPLICATIONS

Related to high levels of PTH and/or elevated calcium

REFERENCES

**CODES**

**ICD10**
- E21.3 Hyperparathyroidism, unspecified
- E21.0 Primary hyperparathyroidism
- E21.1 Secondary hyperparathyroidism, not elsewhere classified

**CLINICAL PEARLS**
- 80% of patients with primary HPT are asymptomatic.
- HPT is often detected by an incidental finding of hypercalcemia on a routine serum chemistry analysis.
- Classic symptoms of HPT include painful bones, renal stones, abdominal pain, and behavioral changes (stones, bones, moans, and groans).
- Repeat calcium (elevated), correct for serum albumin, and obtain intact PTH levels to make an initial diagnosis.
- Secondary HPT is due to excessive secretion of PTH in response to hypocalcemia, which can be caused by vitamin D deficiency or renal failure.
- The most commonly used imaging modalities in HPT are technetium-99m sestamibi scan, US, and 4D-CT.
- Surgery is curative for most cases of primary HPT.
Recommend normal daily calcium intake (1,000 mg) in asymptomatic patients with primary HPT who don’t qualify for surgery.

In patients with primary HPT who are asymptomatic, measurement of serum calcium and creatinine annually and bone density scan every 1 to 2 years is sufficient.
HYPERPROLACTINEMIA

D’Ann Somerall, DNP, MAEd, CRNP, FNP-BC • William E. Somerall Jr., MD, MEd

BASICS

DESCRIPTION

Hyperprolactinemia is an abnormal elevation in the serum prolactin level with multiple possible etiologies.

EPIDEMIOLOGY

Prevalence
- Predominant age: reproductive age
- Predominant sex: female > male
- More readily detected in females because a slight elevation in prolactin causes changes in menstruation and galactorrhea

ETIOLOGY AND PATHOPHYSIOLOGY

- Prolactin, which is produced by lactotrophs in the anterior pituitary, is regulated by:
  - Inhibitory factors, primarily dopamine, produced in the hypothalamus and delivered via the hypothalamic-pituitary vessels in the pituitary stalk
  - Stimulatory factors, primarily thyrotropin-releasing hormone (TRH)
- Causes of hyperprolactinemia include the following:
  - Physiologic
  - Pregnancy due to increased estrogen
  - Breastfeeding
  - Nipple stimulation
  - Stress, including postoperative state
  - Medications
    - Dopamine (D2) blockers: prochlorperazine, metoclopramide
    - Dopamine depleters: α-methyldopa, reserpine
    - Antidepressants: selective serotonin reuptake inhibitors (SSRIs), tricyclic antidepressants (SSRIs do not appear to cause clinically significant hyperprolactinemia.)
- Verapamil (but no other calcium channel blockers; thought to decrease hypothalamic synthesis of dopamine)
- Antipsychotics: haloperidol, fluphenazine, risperidone
  - Hypothyroidism (due to elevated TRH)
  - Chest wall conditions:
    - Herpes zoster
    - After thoracotomy
    - Trauma
  - Prolactin-secreting adenoma (anterior pituitary), categorized:
    - Microadenoma: <1 cm
    - Macroadenoma: >1 cm
  - Pituitary stalk compression/disruption:
    - Craniopharyngioma
    - Rathke cleft cyst
    - Meningioma
    - Astrocytoma
    - Metastases
    - Head trauma
    - Infiltrative/inflammatory disorders
  - Diminished prolactin clearance:
    - Chronic renal failure
    - Cirrhosis
  - Cocaine

**DIAGNOSIS**

**HISTORY**
- Galactorrhea
- Amenorrhea
- Oligomenorrhea
- Infertility
- Osteoporosis/osteopenia
- Decreased libido, impotence
- Weight gain
- Also may have signs and symptoms of pituitary enlargement:
  - Headache
  - Visual field impairment (bitemporal hemianopia)
– Hypopituitarism (secondary to tumor pressure on surrounding structures)

Also may have signs and symptoms of associated conditions:
– Hypothyroidism
– Cushing disease
– Acromegaly
– Multiple endocrine neoplasia (MEN)-1 syndrome

PHYSICAL EXAM

– Visual field testing
– Cranial nerve exam

DIFFERENTIAL DIAGNOSIS

Macroprolactinemia: Macroprolactin, a polymer of several units of prolactin, is detected by immunologically based lab tests but is not biologically active. If patient is asymptomatic but found to have elevated prolactin (PRL), consider this diagnosis and notify the lab. No treatment is required.

DIAGNOSTIC TESTS & INTERPRETATION

• Serum prolactin (most accurate results if checked fasting, in morning) <25 μg/L normal; >25 μg/L abnormal; >250 μg/L often indicates a prolactinoma (1)[A].
• Pregnancy test
• Thyroid-stimulating hormone (TSH)
• Luteinizing hormone (LH)/follicle-stimulating hormone (FSH) if amenorrheic
• Chemistry, renal function
• LFTs

Initial Tests (lab, imaging)

A single measurement of serum prolactin; a level above the upper limit of normal confirms the diagnosis.

• Pituitary MRI: single best imaging
• CT scan if MRI is contraindicated
• Levels should be drawn prior to breast exam.

Follow-Up Tests & Special Considerations

Formal visual field testing if pituitary adenoma is suspected
TREATMENT

GENERAL MEASURES

- Discontinue offending medications, if any (1)[A].
- Treat underlying causes (1)[A].
- For asymptomatic patients with mild prolactin elevations, observation alone may be considered (1,2)[A].
- Medications indicated for (1)[A]:
  - Symptoms of hypogonadism, such as decreased libido
  - Galactorrhea (if bothersome to patient)
  - Restoration of fertility
  - Pituitary adenoma
  - Prevention of osteoporosis

MEDICATION

Dopamine agonists: decrease serum prolactin concentrations and decrease the size of most lactotroph adenomas

- Cabergoline (Dostinex): This is now a first-line choice due to efficacy and favorable side effect profile (1,3)[A]: dosed twice weekly. Cabergoline was more effective than bromocriptine in reducing persistent hyperprolactinemia, galactorrhea, and amenorrhea/oligomenorrhea (2)[A]. Has recently been reported to be associated with significant improvements in the body mass index, total HDL and LDL cholesterol levels, and insulin sensitivity; decrease in proinflammatory markers; and carotid intima-media thickness, indicated with bromocriptine failure or resistance; has been shown to reduce erectile dysfunction in hyperprolactinemic men (1)[A]
  - Adverse effects (better tolerated if start with low dose, slow titration, given at night with food):
    - Nausea/vomiting
    - Headache
    - Dizziness
    - Fatigue
    - Light-headedness
  - Postural hypotension (2)[A]
- Contraindications
  - Uncontrolled hypertension
  - Cardiac valvular disorders
- Pulmonary, pericardial, or retroperitoneal fibrotic disorders

- Bromocriptine (Parlodel): This has the longest clinical history: dosed BID; preferred by some clinicians when infertility is an indication for treatment (2,4)[A]
- Both are effective for reducing tumor size and improving symptoms (2)[A].
- SE less with cabergoline than bromocriptine (2)[A]. Pergolide (Permax) is no longer used in the United States. If patient is still on med, do not withdraw abruptly.

**ADDITIONAL THERAPIES**

Patients with medically and surgically refractory prolactinomas; radiotherapy produced a reduction in prolactin levels in nearly all patients and normalization in over a quarter of patients with low complication rates (2)[A].

**SURGERY/OTHER PROCEDURES**

- For adenomas, medical treatment will be successful in 80–90% of patients. In some cases, surgery is indicated (1).
- Indications
  - Intolerance or resistance to medical treatment
  - Headache
  - Visual field loss
  - CSF leak due to tumor apoplexy or shrinkage
  - Cranial nerve deficit
- Risks
  - High recurrence rate (up to 40%)
  - CSF leakage
  - Meningitis
  - Transient diabetes insipidus (5)
- Pituitary insufficiency

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Depends on etiology
- After at least 2 years of treatment, no tumor and prolactin levels normal may
consider decreasing and stopping medication; must be followed closely, as tumor may grow back (1)

- Consider:
  - Formal visual field testing yearly (4)[A]
  - Serial MRIs if clinically indicated (4)[A]

**Pregnancy Considerations**

- If pregnancy is desired in a woman with hyperprolactinemia, dopamine agonists are not approved during pregnancy and should be discontinued once pregnancy is confirmed, but their use is recommended if neurologic findings are present (1)[A].

- With microprolactinoma: Treat with bromocriptine if symptomatic; monthly pregnancy tests; discontinue bromocriptine when pregnancy is confirmed.

- With macroprolactinomas: a definitive, individualized plan is made. Options include discontinuation of bromocriptine at conception and careful monitoring of prolactin levels and VS, with or without MRI scan evidence of tumor enlargement; prepregnancy transsphenoidal surgery with debulking of tumor; continuation of bromocriptine throughout gestation, with a risk to the fetus.

- Careful monitoring of visual fields in each trimester; no need to monitor prolactin levels, as they are normally high due to pregnancy (1)[A]

**PATIENT EDUCATION**

- Discuss risks of untreated hyperprolactinemia:
  - Headache
  - Visual field loss
  - Decreased bone density
  - Infertility

- Patient guide to hyperprolactinemia diagnosis and treatment

**PROGNOSIS**

- Tends to recur after discontinuation of medical therapy (1)

- >10 years, 7% chance of progression of prolactin-secreting microadenoma (4)

**COMPLICATIONS**

- Depends on underlying cause

- If pituitary adenoma, risk of permanent visual field loss

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

E22.1 Hyperprolactinemia

**CLINICAL PEARLS**

- If a cause for hyperprolactinemia cannot be found by history, examination, and routine laboratory testing, an intracranial lesion might be the cause and
brain MRI with specific pituitary cuts and intravenous contrast media should be performed.

- Treatment of hyperprolactinemia should be targeted at correcting the cause (hypothyroidism, discontinuation of offending medications, etc.).
- There is a difference among antipsychotics in influencing prolactin levels. In general, those with the highest potency D₂ antagonism are most likely to elevate prolactin levels. Among the newer atypical antipsychotics, risperidone has been identified as more likely to elevate prolactin.
- High prolactin levels decrease testosterone by inhibiting gonadotropin-releasing hormone (GnRH), LH, and FSH secretion and by decreasing central dopamine activity, both of which are important in mediating sexual arousal.
HYPERSENSITIVITY PNEUMONITIS

Han Q. Bui, MD, MPH

BASICS

- Hypersensitivity pneumonitis (HP) is also called extrinsic allergic alveolitis (EAA).
- HP is a diffuse inflammatory disease of the lung parenchyma caused by an immunologic reaction to aerosolized antigenic particles found in a variety of environments. Classification depends on time frame involved:
  - Acute: fever, chills, diaphoresis, myalgias, nausea; cough and dyspnea common but not necessarily present. Occurs 4 to 12 hours after heavy exposure to an inciting agent. Symptoms subside within 12 hours to several days after removal from exposure. Complete resolution occurs within weeks.
  - Subacute: mainly caused by continual low-level antigen exposure, could have a low-grade fever in 1st week; cough, dyspnea, fatigue, anorexia, weight loss—develops over days to weeks
  - Chronic: from recurrent exposure either acute or subacute cases, prolonged and progressive cough, dyspnea, fatigue, weight loss, could lead to fibrosis and respiratory failure
- Farmer’s lung is an old term of this disease, a type of HP, particular to the farmer population; causative agent is a bacterium found in moldy hay or straw. Farmer’s lung now has new and different etiologies due to modernization of farming practices (1,2).

EPIDEMIOLOGY

- Not well defined; tends to occur in adults as a result of occupation-related exposure, but some home environmental exposures are also seen
- HP is increasingly recognized as an important cause of fibrotic interstitial lung disease (3).

Incidence

0.9 per 100,000

Prevalence

- Farmers: 1–19% exposed farmers
• Bird fanciers: 6–20% exposed individuals
• Others: 1–8% exposed

ETIOLOGY AND PATHOPHYSIOLOGY
• Hypersensitivity reaction involving immune complexes: Inhaled antigens bind to IgG, triggering complement cascade (types III and IV immunologic reactions) (3).
• Cellular-mediated reaction: T cell–mediated immune inflammatory response
• Farming, vegetable, or dairy cattle workers (1,2)  
  – Moldy hay, grain, silage: thermophilic actinomycetes, such as *Faenia rectivirgula*
  – Mold on pressed sugar cane: *Thermoactinomyces sacchari, Thymus vulgaris*
  – Tobacco plants: *Aspergillus* sp., *Scopulariopsis brevicaulis*
  – Mushroom worker’s lung: *Saccharopolyspora rectivirgula, T. vulgaris, Aspergillus* spp.
  – Wine maker’s lung: *Mucor stolonifer*
  – Cheese washer’s lung: *Penicillium caseifulvum, Aspergillus clavatus*
  – Coffee worker’s lung: coffee bean dust
  – Tea grower’s lung: tea plants
• Ventilation and water-related contamination (1,2)  
  – Contaminated humidifiers and air conditioners: amoebae, nematodes, yeasts, bacteria
  – Unventilated shower: *Epicoccum nigrum*
  – Hot-tub lung: *Cladosporium* sp., *Mycobacterium avium complex*
  – Sauna taker’s lung: *Aureobasidium* sp.
  – Summer-type pneumonitis: *Trichosporon cutaneum*
  – Swimming pool lifeguard’s lung: aerosolized endotoxin and *M. avium complex*
  – Contaminated basement pneumonitis: *Cephalosporium* and *Penicillium* spp.
• Bird and poultry handling (1)  
  – Bird fancier’s lung: droppings, feathers, serum proteins
  – Poultry worker’s lung: serum proteins
  – Turkey-handling disease: serum proteins
  – Canary fancier’s lung: serum proteins
  – Duck fever: feathers, serum proteins
• Veterinary work and animal handling (1,2)
- Laboratory worker’s lung: urine, serum, pelts, proteins
- Pituitary snuff taker’s disease: dried, powdered neurohypophysis
- Furrier’s lung: animal pelts
- Bat lung: bat serum protein
- Fish meal worker’s lung: fish meal
- Coptic lung: cloth wrapping of mummies
- Mollusc shell HP: sea-snail shell
- Pearl oyster shell pneumonitis: oyster shells

- Grain and flour (1,2)
  - Grain measurer’s lung: cereal grain, grain dust
  - Miller’s lung: *Sitophilus granarius*
  - Malt worker’s disease: *Aspergillus fumigatus*, *A. clavatus*

- Lumber milling, construction, wood stripping, paper, wallboard manufacturing (1,2)
  - Wood dust pneumonitis: *Alternaria* sp., *Bacillus subtilis*
  - Sequoiosis: *Graphium*, *Pullularia*, *Trichoderma* sp., *Aureobasidium pullulans*
  - Maple bark disease: *Cryptostroma corticale*
  - Wood trimmer’s disease: *Rhizopus* sp., *Mucor* sp.
  - Wood pulp worker’s disease: *Penicillium* sp.
  - Suberosis: *Trogon viridis*, *Penicillium glabrum*

- Plastic manufacturing, painting, electronics, chemicals (1)
  - Chemical HP: diphenyl diisocyanate, toluene diisocyanate
  - Detergent worker’s lung: *B. subtilis* enzymes
  - Pauli reagent alveolitis: sodium diazobenzene sulfate
  - Vineyard sprayer’s lung: copper sulfate
  - Pyrethrum: *Pyrethrum*
  - Epoxy resin lung: phthalic anhydride
  - Bible printer’s lung: moldy typesetting water
  - Machine operator’s lung: *Pseudomonas fluorescens*, aerosolized metal working fluid

- Textile workers
  - Byssinosis: cotton mill dust
  - Velvet worker’s lung: nylon, tannic acid, potato starch
  - Lycoperdonosis: puffball spores

**Genetics**

No evidence of clear genetic susceptibility; possible genetic predisposition
involving tumor necrosis factor alpha (TNF-α) and major histocompatibility complex (MHC) class II genes (1,3)[B]

RISK FACTORS
- Contact with organic antigens increases the risk of developing HP. Viral infection at time of exposure could also increase risk.
- Nonsmokers have an increased incidence of HP compared with smokers. The mechanisms that account for the “protective” effect of smoking are poorly understood, but nicotine is thought to inhibit macrophage activation and lymphocyte proliferation and function (3).
  - Smokers have a diminished antibody response to inhaled antigens.
  - However, smokers that develop disease tend to have the chronic form, and mortality is higher.

GENERAL PREVENTION
Avoidance of offending antigen and/or use of protective equipment

COMMONLY ASSOCIATED CONDITIONS
Constrictive bronchiolitis

DIAGNOSIS
- Diagnosis criteria most widely used but not validated: (i) history and physical and pulmonary function tests (PFTs) indicating restriction or diffusion disease, (ii) radiologic imaging consent with interstitial lung disease, (iii) exposure to a recognized cause, (iv) proof of sensitization in bronchoalveolar lavage (BAL) fluids (serum precipitins and/or lymphocytosis) (2)
- Six significant predictors: exposure to a known antigen, positive precipitating antibodies (Ab), recurrent episodes of symptoms, inspiratory crackles, symptoms 4 to 8 hours after exposure, weight loss (3)
- Acute form: develops 4 to 12 hours following exposure. Cough, dyspnea without wheezing, fever, chills, diaphoresis, headache, nausea, malaise, chest tightness. Symptoms last hours to days.
- Sequela (prior subacute, chronic): gradual or progressive productive cough, dyspnea, fatigued, anorexia, weight loss can lead to respiratory failure; develops over days, weeks to months
- Symptomatic improvement when away from work or home

mebooksfree.com
PHYSICAL EXAM

- Acute: fever, tachypnea, diffuse fine rales
- Sequela or chronic: inspiratory crackles, progressive hypoxia, weight loss, diffuse rales, clubbing, rarely wheezing

DIAGNOSTIC TESTS & INTERPRETATION

- Testing for Ab is NOT diagnostic as up to 40% may have positive Ab without disease; antigens that cover most cases: pigeon and parakeet sera, dove feather, Aspergillus sp., Penicillium, S. rectivirgula, and Thalassomonas viridans
- PFTs: Typical profile is a restrictive pattern with low diffusing capacity; could also have an obstructive pattern (4)
- BAL with serum precipitins and lymphocytosis: usually with low CD4-to-CD8 ratio; findings not unique to HP (1,4)
- Positive antigen–specific inhalation challenge testing: reexposure to the environment, inhalation challenge to the suspected antigen in a hospital setting but it lacks standardization (3)
- Chest x-ray (CXR): used to rule out other diseases
  - Acute: ground-glass infiltrates, nodular or striated patchy opacities, interstitial pattern in a variety of distributions in lung field. Up to 20% could be normal.
  - Sequela/chronic: upper lobe fibrosis, nodular or ground-glass opacities, volume loss, emphysematous changes
- CT scan of chest; patterns not specific to HP:
  - Acute: ground-glass opacities, poorly defined centrilobular nodules and ground-glass opacities and air trapping on expiratory images (3,5)
  - Chronic: fibrosis, ground-glass attenuation, irregular opacities, bronchiectasis, loss of lung volume, honeycombing, emphysematous changes (3,5)
- High-resolution CT (HRCT) mid-to-upper zone predominance of centrilobular ground glass or nodular opacities with signs of air trapping (3)
- Usually start with CXR; may progress to HRCT based on findings (3)

Diagnostic Procedures/Other

Lung biopsy:

- Transbronchial: reveals small, poorly formed noncaseating granulomas near respiratory or terminal bronchioles, large foam cells, peribronchial fibrosis
- Open lung biopsy: highest yield in advanced disease; reveals varying patterns
of organizing pneumonia, centrilobular and perilobular fibrosis, multinucleated giant cells with clefts

DIFFERENTIAL DIAGNOSIS

- Acute: acute infectious pneumonia: influenza (or other viral pneumonia), mycoplasma, *Pneumocystis jiroveci* pneumonia, asthma, aspiration
- Chronic: sarcoidosis, chronic bronchitis, chronic obstructive pulmonary disease, tuberculosis, collagen vascular disease, idiopathic pulmonary fibrosis, lymphoma, fungal infections, *P. jiroveci* pneumonia

ALERT

HP in farmers must be distinguished from febrile, toxic reactions to inhaled dusts (organic dust toxic syndrome [ODTS]). Nonimmunologic reactions occur 30–50% more commonly than HP in farmers. ODTS is associated with intense exposure occurring on a single day.

TREATMENT

GENERAL MEASURES

Outpatient, except for acute pneumonitis cases and admission for workup (BAL, lung biopsy)

MEDICATION

*First Line*

- Avoidance of offending antigen is primary therapy and results in disease regression (3).
- Corticosteroids: help control the symptoms of exacerbations but do not improve long-term outcomes
  - Prednisone: 20 to 50 mg daily (3,4)
  - For severe symptomatic patients, initial course of 1 to 2 weeks with taper (3,4)

*Second Line*

- Bronchodilators and inhaled corticosteroids may symptomatically improve patients with wheeze and chest tightness (4)[B].
- Oxygen may be needed in advanced cases.
- Lung transplantation may be the last resort in severe cases unresponsive to
therapy.

ISSUES FOR REFERRAL
Referral to pulmonologist/immunologist

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Supportive management, as needed, to maintain oxygenation and ventilation:
- Unstable ventilation, oxygen requirement, mental status changes
- Need for invasive evaluation (lung biopsy)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Initial follow-up should be weekly to monthly, depending on severity and course.
- Follow treatments with serial CXR, PFTs, and circulating antibody levels.

DIET
No dietary restrictions

PATIENT EDUCATION
Note that chronic exposure may lead to a loss of acute symptoms with exposure (i.e., the patient may lose awareness of exposure–symptom relationship).

PROGNOSIS
- Presence of fibrosis is a poor prognosis factor (3).
- Acute: good prognosis with reversal of pathologic findings if elimination of offending antigen early in disease (2)
- Sequela/chronic: Corticosteroids have been found to improve lung function acutely but offer no significant difference in long-term outcome (3)[C].

COMPLICATIONS
- Progressive interstitial fibrosis with eventual respiratory failure
- Cor pulmonale and right-sided heart failure
REFERENCES

CODES

ICD10

- J67.9 Hypersensitivity pneumonitis due to unspecified organic dust
- J67.0 Farmer’s lung
- J67.2 Bird fancier’s lung

CLINICAL PEARLS

- Skin testing is not useful for the diagnosis of HP.
- Diagnosis should be suspected in every patient with unexplained cough and dyspnea on exertion, functional impairment (restriction or diffusion defect), and unclear fever, especially if exposure to potential antigens is known (workplace, domestic bird keeping, moldy walls in the home) (2).
- HP may mimic viral upper respiratory illness or asthma exacerbation. Misdiagnosis has critical therapeutic and prognostic implications as it may delay proper treatment, result in significant morbidity, unnecessary hospitalizations, and irreversible fibrosis to the lungs (3).
- Once the disease is established, smoking does not appear to attenuate its severity, and it may predispose to more chronic and severe course.
- Use of protective gear on individual with high-risk exposure occupations can prevent HP.
Chronic HP is increasingly recognized as an important mimic of other fibrotic lung diseases (3).
HYPERSPLENISM

Shadi Hamdeh, MD • Adil Abdalla, MD

BASICS

DESCRIPTION

- Hypersplenism is defined as overactivity of the spleen and presents as the following:
  - Splenomegaly (commonly but not always)
  - Cytopenias with respective bone marrow hyperplasia of precursors
  - Resolution of cytopenias with splenectomy
- Splenomegaly is not synonymous with hypersplenism. Overactivity of the spleen can occur without enlargement, as is seen in immune thrombocytopenic purpura (ITP) and autoimmune hemolytic anemia. Similarly, splenomegaly is not always associated with hypersplenism.

EPIDEMIOLOGY

May be as common as 30–70% in patients with cirrhosis and portal hypertension (HTN)

ETIOLOGY AND PATHOPHYSIOLOGY

- Enlargement of the spleen results in sequestration of formed blood elements, leading to peripheral cytopenias and concomitant bone marrow precursor hyperplasia.
- Many of the common etiologies are listed below. Almost any process involving the spleen or the hematologic system can result in hypersplenism:
  - Infectious
    - Tuberculosis
    - Brucellosis
    - Malaria
    - Leishmaniasis
    - Ehrlichiosis
    - Schistosomiasis
    - Histoplasmosis
    - Candidiasis
    - Viral
Syphilis
  o Infective endocarditis

Hematologic
  o Myeloproliferative disorders
  o Polycythemia vera
  o Primary hypersplenism
  o ITP
  o Hemolytic anemias

Neoplastic
  o Hematologic malignancies
  o Melanoma
  o Various carcinomas
  o Metastatic cancers

Storage diseases
  o Gaucher disease
  o Niemann-Pick disease
  o Amyloidosis
  o Glycogen storage disease

Inflammatory
  o Sarcoidosis
  o Systemic lupus erythematosus
  o Felty syndrome

Congestive
  o Cirrhosis
  o Heart failure
  o Portal or splenic vein thrombosis
  o Congenital malformations of the portal vein

DIAGNOSIS

HISTORY

• Patients may complain of abdominal fullness or protrusion of the spleen through the abdominal wall; may complain of early satiety if the spleen is compressing stomach
• Patients may complain of tenderness in the left upper quadrant, especially with viral infections. In lymphoproliferative disorders, spleen may be enlarged but asymptomatic unless there is splenic infarction. Given location of the
spleen next to the diaphragm, a sense of fullness may be referred through the phrenic nerve to the C3–C5 dermatomes in the left shoulder.

- Symptoms related to the underlying cause of hypersplenism may be present.

**PHYSICAL EXAM**

**Splenomegaly**

- The normal spleen is not palpable. A palpable spleen always indicates underlying abnormality such as splenomegaly and, in turn, hypersplenism in the appropriate clinical context or may indicate a wandering spleen. Also, spleen can be palpated in chronic obstructive pulmonary disease and acute asthma exacerbation, without coexisting splenomegaly.

- Begin by percussing Traube semilunar space, demarcated laterally by left anterior axillary line, inferiorly by the left costal margin, and superiorly by the left 6th rib. This space is usually hollow. Splenic enlargement may cause dullness to percussion in this area. Other processes that may cause dullness include pleural or pericardial effusions. Additionally, if the patient recently ate a large meal, this area may be dull to percussion.

- With patient supine, rest hand gently on the abdomen to prevent sudden tensing of the abdominal musculature, which may obscure palpation. Better abdominal relaxation can be obtained by flexing the knees toward the abdomen. As the spleen enlarges, it moves caudally and medially. Start by palpating in the right lower quadrant and moving toward the umbilicus, toward the left upper quadrant. If there is doubt about whether the spleen has moved beyond the costal margin, ask patient to take a large breath, which will push the diaphragm, and, in turn, the spleen toward the examiner’s hands.

- Jaundice: if hemolytic anemia is present or in advanced cirrhosis
- Petechiae, purpura, or ecchymosis: if thrombocytopenia is present
- Lymphadenopathy: in hematologic or solid organ malignancies. It also can be seen in infectious etiologies.

**DIAGNOSTIC TESTS & INTERPRETATION**

On CBC, any and all cell lines may be decreased, resulting in the following:

- Anemia
- Leukopenia
- Thrombocytopenia

**Initial Tests (lab, imaging)**

- CBC
Reticulocyte count if anemia
If there is hemolysis, there should be an elevated reticulocyte count, elevated LDH, decreased haptoglobin, along with evidence of hyperbilirubinemia (unconjugated).
US
CT
Tc-99m sulfur colloid scintigraphy
PET
MRI

Follow-Up Tests & Special Considerations
Based on other historical and exam findings, testing for specific infectious etiologies may be warranted:
- Blood parasite smear for malaria and other parasitic infections
- EBV serologies
- HIV ELISA with Western blot
- JAK2 mutation in polycythemia vera
- PPD for tuberculosis
- Hgb electrophoresis in hereditary hemoglobinopathies

Diagnostic Procedures/Other
- Bone marrow biopsy
- Liver biopsy for cirrhosis and storage diseases

Test Interpretation
Hyperplasia of bone marrow precursors, especially those correlating with the patient’s individual cytopenias

TREATMENT
MEDICATION
- No specific medication can be recommended for patients with hypersplenism. The most important intervention is to treat the underlying disorder.
- If ITP is the cause, the patient may benefit from the following:
  - Prednisone or methylprednisolone
  - IVIG
  - Rituximab
- If an infectious cause is discovered, treatment with appropriate antibiotic therapy may help to improve the cytopenias.

**SURGERY/OTHER PROCEDURES**
- Many patients with severe uncontrolled cytopenias undergo splenectomy.
- Laparoscopic splenectomy is preferred over open splenectomy (1)[A].

**ALERT**
Splenectomized patients should receive immunization to pneumococcus, meningococcus, *Haemophilus influenzae*, and influenza at least 14 days prior to splenectomy (2)[A].

- If this cannot be done (i.e., in cases of emergent splenectomy), wait at least 14 days postsplenectomy to immunize.
  - Pneumococcal vaccine
    - Pneumococcal polyvalent-23 vaccine (PPSV23) for use in adults and fully immunized children ≥2 years of age
    - Pneumococcal polyvalent-13 vaccine (PCV13) for infants and young children ≥2 months of age as part of routine immunization schedule (3)[A]
    - PCV13 for children >2 years of age, adolescents and adults in addition to PPSV23; refer to CDC for timing of administration.
    - Current guidelines recommend single revaccination of PPSV23 5 years after the initial dose and again at age of ≥65 years, at least 5 years after the previous dose.
  - *H. influenzae* vaccine
    - All unvaccinated individuals ≥5 years of age should be given 1 dose of *H. influenzae* type B (Hib) conjugate vaccine.
    - Children <5 years old should also be vaccinated. Refer to CDC for timing.
    - Vaccinated individuals can also be given additional dose of vaccine (4)[A].
  - Meningococcal vaccine (5)[A]
    - Meningococcal conjugate vaccine (MCV4) for use in patients between 2 and 55 years
    - Meningococcal polysaccharide vaccine (MPSV4) for use in patients >55 years of age
    - Revaccination is recommended every 5 years.
    - Influenza vaccine should be administered yearly based on prevalent
circulating strains. Although patients are not at higher risk from influenza itself, infection with influenza may place patients at higher risk for secondary bacterial infections.

- Radiofrequency ablation (RFA) is becoming more available and can be successful at preventing recurrence of hypersplenism. It is not currently known whether there are differences between RFA and splenectomy in terms of postprocedure infectious risks. Other alternatives to splenectomy include total and partial splenic embolization and shunting, although these techniques are evolving and additional studies are needed to evaluate efficacy and morbidity as compared to splenectomy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Hypersplenism alone generally does not warrant admission. However, all patients should be monitored closely for complications of the resulting cytopenias, including bleeding and infection, as well as complications of splenomegaly, including increased risk of splenic rupture. In some patients, the large spleen compresses the stomach and prevents adequate oral intake.
- Splenectomized patients are at increased risk of infection and postsplenectomy sepsis, especially with *Streptococcus pneumoniae*. Fevers, chills, or pain concerning for underlying infection warrant immediate attention as clinical decompensation can occur within hours. Empiric broad-spectrum antibiotics should not be delayed while evaluation is ongoing. Common empiric regimens include the following:
  - Ceftriaxone: 2 g IV q24h and vancomycin 1 g IV q12h
  - Levofloxacin: 750 mg IV q24h and vancomycin 1 g IV q12h in β-lactam–allergic patients

ONGOING CARE

- Adult patients who are splenectomized should be advised to monitor closely for fever or rigors at home, which may be an early sign of bacteremia. They should be instructed to begin antibiotics immediately prior to proceeding to a medical facility for evaluation. Early antibiotics have been shown to reduce the mortality from overwhelming postsplenectomy sepsis.
- Controlled trials have not been performed, but some regimens include the following:
– Amoxicillin-clavulanate: 875 mg PO twice daily
– Cefuroxime axetil: 500 mg PO twice daily

- Patients allergic to β-lactam antibiotics can be given an extended-spectrum fluoroquinolone such as levofloxacin 750 mg PO or moxifloxacin 400 mg PO daily.
- In children with splenectomy, daily antibiotic prophylaxis for overwhelming postsplenectomy sepsis with penicillin VK or amoxicillin is recommended until age 5 years or at least 3 years after splenectomy:
  – Age 2 months to 5 years: 125 mg PO BID
  – >5 years old: 250 mg PO BID

**PATIENT EDUCATION**

Patients who are splenectomized should be counseled extensively about the risk of overwhelming postsplenectomy sepsis and the need to obtain prompt medical evaluation in the event of fevers, chills, or any other concerning symptoms.

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Anemia, Autoimmune Hemolytic; *Malaria*; *Polycythemia Vera*; *Tuberculosis*

**CODES**

**ICD10**

D73.1 Hypersplenism

**CLINICAL PEARLS**

- Splenectomy is not necessary to make the diagnosis.
- Avoid splenectomy in patients unless absolutely necessary. Splenectomized patients are at lifelong risk for overwhelming postsplenectomy infection and
sepsis.

- If splenectomy is to be performed, give immunization for pneumococcus, meningococcus, *Haemophilus*, and influenza at least 14 days prior to surgery. Otherwise, wait until the 14th postop day to immunize.
HYPERTENSION, ESSENTIAL

Ronald Adler, MD • Jeremy Golding, MD, FAAFP

BASICS

DESCRIPTION

- Essential hypertension (HTN) is HTN without an identifiable cause; it is also known as primary HTN and benign HTN. Although its importance as a risk factor for cardiovascular and other morbidity and mortality is well-established, there is significant and increasing controversy regarding recommended thresholds for diagnosis and treatment.

- HTN is defined (Joint National Committee [JNC] 8) as ≥2 elevated BPs (1).
  - Age <60 years: systolic BP (SBP) ≥140 mm Hg and/or diastolic BP (DBP) ≥90 mm Hg at ≥2 visits
  - Age 60 years or older: SBP ≥150 mm Hg and/or DBP ≥90 mm Hg at ≥2 visits
  - With diabetes or chronic kidney disease: SBP ≥140 and/or DBP ≥90 mm Hg

- Synonym(s): benign, chronic, idiopathic, familial, or genetic HTN; high BP

Geriatric Considerations

- Isolated systolic HTN is common.
- Therapy has been shown to be effective and beneficial at preventing stroke, although target SBP is higher than in younger patients (~150 mm Hg systolic), and adverse reactions to medications are more frequent (2)[A]. The benefit of therapy has been conclusively demonstrated in older patients for SBP ≥160 mm Hg. More aggressive targets may be appropriate for higher risk individuals (2)[A].

Pediatric Considerations

- Measure BP during routine exams for >3 years of age.
- Defined as SBP or DBP ≥95th percentile on repeated measurements
- Pre-HTN: SBP or DBP between 90th and 95th percentile

Pregnancy Considerations

- Elevated BP during pregnancy may be either chronic HTN or pregnancy-
induced HTN or preeclampsia. ACE inhibitors and angiotensin II receptor blockers (ARBs) are contraindicated.

- Maternal and fetal mortality benefit from treatment of severe HTN. Evidence is not clear for mild HTN (see topic “Preeclampsia and Eclampsia (Toxemia of Pregnancy)”).
- Preferred agents: methyldopa, labetalol, hydralazine, or nifedipine

**Epidemiology**

*Incidence*

Incidence and prevalence is higher among men. Depending on the definition used, 32–46% of adults in the United States have HTN.

**Etiology and Pathophysiology**

- >90% of cases of HTN have no identified cause.
- For differential diagnosis and causes of secondary HTN, see “Hypertension, Secondary and Resistant.”

**Genetics**

BP levels are strongly familial, but no clear genetic pattern exists. Familial risk for cardiovascular diseases should be considered.

**Risk Factors**

Family history, obesity, alcohol use, excess dietary sodium, stress, physical inactivity, tobacco use, insulin resistance

**Diagnosis**

Despite 2017 guidelines suggested by the ACC/AHA (3)[C] (heavily influenced by the findings of SPRINT which was conducted in a relatively high-risk population and therefore less applicable to many patients seen in primary care), noting multiple methodologic concerns, many experts consider recommendations from JNC 8 to still be valid. Embracing the AHA/ACC guidelines (diagnostic threshold <130/80) compared to JNC 8 would result in the diagnosis of and treatment for HTN of millions more people, with unclear benefits and likely harm. Therefore, this chapter uses as its basis JNC 8 but focuses on recommendations that are relevant regardless of the specific guideline which is being applied. These include the approach to diagnosis and principles
of implementing treatment.

HISTORY

- HTN is asymptomatic except in extreme cases or after related cardiovascular complications develop.
- Headache can be seen with higher BP, often present on awakening and occipital in nature.

PHYSICAL EXAM

- Body mass index (BMI), waist circumference
- BP in both arms (see below for correct technique—very important to accurate diagnosis and treatment)
- Complete cardiac and peripheral pulse exam: Compare radial and femoral pulse for differences in volume and timing, auscultation for carotid and femoral bruits.
- Evaluate for signs of end-organ damage.
- Funduscopic exam for arteriolar narrowing, AV compression, hemorrhages, exudates, and papilledema.

DIFFERENTIAL DIAGNOSIS

- Secondary HTN: Because of the low incidence of reversible secondary HTN, special tests should be considered only if the history, physical exam, or basic laboratory evaluation indicate the possibility or for patients who prove nonresponsive to treatment. (See “Hypertension, Secondary and Resistant.”)
- White coat HTN: elevation of BP in office setting and normal BP outside office
- Masked HTN: elevated BP at home and normal BP in office

DIAGNOSTIC TESTS & INTERPRETATION

- Measuring BP:
  - Caffeine, exercise, and smoking avoided >30 minutes before measurement
  - Patient seated quietly for 5 minutes with feet on floor
  - Patient’s arm supported at heart level
  - Correct cuff size
  - Average of two or more measurements
  - Avoid “rounding” results.
- A diagnosis of HTN should be made under the following circumstances:
  - Age <60 years: SBP ≥140 mm Hg and/or DBP ≥90 mm Hg at ≥2 visits
– Age 60 years or older: SBP ≥150 mm Hg and/or DBP ≥90 mm Hg at ≥2 visits
– Age 60 years or older with CKD or diabetes: SBP ≥140 mm Hg and/or DBP ≥90 mm Hg at ≥2 visits

**Initial Tests (lab, imaging)**
- Hemoglobin or hematocrit or CBC
- Complete urinalysis (may reveal proteinuria)
- Potassium, calcium, creatinine, and uric acid
- Lipid panel (total, HDL, LDL, triglyceride [TG])
- Fasting blood glucose or hemoglobin A1c
- ECG to evaluate possible presence of left ventricular hypertrophy (LVH) or rhythm abnormalities

**Follow-Up Tests & Special Considerations**
- Special tests only if suggested by history, physical, or labs. In particular, consider possibility of sleep apnea.
- Ambulatory (24-hour) BP monitoring if “white coat” HTN is suspected, episodic HTN, or autonomic dysfunction
- Home BP monitoring is effective, especially when white coat HTN is a consideration; elevated home BPs correlate with adverse outcomes, possibly more so than office BPs, and normal readings are reassuring.

---

**TREATMENT**

**GENERAL MEASURES**
- The treatment discussed follows JNC 8 guidelines. Some recent studies (e.g., SPRINT) have concluded that more intensive therapy may be warranted for certain high-risk individuals (4)[B].
- Individual treatment goals should be jointly established with patients after discussion of the anticipated potential benefits and harms (shared decision making) (1)[A],(2)[C].
- Recommend lifestyle improvements, including diet, exercise, and reducing or eliminating tobacco/alcohol.
- Benefit of pharmacologic treatment of low-risk patients with class I HTN (SBP 140 to 150 mm Hg, DBP 90 to 99 mm Hg) remains uncertain (5)[A].
- Treating patients age <60 years or with CKD or diabetes to lower-than-
standard BP targets, <140/90 mm Hg, does not further reduce mortality or morbidity. Individualize goal BP based on risk factors.

- Target SBP at or just below 150 mm Hg in patients >60 years of age is acceptable in the general population (1).
- Majority of treatment benefit is attained with initial 2 to 3 medications. Striving for small additional drops in BP to achieve a “target” is less clinically beneficial and more likely to cause adverse effects.
- Lower than standard DBP targets are not associated with decreased morbidity/mortality.
- Assess overall risk and individualize treatment decisions.
- The decision to treat more aggressively should be considered in patients meeting enrollment criteria for SPRINT, as aggressive treatment does show improvement in outcomes, but 61 nondiabetic patients would need to be treated to a goal of SBP <120 to prevent a major cardiovascular outcome and 90 to prevent one death (4)[B].

**MEDICATION**

- Multiple drugs at submaximal dose may achieve target BP with fewer side effects. In patients on >1 medication, divide between morning and nighttime for better 24-hour antihypertensive effect.
- Sequential monotherapy attempts should be tried with different classes because individual responses vary.
- Many patients will require multiple medications.
- For initial monotherapy, choose from one of four classes of medications: ACE inhibitors, ARBs, calcium channel blockers (CCBs), or diuretics (1)[A].
- Thiazide diuretics or CCB preferred as first line in the general black population
- Chlorthalidone has a longer half-life than HCTZ and is the preferred diuretic based on established trial evidence of benefit.
- If concomitant conditions, choose first-line agent based on comorbidity.
- β-Blockers had been strongly recommended until recent meta-analyses. Atenolol may be particularly ineffective in reducing adverse outcomes of HTN (except in patients with left ventricle hypertrophy undergoing dialysis).
- β-Blockers might benefit patients with ischemic heart disease, CHF, migraine, and patients with history of ST-segment elevation myocardial infarction (STEMI).
- ACE inhibitors should be used in patients with diabetes, proteinuria, atrial fibrillation, or heart failure with reduced ejection fraction (HFrEF) but *not in pregnancy*.
- α-Adrenergic blockers are not the first choice for monotherapy but remain as second line after combination therapy of first-line agents; might benefit males with benign prostatic hypertrophy (BPH)
- CCB could be considered in patients with isolated systolic HTN, atherosclerosis, angina, migraine, or asthma; well documented to reduce risk of stroke

**First Line**

- Thiazide diuretics (4)[A] may not be effective with Cr clearance <30.
  - Chlorthalidone: 12.5 to 25.0 mg/day (more potent than hydrochlorothiazide but causes more hyponatremia and hypokalemia)
  - Hydrochlorothiazide: 12.5 to 50.0 mg/day
  - Indapamide: 1.25 to 2.50 mg/day
- ACE inhibitors
  - Lisinopril: 10 to 40 mg/day
  - Enalapril: 5 to 40 mg/day
  - Ramipril: 2.5 to 20.0 mg/day
  - Benazepril: 10 to 40 mg/day
- CCB
  - Diltiazem CD: 180 to 360 mg/day
  - Nifedipine (sustained release): 30 to 90 mg/day
  - Verapamil (sustained release): 120 to 480 mg/day
  - Amlodipine: 2.5 to 10.0 mg/day
- ARBs
  - Losartan: 25 to 100 mg in 1 or 2 doses; has unique but modest uricosuric effect
  - Valsartan: 80 to 320 mg daily
  - Irbesartan: 75 to 300 mg daily
  - Candesartan: 4 to 32 mg daily
  - Renin inhibitor: aliskiren 150 to 300 mg daily
- Contraindications
  - Diuretics may worsen gout.
  - β-Blockers (relative) in reactive airway disease, heart block, diabetes, and peripheral vascular disease; probably should be avoided in patients with metabolic syndrome or insulin-requiring diabetes
  - Diltiazem or verapamil: Do not use with systolic dysfunction or heart block. Amlodipine may cause peripheral edema.
Second Line
- Before escalating therapy, ensure that patient is adherent to prescribed regimen.
- Many may be combined. Choose additional medications with complementary effects (i.e., ACE inhibitors/ARBs with diuretic or a vasodilator with a diuretic or β-blocker). Don’t combine ACE-I and ARB.
- Medication-refractory HTN: spironolactone: 25 to 100 mg/day especially effective (6)[B]
- Centrally acting α-2 agonists: clonidine 0.1 to 1.2 mg BID or weekly patch 0.1 to 0.3 mg/day, guanfacine 1 to 3 mg daily, or methyldopa 250 to 2,000 mg BID
- α-Adrenergic antagonists: prazosin 1 to 10 mg BID, terazosin 1 to 20 mg/day, or doxazosin 1 to 16 mg/day
- Vasodilators
  - Hydralazine: 10 to 25 mg QID; risk of tachycardia, so generally combined with β-blocker; also drug-induced systemic lupus erythematosus (SLE)
  - Minoxidil: rarely used due to adverse effects; may be more effective than other medications in renal failure and refractory HTN
- Metolazone and loop diuretics may be used with more severe renal impairment, but outcomes data are absent; loop diuretics (for volume overload): furosemide 20 to 320 mg/day or bumetanide 0.5 to 2.0 mg/day
- K⁺-sparing diuretics in patients with hypokalemia while taking thiazides: amiloride 5 to 10 mg/day or triamterene 50 to 150 mg/day

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Biofeedback and relaxation exercise
- Dietary supplements such as garlic have been suggested for lowering BP, but evidence is lacking.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Reevaluate patients q3–6mo until stable and then q6–12mo. Consider use of home self-BP monitoring; quality-of-life issues including sexual function
should be considered.
- Poor medication adherence is a leading cause of apparent medication failure.
- At least annual creatinine, and potassium for patients on diuretics, ACE inhibitors, and ARBs

**DIET**
- ~20% of patients will respond to reduced-salt diet (<100 mmol/day; <6 g NaCl or <2.4 g Na).
- Limit alcohol consumption to <1 oz/day.

**PATIENT EDUCATION**
- Emphasize the asymptomatic nature of HTN.

**COMPLICATIONS**
Heart failure, renal failure, LVH, myocardial infarction, retinal hemorrhage, stroke, hypertensive heart disease, drug side effects, erectile dysfunction

**REFERENCES**

**SEE ALSO**

Hypertension, Secondary and Resistant; Hypertensive Emergencies; Polycystic Kidney Disease

**CODES**

**ICD10**

I10 Essential (primary) hypertension

**CLINICAL PEARLS**

- Treatment of HTN reduces risk of many serious medical conditions with numbers needed to treat to prevent one serious event (e.g., stroke or myocardial infarction) ranging from ~20 patients per year for severe HTN to more than several hundred per year for milder HTN.
- Multiple submaximal doses are likely to have fewer side effects and more effectiveness than fewer maximum-dosed drugs.
- Treatment decisions should always be informed by BP measured by proper technique; measures obtained outside the clinical office may be more predictive of CV risk.
- Appropriate lifestyle changes should be recommended before and during pharmacologic treatment.
- Overly-aggressive treatment may cause significant harms, including syncope and electrolyte abnormalities; such effects are more likely and often more significant in the elderly.
- Treatment goals should be periodically revisited and jointly established.
through shared decision making informed by anticipated potential benefits and harms.
BASICS
DESCRIPTION
Uncontrolled hypertension (HTN) comprises the following entities (see “Alert” below):

- Resistant HTN: defined as blood pressure that remains above goal in spite of the concurrent use of three antihypertensive agents of different classes. Ideally, one of the three agents should be a diuretic, and all agents should be prescribed at optimal dose amounts (1)[C].
- Secondary HTN: elevated BP that results from an identifiable underlying mechanism (1)
- Both the Eighth Joint National Committee (JNC 8) and AHA/ACC/CDC guidelines recommend a goal BP of <140/90 mm Hg, although JNC 8 allows for a goal of <150/90 mm Hg for patients age >60 years (2,3)[C].
- The SPRINT study suggests that a lower blood pressure may be preferable in some high-risk patients. This is controversial and evolving (4)[B].

Geriatric Considerations
- Onset of HTN in adults >60 years of age is a strong indicator of secondary HTN.
- In patients >80 years of age, consider a higher target systolic blood pressure (SBP) of ≥150 mm Hg. Be cautious to avoid excessive diastolic lowering.
- Elderly may be particularly responsive to diuretics and dihydropyridine calcium channel blockers.
- Systolic HTN is particularly problematic in the elderly.
- Secondary causes more common in the elderly include sleep apnea, renal disease, renal artery stenosis, and primary aldosteronism (PA).

Alert
Pseudoresistance
- Inaccurate measurement of BP
Cuff too small
Patient not at rest; sitting quietly for 5 minutes
- Poor adherence: In primary care settings, this has been estimated to occur in 40–60% of patients with HTN.
- White coat effect: prevalence 20–40%. Do not make clinical decisions about HTN based solely on measurement in the clinic setting. Home BP monitoring and/or ambulatory BP monitoring is more reliable. See USPSTF recommendations.
- Inadequate treatment

EPIDEMIOLOGY
- Predominant age: In general, HTN has its onset between ages 30 and 50 years. Patients with resistant HTN are more likely to experience the combined outcomes of death, myocardial infarction, congestive heart failure (CHF), stroke, or chronic kidney disease.
- Depending on etiology, age of onset can vary. Age of onset <20 or >50 years increases likelihood of a secondary cause for HTN.
- The strongest predictors for resistant HTN are age (>75 years), presence of left ventricular hypertrophy (LVH), obesity (body mass index [BMI] >30), and high baseline systolic BP. Other predictors include chronic kidney disease, diabetes, living in the southeastern United States, African American race (especially women), and excessive salt intake.

Prevalence
- Prevalence of resistant HTN is unknown. NHANES analysis indicates only 53% of adults are controlled to a BP of <140/90 mm Hg.
- Secondary HTN occurs in about 5–10% of adults with chronic HTN.

ETIOLOGY AND PATHOPHYSIOLOGY
- Obstructive sleep apnea (OSA): One study diagnosed OSA in 83% of treatment-resistant hypertensives.
- Primary hyperaldosteronism (17–22% of resistant HTN cases)
- Chronic renal disease (2–5% of hypertensives)
- Renovascular disease (0.2–0.7%, up to 35% of elderly, 20% of patients undergoing cardiac catheterization)
- Cushing syndrome (0.1–0.6%)
- Pheochromocytoma (0.04–0.1% of hypertensives)
- Other rare causes: hyperthyroidism, hyperparathyroidism, aortic coarctation,
intracranial tumor

- Drug-related causes
  - Medications, especially NSAIDs (may also blunt effectiveness of ACE inhibitors), decongestants, stimulants (e.g., amphetamines, attention deficit hyperactivity disorder [ADHD] medications), anorectic agents (e.g., modafinil, ephedra, guarana, ma huang, bitter orange), erythropoietin, natural licorice (in some chewing tobacco), yohimbine, glucocorticoids
  - Oral contraceptives: unclear association; mainly epidemiologic and with higher estrogen pills
  - Cocaine, amphetamines, other illicit drugs; drug and alcohol withdrawal syndromes

- Lifestyle factors: Obesity and dietary salt may negate the beneficial effect of diuretics. Excessive alcohol may cause or exacerbate HTN. Physical inactivity also contributes.

**RISK FACTORS**

A recent large cohort study revealed that those with resistant HTN (16.2%) were more likely to be male, Caucasian, older, and diabetic. They were also more likely to be taking β-blockers, calcium channel blockers, and α-adrenergic blockers compared with other drug classes. Factors predictive of resistant or secondary HTN: female sex, African American race, obesity, diabetes, worsening of control in previously stable hypertensive patient, onset in patients age <20 years or >50 years, lack of family history of HTN, significant target end-organ damage, stage 2 HTN (systolic BP >160 mm Hg or diastolic BP >100 mm Hg), renal disease, and alcohol or drug use

**GENERAL PREVENTION**

The prevention of resistant and secondary HTN is thought to be the same as for primary or essential HTN: Adopting a Dietary Approaches to Stop Hypertension (DASH) diet, a low-sodium diet, weight loss in obese patients, exercise, limitation of alcohol intake, and smoking cessation may all be of benefit. Relaxation techniques may be of help, but data are limited.

**DIAGNOSIS**

**HISTORY**

- Ask or review at every visit: “The Big Four” SANS mnemonic: (i) Salt intake,
(ii) Alcohol intake, (iii) NSAID use, (iv) Sleep (author’s suggestion, based on reference listed)
- Review home BP readings; consider ambulatory BP monitoring.
- History will vary with etiology of HTN.
- Pheochromocytoma: episodes of headache, palpitations, sweating
- Cushing syndrome: weight gain, fatigue, weakness, easy bruising, amenorrhea
- OSA: loud snoring while asleep, daytime somnolence
- Increased intravascular volume: swelling

PHYSICAL EXAM
- Ensure that the BP is measured correctly. The patient should be sitting quietly with back supported for 5 minutes before measurement. Proper cuff size: bladder encircling at least 80% of the arm. Support arm at heart level. Minimum of two readings at least 1 minute apart. Check BP in both arms. Also check standing BP for orthostasis.
- The USPSTF recommends “obtaining measurements outside of the clinical setting for diagnostic confirmation.” Attention to findings related to possible etiologies: renovascular HTN: systolic/diastolic abdominal bruit; pheochromocytoma: diaphoresis, tachycardia; cushing syndrome: hirsutism, moon facies, dorsal hump, purple striae, truncal obesity; thyroid disease: enlarged thyroid, tremor, exophthalmos, tachycardia; coarctation of the aorta: upper limb HTN with decreased or delayed femoral pulses
- Funduscopic exam

DIAGNOSTIC TESTS & INTERPRETATION
- ECG performed as part of the initial workup; LVH is an important marker of resistant HTN.
- Sleep study if history and physical indicate. The Epworth Sleepiness Scale is recommended.
- Home-based polysomnography has been shown to be accurate in screening for OSA. Overnight oximetry is not helpful.

Initial Tests (lab, imaging)
Initial limited diagnostic testing should include urinalysis, CBC, potassium, sodium, glucose, creatinine, lipids, thyroid-stimulating hormone (TSH), and calcium. 50% of patients with hyperaldosteronism may have normal potassium levels.
- Imaging tests listed are necessary only if history, physical, or lab data indicate.
Abdominal US: if renal disease is suspected
- Duplex ultrasonography may be the preferred test for renovascular disease. MR angiography (MRA) of renal vasculature is sensitive but has low specificity and potentially more harmful. Conventional catheter angiography or CT angiography may be required to confirm the diagnosis.
- Adrenal “incidentaloma” frequently arises in this era of multiple CT studies. If present in the setting of resistant HTN, consider hyperaldosteronism or hyperadrenal corticoid states.

Follow-Up Tests & Special Considerations
Further testing for PA may be considered.
- Empiric treatment with an aldosterone inhibitor may be preferable and more clinically relevant: spironolactone or eplerenone. Amiloride may be more effective in African Americans.
- Plasma aldosterone-to-renin ratio (ARR) is the preferred lab test, but the test is difficult to perform and interpret properly. Consult your reference lab and interpret results with caution.
  - Further testing for pheochromocytoma: plasma
  - Other tests to consider for resistant or secondary HTN: 24-hour urine for free cortisol, calcium, parathyroid hormone (PTH), overnight 1-mg dexamethasone suppression test, urine toxicology screen

Diagnostic Procedures/Other
Consider 24-hour ambulatory BP monitoring, especially if white coat effect is suspected. Home BP monitor results predict mortality, stroke, and other target organ damage better than office BP. Optimal protocol involves two paired measurements: morning and evening (four measurements) over 4 to 7 days.
- Oscillometric, electronic, upper arm, fully automatic device with memory: average multiple readings over several days

TREATMENT
- Treatment modality depends on etiology of HTN. Please see each etiology listed for information on proper treatment.
- Emphasize adherence to JNC 8 and/or AHA/ACC guidelines, with emphasis on lifestyle modification (2,3)[C].

mebooksfree.com
– Obese patients, African Americans, and elderly may be particularly responsive to diuretics.
– Tolerance to diuretics may occur: long-term adaptation to thiazides or the “braking effect.” Consider increasing the dose of thiazide or adding an aldosterone inhibitor.

- Treatment specific to certain secondary etiologies
  - PA: aldosterone receptor antagonist: spironolactone or eplerenone
  - Cushing syndrome: aldosterone receptor antagonist
  - OSA: continuous positive airway pressure (CPAP) ± oxygen, surgery, weight loss
    - Mandibular advancement devices may be equally effective in some patients.
  - Nocturnal hypoxia: oxygen supplementation
  - Renal sympathetic denervation has been disproven as an effective strategy.

- The treatment of atherosclerotic renal artery stenosis (ARAS) is controversial. A recent meta-analysis again questions the value of percutaneous stenting (5) [B].

**MEDICATION**
- Follow treatment guidelines and algorithms by JNC8 and AHA/ACC/CDC, understanding the differences between them (2,3)[C].
- Adding a medication to the regimen may have greater efficacy than increasing the dose of medications (see JNC8 management algorithm option B) (2).
- Aldosterone antagonists may offer significant benefit (6)[B].
- Central-acting agents (e.g., clonidine) are effective at reducing BP, but outcome data are lacking.

**ALERT**
- Agents specific for treatment of HTN emergencies should be initiated under a situation in which immediate BP reduction will prevent or limit end-organ damage (see “Hypertensive Emergencies”).
- Renovascular HTN: Angioplasty is the treatment of choice for fibromuscular dysplasia of a renal artery.
- The recent CORAL study concluded that in patients with atherosclerotic renovascular disease and HTN, renal artery stenting did not improve outcomes over medical therapy alone.
- Referral to an HTN specialist or clinic: Retrospective studies indicate improved control rates for patients with resistant HTN referred to special HTN clinics.
**First Line**
- For non-black patients: thiazide diuretics, ACEi or ARB (not both), CCB
- For black patients: thiazide diuretics, CCBs

**Second Line**
Combine thiazide diuretic with ACEi, ARB, or CCB or add a K⁺-sparing diuretic

**Third Line**
Add agent not used in second line; if this does not adequately lower BP, initiate work up for secondary causes (chronic NSAID use, alcohol abuse, RAS, etc.).

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Hospitalization may be necessary for hypertensive urgency or emergency general measures.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Encourage aerobic activity of 30 min/day, depending on patient’s condition.

**DIET**
- Reduced salt may lower BP in some patients.
- Recommend the Mediterranean diet or DASH.

**PATIENT EDUCATION**
Home BP monitoring is recommended.

CODES

ICD10
- I15.9 Secondary hypertension, unspecified
- I15.8 Other secondary hypertension
- I15.0 Renovascular hypertension

CLINICAL PEARLS
- Onset of HTN in adults >60 years of age is a strong indicator of secondary HTN.
- Common causes of resistant HTN: OSA, excessive salt intake, medication nonadherence, alcohol, NSAIDs
- Common secondary causes include sleep apnea, renal disease, renal artery stenosis, and PA.
- Aldosterone inhibitors should be considered in all cases of resistant HTN.
- Home BP monitoring predicts outcomes better than office monitoring of BP.
HYPERTHYROIDISM
Anup K. Sabharwal, MD, MBA, FACE • Atil Y. Kargi, MD

BASICS
- Hyperthyroidism or thyrotoxicosis is composed of a spectrum of clinical findings consistent with thyroid hormone excess. The former describes excess from the thyroid gland, whereas the latter can be produced from another source.
- In general, patients with thyrotoxicosis have hyperthyroidism. However, this is not always the case. Patients could suffer from thyrotoxicosis not due to a prolonged elevation in thyroid hormone synthesis. Examples include subacute thyroiditis, exogenous thyrotoxicosis, and radiation-induced thyroiditis.
- Also, medications (such as amiodarone and interferon-α) have cytotoxic effects on thyroid cells resulting in thyrotoxicosis from preformed thyroid hormones.

DESCRIPTION
- Graves disease (GD): the most common form; diffuse goiter and thyrotoxicosis are common characteristics. Infiltrative orbitopathy is seen in up to 50% of patients. Infiltrative dermopathy is rare. Autoantibodies are directed at the thyroid-stimulating hormone (TSH) receptors.
- Toxic multinodular goiter (TMNG): second most common; most common cause of hyperthyroidism in patients age >65 years; patients >40 years, insidious onset, frequent in iodine-deficient areas
- Toxic adenoma (Plummer disease): younger patients, autonomously functioning nodules
- Iodine-induced hyperthyroidism
- Thyroiditis: transient autoimmune process:
  - Subacute thyroiditis/de Quervain: granulomatous giant cell thyroiditis, benign course; viral infections have been involved.
  - Postpartum thyroiditis
  - Drug-induced thyroiditis: amiodarone, interferon-α, interleukin-2, lithium
  - Miscellaneous: thyrotoxicosis factitia, TSH-secreting pituitary tumors, and functioning trophoblastic tumors
- Subclinical hyperthyroidism: suppressed TSH with normal thyroxine (T₄); may be associated with osteoporosis and atrial fibrillation
Thyroid storm: rare hyperthyroidism; fever, tachycardia, gastrointestinal symptoms, CNS dysfunction (e.g., coma); up to 50% mortality

**Geriatric Considerations**
- Characteristic symptoms and signs may be absent.
- Atrial fibrillation is common when TSH <0.1 mIU/L (2)[A].

**Pediatric Considerations**
- Neonates and children are treated with antithyroids for 12 to 24 months.
- Radioactive iodine treatment is controversial in patients <15 to 18 years.

**Pregnancy Considerations**
Propylthiouracil (PTU) is currently the drug of choice during 1st trimester of pregnancy, and methimazole (MMI) is preferred in the 2nd and 3rd trimester (3)[A]. Treat with lowest effective dose. Avoid treatment-induced hypothyroidism. Radioiodine therapy is contraindicated.

**EPIDEMIOLOGY**
- 1.3% of population
- Predominant sex: female > male (7 to 10:1)
- Predominant age: autoimmune thyroid disease (GD) in 2nd and 3rd decades. TMNG more common in patients >40 years.

**Incidence**
- Female: 1/1,000
- Male: 1/3,000

**ETIOLOGY AND PATHOPHYSIOLOGY**
- GD: autoimmune disease
- TMNG: 60% TSH receptor gene abnormality; 40% unknown
- Toxic adenoma: point mutation in TSH receptor gene with increased hormone production
- Thyroiditis:
  - Hashitoxicosis: autoimmune destruction of the thyroid; antimicrosomal antibodies present
  - Subacute/de Quervain thyroiditis: granulomatous reaction; genetic predisposition in specific human leukocyte antigens; viruses, such as coxsackievirus, adenovirus, echovirus, and influenza virus, have been
implicated; self-limited course, 6 to 12 months
- Suppurative: infectious
- Drug-induced thyroiditis: Amiodarone produces an autoimmune reaction and a destructive process. Lithium, interferon-α, and interleukin-2 cause an autoimmune thyroiditis.
- Postpartum thyroiditis: autoimmune thyroiditis that lasts up to 8 weeks, and in 60% of patients, hypothyroidism manifests in the future

**Genetics**
Concordance rate for GD among monozygotic twins is 35%.

**RISK FACTORS**
- Positive family history, especially in maternal relatives
- Female
- Other autoimmune disorders
- Iodide repletion after iodide deprivation, especially in TMNG

**COMMONLY ASSOCIATED CONDITIONS**
- Autoimmune diseases
- Down syndrome
- Iodine deficiency

**DIAGNOSIS**

**HISTORY**
- Thyrotoxicosis is a hypermetabolic state in which energy production exceeds needs, causing increased heat production, diaphoresis, and even fever.
- Thyrotoxicosis affects several different systems:
  - Constitutional: fatigue, weakness, increased appetite, weight loss
  - Neuropsychiatric: agitation, anxiety, emotional lability, psychosis, coma, and poor concentration and memory
  - GI: increased appetite, hyperdefecation
  - Gynecologic: oligomenorrhea, amenorrhea
  - Cardiovascular: tachycardia (most common) and chest discomfort that mimics angina

**Geriatric Considerations**
Apathetic hyperthyroidism in the elderly

PHYSICAL EXAM

- **Adults:**
  - Skin: warm, moist, pretibial myxedema (GD only)
  - Head, eye, ear, nose, throat (HEENT): exophthalmos, lid lag
  - Endocrine: hyperhidrosis, heat intolerance, goiter, gynecomastia, low libido, and spider angiomata (males)
  - Cardiovascular: tachycardia, atrial fibrillation, cardiomegaly
  - Musculoskeletal: skeletal demineralization, osteopenia, osteoporosis, fractures
  - Neurologic: tremor, proximal muscle weakness, anxiety and lability, brisk deep tendon reflexes
  - Rarely: thyroid acropathy (clubbing), localized dermopathy

- **Children:**
  - Linear growth acceleration
  - Ophthalmic abnormalities more common

DIFFERENTIAL DIAGNOSIS

- Anxiety
- Malignancy
- Diabetes mellitus
- Pregnancy
- Menopause
- Pheochromocytoma
- Depression
- Carcinoid syndrome

DIAGNOSTIC TESTS & INTERPRETATION

- 95% have suppressed TSH and elevated free T<sub>4</sub>. Total T<sub>4</sub> and triiodothyronine (T<sub>3</sub>) represent the bound hormone and can be affected by pregnancy and hepatitis (1)[A].

- T<sub>3</sub>: elevated, especially in T<sub>3</sub> toxicosis or amiodarone-induced thyrotoxicosis (AIT): Presence of TSH receptor antibody or thyroid-stimulating immunoglobulin is diagnostic of GD.

- Free thyroxine index (FTI): calculated from T<sub>4</sub> and thyroid hormone–binding ratio; corrects for misleading results caused by pregnancy and estrogens

- Inappropriately normal or elevated TSH with high T<sub>4</sub> suspicious for pituitary
tumor or thyroid hormone resistance
- Drugs may alter lab results: estrogens, heparin, iodine-containing compounds (including amiodarone and contrast agents), phenytoin, salicylates, and steroids (e.g., androgens, corticosteroids).
- Drug precautions: Amiodarone and lithium may induce hyperthyroidism; MMI may cause warfarin resistance.
- Other findings that can occur: anemia, granulocytosis, lymphocytosis, hypercalcemia, transaminase, and alkaline phosphate elevations

**Initial Tests (lab, imaging)**

- TSH, free T<sub>4</sub>, total T<sub>4</sub>, and T<sub>3</sub> will establish the hyperthyroid diagnosis (4)[A].
- Thyrotropin receptor antibody (TRAb) (5)[A]
- TSH receptor antibodies (TSH-R Abs): The routine assay is the TSH-binding inhibitor immunoglobulin assay (TBII). TSH-R Abs are useful in the prediction of postpartum Graves thyrotoxicosis and neonatal thyrotoxicosis (4)[A].
- Thyroxine/triiodothyronine ratio: The T<sub>4</sub>-to-T<sub>3</sub> ratio may be a useful tool when the iodine uptake testing is not available/contraindicated. ~2% of thyrotoxic patients have “T<sub>3</sub> toxicosis.”
- Nuclear medicine uptake and scanning (123<sup>I</sup> or 131<sup>I</sup>): The reference-range value for 24-hour radioiodine uptake is between 5% and 25%.
- Increased thyroid iodine uptake is seen with TMNG, toxic solitary nodule, and GD.
- GD shows a diffuse uptake and can have a paradoxical finding of high uptake at 4 to 6 hours but normal uptake at 24 hours because of the rapid clearance.
- TMNG will show a heterogeneous uptake, whereas solitary toxic nodule will show a warm or “hot” nodule.
- In iodine-deficient areas, an increased uptake is associated with low urine iodine levels.
- Causes of thyrotoxicosis with low iodine uptake:
  - Acute thyroiditis, thyrotoxicosis factitia, and iodine intoxication with amiodarone or contrast material can cause low-uptake transient thyrotoxicosis. After thyroiditis resolves, the patient can become euthyroid or hypothyroid.
  - Iodine loading can cause iodine trapping and decreased iodine uptake (Wolff-Chaikoff effect).
  - Thyrotoxicosis factitia: Thyroglobulin levels are low in exogenous intake and high in endogenous production.
– Other extrathyroidal causes include struma ovarii and metastatic thyroid carcinoma.
– Technetium-99m scintigraphy: controversial because it has a 33% discordance rate with radioactive iodine scanning

**Follow-Up Tests & Special Considerations**
In severe cases, such as thyroid storm, hospitalize until stable, especially if >60 years of age, because of the risk of atrial fibrillation.

**Diagnostic Procedures/Other**
Neck ultrasound will show increased diffuse vascularity in GD.

**Test Interpretation**
- GD: hyperplasia
- Toxic nodule: nodule formation

**TREATMENT**
- Decision of which patients to treat and how to treat should be individualized.
- Observation may be appropriate for patients with mild hyperthyroidism (TSH >0.1 or with no symptoms) especially those who are young and with low risk of complications (Afib, osteoporosis).
- Antithyroid medication is contraindicated in patients with thyroiditis.
  Treatment for subacute thyroiditis is supportive with NSAIDs and β-blockers.
  Steroids can be used for 2 to 3 weeks (3). GD or TMNG can be managed by either antithyroid medication, radioactive iodine therapy (RAIT), or thyroidectomy.
- RAIT: most common definitive treatment used in United States for GD and TMNG
  - Pretreatment with antithyroid drugs is preferred to avoid worsening thyrotoxicosis after RAIT. MMI is preferred over PTU as pretreatment because of decreased relapse, but it is held 3 to 5 days before therapy (3)[A].
  - Usually, patients become hypothyroid 2 to 3 months after RAIT; therefore, antithyroid medications are continued after ablation.
  - Glucocorticoids: reduce the conversion of active T4 to the more active T3. In Graves ophthalmopathy, the use of prednisone before and after RAIT prevents worsening ophthalmopathy (3)[B].
Smoking in GD patients is a risk factor for ophthalmopathy, especially after RAIT.

For GD, due to the chance of remission, 12- to 18-month trial of antithyroid medications may be considered prior to offering RAIT.

For TMNG, the treatment of choice is RAIT. Medical therapy with antithyroid medications has shown a high recurrence rate. Surgery is considered only in special cases (3)[B].

For AIT type I, the treatment is antithyroid drugs and β-blockers. Thyroidectomy is the last option. AIT type II is self-limited but may use glucocorticoids.

**MEDICATION**

**First Line**

- Antithyroid drugs: MMI and PTU are thioamides that inhibit iodine oxidation, organification, and iodotyrosine coupling. PTU can block peripheral conversion of T₄ to active T₃. Both can be used as primary treatment for GD and prior to RAIT or surgery (1)[A].

  - Duration of treatment: 12 to 18 months; 50–60% relapse after stopping; treatment beyond 18 months did not show any further benefit on remission rate. The most serious side effects are hepatitis (0.1–0.2%), vasculitis, and agranulocytosis; baseline CBC recommended:
    - MMI (preferred): adults: 10 to 15 mg q12–24h; children aged 6 to 10 years: 0.4 mg/kg/day PO once daily
    - PTU: adults (preferred in thyroid storm and 1st trimester of pregnancy): 100 to 150 mg PO q8h, not to exceed 200 mg/day during pregnancy

- β-Adrenergic blocker: Propranolol in high doses (>160 mg/day) inhibits T₃ activation by up to 30%. Atenolol, metoprolol, and nadolol can be used.

- Glucocorticoids: reduce the conversion of active T₄ to the more active T₃

- Cholestyramine: anion exchange resin that decreases thyroid hormone reabsorption in the enterohepatic circulation; dose: 4 g QID (1)[B]

- Other agents:
  - Lithium: inhibits thyroid hormone secretion and iodotyrosine coupling; use is limited by toxicity.
  - Lugol solution or saturated solution of potassium iodide (SSKI); blocks release of hormone from the gland but should be administered at least 1 hour after thioamide was given; otherwise, acts as a substrate for hormone production (Jod-Basedow effect)
– RAIT: See “Treatment” section.

**ISSUES FOR REFERRAL**
Patients with Graves ophthalmopathy should be referred to an experienced ophthalmologist.

**SURGERY/OTHER PROCEDURES**
Thyroidectomy for compressive symptoms, masses, and thyroid malignancy may be performed in the 2nd trimester of pregnancy only.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*
- Repeat thyroid tests q3mo, CBC, and liver function tests (LFTs) on thioamide therapy; continue therapy with thioamides for 12 to 18 months.
- After RAIT, thyroid function tests at 6 weeks, 12 weeks, 6 months, and annually thereafter if euthyroid; TSH may remain undetectable for months even after patient is euthyroid; follow T₃ and T₄.

**DIET**
Sufficient calories to prevent weight loss

**PROGNOSIS**
Good (with early diagnosis and treatment)

**COMPLICATIONS**
- Surgery: hypoparathyroidism, recurrent laryngeal nerve damage, and hypothyroidism
- RAIT: postablation hypothyroidism
- GD: high relapse rate with antithyroid drug as primary therapy
- Graves ophthalmopathy, worsening heart failure if cardiac condition, atrial fibrillation, muscle wasting, proximal muscle weakness, increased risk of cerebrovascular accident (CVA) and cardiovascular mortality

**REFERENCES**

**CODES**

**ICD10**
- E05.90 Thyrotoxicosis, unspecified without thyrotoxic crisis or storm
- E05.20 Thyrotoxicosis w toxic multinod goiter w/o thyrotoxic crisis
- E06.1 Subacute thyroiditis

**CLINICAL PEARLS**
- Not all thyrotoxicoses are secondary to hyperthyroidism.
- GD presents with hyperthyroidism, ophthalmopathy, and goiter.
- Medical treatment for GD has a high relapse rate after stopping medications.
- Thyroid storm is a medical emergency that needs hospitalization and aggressive treatment.
- Serum TSH level may be misleading and remain low in the early period after initiating treatment, even when T₄ and T₃ levels have decreased.
HYPERTHYROIDISM

S. Lindsey Clarke, MD, FAAFP

BASICS

DESCRIPTION

- Hypertriglyceridemia (HTG) is a common form of dyslipidemia characterized by an excess fasting plasma concentration of triglycerides (TG).
  - TG are fatty molecules that occur naturally in vegetable oils and animal fats and are major sources of dietary energy.
  - TG are packaged into chylomicrons and very-low-density lipoproteins (VLDL).
- HTG is a risk factor for acute pancreatitis at levels ≥1,000 mg/dL.
  - Risk is 10–20% at these TG levels.
  - Third leading cause of acute pancreatitis
- HTG also is independently associated with cardiovascular disease at levels ≥200 mg/dL.
  - The degree to which excess TG cause atherosclerosis is uncertain and debatable.
  - Lowering TG has not been proven to reduce cardiovascular risk.
- The Endocrine Society classifies HTG as follows based on fasting TG levels:
  - Normal: <150 mg/dL
  - Mild: 150 to 199 mg/dL
  - Moderate: 200 to 999 mg/dL
  - Severe: 1,000 to 1,999 mg/dL
  - Very severe: ≥2,000 mg/dL
  - Divide by 88.5 to convert to mmol/L.
- TG are considered high in children when TG exceed the 95th percentiles for age:
  - ≥100 mg/dL for ages 0 to 9 years
  - ≥130 mg/dL for ages 10 to 19 years

EPIDEMIOLOGY

- Predominant gender: male > female
- Predominant race: Hispanic, white > black
Prevalence

- 33% of U.S. population has TG levels ≥150 mg/dL.
- 1.7% has TG levels ≥500 mg/dL.
- Highest prevalence at age 50 to 70 years
- The most common genetic syndromes with HTG, familial combined hyperlipidemia and familial HTG, each affects ≤1% of general population.

ETIOLOGY AND PATHOPHYSIOLOGY

- Primary
  - Familial
  - Acquired (sporadic)
- Secondary
  - Obesity and overweight
  - Physical inactivity
  - Cigarette smoking
  - Excess alcohol intake
  - Very high carbohydrate diets (>60% of total caloric intake)
  - Certain medications
    - Interferon-α
    - Atypical antipsychotics
    - β-Blockers other than carvedilol
    - Bile acid sequestrants
    - Corticosteroids
    - Oral estrogens
    - Protease inhibitors
    - Raloxifene
    - Retinoic acid
    - Tamoxifen
    - Thiazides
  - Medical conditions
    - Type 2 diabetes mellitus
    - Hypothyroidism
    - Chronic renal failure, nephrotic syndrome
    - Autoimmune disorders (e.g., systemic lupus erythematosus)
    - Paraproteinemias (e.g., macroglobulinemia, myeloma, lymphoma, lymphocytic leukemia)
    - Pregnancy (usually physiologic and transient)
**Genetics**
- Familial combined hyperlipidemia (type IIb hyperlipoproteinemia): usually autosomal dominant, caused by overproduction of apolipoprotein (APO) B-100; approximately 1% prevalence
- Familial dysbetalipoproteinemia (type III): usually autosomal recessive, caused by lipoprotein overproduction due to inheritance of two APOE2 variants; 0.01% prevalence
- Familial HTG (type IV): autosomal dominant, caused by an inactivating mutation of the lipoprotein lipase gene; 1% prevalence

**RISK FACTORS**
- Genetic susceptibility
- Obesity, overweight
- Lack of exercise
- Diabetes
- Alcoholism
- Certain medications (see “Etiology and Pathophysiology”)
- Medical conditions (see “Etiology and Pathophysiology”)

**GENERAL PREVENTION**
- Weight reduction
- Moderation of dietary fat and carbohydrates
- Regular aerobic exercise

**COMMONLY ASSOCIATED CONDITIONS**
- Coronary artery disease
- Diabetes mellitus type 2 and insulin resistance
- Dyslipidemias
  - Decreased high-density lipoprotein (HDL) cholesterol
  - Increased low-density lipoprotein (LDL), non-HDL, and total cholesterol
  - Small, dense LDL particles
- Metabolic syndrome (three of the following):
  - Abdominal obesity (waist circumference >40 inches in men, >35 inches in women)
  - TG ≥150 mg/dL
  - Low HDL cholesterol (<40 mg/dL in men, <50 mg/dL in women)
  - BP ≥130/85 mm Hg
  - Fasting glucose ≥100 mg/dL
- Nonalcoholic steatohepatitis
- Pancreatitis
- Polycystic ovary syndrome

DIAGNOSIS

HISTORY
- Usually asymptomatic
- Patients with chylomicronemia syndrome can have memory loss, headache, vertigo, dyspnea, and paresthesias.
- Pancreatitis: epigastric pain, nausea, and vomiting
- Assess for other cardiac risk factors.
- Family history of coronary artery disease

PHYSICAL EXAM
- Obesity, overweight (body mass index ≥25 kg/m²)
- Eruptive cutaneous, tuberous, and striate palmar xanthomas
- Lipemia retinalis
- Epigastric tenderness in pancreatitis
- Hepatomegaly in NASH and chylomicronemia

DIFFERENTIAL DIAGNOSIS
Primary and secondary HTG

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Serum: turbid with milky supernatant
- Fasting lipid profile (12-hour fast)
  - Routine screening every 5 years beginning at age 35 years for men and age 45 years for women
  - Begin screening earlier in those at higher risk for coronary heart disease.
  - For interpretation, see “Description.”
- Secondary causes
  - Glycosylated hemoglobin, fasting or postprandial glucose for type 2 diabetes mellitus
  - Creatinine, urinary protein measurement for nephrotic syndrome, renal failure
- Thyroid-stimulating hormone for hypothyroidism
- Human chorionic gonadotropin for pregnancy

- Atherosclerosis: cardiac stress imaging, coronary angiography, CT arteriography
- Pancreatitis: serum lipase; CT scan, US of pancreas

**Follow-Up Tests & Special Considerations**
- Repeat lipid panel after 2 months of therapy.
- High levels of APO B (≥90 mg/dL) are a strong predictor of coronary death in patients whose LDL cannot be calculated because of very high TGs. However, evidence for routine clinical use is lacking.

**Test Interpretation**
- Chylomicronemia syndrome: lipid-laden macrophage (foam cell) infiltration of visceral organs, bone marrow, and skin
- Atherosclerosis
- Pancreatitis

**TREATMENT**

**GENERAL MEASURES**
- Cardiovascular risk reduction through LDL lowering should be prioritized over TG lowering unless patient is at risk for pancreatitis because of very high TG (≥500 mg/dL) (1)[C].
- Therapeutic lifestyle changes are first-line interventions for all patients and can reduce TG by as much as 50% (1)[C]:
  - Dietary modification (by decreasing carbohydrate intake to <50% of calories and limiting alcohol intake)
  - Moderate-intensity physical activity can reduce TG by 20–30%.
  - Weight loss of 5–10% can reduce TG by 20%.
  - Persons with very high TG should abstain from alcohol.
- Search for correctable secondary causes, treat underlying illness, or remove offending drug.
- Improve glycemic control if diabetic.
- Control other cardiac risk factors such as hypertension, diabetes mellitus, and smoking.
- Primary HTG: Screen other family members.
**MEDICATION**

**First Line**

| Fibrates: the most effective agents for reducing TG up to 50%; used primarily to reduce risk of pancreatitis when TGs are severe or very severe; have been shown to decrease nonfatal myocardial infarction but not all-cause mortality (1)[C],(2)[A]: |
| Fenofibrate: 30 to 200 mg daily |
| Gemfibrozil: 600 mg BID |
| Adverse reactions: GI upset, hepatotoxicity, cholelithiasis, myalgias, rhabdomyolysis (when combined with a statin), gemfibrozil–warfarin interaction (enhanced anticoagulation) |
| Gemfibrozil should be avoided in combination with statins due to high risk of muscle injury. If combination therapy is needed, use fenofibrate. |

| Statins: the most effective agents for reducing cardiovascular risk; primarily affect LDL but also may lower TG 15–30% (3)[A]; dosing depends on intensity of statin desired based on 10-year cardiovascular risk; 2013 ACC/AHA guidelines recommend initiating therapy for 7.5% 10-year risk and other clinical factors (4)[C]: |
| Rosuvastatin: 5 to 40 mg/day |
| Atorvastatin: 10 to 80 mg/day |
| Adverse reactions: myalgias, myopathy, rhabdomyolysis (especially if combined with fibrates); contraindicated in pregnancy and lactation |

**Second Line**

Omega-3 fatty acids

| Lovaza, others: 4 g daily or 2 g BID (5)[C] |
| May lower TG 30–50% |
| Limited tolerability due to adverse GI effects (diarrhea in up to 15%; also nausea, abdominal pain, dysgeusia, eructation, dyspepsia) |
| Limited outcomes data |

**ISSUES FOR REFERRAL**

| HTG refractory to treatment |
| Familial HTG syndromes |

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Acute pancreatitis
Acute coronary syndrome
In acute hypertriglyceridemic pancreatitis with TG >1,000 mg/dL, the following interventions can be used to lower TG rapidly and safely to <500 mg/dL:
- Apheresis (therapeutic plasma exchange)
- Insulin infusion
  - Regular insulin 0.1 to 0.3 units/hr IV
  - Administer separate infusion of dextrose 5% if blood glucose <200 mg/dL.
- Discharge criteria: stabilization of acute complicating illness

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
2 months after initiation or modification of therapy (repeat fasting lipid profile)

Patient Monitoring
- Fasting lipid profile q6–12mo
- Maintain TG <1,000 mg/dL to reduce risk of acute pancreatitis.
- Hepatic transaminases
- Creatine phosphokinase if patient has myalgias

DIET
- Restrict dietary fat to 30% of total caloric intake; restrict further to 15% of caloric intake if TG ≥1,000 mg/dL (1)[C].
- Limit carbohydrates (especially simple carbohydrates and sugars) to 60% of total caloric intake.
- Mediterranean-style diet reduces TG 10–15% more than a low-fat diet.
- Increase marine-derived omega-3 polyunsaturated fatty acids (4 g/day reduces TG by 25–30%, dose–response relationship).
- Eliminate trans fatty acids.
- Increase dietary fiber.
- Avoid concentrated sugars such as fructose.
- Moderate alcohol intake (<1 oz/day or complete abstinence if TGs are very high)
PATIENT EDUCATION
Smoking cessation for cardiovascular risk reduction

PROGNOSIS
- Good with correction of TG levels
- Patients with primary HTG usually require lifelong treatment.

COMPLICATIONS
- Atherosclerosis
- Chylomicronemia syndrome
- Pancreatitis

REFERENCES

ADDITIONAL READING
SEE ALSO
- Hypercholesterolemia; Pancreatitis, Acute
- Algorithm: Hypertriglyceridemia

CODES

ICD10
E78.1 Pure hyperglyceridemia

CLINICAL PEARLS
- HTG is a risk factor for pancreatitis at levels ≥1,000 mg/dL and for coronary artery disease at levels ≥200 mg/dL.
- Diet and exercise are first-line interventions for all patients who have HTG.
- For patients with TG levels ≥500 mg/dL, the greatest amount of TG lowering is achieved with fibrates, although magnitude of clinical benefit is uncertain.
- In patients with TG levels <500 mg/dL, the primary treatment for cardiovascular risk management is statins.
HYPOGLYCEMIA, DIABETIC

Joseph A. Florence, MD • Emily K. Flores, PharmD, BCPS

BASICS

DESCRIPTION

● Abnormally low concentration of glucose in circulating blood of a patient with diabetes mellitus (DM); often referred to as an insulin reaction

● Classification includes the following (1,2)[A]:
  – <70 mg/dL (3.9 mmol/L) glucose alert value (level 1): sufficiently low for treatment with fast acting carbohydrate (CHO) and dose adjustment of glucose-lowering therapy (may or may not be accompanied by symptoms; asymptomatic hypoglycemia if symptoms not present)
  – <54 mg/dL (3.0 mmol/L) clinically significant hypoglycemia (level 2): sufficiently low to indicate serious, clinically important hypoglycemia
  – No specific glucose threshold for severe hypoglycemia (level 3): hypoglycemia associated with severe cognitive impairment requiring external assistance for recovery
  – Probable symptomatic hypoglycemia: event with symptoms but glucose not tested
  – Pseudohypoglycemia: an event with typical symptoms but glucose ≥70 mg/dL (3.9 mmol/L)

● Hypoglycemia is the leading limiting factor in the glycemic management of type 1 DM (T1DM) and type 2 DM (T2DM). Severe or frequent hypoglycemia requires modification of treatment regimens, including higher treatment goals.

ALERT

Hypoglycemia unawareness

● Major risk factor for severe hypoglycemic reactions
● Most commonly found in patients with long-standing T1DM and children age <7 years

EPIDEMIOLOGY

mebooksfree.com
**Incidence**
- From the ACCORD study, the annual incidence of hypoglycemia was the following:
  - 3.14% in the intensive treatment group
  - 1.03% in the standard group
  - Increased risk among women, African Americans, those with less than high school education, aged participants, and those who used insulin at trial entry
- From the RECAP-DM study: Hypoglycemia was reported in 35.8% of patients with T2DM who added a sulfonylurea or thiazolidinedione to metformin therapy during the past year.

**Etiology and Pathophysiology**
- Loss of hormonal counterregulatory mechanism in glucose metabolism
- Too little food (skipping or delaying meals), decreased CHO intake
- Too much insulin or oral hypoglycemic agent (improper dose, timing, or erratic absorption)
- Unplanned or excessive exercise/physical activity
- Alcohol consumption
- Vomiting or diarrhea

**Risk Factors**
- Nearly 3/4 of severe hypoglycemic episodes occur during sleep.
- Severe hypoglycemia is associated with comorbid conditions in patients aged ≥65 years and in users of a long-acting sulfonylurea.
- Intensive insulin therapy (further lowering A1C from 7% to 6%) is associated with higher rate of hypoglycemia.
- Comorbidities: renal/liver disease, congestive heart failure (CHF), hypothyroidism, hypoadrenalism, gastroenteritis, gastroparesis (unpredictable CHO delivery), autonomic neuropathy, pregnancy, anxiety, depression, disordered eating behavior, illness/stress, and unplanned life events
- Duration of DM >5 years
- Young children with type 1 diabetes
- Advanced age
- Starvation, prolonged fasting, or food insecurity
- Current smokers with T1DM
- Alcoholism: Alcohol consumption may increase risk of delayed hypoglycemia, especially if on insulin or insulin secretagogues. Evening
consumption of alcohol is associated with an increased risk of nocturnal and fasting hypoglycemia, especially in patients with T1DM.

- Insulin secretagogues: Sulfonylureas (glyburide, glimepiride, glipizide, etc.) and glinide derivatives (repaglinide, nateglinide) stimulate insulin secretion.
- Hypoglycemia is rare in diabetics not treated with insulin or insulin secretagogues.
- Other antidiabetes medications such as dipeptidyl peptidase 4 (DPP-4) inhibitors, glucagon-like peptide-1 (GLP-1) agonists, and sodium-glucose contransporter-2 (SGLT-2) agents carry a lower but present risk of hypoglycemia, which may increase when combining agents from different categories.

**Geriatric Considerations**

- American Geriatric Society Beers criteria recommend avoiding glyburide and chlorpropamide due to their prolonged half-life in older adults and risk for prolonged hypoglycemic episodes. Medications should be dosed for age and renal function.
  - In type 2 diabetes, severe hypoglycemia has been associated with reduced cognitive function, and patients with reduced cognitive function have more severe hypoglycemia. Tailoring glycemic control to avoid hypoglycemia is recommended in patients with cognitive dysfunction (1)[A].
  - Insulin-treated patients 80 years or older are more than twice as likely to have emergency room visits and nearly 5 times as likely to be admitted for insulin-related hypoglycemia as those 45 to 64 years of age (1)[A].

**Pediatric Considerations**

Children may not realize when they have hypoglycemia, needing increased supervision during times of higher activity. Children may have higher glycemic goals for this reason. Caregivers should be instructed in use of glucagon (1,2) [A].

**Pregnancy Considerations**

Hypoglycemia management and avoidance education should be reemphasized and blood glucose monitoring increased due to more stringent glycemic goals and increased risk in early pregnancy (1)[A].

**GENERAL PREVENTION**

- Maintain routine schedule of diet (consistent CHO intake), medication, and
- Exercise (1)[A].
- Regular self-monitoring of blood glucose (SMBG), if taking insulin or secretagogue
  - ³3 times daily testing if multiple injections of insulin, insulin pump therapy, or pregnant diabetic; frequency and timing dictated by needs and treatment goals
  - Particularly helpful for asymptomatic hypoglycemia
- Diabetes treatment and teaching programs (DTTPs) especially for high-risk type 1 patients, which teach flexible insulin therapy to enable dietary freedom
- Hypoglycemia may be prevented with use of insulin analogs, continuous SC insulin infusion (CSII) pumps, and continuous glucose monitoring (CGM) systems (1)[A].

COMMONLY ASSOCIATED CONDITIONS
- Autonomic neuropathy
- Neuropathies
- Cardiomyopathies

DIAGNOSIS

HISTORY
- Discuss quality, quantity, awareness, and causes of hypoglycemia (1)[A].
- Symptoms vary considerably between individuals.
- Adrenergic symptoms
  - Hunger, trembling, pallor, sweating, shaking, pounding heart, anxiety, urinary incontinence
- Neurologic symptoms
  - Dizziness, poor concentration, drowsiness, weakness, confusion, lightheadedness, slurred speech, blurred vision, double vision, unsteadiness, poor coordination
  - Hypoglycemia causes a significant deterioration in reading span and subject-verb agreement, demonstrating that language processing is impaired during moderate hypoglycemia (3)[A].
- Behavioral symptoms
  - Tearfulness, confusion, fatigue, irritability, aggressiveness
- If altered cognition, consider hypoglycemia.
PHYSICAL EXAM
- General: confusion, lethargy
- HEENT: diplopia
- Coronary: tachycardia
- Neurologic: tremulousness, weakness, paresthesia, stupor, seizure, or coma
- Mental status: irritability, inability to concentrate, or short-term memory loss
- Skin: pale, diaphoresis
- End-organ damage: microvascular, macrovascular, ophthalmologic, neurologic, renal

DIFFERENTIAL DIAGNOSIS
Hypoglycemia not associated with DM may be seen in:
- Chronic alcoholics and binge drinkers
- GI dysfunction causing postprandial hypoglycemia or alimentary reactive hypoglycemia
- Hormonal deficiency states (hormonal reactive hypoglycemia)
- Hypoglycemia of sepsis
- Islet cell tumors
- Factitious hypoglycemia from surreptitious injection of insulin

DIAGNOSTIC TESTS & INTERPRETATION
- Plasma, serum, or whole-blood glucose
- SMBG and CGM are especially useful for asymptomatic hypoglycemia (2)[A].
  A hypoglycemic reading from a CGM sensor should be verified by SMBG fingerstick glucose testing prior to treatment (1)[A].
- Suspect hypoglycemic unawareness in T2DM with low/normal HgbA1c (2)[A].
- Chronic hypoglycemia is indicated by low HgbA1c level.
- Disorders that may alter lab results
  - Conditions that affect erythrocyte turnover, such as hemolysis or blood loss, and hemoglobin variants may alter HgbA1c (1)[A].

TREATMENT
GENERAL MEASURES
Glucose: pure glucose preferred; any form of CHO that contains glucose should be effective (see “Medication” section below) (1)[A].
Glucagon should be prescribed to patients at significant risk of severe hypoglycemia. People in close contact with these individuals should be instructed in using an emergency glucagon kit (1)[A].

α-Glucosidase inhibitors (acarbose) prevent digestion of complex CHOs; therefore, hypoglycemia must be treated with monosaccharides, such as glucose tablets.

Patients with severe hypoglycemia combined with hypoglycemic unawareness should have glycemic targets raised to avoid hypoglycemia (1)[A].

Patients with T1DM should use insulin analogs to reduce hypoglycemia risk (1)[A].

Address medications (i.e., insulin, sulfonylureas, GLP-1 agonists, TZD’s) that may induce hypoglycemia

CGM augmented CSII with automated insulin suspension when blood glucose falls below a threshold value reduces the combined rate of severe and moderate hypoglycemia in T1DM and reduces nocturnal hypoglycemia without increasing A1c levels in patients >16 years old (1,4)[A].

MEDICATION

Conscious patients (1)[A]:

– Glucose (15 to 20 g) is preferred, although any form of CHO may be used.
  ○ Any sugar-containing food or beverage that can be rapidly absorbed: juice or nondiet soda (4 to 5 oz), candy (5 to 6 pieces of hard candy), or OTC glucose tablets (4 tablets = 16 g CHO)
  ○ Takes ~15 minutes for CHOs to be digested and enter bloodstream as glucose
  ○ Blood glucose value may correct prior to symptoms resolving.
  ○ “Rule of 15”: 15 to 20 g CHO (~60 to 80 calories simple CHO) repeated q15min until blood sugar is ≥70 mg/dL
– Once sugar has normalized, a meal or snack may need to be consumed to prevent recurrence of hypoglycemia.

Loss of consciousness at home (4)[A]:

– Administer glucagon.
– IM or SC in the deltoid or anterior thigh
  ○ Age <6 years and/or weight <20 to 25 kg: 0.50 mg
  ○ Age ≥6 years and/or weight >20 to 25 kg: 1 mg
  ○ May repeat dose in 15 minutes if needed
In unconscious, with emergency medical personnel present or patient hospitalized (4)[A]:

- Give 25 g IV 50% dextrose every 5 to 10 minutes until patient awakens.
- Then, feed orally and/or administer 5% dextrose IV at level that will maintain blood glucose >100 mg/dL.
- Patients with hypoglycemia secondary to oral hypoglycemics should be monitored for 24 to 48 hours because hypoglycemia may recur after apparent clinical recovery.

Significant possible interactions:
- Overtreatment may cause hyperglycemia.
- Clearance of certain oral hypoglycemics may be prolonged in persons with renal or liver disease.

ISSUES FOR REFERRAL
Frequent or recurring episodes that do not readily respond to treatment

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- A hypoglycemia prevention and management protocol should be adopted and implemented by each hospital or hospital system (1)[A].

- Admission criteria/initial stabilization
  - Any doubt of cause
  - Expectation of prolonged hypoglycemia (e.g., caused by sulfonylurea drug)
  - Inability to drink
  - Treatment has not resulted in prompt sensory recovery.
  - Seizures, coma, or altered behavior (e.g., ataxia, disorientation, unstable motor coordination, dysphasia) secondary to documented or suspected hypoglycemia

- Discharge criteria: Normoglycemia and risk of severe hypoglycemia are negligible.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Rest until glucose is normal. Individuals with poor cognitive function or severe hypoglycemia should have their glycemic therapy tailored to avoid significant hypoglycemia (1)[A]. Patients with hypoglycemia unawareness or unexplained
severe hypoglycemia should raise their glycemic targets to avoid further hypoglycemia for several weeks to partially reverse hypoglycemia unawareness and reduce risk of additional episodes (1)[A]. Less stringent A1c goals should be utilized in patients with history of severe hypoglycemia or frequent hypoglycemia (1)[A].

**Patient Monitoring**

**SMBG**

**Diet**

- Alcohol consumption may place patients with diabetes at increased risk for delayed hypoglycemia (1)[A].
- CHO sources high in protein should not be used to treat or prevent hypoglycemia (1)[A].
- Fats may slow absorption of CHOs and may retard and then prolong the acute glycemic response (1)[A].

**Patient Education**

- Always have access to quick-acting CHO.
- For exercise, consider ingestion of added CHO if preexercise blood sugar <100 mg/dL or a reduced insulin dose.
- Educate patients and their relatives, close friends, teachers, and supervisors to be aware of DM diagnosis and signs/symptoms of hypoglycemia and treatment.
- Teach SMBG and self-adjustment for insulin therapy, diet control, and exercise regimen.
- Wear medical alert identification bracelet or necklace.

**Prognosis**

Full recovery usually depends on rapidity of diagnosis and treatment.

**Complications**

- Coma, seizure, myocardial infarction, stroke (especially in elderly)
- Prolonged or severe hypoglycemia may cause permanent neurologic damage and/or cognitive impairment.
- Children with T1DM have a greater vulnerability to neurologic manifestations of hypoglycemia.
ALERT
The ACCORD trial (adults with T2DM) demonstrated that intensively lowering blood glucose below current recommendations increased the risk of death versus standard treatment strategy.

SEE ALSO
- Diabetes Mellitus, Type 1
- Algorithm: Hypoglycemia

CODES

ICD10
- E11.649 Type 2 diabetes mellitus with hypoglycemia without coma
- E10.649 Type 1 diabetes mellitus with hypoglycemia without coma
- E13.649 Oth diabetes mellitus with hypoglycemia without coma

CLINICAL PEARLS
- Address hypoglycemia in every visit with patients at risk.
- Best treatment includes:
  - Patient education and empowerment
  - Frequent SMBG
  - Flexible insulin (or other drug) regimens
  - Regular professional guidance and support
  - Individualized glycemic goals based in part on the risk of hypoglycemia
- Hypoglycemia unawareness should be recognized and addressed by less aggressive glycemic goals.
- Any form of CHO that contains glucose should be effective, such as sugar-containing food or beverage that can be rapidly absorbed:
  - Using the “rule of 15” is an easy way to teach patients to manage hypoglycemia at home. “Rule of 15”: 15 to 20 g CHO (~60 to 80 calories simple CHO) SMBG and repeated q15min until blood sugar is ≥70 mg/dL.
HYPOGLYCEMIA, NONDIABETIC

Matthew A. Silva, PharmD, RPh, BCPS • Pablo Hernandez Itriago, MD, MHCM, FAAFP

BASICS

DESCRIPTION

- Hypoglycemia defined by the Whipple triad
  - Low plasma glucose level (≤60 mg/dL) with hypoglycemic symptoms that are relieved when glucose is corrected
  - Occurs commonly in patients with diabetes receiving sulfonylurea or insulins; less commonly in patients without diabetes
- Reactive hypoglycemia occurs in response to a meal, drugs, herbal substances, or nutrients and may occur 2 to 3 hours postprandially or later (1).
  - Symptoms are generally observed with serum glucose ≤60 mg/dL, lower in patients with hypoglycemic unawareness.
  - Also seen after GI surgery (in association with dumping syndrome in some patients)
- Spontaneous (fasting) hypoglycemia may be associated with primary conditions including hypopituitarism, Addison disease, myxedema, or disorders related to hepatic dysfunction or renal failure (1,2).
  - If hypoglycemia presents as a primary disorder, consider hyperinsulinism and extrapancreatic tumors.

EPIDEMIOLOGY

Incidence

- True incidence is unknown.
- 0.5–8.6% of hospitalized patients ≥65 years (3–5)
  - Asymptomatic in 25% of cases

Prevalence

True prevalence is unknown:

- Predominant age: older adult
- Predominant sex: female > male
ETIOLOGY AND PATHOPHYSIOLOGY

- Reactive, postprandial
  - Alimentary hyperinsulinism
  - Meals high in refined carbohydrate
  - Certain nutrients, including fructose, galactose, leucine
  - Glucose intolerance (prediabetes)
  - GI surgery, especially gastric bypass
  - Idiopathic (unknown cause)

- Spontaneous
  - Fasting
  - Alcohol or prescription medication–associated (6) (insulin, sulfonylureas, thiazolidinediones, incretin mimetics, DPP-IV inhibitors, β-blockers, salicylates, quinine, hydroxychloroquine, fluoroquinolones, doxycycline, sertraline, disopyramide, pentamidine, gabapentin, tramadol)
  - Nonprescription over-the-counter (OTC) agents, including performance-enhancing agents. Adulterated versions of phosphodiesterase inhibitors and performance-enhancing agents are routinely imported and may contain sulfonylureas and other hypoglycemic agents.
  - Consider medication errors as a source of unexplained hypoglycemia even in patients without diabetes.
  - Surreptitious drug use (self-injection of insulin or ingestion of oral hypoglycemic medications in patients with diabetes)
  - Natural medicines or herbs (bitter melon, caffeine, cassia cinnamon, chromium, fenugreek, ginseng, guarana, mate, stevia, vanadium)
  - Postsurgical (e.g., bariatric surgery, gastrectomy, Roux-en-Y) hypoglycemia/dumping syndrome
  - Islet cell hyperplasia or tumor (insulinoma)
  - Extrapancreatic insulin-secreting tumor
  - Autoimmune hypoglycemia (Hirata disease)
  - Hepatic disease
  - Glucagon deficiency
  - Adrenal insufficiency
  - Catecholamine deficiency
  - Hypopituitarism
  - Hypothyroidism
  - Eating disorders
  - Exercise
  - Fever
- Pregnancy
- Renal glycosuria
- Large tumors
- Ketotic hypoglycemia of childhood
- Enzyme deficiencies or defects
- Severe malnutrition
- Sepsis
- Total parenteral nutrition therapy
- Hemodialysis

**Genetics**
Some aspects may involve genetics (e.g., hereditary fructose intolerance).

**RISK FACTORS**
Refer to “Etiology and Pathophysiology.”

**GENERAL PREVENTION**
- Follow dietary and exercise guidelines.
- Patient recognition of early symptoms and knowledge of corrective action

**Pediatric Considerations**
- Usually divided into two syndromes
  - Transient neonatal hypoglycemia
  - Hypoglycemia of infancy and childhood
- Screening infants for hypoglycemia is appropriate when pregnancy was complicated by maternal diabetes.
- Cases of hypoglycemia observed in children taking propranolol for infantile hemangioma
- Associated with indomethacin when treating patent ductus arteriosus

**Geriatric Considerations**
- More likely to have underlying disorders or be caused by medications
- Iatrogenic hypoglycemia is common in the hospitalized elderly with renal insufficiency.

**COMMONLY ASSOCIATED CONDITIONS**
- Severe liver disease; alcoholism
- Addison disease; adrenocortical insufficiency
• Myxedema
• Malnutrition (patients with renal failure)
• GI surgery
• Panhypopituitarism
• Insulinoma

**DIAGNOSIS**

**HISTORY**

• CNS (neuroglycopenic) symptoms predominate with gradual glucose reduction:
  – Headache
  – Confusion
  – Light-headedness
  – Fatigue and weakness
  – Visual disturbances
  – Changes in personality
• Adrenergic symptoms: more prominent in acute drop in glucose
  – Anxiety
  – Tremulousness
  – Dizziness
  – Diaphoresis
  – Warmth/flushing
  – Heart palpitations
• GI symptoms
  – Hunger
  – Nausea
  – Belching

**PHYSICAL EXAM**

• CNS (neuroglycopenic) symptoms predominate with gradual glucose reduction:
  – Convulsions
  – Coma
  – Hypotension
• Adrenergic symptoms: more prominent in acute drop in glucose
  – Tremulousness
– Diaphoresis
– Warmth/flushing
– Heart palpitations

DIFFERENTIAL DIAGNOSIS
CNS disorders

- Psychogenic
- Pseudohypoglycemia: symptoms of hypoglycemia or self-diagnosis in patients in whom low blood glucose may not be detectable and may be impossible to convince that they do not suffer from hypoglycemia after all tests are found to be normal

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Blood glucose ≤45 mg/dL (≤2.5 mmol/L) when symptomatic followed by symptom resolution with feeding (2)[C]
- Plasma glucose overnight fasting: ≤60 mg/dL (≤3.33 mmol/L); confirm on ≥2 occasions (2)[C].
- Plasma glucose 72-hour fasting: ≤45 mg/dL (≤2.5 mmol/L) for females; ≤55 mg/dL (≤3.05 mmol/L) for males; fasting may be ended when Whipple triad is achieved or hypoglycemia is demonstrated (2)[C].
- Abdominal CT to rule out abdominal tumor

Follow-Up Tests & Special Considerations

- Misinterpretation of glucose tolerance tests may lead to misdiagnosis of hypoglycemia; ≥1/3 of normal patients have hypoglycemia, with or without symptoms, during the 4-hour glucose tolerance test. These patients may be at future risk for type 2 diabetes.
- C-peptide measurement (2)[C]
- Check liver studies, serum insulin, adrenocorticotropic hormone (ACTH), and cortisol. Serum insulin should be suppressed when glucose is <60 mg/dL.
- Serum β-hydroxybutyrate (2)[C]
- Insulin radioimmunoassay: Elevated insulin levels suggest islet cell hyperplasia or tumor.
- Drugs that may alter lab results: Many drugs can affect glucose levels; refer to drug or laboratory reference.

Diagnostic Procedures/Other
For definitive diagnosis, patient should have
- Documented low glucose levels
- Symptoms when glucose levels are low
- Evidence that symptoms are relieved specifically by ingestion of sugar or other food
- Identification of the specific type of hypoglycemia

Serum β-hydroxybutyrate <2.7 mg/dL in the presence of high-serum insulin, C-peptide, and low-serum glucose suggests excessive insulin production (2) [C].

**TREATMENT**

**GENERAL MEASURES**
- Outpatient except for severe cases; may also be inpatient for testing
- Oral carbohydrate for alert patient without drug overdose (2 to 3 tbsp of sugar in glass of water or fruit juice, 1 to 2 cups of milk, piece of fruit, or several soda crackers)
- If unable to swallow: Use glucagon IM or SC.
- If caused by medication or nutrients: Avoid or control causative agents.
- If triggered by meals: Try high-protein diet with carbohydrate restriction.

Nonhypoglycemic hypoglycemia or pseudohypoglycemia
- Many patients (often women aged 20 to 45 years) present with diagnosis of reactive hypoglycemia (self-diagnosed or misinterpretation of tests).
- Symptoms may pertain to chronic fatigue and somatic complaints (stress often plays a role in these symptoms).
- Management difficult; listening is important. Try 120-g carbohydrate diet.
- Counseling may be useful for stress and other problems.

**MEDICATION**
- Once diagnosis is established, begin therapy appropriate for underlying disorder.
- If unable to swallow: glucagon 1 mg (1 unit) IM or SC. If no response, give IV bolus of 25 to 50 g of 50% glucose solution followed by continuous infusion until patient able to take by mouth.
- Postsurgical gastrectomy patients unresponsive to dietary changes may benefit from propantheline, psyllium, fiber, or oat bran, which delays gastric emptying.
Insulinoma

SURGERY/OTHER PROCEDURES
If islet cell tumor (insulinoma) or other insulin-secreting tumor, surgery is treatment of choice; if inoperable, diazoxide may relieve symptoms (1)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Hypoglycemia unresponsive to oral intake

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Exercise routine or daily activity may need to be reevaluated.
- Patients with recurrent hypoglycemia should have glucose source at hand for immediate ingestion during symptoms.

Patient Monitoring
- Depends on type and severity of symptoms and treatment of underlying cause
- Hypoglycemia from sulfonylureas can last for hours to days depending on half-life and renal function.

DIET
- High protein, high fiber, complex carbohydrates from multigrain, and whole foods in moderation
- Frequent small feedings (six daily)
- Avoid fasting.

PATIENT EDUCATION
- Dietary instruction
- Counseling for stress, if appropriate
- Recognition of early symptoms of hypoglycemia and how to take corrective action

PROGNOSIS
Favorable, with appropriate treatment
COMPLICATIONS

- Insulinoma: If tumor identified and removed, some surgical risk is involved.
- Organic brain syndrome: may occur with extensive, prolonged hypoglycemia

REFERENCES

ADDITIONAL READING

SEE ALSO

mebooksfree.com
- Hypoglycemia, Diabetic; Insulinoma
- Algorithm: Hypoglycemia

**CODES**

**ICD10**
- E16.2 Hypoglycemia, unspecified
- E16.1 Other hypoglycemia
- P70.4 Other neonatal hypoglycemia

**CLINICAL PEARLS**
- Symptoms coincide with low-blood glucose levels and resolve with PO/IV glucose or glucagon.
- Avoid known agents/nutrients that trigger hypoglycemia.
- Treat underlying cause.
HYPOKALEMIA

James Auteri Ferguson, MD, MPH, CPH • Jason Chao, MD, MS

BASICS

DESCRIPTION
Hypokalemia is defined as a serum potassium concentration <3.5 mEq/L (normal range, 3.5 to 5.0 mEq/L).
- Mild hypokalemia (serum potassium 3.0 to 3.5 mEq/L)
- Moderate hypokalemia (serum potassium 2.5 to 3.0 mEq/L)
- Severe hypokalemia (serum potassium <2.5 mEq/L)

EPIDEMIOLOGY
Predominant sex: male = female

Incidence
- Electrolyte abnormality is commonly encountered in clinical practice and in the elderly (1).
- Found in >20% of hospitalized patients (when defined as potassium <3.6 mEq/L)
- Higher incidence (5–20%) in individuals with eating disorders
- >10% of inpatients with alcoholism
- Higher incidence in patients with AIDS
- Higher incidence in patients receiving diuretics
- 12–18% in patients with CKD
- Associated risk after bariatric surgery

ETIOLOGY AND PATHOPHYSIOLOGY
Most common causes:
- Decreased intake: deficient diet in alcoholics and elderly; anorexia nervosa
- GI loss: vomiting, diarrhea, nasogastric tubes, laxative abuse, fistulas, villous adenoma, ureterosigmoidostomy, malabsorption, chemotherapy, radiation enteropathy, bulimia
- Intracellular shift of potassium: metabolic alkalosis, insulin excess, β-
adrenergic catecholamine excess (acute stress, $\beta_2$-agonists), hypokalemic periodic paralysis, intoxications (theophylline, caffeine, barium, toluene)

- Renal potassium loss
  - Drugs: diuretics (especially loop and thiazides), amphotericin B, aminoglycosides
  - Mineralocorticoid excess states: primary hyperaldosteronism; secondary hyperaldosteronism (congestive heart failure [CHF], cirrhosis, nephrotic syndrome, malignant hypertension, renin-producing tumors); renovascular hypertension; Bartter syndrome; Gitelman syndrome; congenital adrenogenital syndromes; exogenous mineralocorticoids (glycyrrhizic acid in licorice, carbenoxolone, steroids in nasal sprays); Liddle syndrome; vasculitis
  - Osmotic diuresis (e.g., poorly controlled diabetes)
  - Renal tubular acidosis (type I and II)
  - Magnesium depletion

- Glucocorticoid excess states: Cushing syndrome, exogenous steroids, ectopic adrenocorticotropic hormone production, II-$\beta$-hydroxysteroid dehydrogenase deficiency, refeeding syndrome

**Genetics**

Some rare, familial disorders can cause hypokalemia.

- Familial hypokalemic periodic paralysis: hypokalemia after a high-carbohydrate or high-sodium meal or after exercise
- Congenital adrenogenital syndromes
- Liddle syndrome: increases K+ secretion
- Familial interstitial nephritis

**GENERAL PREVENTION**

When initiating a diuretic, especially loop and thiazide diuretics, advise patients to increase their dietary potassium intake (see “Diet”).

**COMMONLY ASSOCIATED CONDITIONS**

- Acute GI illnesses with severe vomiting or diarrhea
- Increased risk of cardiac arrhythmias; atrial fibrillation (2,3)
- Hypokalemia is a predictor of development of severe alcohol withdrawal syndrome (4).
DIAGNOSIS

- Patients with hypokalemia often have no symptoms, especially if the hypokalemia is mild (serum potassium 3.0 to 3.5 mEq/L).
- Neuromuscular (most prominent manifestations)
  - Skeletal muscle weakness (proximal > distal muscles, lower limbs > upper limbs) may range from mild weakness to total paralysis, including respiratory muscles; it may lead to rhabdomyolysis and/or respiratory arrest in severe cases.
  - Smooth muscle involvement may lead to GI hypomotility, producing ileus and constipation.
- Cardiovascular
  - Ventricular arrhythmias; higher risk if underlying CHF, left ventricular failure (LVF), cardiac ischemia
  - Increased risk of atrial fibrillation
  - Hypotension
  - Cardiac arrest
- Renal: polyuria, polydipsia, nocturia owing to impaired ability to concentrate, myoglobinuria
- Metabolic: hyperglycemia

HISTORY
Muscle weakness, hypotension, vomiting, diarrhea, polyuria, polydipsia

PHYSICAL EXAM
Decreased skin turgor in dehydration, hypotension, orthostasis, pulmonary congestion/rales, peripheral edema in heart failure

DIFFERENTIAL DIAGNOSIS
- Spurious hypokalemia occurs when blood with high WBC count (>100,000/mm$^3$) is allowed to stand at room temperature (WBCs extract potassium from plasma).
- Thyrotoxicosis

DIAGNOSTIC TESTS & INTERPRETATION
- Serum potassium <3.5 mEq/L (<3.5 mmol/L)
- Disorders that may alter lab results: leukemia and other conditions with high WBCs
**Initial Tests (lab, imaging)**
- ECG
- If source of potassium loss not likely to be medications or GI tract: serum electrolytes, urinary potassium
- Calculate plasma anion gap \((\text{anion gap} = \text{Na} - [\text{Cl} + \text{HCO}_3^-])\); normal values, 12 ± 4 mEq/L. Must correct calculated anion gap for hypoalbuminemia. Increase calculated anion gap by 2.5 mEq/L for each 1 g/dL decrease in albumin <4 g/dL.
- CT scan of adrenal glands if there is evidence of mineralocorticoid excess

**Follow-Up Tests & Special Considerations**
- If excessive renal potassium loss (>20 mEq/day) and hypertension, plasma renin and aldosterone levels should be determined to differentiate adrenal from nonadrenal causes of hyperaldosteronism. If hypertension is absent and the patient is acidotic, renal tubular acidosis should be considered.
- In severe hypokalemia, rhabdomyolysis may result.
- Hypokalemia increases the myocyte resting potential, which increases the refractory period; this can lead to cardiac arrhythmias.

**Test Interpretation**
- If hypertension is absent and serum pH is normal to alkalotic
  - High urine chloride (>10 mEq/day [>10 mmol/day])—diuretics or Bartter and Gitelman syndromes
  - Low urine chloride (<10 mEq/day [<10 mmol/day])—GI losses likely
- ECG
  - Flattening or inversion of T waves
  - Increased prominence of U waves (small, positive deflection after T wave, best seen in V2 and V3)
  - Depression of ST segment
  - Ventricular ectopia

**TREATMENT**

**GENERAL MEASURES**
- Underlying cause of hypokalemia should be identified.
- For asymptomatic patients treated with oral replacement, outpatient follow-up
is sufficient.

- Patients with cardiac manifestations require IV replacement with cardiac monitoring in an intensive care setting.

**MEDICATION**

- Nonemergent conditions (serum potassium >2.5 mEq/L [>2.5 mmol/L], no cardiac manifestations)
  - Oral therapy preferred: 40 to 120 mEq/day (40 to 120 mmol/day) in divided doses usually is adequate.
  - IV potassium should be given only when oral administration is not feasible (e.g., vomiting, postoperative state). Rate should not exceed 10 mEq/hr, and concentration should not exceed 40 mEq/L. Up to 40 mEq in 100 mL over 1 hour can be given safely through a central venous line. The patient’s cardiac rhythm should be closely monitored.
  - Potassium chloride is suitable for all forms of hypokalemia.
  - Other potassium salts may be indicated if a coexisting disorder is present: potassium bicarbonate or bicarbonate precursor (gluconate, acetate, or citrate) in metabolic acidosis or phosphate in phosphate deficiency.

- Emergent situations (serum potassium <2.5 mEq/L [<2.5 mmol/L], arrhythmias), IV replacement: Rate of administration should not exceed 20 mEq/hr (20 mmol/hr); maximum recommended concentration, 60 mEq/L (60 mmol/L) of saline for peripheral administration; administration through central venous lines preferred for rates above 20 mEq/hr

- Check serum magnesium and replace, if needed; cannot adequately replace potassium in a setting of low magnesium

- Precautions
  - Any form of potassium replacement carries the risk of hyperkalemia.
  - Serum potassium should be checked more frequently in groups at higher risk: the elderly, diabetic patients, and patients with renal insufficiency.
  - Patients receiving digitalis and patients with diabetic ketoacidosis in whom intracellular shift in potassium is expected after insulin therapy is initiated must have more aggressive replacement.

- Significant possible interactions: Concomitant administration of potassium-sparing diuretics (spironolactone, triamterene, amiloride, ACE inhibitors) magnifies risk of hyperkalemia.

**Geriatric Considerations**

May need to correct magnesium depletion

mebooksfree.com
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

**Patient Monitoring**
- Patients receiving IV therapy should have cardiac monitoring and serum potassium level checked frequently (q4–6h).
- Patients requiring potassium supplements should have serum potassium studied at intervals and magnesium level dictated by clinical judgment and patient compliance (5)[C].

**DIET**
In patients with mild hypokalemia (potassium, 3.0 to 3.5 mEq/L [3.0 to 3.5 mmol/L]) not caused by GI losses, dietary supplementation may be sufficient; potassium-rich foods include oranges, bananas, cantaloupes, prunes, raisins, dried beans, dried apricots, and squash.

**PATIENT EDUCATION**
- Instructions for appropriate diet
- If potassium supplementation is necessary, stress the need for compliance.

**PROGNOSIS**
- Associated with higher morbidity and mortality because of cardiac arrhythmias
- Ease of correction of hypokalemia and need for prolonged treatment rest on the primary cause; if it can be eliminated (e.g., resolution of diarrhea, discontinuation of diuretics, removal of adrenal tumor), hypokalemia can be expected to resolve and no further treatment is indicated.

**COMPLICATIONS**
- Hyperkalemia can occur during the course of treatment.
- Increased risk of digoxin toxicity
- Increased risk of atrial fibrillation (2,3)[B]

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

- Hyperkalemia
- Algorithm: Hypokalemia
CLINICAL PEARLS

- In patients without heart disease, a mildly low potassium level will rarely cause cardiac disturbances. In an otherwise healthy patient, gentle repletion using oral potassium or an increase in potassium-rich foods should be adequate.
- In patients with cardiac ischemia, heart failure, or left ventricular hypertrophy, even mild to moderate hypokalemia can cause arrhythmias. These patients should receive potassium repletion as well as cardiac monitoring.
- To safely prevent hypokalemia in diabetic and renal insufficiency patients, ensure adequate dietary potassium intake with foods rich in potassium, including spinach, tomatoes, broccoli, squash, potatoes, bananas, cantaloupe, and oranges. Avoid potassium-wasting diuretics, if possible.
- Uncorrected hypomagnesemia can hinder the correction of hypokalemia. Check magnesium levels and replete as necessary.
- Hypokalemia in an otherwise healthy young woman should prompt evaluation for bulimia nervosa.
HYPONATREMIA

Jane M. Chung, MD • Patricia Martinez Quinones, MD • Cassandra Q. White, MD, FACS

BASICS

DESCRIPTION
- Hyponatremia is a plasma sodium (Na) concentration of ≤135 mEq/L. Hyponatremia itself does not provide information about the “total body water (TBW)” state of the patient. Patients with hyponatremia may be hypervolemic, hypovolemic, or euvoletic.
- System(s) affected: endocrine/metabolic, renal, cardiovascular

EPIDEMIOLOGY

Incidence
- Most common electrolyte disorder seen in the general hospital population
- Predominant age: all ages
- Predominant sex: male = female

Prevalence
2.5% of hospitalized patients

Geriatric Considerations
The elderly have lower TBW, a decreased thirst mechanism, and decreased urinary concentrating ability; their kidneys are less responsive to antidiuretic hormone (ADH), and they show decreased renal mass, renal blood flow, and glomerular filtration rate, putting them at higher risk for hyponatremia.

Pediatric Considerations
Children <16 years of age have less intracranial volume and are at increased risk of brain herniation from cerebral edema.

ETIOLOGY AND PATHOPHYSIOLOGY
- Assess serum osmolality and volume status to determine etiology. The etiology directs the management.
- Hypertonic hyponatremia: serum osmolarity (Osm) >285 mOsm
- Shift of water from intracellular fluid (ICF) to extracellular fluid (ECF), resulting in dilution
  - Unchanged TBW and Na
  - Causes: hyperglycemia, mannitol, sorbitol, radiologic contrast
- Isotonic hyponatremia (“pseudohyponatremia”): serum Osm 280 to 285 mOsm
  - Excessive osmoles leading to dilution
  - Unchanged TBW and Na
  - Causes: hyperlipidemia, hyperproteinemia (e.g., multiple myeloma)
- Hypotonic hyponatremia: serum Osm <280 mOsm
  - Subdivided by volume status into hypovolemic, euvoletic, or hypervolemic
- Hypovolemic hyponatremia: subtype of hypotonic hyponatremia with decreased TBW and Na
  - Signs include orthostatic hypotension, decreased skin turgor, dry mucous membranes.
  - Urine Na <20 mmol/L; indicates extrarenal loss
    - Causes include GI loss (vomiting, diarrhea), third spacing (pancreatitis, peritonitis, burns, rhabdomyolysis), skin loss (burns, cystic fibrosis, sweating), and heat-related illnesses.
  - Urine Na >20 mmol/L; indicates renal loss
    - Causes include cerebral salt-wasting syndrome, adrenal insufficiency, diuretics, osmotic diuresis.
- Euvolemic hyponatremia: subtype of hypotonic hyponatremia with increased TBW and normal Na
  - Signs include a nonedematous state.
  - Urine Osm >100 mOsm/kg
    - Causes include syndrome of inappropriate antidiuretic hormone (SIADH), hypothyroidism, adrenal insufficiency, medications (e.g., carbamazepine, clofibrate, cyclosporine, levetiracetam, opiates, oxcarbazepine, phenothiazines, SSRIs, TCAs, vincristine).
  - Urine Osm <100 mOsm/kg
    - Causes include primary polydipsia, beer potomania.
- Hypervolemic hyponatremia: subtype of hypotonic hyponatremia with increased TBW and Na
  - Signs include edematous state.
  - Urine Na <20 mmol/L
    - Causes include congestive heart failure (CHF), cirrhosis, nephrotic
syndrome, hypoalbuminemia.
- Urine Na >20 mmol/L
  - Causes include renal failure.

**Genetics**
- Polymorphisms have been demonstrated.
- Mutations have been associated with nephrogenic syndrome of inappropriate antidiuresis (NSAID; SIADH).

**GENERAL PREVENTION**
Depends on underlying etiology

**COMMONLY ASSOCIATED CONDITIONS**
- Hypothyroidism
- Hypopituitarism
- Adrenocortical hormone deficiency
- HIV patients
- SIADH is associated with cancers, pneumonia, tuberculosis, encephalitis, meningitis, head trauma, cerebrovascular accident, HIV infection.
- Acute neurologic patients, brain injury
- Marathon runners in hot environments

**DIAGNOSIS**
- Symptoms related to the rate of fall in serum Na and the degree of hyponatremia
- Mild (serum Na 130 to 135 mEq/L): usually asymptomatic
- Moderate (serum Na 120 to 130 mEq/L): nausea, vomiting, malaise
- Severe (serum Na 115 to 120 mEq/L): headache, lethargy, restlessness, disorientation
- Severe/rapid decrease in serum Na can cause seizure, coma, and respiratory arrest and may be fatal.
- Other signs and symptoms: weakness, muscle cramps, anorexia, hiccups, depressed deep tendon reflexes, hypothermia, positive Babinski responses, cranial nerve palsies, orthostatic hypotension

**ALERT**
Low Na creates an osmotic gradient between plasma and cells, resulting in
fluid shift into cells. This causes cerebral edema and increased intracranial pressure; eventually, this can lead to hyponatremic encephalopathy and brain herniation.

HISTORY
● Symptoms include headache, nausea, vomiting, muscle cramps.
● Can progress to lethargy or restlessness and disorientation

PHYSICAL EXAM
● Volume status: skin turgor, jugular venous pressure, heart rate, orthostatic BP
● Evaluate for underlying illness: signs of CHF, cirrhosis, hypothyroidism
● Decreased reflexes may be seen

DIFFERENTIAL DIAGNOSIS
See “Etiology and Pathophysiology.”

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
● Comprehensive metabolic profile (BUN, creatinine, glucose, electrolytes, liver function studies, etc.)
● Thyroid-stimulating hormone (TSH)
● Lipid panel
● Serum osmolality
● Urine Na and osmolality
● Chest x-ray to rule out pulmonary pathology if SIADH is diagnosed

Follow-Up Tests & Special Considerations
CT scan of head if pituitary problem is suspected or if SIADH from CNS problem is suspected

TREATMENT

GENERAL MEASURES
● Assess all medications patient is taking.
● Institute seizure precautions.
MEDICATION

ALERT
Rapid correction of severe symptomatic hyponatremia has been associated with central pontine myelinolysis, a neurologic disorder in which loss of myelin and supportive structures in pons and occasionally in other areas of the brain occurs (1). This results in irreversible injury. Symptoms are apparent 2 to 6 days after injury and include seizure, coma, spastic paraparesis, dysarthria, and dysphagia.

- Treatment is tailored to etiology, degree of hyponatremia, onset, and symptomatology.
- Some general principles apply:
  - Expected change in serum Na with selected infusate: \[ \Delta \text{Na} = \frac{(\text{infusate Na} + \text{infusate K} - \text{serum Na})}{(\text{TBW} + 1)} \]
  - TBW = a coefficient × weight (kg) as in the following table:

<table>
<thead>
<tr>
<th>Total Body Water</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Children</td>
<td>0.6 × weight</td>
</tr>
<tr>
<td>Women</td>
<td>0.5 × weight</td>
</tr>
<tr>
<td>Men</td>
<td>0.6 × weight</td>
</tr>
<tr>
<td>Elderly women</td>
<td>0.45 × weight</td>
</tr>
<tr>
<td>Elderly men</td>
<td>0.5 × weight</td>
</tr>
</tbody>
</table>

- Formula to determine correction available at http://www.medcalc.com/sodium.html
- Asymptomatic, euvoletic patients can be treated with fluid restriction; etiology must be addressed.
- For severely hyponatremic/symptomatic patients, administer 3% hypertonic saline, 2 mL/kg up to 100 mL, over a 20-minute period. Check serum Na levels after bolus. Repeat as necessary until a 5 mmol/L increase in serum Na is seen.
  - If symptoms improve after a 5 mmol/L increase, discontinue the hypertonic saline and switch to 0.9% isotonic saline solution. Increase serum Na with a limit of 10 mmol/L during the first 24 hours and then 8 mmol/L every day afterward until serum Na is 130 mmol/L.
  - If symptoms do not improve after a 5 mmol/L increase, continue the hypertonic saline infusion until 1 mmol/L/hr increase in serum Na is achieved. Discontinue infusion if symptoms improve, serum Na increases by 10 mmol/L, or serum Na is 130 mmol/L.
For mild to moderate hyponatremia, use isotonic saline solution (0.9%). For moderate to severe hyponatremia, consider specialist consultation for use of hypertonic saline (3%) via central venous access at a rate of 1 to 2 mL/kg/hr; increasing serum Na levels by 0.5 mmol/L/hr and monitoring frequently the plasma Na level (approximately every 2 hours).

In patients with severe hyponatremia (euvoletic and hypervolemic state) who do not respond to the aforementioned approach, consider the use of vasopressin V2-receptor antagonists, such as tolvaptan, or conivaptan (2)[A].

Treat etiology: heart failure, cirrhosis, and so forth.

Chronic hyponatremia resulting from SIADH (3): demeclocycline (inhibits ADH action at the collecting duct) if fluid restriction alone is not effective
- Contraindications: drug allergy, pregnancy, children <8 years old; caution in renal and hepatic disease
- In doses of 600 to 1,200 mg/day, the drug produces a nephrogenic diabetes insipidus.
- Significant possible interactions: oral anticoagulants, oral contraceptives, penicillin

**ALERT**
Caution: If severe, consider hypertonic saline (3% Na chloride) with central line access, exercise extreme caution, and monitor serum Na as frequently as q1–2h.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission is mandatory if the patient has acute hyponatremia or is symptomatic; acute hyponatremia (developing over <48 hours) increases the risk of cerebral edema.
- Admission is advised if patient is asymptomatic and has a serum Na <125 mEq/dL.

**ONGOING CARE**

**DIET**
- Euvolemic hyponatremia: Restrict water to 1 L/day.
- Hypervolemic hyponatremia: water and Na restriction
PROGNOSIS

- In hospitalized patients, hyponatremia is associated with an elevated risk of adverse clinical outcomes and higher mortality \( (4)[B] \).
- Recently, in community-dwelling, middle-aged, and elderly adults, mild hyponatremia has been shown to be an independent predictor of death.
- Associated with poor prognosis in patients with acute pulmonary embolism
- Associated with poor prognosis in patients with liver cirrhosis and those waiting for liver transplant; it is associated with significant postoperative risk and short-term graft loss.

COMPLICATIONS

- Occult tumor may be present if SIADH is identified.
- Hypervolemia if isotonic saline solution is used
- Osmotic demyelination (central pontine and extrapontine irreversible myelinolysis) \( (1) \)
- Hyponatremia is the cause of 30% new-onset seizures in intensive care settings.
- Can cause hyponatremic encephalopathy and brain herniation if severe and untreated, especially in young women and children \( (5) \)
- Chronic hyponatremia is associated with increased risk of osteoporosis.

REFERENCES

ADDITIONAL READING

SEE ALSO
Algorithm: **Hyponatremia**

**CODES**

**ICD10**

E87.1 Hypo-osmolality and hyponatremia

**CLINICAL PEARLS**

- Alcohol-dependent individuals with vitamin deficiencies, elderly women
taking thiazide diuretics, and people with hypokalemia or burns are at increased risk of central pontine myelinolysis. Chronic hyponatremia is also a risk factor.

- Bronchogenic carcinoma, pancreatic, duodenal, and prostate cancer, as well as thymoma, lymphoma, and mesothelioma are neoplastic diseases associated with SIADH.
- Formulas have been developed (Adrogue and Madias) for safe correction of hyponatremia and are available online (see http://www.medcalc.com/sodium.html).
BASICS

DESCRIPTION

- Deficient or absent secretion of parathyroid hormone (PTH), a major hormone regulator of serum calcium and phosphorus levels in the body (1)
- Often asymptomatic
- Acute hypoparathyroidism: tetany that is mild (muscle cramps, perioral numbness, paresthesias of hands and feet) or severe (carpopedal spasm, laryngospasm, heart failure, seizures, stridor)
- Chronic: lethargy, anxiety/depression, urolithiasis and renal impairment, dementia, blurry vision from cataracts or keratoconjunctivitis, parkinsonism or other movement disorders, mental retardation, dental abnormalities, and dry, puffy, coarse skin
- System(s) affected: endocrine/metabolic, musculoskeletal, nervous, ophthomalogic, renal

Pediatric Considerations

- May occur in premature infants
- Neonates born to hypercalcemic mothers may experience suppression of developing parathyroid glands.
- Congenital absence of parathyroids
- May appear later in childhood as autoimmune or APS-1

Geriatric Considerations

Hypocalcemia is fairly common in elderly, however, rarely secondary to hypoparathyroidism.

Pregnancy Considerations

- Use of magnesium as a tocolytic may induce functional hypoparathyroidism.
- For women with hypoparathyroidism, calcitriol requirements decrease during lactation.
EPIDEMIOLOGY
More common in women; affects all ages

Incidence
Most common after surgical procedure of the anterior neck (75% of all cases). Transient hyperparathyroidism is seen after 6.9–46% of thyroidectomies, whereas permanent hypoparathyroidism, 0.9–1.6% at experienced centers.

Prevalence
Affects 24 to 37/100,000 persons per year (1). Autosomal dominant hypocalcemia with hypercalciuria (ADHH): 1/70,000 typically in infancy with hypocalcemic seizures

ETIOLOGY AND PATHOPHYSIOLOGY
- PTH aids in regulating calcium homeostasis (1):
  - Mobilizes calcium and phosphorus from bone stores
  - Increases calcium absorption from the intestine by stimulating formation of 1,25-dihydroxy-vitamin D (1)
  - Stimulates reabsorption of calcium in the distal convoluted tubule and phosphate excretion in proximal tubule
- Reduced or absent PTH action results in hypocalcemia, hyperphosphatemia, and hypercalciuria (1).
- Acquired hypoparathyroidism
  - Surgical: removal or damage to parathyroid glands or their blood supply; thyroid, parathyroid, or radical neck surgery for head and neck cancers (2)
  - Autoimmune: isolated or combined with other endocrine deficiencies in polyglandular autoimmune (PGA) syndrome
  - Deposition of heavy metals in gland: copper (Wilson disease) or iron (hemochromatosis, thalassemias), radiation-induced destruction, and metastatic infiltration
  - Functional hypoparathyroidism: may result from hypomagnesemia or hypermagnesemia as magnesium is crucial for PTH secretion and activation of the PTH receptor
  - Congenital
    - Calcium-sensing receptor (CaSR) abnormalities: hypocalcemia with hypercalciuria
    - HDR or Barakat syndrome: deafness, renal dysplasia
    - Familial: mutations of the TBCE gene; abnormal PTH secretions
22q11.2 deletion syndrome

- Autoimmune: genetic gain-of-function mutation in CaSR
- Infiltrative: metastatic carcinoma, hemochromatosis, Wilson disease, granulomas
- Hypo- (alcoholics) or hypermagnesemia: chronic iron overloads

**Genetics**

- Genetic defects may result in X-linked or in autosomal recessive hypoparathyroidism due to abnormal parathyroid gland development; associated with mutations in the transcription factor glial cell missing B (GCMB)
- Mutations in transcription factors or regulators of parathyroid gland development
  - Component of a larger genetic syndrome (APS-1 or DiGeorge syndrome) or in isolation (X-linked hypoparathyroidism) (3)
  - May be autosomal dominant (DiGeorge), autosomal recessive (APS-1), or X-linked recessive (X-linked hypoparathyroidism) (3)
  - Congenital syndromes
    - 22q11.2 deletion syndrome, familial hypomagnesemia, hypoparathyroidism with lymphedema (3)
    - Hypoparathyroidism with sensorineural deafness
    - ADHH: mutations gain-of-function of the CaSR gene suppressing the parathyroid gland, without elevation of PTH
    - PGA syndrome type I: mucocutaneous candidiasis, hypoparathyroidism, and Addison disease

**RISK FACTORS**

- Neck surgery and neck trauma, neck malignancies, family history of hypocalcemia, PGA syndrome

**GENERAL PREVENTION**

- Intraoperative identification and preservation of parathyroid tissue

**COMMONLY ASSOCIATED CONDITIONS**

- DiGeorge syndrome
- Bartter syndrome
- PGA syndrome type I
- Multiple endocrine deficiency autoimmune candidiasis (MEDAC) syndrome
• Juvenile familial endocrinopathy
• Addison disease
• Moniliasis (HAM) syndrome: a polyglandular deficiency syndrome, possibly genetic, characterized by hypoparathyroidism

**DIAGNOSIS**

**HISTORY**
Often asymptomatic; ask about previous neck trauma or surgery, head or neck irradiation, family history of hypocalcemia, or presence of other autoimmune endocrinopathies.

• Cardinal clinical feature: neuromuscular hyperexcitability
• Also includes: fatigue, circumoral or distal extremity paresthesias, muscle spasm, seizures, neuropsychiatric symptoms

**PHYSICAL EXAM**
• Surgical scar on neck
• Chvostek sign: ipsilateral twitching of the upper lip on tapping the facial nerve on the cheek. 15% of normocalcemic people have positive Chvostek sign (1).
• Trousseau sign: painful carpal spasm after 3-minute occlusion of brachial artery with BP cuff. BP cuff inflation to above systolic BP for 3 minutes leads to carpal spasm (flexion of metacarpophalangeal [MCP] joints, extension of interphalangeal [IP] joints, adduction of fingers and thumb).
• Tetany, laryngo- or bronchospasm, cardiac arrhythmias, refractory heart failure, dyspnea, edema
• Dry, coarse, puffy hair; brittle nails
• Loss of deep tendon reflexes
• Dysrhythmias (secondary hypocalcemia)
• Cataracts or ectopic calcifications
• Tooth enamel defects
• Vitiligo

**DIFFERENTIAL DIAGNOSIS**
• Vitamin D deficiency/resistance
• Pseudohypoparathyroidism, which presents in childhood, kidney and bone unresponsiveness to PTH; characterized by hypocalcemia, hyperphosphatemia, and, in contrast to hypoparathyroidism, elevated rather
than reduced PTH concentrations
• Hypoalbuminemia, renal failure, malabsorption, familial hypocalcemia, hypomagnesemia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Calcium: ionized (low) and total (low) (correct serum calcium level for albumin)
  – Corrected serum calcium = total serum calcium + 0.8 (4 – serum albumin)
• Phosphorus (high)
• Intact or “whole” PTH (low); how to distinguish from pseudohypoparathyroidism or secondary causes
• Magnesium (low may be cause of hypoparathyroidism; may also be normal)
• BUN, creatinine, 25-OH vitamin D level (especially in elderly)
• Urinary calcium (normal or high)
• Calcium should be monitored after thyroid or parathyroid surgery.
• Radiographs may show absent tooth roots, calcification of cerebellum, choroid plexus, or cerebral basal ganglia.

Follow-Up Tests & Special Considerations
• ECG: prolongation of ST and QTc intervals, nonspecific repolarization changes, dysrhythmias
• Urine calcium: Creatinine ratio (normal 0.1 to 0.2) may be low before treatment but should be monitored to prevent stones due to hypercalciuria.
• Gene sequencing: Evaluation of other hormone levels may be required to diagnose APS-1.
• Hungry bone syndrome (transient hypoparathyroidism after parathyroid surgery)
  – Hypocalcemia due to hungry bone syndrome may persist despite recovery of PTH secretion from the remaining normal glands. Thus, serum PTH concentrations may be low, normal, or even elevated.
• Infiltrative: osteoblastic metastasis of prostate, breast, or lung cancer
• Metabolic/nutritional: renal failure, neonatal hypocalcemia, hypoalbuminemia, malabsorption, calcium (Ca++) chelators, and hypomagnesemia
• Familial hypocalcemia, acute hyperphosphatemia (rare), vitamin D deficiency
• Autoantibodies against NACHT leucine-rich-repeat protein 5(NALPS) found in 49% of 73 patients with APS-1 and hypoparathyroidisms
TREATMENT

GENERAL MEASURES

- Monitor ECG during calcium repletion.
- Maintenance therapy: may require lifelong treatment with calcium and calcitriol
  - Maintain serum calcium in low normal range: 8 to 8.5 mg/dL (2 to 2.12 mmol/L).
- If hypercalcemia occurs, hold therapy until calcium returns to normal. Treat magnesium deficiency if present.
- Phosphate binders are required if high calcium-phosphate product.
- Thiazide diuretics combined with a low-salt diet may be used to prevent hypercalciuria, nephrocalcinosis, and nephrolithiasis.
- Oral calcium administration and vitamin D supplementation after thyroidectomy may reduce the risk for symptomatic hypocalcemia after surgery.

MEDICATION

- Acute hypoparathyroidism
  - Hypoparathyroid with severe symptoms (tetany, seizures, cardiac failure, laryngospasm, bronchospasm)
    - IV calcium gluconate: 1 or 2 g, each infused over a period of 10 minutes. Central venous catheter is preferred because calcium-containing solutions can irritate surrounding tissues. Follow with infusion of 10 g calcium gluconate in 1 L 5% dextrose water at a rate of 1 to 3 mg calcium gluconate per kg body weight per hour (2)[B].
  - Hypomagnesemia: acutely: 1 to 2 g IV q6h; long-term magnesium oxide tablets (600 mg) once or twice per day
- Chronic hypoparathyroidism

First Line

- Adults
  - Oral calcium carbonate: calcium salts: Start with 1 to 3 g/day PO but dose varies. For geriatric patients, those on a PPI or those who have constipation on the carbonate form, consider using calcium citrate instead (4)[B].
  - Calcitriol: (vitamin D 1, 25-dihydroxycholecalciferol): 0.25 μg/day. Doses 0.5 to 2.0 μg/day are usually required (3)[A].
– Either parental form of vitamin D (D2 ergocalciferol or D3 cholecalciferol) for tissues to generate their own 1,25 form
– For hypercalciuria, consider a thiazide diuretic.
– For phosphate level well above normal (>6.5 mg/dL), use low phosphate diet or phosphate binder.

● Children
  – Oral elemental calcium: 25 to 50 mg/kg daily
  – Calcitriol: 0.25 μg daily for age >1 year

ISSUES FOR REFERRAL
Endocrinologist, nephrologist, ophthalmologist

ADDITIONAL THERAPIES
PTH peptides 1-34 and 1-84 SC
● rhPTH 1-84—FDA-approved, 50 μg SC daily

- For patients with frequent episodes of hyper- and hypocalcemia, nephrolithiasis, nephrocalcinosis, GFR <60 mL/min, persistently high phosphate

● Treatment goal: Eliminate use of active vitamin D₃, reduce supplemental calcium to 500 mg daily; maintain consistent Ca level in low normal range.
● Improved well-being and increased bone mineral density have been shown for these patients.

SURGERY/OTHER PROCEDURES
Autotransplantation of cryopreserved parathyroid tissue: restores normocalcemia in 23% of cases

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
● Admission criteria/initial stabilization: laryngospasm, seizures, tetany, QT prolongation
● Discharge criteria: resolution of hypocalcemic symptoms, patient educated on hypoparathyroidism and treatment

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Goal is a total corrected serum calcium level in low normal range (8 to 8.5 mg/dL or 2 to 2.12 mmol/L), 24-hour urine calcium <300 mg, and calcium-phosphate product <55. If Ca <2.0 mmol/L or <8.0 mg/dL, then treat even if asymptomatic (4)[B].
- Outpatient measurement of serum calcium, phosphate, magnesium, and creatinine weekly to monthly during initial management; for changes in medication, check weekly or every other week; when stable, measure every 6 months (4)[B].
- 24-hour urine for calcium and Cr secretion yearly
- If symptoms of renal stone disease or increasing Cr, get renal imaging every 5 years (4)[B].
- Annual slit-lamp and ophthalmologic evaluations are recommended.
- DEXA scan: standard monitoring recommended (4)[B]

DIET

Low-phosphate diet in patients with hyperphosphatemia

PATIENT EDUCATION

https://www.hypopara.org/

PROGNOSIS

Hypoparathyroidism following neck surgery is often transient. Length of required treatment may vary depending on origin.

COMPLICATIONS

- Reversible: due to low calcium levels, most likely to improve with adequate treatment
  - Neuromuscular symptoms: Paresthesias (circumoral, fingers, toes), tetany, seizures, parkinsonian symptoms; pseudotumor cerebri has been described.
  - Renal: hypercalciuria, nephrocalcinosis, nephrolithiasis
  - Cardiovascular: heart failure, arrhythmias
- Irreversible: when condition starts early in childhood and will not improve with calcium and vitamin D treatment
  - Stunting of growth
  - Enamel defects and hypoplasia of teeth
- Atrophy, brittleness, and ridging of nails
- Cataracts and basal ganglia calcifications

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- E20.9 Hypoparathyroidism, unspecified
- P71.4 Transitory neonatal hypoparathyroidism
CLINICAL PEARLS

Often asymptomatic; consider if hypocalcemic with fatigue and circumoral or distal extremity paresthesias.

- Correct the serum calcium level for albumin level.
- Monitor calcium after thyroid or parathyroid surgery.
- Distinguish hypoparathyroidism from pseudohypoparathyroidism and secondary causes by PTH level.
- Not much clinical difference between 2nd- and 3rd-generation PTH assays
- Serum levels of magnesium and 25-OH should be measured to rule out deficiency that could contribute to reduced serum calcium levels.
HYPOThERMIA

Scott T. Henderson, MD

BASICS

DESCRIPTION
- A core temperature of <35°C (95°F)
- May take several hours to days to develop
- Patients with cold-water immersion may appear dead but can sometimes still be resuscitated.
- System(s) affected: all body systems
- Synonym(s): accidental hypothermia

EPIDEMIOLOGY
- Predominant age: very young and the elderly
- Predominant sex: male > female

Geriatric Considerations
More common in elderly due to lower metabolic rate, impaired ability to maintain normal body temperature, and impaired ability to detect temperature changes

Prevalence
Estimates vary widely; typically a secondary issue

ETIOLOGY AND PATHOPHYSIOLOGY
- Overwhelming environmental cold stress
- Decreased heat production
- Increased heat loss
- Impaired thermoregulation

RISK FACTORS
- Alcohol consumption
- Bronchopneumonia
- Cardiovascular disease
- Cold-water immersion
- Dermal dysfunction (burns, erythrodermas)
- Drug intoxication
- Endocrinopathies (myxedema, severe hypoglycemia)
- Excessive fluid loss
- Hepatic failure
- Hypothalamic and central nervous system (CNS) dysfunction
- Malnutrition
- Mental illness; Alzheimer disease
- Prolonged cardiac arrest
- Prolonged environmental exposure
- Renal failure
- Sepsis
- Trauma (especially head)
- Uremia

**GENERAL PREVENTION**
- Appropriate clothing, with particular attention to head, feet, and hands
- For outdoor activities, carry survival bags with rescue foil blanket for use if stranded or injured.
- Avoid alcohol.
- Alertness to early symptoms and initiating preventive steps (e.g., drinking warm fluids)
- Identify medications that may predispose to hypothermia (e.g., neuroleptics, sedatives, hypnotics, tranquilizers).

**COMMONLY ASSOCIATED CONDITIONS**
- Addison disease
- CNS dysfunction
- Congestive heart failure
- Diabetes
- Hypopituitarism
- Hypothyroidism
- Ketoacidosis
- Pulmonary infection
- Sepsis
- Uremia
DIAGNOSIS

HISTORY

Presentation varies with the temperature of the patient at the time of presentation.

ALERT

History of prolonged exposure to cold may make the diagnosis obvious, but hypothermia may be overlooked in other situations, especially in comatose patients. Always obtain a core temperature if hypothermia is suspected.

PHYSICAL EXAM

Esophageal temperature is most accurate, minimally invasive method of assessing core temperature \((1^\circ C)\).

- Must have secure airway
- Probe inserted into lower 3rd of esophagus
- Peripheral thermometers (typanic membrane, temporal artery, axillary, or oral) associated with reduced accuracy

Exam findings vary with the temperature of the patient at the time of presentation.

- Mild (32–35°C)
  - Lethargy and mild confusion
  - Shivering
  - Tachypnea
  - Tachycardia
  - Loss of fine motor coordination
  - Increased BP
  - Peripheral vasoconstriction
  - Hyperactive reflexes

- Moderate (28–32°C)
  - Delirium
  - Bradycardia
  - Hypotension
  - Hypoventilation
  - Cyanosis
  - Arrhythmias (prolonged PR interval, AV junctional rhythm, accelerated idioventricular rhythm, prolonged QT interval, altered T waves)
– Semicoma and coma
– Muscular rigidity
– Generalized edema
– Slowed reflexes

• Severe (<28°C)
  – Very cold skin
  – Rigidity
  – Apnea
  – Bradycardia
  – No pulse: ventricular fibrillation or asystole
  – Areflexia
  – Unresponsive
  – Pupils (dilated <27°C; fixed and dilated <27°C)

**ALERT**
Use specially designed thermometers that can record low temperatures and measure core temperatures.

**Pediatric Considerations**
• Infants may present with bright red, cold skin and very low energy.
• A child’s body temperature drops faster than an adult does when immersed in cold water.

**DIFFERENTIAL DIAGNOSIS**
• Cerebrovascular accidents
• Intoxication
• Drug overdose
• Complications of diabetes, hypothyroidism, hypopituitarism

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
• Arterial blood gases (corrected for temperature)
• CBC and platelet counts
• Serum electrolytes; BUN/creatinine; glucose; calcium; magnesium
• Urinalysis
• Coagulation studies; fibrinogen level
• Blood culture
• Liver function studies; amylase
Follow-Up Tests & Special Considerations
Serum cortisol and TSH if underlying endocrine dysfunction (hypothalamus stimulates release of hormones in response to hypothermia)

Diagnostic Procedures/Other
ECG

Test Interpretation
Serum potassium >12 mmol/L associated with nonsurvival

TREATMENT

GENERAL MEASURES

- Prehospital (1)[C]
  - Factors to guide treatment
    - Level of consciousness
    - Shivering intensity
    - Cardiovascular stability based on blood pressure and cardiac rhythm
    - ABCs of basic life support
    - Remove wet garments.
      - Dry patient.
      - Protect against heat loss and wind chill.
      - If far from definitive care, begin active rewarming but do not delay transport.
      - Mild hypothermic patients with shivering ability will have improved comfort and might have a reduced cold-stress response with active rewarming (2)[B].
      - Give warm humidified oxygen if available.

- See “Admission, Inpatient, and Nursing Considerations”

MEDICATION
For sepsis or bacterial infections: antibiotics based on site and etiology
For hypoglycemia: D50W at a dose of 1 mg/kg
Thiamine: 100 mg, if alcoholic or cachectic
Naloxone: 2 mg
Levothyroxine: 150 to 500 μg for myxedema
For severe acidosis: sodium bicarbonate
Precautions
  - Medications including epinephrine, lidocaine, and procainamide can accumulate to toxic levels if used repeatedly; should be avoided until core temperature is >30°C:
    o When temperature reaches >30°C, IV medications are indicated. Administer slowly.
  - Consider vasopressors according to standard ACLS algorithm with concurrent rewarming in setting of cardiac arrest.
Significant possible interactions:
  - Use all drugs cautiously due to impaired metabolism and renal elimination.
Once rewarming has occurred, there is mobilization of depot stores.
Routine use of steroids or antibiotics does not increase survival or decrease postresuscitative damage.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Rewarming depends on severity of hypothermia and presence of cardiac arrest.

If no cardiac arrest, consider active external rewarming (3)[B].
If cardiac arrest is present, consider active internal rewarming (3)[B].
Warm center of body first (4)[C].
The rate of rewarming is determined by whether a perfusing cardiac output is present.
  - If a perfusing cardiac output is present, 1–2°C/hr is appropriate.
  - If not, then a faster rate of >2°C/hr should be used.
Monitor core temperature; use a consistent method.
Monitor BP and cardiac rhythm.
Correct metabolic acidosis.
Evaluate for frostbite and other trauma.
Mild hypothermia
  - Passive rewarming
  - Administration of heated IV solutions
– Provide warm fluids by mouth if fully alert.

- Moderate hypothermia
  – Active external rewarming

- Severe hypothermia (active internal [core] rewarming)
  – Minimally invasive
  – Heated IV fluids
  – Heated humidified oxygen
  – Body cavity lavage
    o Thoracic cavity lavage (40–45°C)
    o Peritoneal lavage (40–45°C)
  – Extracorporeal blood rewarming
    o Cardiopulmonary bypass
    o Extracorporeal membrane oxygenation
    o Continuous arteriovenous rewarming
    o Hemodialysis and hemofiltration

- Cardiac arrhythmias
  – Atrial fibrillation and sinus bradycardia are common—patients usually convert to normal sinus rhythm with rewarming.
  – If ventricular fibrillation is present, treat with one shock. If patient does not respond, consider deferring further attempts until rewarm has occurred.
  – Do not treat transient ventricular arrhythmias.
  – If cardiac pacing required, preferable to use external noninvasive pacemaker

- Admit patients, preferably to the ICU, with underlying disease, physiologic abnormalities, or core temperature <32°C.

- Normal saline is preferred as fluid of choice (1)[C].

- Heat IVs from 40°C to 45°C if possible—should at least be no colder than patient core temperature.

**ALERT**
- Avoid fluid overload.
- Avoid overheating dextrose solutions; dextrose caramelizes at 60°C.
- Avoid lactated Ringer solution because of decreased lactate metabolism.
- Heart is irritable and susceptible to arrhythmias; take care transporting.
- Electrolytes may fluctuate with rewarming, check electrolytes (particularly potassium) frequently.
- Discharge from emergency department once normothermic, if mild hypothermia and no predisposing conditions or complications and has suitable place to go. All others require admission.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

**Patient Monitoring**
- During acute episode
  - Monitor cardiac rhythm.
  - Monitor electrolytes and glucose frequently.
  - Monitor urinary output.
  - Follow blood gases.
- Following acute episode
  - Continued therapy for any underlying disorder

**DIET**
Warm fluids only if alert and able to swallow
- Alcohol intake increases risk of becoming hypothermic in cold conditions.
- Encourage persons with cardiovascular disease to avoid outdoor exercise in cold weather.
- Refer to social service agency for help with adequate housing, heat, and/or clothing, if appropriate.

**PROGNOSIS**
- Mortality rates are decreasing due to increased recognition and advanced therapy.
- Mortality usually depends on age and the severity of underlying cause and comorbidities.
  - Mortality rate in healthy patients is <5%.
  - Mortality rate with coexisting illness is >50%.
  - Alcohol or drug poisoning seen in 10% of deaths

**Geriatric Considerations**
Mortality rates increase with increasing age. Over half of deaths are seen in patients >65 years.

**COMPLICATIONS**
- Core temperature after drop
- Cardiac arrhythmias
- Hypotension
- Hyperkalemia, hypoglycemia
- Rhabdomyolysis
- Sepsis
- Pneumonia (aspiration and bronchopneumonia), pulmonary edema
- Acute respiratory distress syndrome
- Pancreatitis, peritonitis, GI bleeding, ileus
- Acute tubular injury, bladder atony
- Intravascular thromboses/disseminated intravascular coagulation
- Metabolic acidosis
- Gangrene of extremities
- Compartment syndromes
- Seizures, cerebral ischemia, delirium

SEE ALSO

- Frostbite; Nonfatal Drowning
Algorithm: Hypothermia

**CODES**

**ICD10**
- T68.XXXA Hypothermia, initial encounter
- T68.XXXD Hypothermia, subsequent encounter
- T68.XXXS Hypothermia, sequela

**CLINICAL PEARLS**
- The most common cause of hypothermia in the United States is cold exposure due to alcohol intoxication.
- With a severely decreased core temperature, begin resuscitation (if possible) unless there are obvious lethal injuries. Continue resuscitation and rewarm to 33–35°C (“not dead until warm and dead”).
- ECG changes associated with hypothermia: slowing of sinus rate with T-wave inversion; QT, QRS, and PR interval prolongation; atrial and ventricular arrhythmias; J waves (Osborn waves)
HYPOTHYROIDISM, ADULT
Adithi Naidu, MD • Faraz Ahmad, MD, MPH • Hiba Ahmad, PharmD

BASICS
DESCRIPTION
• Clinical and metabolic state resulting from decreased levels of free thyroid hormone or from resistance to hormone action
• Primary (intrinsic thyroid disease) or central (secondary or tertiary resulting from hypothalamic-pituitary disease)
• Subclinical: serum TSH above the upper reference limit with a normal free T4 and normal hypothalamic-pituitary-thyroid axis
• Overt: elevated TSH, usually >10 mIU/L with a subnormal free T4

EPIDEMIOLOGY
Incidence
• Women: 3.5 per 1,000 persons per year
• Men: 0.6 per 1,000 persons per year

Prevalence
• The National Health and Nutrition Examination Survey III (NHANES III), SHypo (subclinical hypothyroidism) 9.3%, overt 0.3–3.7% in an unselected U.S. population age >12 years, with upper limit TSH 4.5
• Framingham study, 5.9% of women and 2.3% of men age >60 years had a serum TSH >10 mIU/L.

ETIOLOGY AND PATHOPHYSIOLOGY
• Primary: abnormality at the thyroid gland (>95% of cases)
  • Most common cause worldwide: environmental iodine deficiency
  • Most common cause in the United States: Hashimoto thyroiditis (chronic autoimmune thyroiditis)
    – Hashimoto is characterized pathologically by infiltration of the thyroid with sensitized T lymphocytes and serologically by circulating antithyroid antibodies.
Autoimmunity to the thyroid gland is an inherited defect in immune surveillance, leading to abnormal regulation of immune responsiveness or alteration of presenting antigen in the thyroid (1).

- **Postablative/posttherapeutic:** follows radioactive iodine therapy or hemithyroidectomy for hyperthyroidism; radiotherapy or surgery for thyroid cancer, benign nodular thyroid disease or neck malignancies
- **Transient hypothyroidism:** De Quervain syndrome (viral), postpartum, silent thyroiditis (2)
- **Drug use:** propylthiouracil, methimazole, lithium, amiodarone, antiepileptic drugs and newer chemotherapeutic agents such as tyrosine kinase inhibitors (sunitinib), interleukin-2, or interferon-α
- **Central:** hypothyroidism due to insufficient stimulation by TSH of an otherwise normal thyroid gland
- **Can be secondary** (level of the pituitary) or tertiary (level of the hypothalamus)
- **Etiology** involves genetic defects, tumors, vascular, empty sella syndrome, inflammatory, infiltrative, iatrogenic, posttrauma, or drug related.

**RISK FACTORS**
- Women >60 years of age
- Personal or family history of autoimmune diseases
- Pregnant women or those with previous postpartum thyroiditis
- Previous head or neck irradiation
- Past history of thyroid dysfunction or thyroid surgery
- Abnormal thyroid examination, presence of goiter and/or TPOAb positivity
- Treatment with amiodarone, lithium, interferon-α, sunitinib, or sorafenib
- Those with Down syndrome or Turner syndrome

**COMMONLY ASSOCIATED CONDITIONS**
- Type 1 and 2 diabetes
- Pernicious anemia
- Primary adrenal failure (Addison disease)
- Myasthenia gravis
- Celiac disease
- Rheumatoid arthritis
- Systemic lupus erythematosus
- Vitiligo
- Depression
- Genetic syndromes that have multiple autoimmune endocrinopathies (MAE)
such as type 1 MAE and type 2 MAE.

**DIAGNOSIS**

**HISTORY**
- Lethargy
- Fatigue
- Cold intolerance
- Slowed thinking
- Hearing impairment
- Constipation
- Dry skin
- Muscle cramps, arthralgias, paresthesias
- Modest weight gain (10 lb [4.5 kg])
- Menstrual disturbances
- Depression
- Change in voice (hoarseness)
- Carpal tunnel syndrome
- Symptoms can vary and can be nonspecific.

**PHYSICAL EXAM**
- Dry, coarse, thickened skin
- Hair loss/brittle hair
- Coarsening of voice
- Periorbital puffiness
- Swelling of hands and feet (nonpitting)
- Bradycardia
- Reduced systolic BP; increased diastolic BP
- Delayed relaxation of deep tendon reflexes
- Macroglossia
- Goiter (particularly in patient with Hashimoto thyroiditis)

**Geriatric Considerations**
- Characteristic signs and symptoms frequently nonspecific, changed, or absent
- Normal serum thyrotropin ranges are higher (in those >65 years of age),

**DIFFERENTIAL DIAGNOSIS**
Chronic fatigue syndrome
Depression
Euthyroid sick syndrome
Congestive heart failure
Primary amyloidosis
Dementia from other causes
Primary adrenal insufficiency
Thyrotropin-secreting pituitary adenoma

**DIAGNOSTIC TESTS & INTERPRETATION**

- **Primary hypothyroidism**
  - Elevated TSH (>4.5 mIU/L)
  - Decreased serum free T₄ (2)[A]

- **Central (secondary or tertiary) hypothyroidism**
  - Assess only free T₄ or free T₄ index, not TSH (1)[A].
  - Decreased serum free T₄
  - Antithyroid antibodies absent
  - TRH stimulation test, especially if free T₄ and/or TSH is low-normal and patient has hypothalamo-pituitary pathology
  - Imaging of the hypothalamus and pituitary gland

- **Subclinical hypothyroidism**
  - Elevated serum TSH (>4.5 mIU/L)
  - Normal serum free T₄ (3)[A]
  - Note: Serum free triiodothyronine (T₃) or total T₃ should not be done to diagnose hypothyroidism (1)[A].

**Follow-Up Tests & Special Considerations**

- Antithyroid antibodies may define the cause of primary hypothyroidism but are not necessary in all settings.
- Drugs that may alter lab results:
  - Drugs that decrease TSH:
    - Thyroid supplement, cortisone, dopamine, octreotide
  - Drugs that increase TSH:
    - Phenytoin, amiodarone, dopamine antagonist (metoclopramide/domperidone, salicylates, oral colecystographic dyes [sodium ipodate]), or estrogen or androgen in excess
  - Drugs that increase free thyroxine:
○ Heparin, high intake of biotin

- Disorders that may alter lab results
  - Any severe illness, pregnancy, chronic protein malnutrition, hepatic failure, or nephrotic syndrome

**TEST INTERPRETATION**

**SCREENING**

- Patient with risks factors as described above (1)[A]
- Patient with laboratory or imaging abnormalities
  - Substantial hyperlipidemia or change in lipid pattern
  - Hyponatremia, often resulting from inappropriate production of antidiuretic hormone
  - High serum muscle enzyme concentrations
  - Macrocytic anemia
  - Pericardial or pleural effusion
  - Pituitary or hypothalamic disorder
- Pregnant women
  - Personal or family history of thyroid disease
  - Diabetes mellitus (DM) type 1
  - H/o recurrent miscarriage, morbid obesity, or infertility; TPOAb should be considered (1)[A].
  - Universal screening not recommended for patients pregnant or planning pregnancy
- U.S. Preventive Services Task Force found insufficient evidence for or against screening nonpregnant, asymptomatic children or adults (2)[A].
- Recommendations by expert groups:
  - ATA recommends screening in all adults at age 35 years and every 5 years thereafter (1)[A].
  - AACE recommends screening older patients (age not specified), especially women.
  - AAFP recommends against routine screening in asymptomatic patients <60 years.
  - ACOG recommends women with h/o autoimmune disease or strong family h/o thyroid disease should be screened at age 19 years.

**TREATMENT**
MEDICATION

**First Line**

- **Levothyroxine (Synthroid, Levothroid)**
  - 1.5 to 1.8 μg/kg/day (use ideal body weight) (2)[A]; titrate by 12.5 to 25 μg/day every 4 to 8 weeks until TSH in normal range.
  - Dosage requirements may vary with age, gender, residual secretory capacity of thyroid gland, other drugs being taken by patient, and intestinal function (1)[A].
  - Use caution when changing between capsule, tablet, and injection as dose conversions are not a 1:1 ratio.
  - Elderly patients may require 2/3 of dose used in young adults because clearance is decreased.
  - Levothyroxine should be taken on an empty stomach, ideally an hour before breakfast. Administering at bedtime may result in higher levels than administering in the morning (4)[A].
  - Medications that interfere with its absorption should be taken 4 hours after the T₄ dose: ferrous sulfate, proton pump inhibitors, calcium carbonate, bile acid resins.

- **Contraindications**
  - Thyrotoxic heart disease
  - Uncorrected adrenocorticoid insufficiency
  - MI, acute
  - TSH suppression, preexisting

- **Precautions**
  - If elderly or known coronary artery disease, start with lower doses, such as 12.5 to 25 μg.
  - Diabetic patients may need readjustment of hypoglycemic agents with institution of T₄.
  - Dosage of oral anticoagulants may need adjustment; monitor prothrombin time while initiating treatment.
  - Patients on digoxin may need close monitoring.
  - Elderly patients more susceptible to AFib and osteoporotic fracture with thyroid hormone excess
  - Patients requiring doses that are higher than expected should be evaluated for GI disorders (*Helicobacter pylori*, celiac disease).

- **Possible interactions with the following medications:**
  - Oral anticoagulants, insulin, oral hypoglycemic, estrogen, OCP, PPI,
cholestyramine
– Ferrous sulfate, calcium carbonate, antacids, laxatives, colestipol, sucralfate, ciprofloxacin, and cholestyramine may decrease absorption.

Controversy exists whether subclinical hypothyroidism should be treated. Cochrane Review found no improvement in survival, cardiovascular morbidity, or health-related quality of life. Some evidence indicates improvement in lipid profiles and left ventricular function. Subclinical hypothyroidism should be treated in patients with iron deficiency anemia and in patients with TSH >10 (3,5)[B],(6).

• If surgery is elective, render patient euthyroid prior to procedure.
• If surgery is urgent, proceed with individualized replacement therapy preoperatively and postoperatively.

**Pregnancy Considerations**
• Replacement therapy may need adjustment; average dose increases from 25% to 50% (6)[A].
• TSH levels should be monitored monthly during 1st trimester; goal TSH of 2 to 2.5 mIU/L for 1st trimester, <3.0 mIU/L for 2nd trimester, and <3.5 mIU/L for 3rd trimester (6)[A]
• Postpartum: Check TSH levels at 6 weeks (6)[A].
• Painless subacute thyroiditis may occur in postpartum period, leading to transient hypothyroidism lasting 3 months. Treatment with replacement therapy may be warranted. Up to 30% of these individuals develop permanent hypothyroidism.

**Second Line**
• No benefit to adding T₃ to T₄ (6)[A]
• Desiccated thyroid hormone is not recommended for the treatment of hypothyroidism (1).
• Liothyronine (T₃) or desiccated thyroid hormone (T₃ and T₄) may be an alternative for patients who do not feel balanced on T₄ alone.

**ISSUES FOR REFERRAL**
• Children and infants
• Pregnancy or women planning conception
• Patient in whom it is difficult to maintain a euthyroid state
• Cardiac disease
• Presence of goiter, nodule, or other structural changes in the thyroid gland
• Presence of adrenal or pituitary disorders (1)[C]

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

• Myxedema coma (decompensated severe untreated hypothyroidism)
• True clinical emergency (requires ICU care)
• Profound hypothermia and unconsciousness
• Increased risk of shock and potentially fatal arrhythmias
• Postponing surgery for initiating therapy for hypothyroidism is not indicated.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
• Monitor TSH and free $T_4$ every 4 to 8 weeks after initiating treatment or after change in dose. Once stabilized, periodic TSH level should be done after 6 months and then at 12-month intervals or more frequently if the clinical situation dictates otherwise (1)[B].
• Monitor cardiac function closely in older patients.
• Check TSH more frequently during pregnancy, initiation of estrogen supplementation, or after large changes in body weight.
• In central hypothyroidism, TSH is unreliable; must monitor free $T_4$ and $T_3$.
• Thyroid hormones should not be used to treat obesity in euthyroid patients (1)[A].

**PATIENT EDUCATION**
• Stress importance of compliance with thyroid replacement therapy.
• Explain need for lifelong treatment.
• Further education required for patients taking multiple medications that may interact.
• Instruct to report to physician any signs of infection or heart problems.
• Describe signs of thyrotoxicity.
• High-bulk diet may help avoid constipation.

**PROGNOSIS**
• Return to normal state is the rule.
Relapses will occur if treatment is interrupted.  
If untreated, may progress to myxedema coma

**COMPLICATIONS**

- Mortality and complication rates from surgery are similar between hypothyroid and euthyroid patients.  
- Myxedema coma: mortality 30–60%  
- Increased susceptibility to infection  
- Megacolon  
- Sexual dysfunction  
- Organic psychosis with paranoia  
- Infertility  
- Hypersensitivity to opiates  
- Treatment over long periods can lead to bone demineralization.  
- Iatrogenic thyrotoxicosis can lead to AFib and osteoporosis.  
- Can lead to adrenal crisis with vigorous treatment, especially in patients with undiagnosed polyendocrine syndromes  
- Treatment-induced congestive heart failure in people with coronary artery disease

CODES

ICD10
- E03.9 Hypothyroidism, unspecified
- E06.3 Autoimmune thyroiditis
- E89.0 Postprocedural hypothyroidism

CLINICAL PEARLS
- Monitor TSH and free T4 every 4 to 8 weeks after initiating treatment or after change in dose. Once stabilized, periodic TSH level should be done after 6 months and then at 12-month intervals, or more frequently if the clinical situation dictates otherwise (1)[B].
- Screening test: TSH levels (1)[A]
- Serum free T3 or total T3 should not be done to diagnose hypothyroidism (1)[A].
- Dosage requirements may vary with age, gender, residual secretory capacity of thyroid gland, other drugs being taken by patient, and intestinal function (1)[A].
ID REACTION
Sahil Mullick, MD

BASICS
DESCRIPTION
A generalized skin reaction associated with various infectious (fungal, bacterial, viral, or parasitic) or inflammatory cutaneous conditions distant from the primary disease site (1)

- “Id” is often combined with a root to reflect the causative factor (i.e., bacterid, syphilid, and tuberculid). Dermatophytid is the most frequently referenced id reaction. A dermatophytid is an autosensitization reaction in which a secondary cutaneous reaction occurs at a site distant to a primary fungal infection. The eruption typically begins within 1 to 2 weeks of the onset of the main lesion or following exacerbation of the main lesion.
- Most commonly localized vesicular lesions, erythema nodosum, and erythema multiforme
- System(s) affected: skin/exocrine
- Synonym(s): dermatophytid, trichophytid, autoeczematization

EPIDEMIOLOGY
- Predominant age: all ages
- Predominant sex: male = female
- Predominant race: all races

Incidence
Unknown

Prevalence
Common

ETIOLOGY AND PATHOPHYSIOLOGY
Precise pathophysiology is uncertain. Circulating antigens may react with antibodies at sensitized areas of the skin. An abnormal immune recognition of autologous skin antigens may also occur. Inflammation may lower the irritation threshold of the skin, and hematogenous spread of cytokines from the primary
site of inflammation may also play a role (1).

- **Etiology**
  - **Infectious**
    - Fungal infections: *Trichophyton mentagrophytes*, *Trichophyton rubrum*, *Epidermophyton floccosum*, and *Candida* spp.
    - Bacterial infections: *Streptococcus pyogenes*, *Staphylococcus aureus*, and *Mycobacterium tuberculosis*
    - Viral infections: HSV, *Molluscum contagiosum*, orf, and milker’s nodules
    - Parasitic infections: *Sarcoptes scabiei* and *Leishmania* spp.
  - **Allergic**
    - Id reactions occur in patients with nickel and aluminum allergy.
  - **Miscellaneous**
    - Id reaction rarely develops due to retained postoperative sutures, ionizing radiation, and blunt trauma.
    - Rarely, id reaction has been documented in patients receiving intravesical BCG live therapy for transitional cell carcinoma.

**RISK FACTORS**
- Fungal infection of the skin, especially tinea pedis
- Stasis dermatitis

**GENERAL PREVENTION**
- Good skin hygiene (particularly in intertriginous areas) to minimize risk of developing fungal infections
- Promptly treat any developing fungal infection.

**COMMONLY ASSOCIATED CONDITIONS**
- Primary fungal infection
- Stasis dermatitis

**DIAGNOSIS**

**HISTORY**
Itchy rash: Inquire about presence of lesions (typically fungal or bacterial) that could have incited the id reaction in the preceding days to weeks.

**PHYSICAL EXAM**
• Common
  – Symmetric, pruritic vesicles on the palms and, most commonly, on lateral aspects of fingers
  – Tinea infection on the feet; contact or other eczematous dermatitis; bacterial, fungal, or viral infection of the skin
• Less common
  – Papules
  – Lichenoid eruption
• Eczematoid eruption

DIFFERENTIAL DIAGNOSIS
• Pompholyx (dyshidrotic eczema)
• Contact dermatitis
• Drug eruptions
• Pustular psoriasis
• Folliculitis
• Scabies

DIAGNOSTIC TESTS & INTERPRETATION
• Potassium hydroxide (KOH) or fungal culture of primary lesion
• No fungal elements are present at the site of the id reaction.
• Special tests: Skin shows a positive trichophyton reaction. A wheal >10 mm at 20 minutes and induration >5 mm at 72 hours is a positive response.

Follow-Up Tests & Special Considerations
• The id reaction resolves with successful eradication of the primary skin condition.
• It is important to distinguish dermatophytids from drug-induced allergic reactions, as continued treatment is essential to clear the underlying infection.

Test Interpretation
Histology
• Vesicles in the upper dermis
• Superficial perivascular lymphohistiocytic infiltrate with small numbers of eosinophils and increased granular cell layer
• No infectious agents present in biopsy specimen.
TREATMENT

GENERAL MEASURES
- Outpatient treatment of the underlying infection or eczematous dermatitis
- Symptomatic treatment of pruritus with antihistamines and/or topical steroids if needed (may require class 1 or 2 steroid)
- Treatment for secondary bacterial infection

MEDICATION

First Line
- PO antihistamines for pruritus (2)
  - Chlorpheniramine: 4 mg PO q4–6h PRN; max 24 mg/24 hr (pediatric: 6 to 11 years 2 mg PO q4–6h PRN; max 12 mg/24 hr; ≥12 years, refer to adult dosing)
  - Diphenhydramine: 25 to 50 mg PO q4–6h PRN; max 400 mg/24 hr (pediatric: 5 mg/kg/24 hr divided q6h PRN; 2 to 5 years max 37.5 mg/24 hr; 6 to 11 years max 150 mg/24 hr; ≥12 years, refer to adult dosing)
  - Hydroxyzine: 25 to 100 mg PO q6–8h PRN; max 600 mg/24 hr (pediatric: 2 mg/kg/24 hr divided q6h PRN)
- Topical treatments for pruritus
  - Triamcinolone 0.1% ointment TID
  - Hydrocortisone 0.5%, 1%, 2.5%: up to QID
  - Capsaicin 0.025%, 0.075% cream: Apply TID–QID; EMLA (2.5% lidocaine + 2.5% prilocaine) applied 30 to 60 minutes prior to capsaicin may minimize burning.
  - Doxepin 5% cream: Apply QID for up to 8 days (to max of 10% of the body).
  - Permethrin 5% cream (for scabies)
    - Apply from neck down after bath.
    - Wash off thoroughly with water in 8 to 12 hours.
    - May repeat in 7 days
  - Permethrin 1% cream rinse (for lice)
    - Shampoo, rinse, towel dry, saturate hair and scalp (or other affected area), leave on 10 minutes and then rinse.
    - May repeat in 7 days
  - White petroleum emollients: Apply after short bath/shower in warm (not hot) water.
- Systemic steroids only if reaction is severe or generalized (e.g., prednisone 20 mg)

**Second Line**
- Topical and/or systemic antifungals for identified associated fungal infection (common)
  - Tinea cruris/corporis
    - Topical azole antifungal compounds econazole (Spectazole) and ketoconazole (Nizoral): usually applied BID for 2 to 4 weeks
    - Terbinfine (Lamisil): over-the-counter (OTC) compound; can be applied daily or BID for 1 to 2 weeks
    - Butenafine (Mentax): applied once daily for 2 weeks; also very effective
  - Tinea capitis
    - PO griseofulvin for *Trichophyton* and *Microsporum* sp.; microsized preparation available; dosage 20 to 25 mg/kg/day divided BID or as a single dose daily for 6 to 12 weeks
    - PO terbinafine can be used for *Trichophyton* sp. at 62.5 mg/day in patients weighing 10 to 20 kg, 125 mg/day if weight 20 to 40 kg, 250 mg/day if weight >40 kg, and use for 4 to 6 weeks.
- Topical or systemic antibiotics for any secondary bacterial infection
- Treatment with antiviral agents for erythema multiforme associated with HSV is required.

**ONGOING CARE**

**PATIENT EDUCATION**
Avoid hot, humid conditions that promote fungal growth. Aerate susceptible body areas (e.g., wear sandals or open footwear). If possible, wear loose-fitting clothing and undergarments, dry wet skin after bathing, and use powders and antiperspirants to discourage fungal growth. Treat primary dermatitis promptly.

**PROGNOSIS**
After appropriate treatment, complete resolution in days to weeks

**COMPLICATIONS**
- Secondary bacterial infection (cellulitis)
- After resolution of dermatophytid, postinflammatory hyperpigmentation is
common and disappears without treatment in 1 month.

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- L30.2 Cutaneous autosensitization
- B35.9 Dermatophytosis, unspecified

CLINICAL PEARLS

- When one skin eruption follows another closely in time, consider an id reaction.
- When assessing an itchy rash, inquire about potential fungal or bacterial lesions in the preceding days to weeks as a potential prelude to the id reaction.
BASICS

DESCRIPTION

- Immune thrombocytopenia (ITP) is a condition characterized by the immunologic destruction of normal platelets and/or impaired thrombopoiesis in response to an unknown stimulus.
- It is defined as a platelet count <100 × 10^9/L, once other causes of thrombocytopenia have been ruled out (1).
- ITP nomenclature:
  - Newly diagnosed (<3 months), persistent (3 to 12 months), and chronic (>12 months)
  - Primary when it presents in isolation; secondary when associated with other disorders
- ITP is a relatively common disease of childhood that typically follows a viral infection. Onset is within 1 week, and spontaneous resolution occurs within 2 months in >80% of patients.
- In adults, ITP is usually a chronic disease and spontaneous remission is rare.
- Synonym(s): idiopathic thrombocytopenic purpura; immune thrombocytopenic purpura; and Werlhof disease

EPIDEMIOLOGY

- Peak age
  - Pediatric ITP: 2 to 4 years
  - Chronic ITP: >50 years with incidence 2 times higher in persons 60 years than those <60 years of age
- Predominant gender
  - Pediatric ITP: male = female
  - Chronic ITP: female > male (1.2 to 1.7:1)

Incidence

- Pediatric acute ITP: 1.9 to 6.4/100,000 children/year (2)
- Adult ITP: 1.6/100,000 per year (1)
Prevalence
Limited data. In one population (in Oklahoma) (3):
- Overall prevalence of 11.2/100,000 persons
- In children (<16 years): 8.1/100,000 with average age of 6 years
- In adults (>16 years): 12.1/100,000 persons with average age of 55 years

ETIOLOGY AND PATHOPHYSIOLOGY
- Accelerated platelet uptake and destruction by reticuloendothelial phagocytes results from action of IgG autoantibodies against platelet membrane glycoproteins IIb/IIIa. There is also cell-mediated platelet destruction by CD8+ T cells.
- Autoantibodies interfere with megakaryocyte maturation, resulting in decreased production.

RISK FACTORS
- Autoimmune thrombocytopenia (e.g., Evans syndrome)
- Common variable immune deficiency (CVID)
- Drug side effect (e.g., quinidine, vancomycin, penicillin, sulfonamides)
- Infections: Helicobacter pylori, hepatitis C, HIV, CMV, varicella zoster, measles, rubella, influenza, EBV
- Vaccination side effect. Live virus vaccinations carry a lower risk than natural viral infection: 2.6/100,000 cases MMR vaccine doses versus 6 to 1,200/100,000 cases of natural rubella or measles infections
- Bone marrow transplantation side effect
- Connective tissue disease, such as systemic lupus erythematosus, antiphospholipid antibody syndrome
- Lymphoproliferative disorders

DIAGNOSIS
A careful history, physical exam, and review of CBC and peripheral blood smear remain the key components of the diagnosis of ITP.

HISTORY
- Often asymptomatic; found incidentally on routine CBC
- Posttraumatic bleeding occurs at counts of 40 to 60 × 10^9/L.
- With counts <30 × 10^9/L, bruising tendency, epistaxis, menorrhagia, and
gingival bleeding are common.
- Spontaneous bleeding may occur with platelet count <20 × 10^9/L.
- Intracerebral bleeding is rare and may occur with counts <20 × 10^9/L and associated trauma or vascular lesions, resulting in neurologic symptoms.

**PHYSICAL EXAM**
- Ecchymoses, petechiae, epistaxis, and gingivorrhagia are common.
- Abnormal uterine bleeding may be present.
- Hemorrhagic bullae on buccal mucosa reflect acute, severe thrombocytopenia.
- Absence of splenomegaly, hepatomegaly, lymphadenopathy, stigmata of congenital disease

**DIFFERENTIAL DIAGNOSIS**
- Acute leukemia
- Thrombotic thrombocytopenic purpura
- Hemolytic uremic syndrome
- Factitious: platelet clumping on peripheral smear
- Thrombocytopenia secondary to sepsis
- Myelodysplastic syndrome, particularly in older patients
- Decreased marrow production: malignancy, drugs, viruses, megaloblastic anemia
- Posttransfusion
- Gestational thrombocytopenia
- Isoimmune neonatal purpura
- Congenital thrombocytopenias
- Disseminated intravascular coagulation
- Alcohol-induced thrombocytopenic purpura

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- CBC with differential and peripheral smear:
  - Isolated decreased platelet count <100 × 10^9/L
  - Giant platelets are usually present.
  - Normal red and white blood cell morphology
- For patients with history, exam, CBC, and peripheral smear typical of ITP, consider the following:
  - PT/PTT is normal.
  - In adults, serologies for hepatitis B, hepatitis C, and HIV infections are
recommended (1)[B].

- In pediatric ITP, immunoglobulin levels to exclude common variable immunodeficiency are commonly obtained (1)[B].

- Other tests are not necessary for patients with typical ITP presentation: antiplatelet, antinuclear, antiphospholipid antibodies; H. pylori testing; thrombopoietin; platelet parameters; direct antiglobulin test; reticulocyte count; urinalysis; and thyroid function tests (1)[C].

Further studies should be considered if the patient with thrombocytopenia also presents with:
- Fever
- Arthralgia
- Lymphadenopathy
- Family history of bleeding disorder
- Risk factors for HIV
- Abnormalities in other cell lines

Diagnostic Procedures/Other

- Imaging is not necessary.
- Bone marrow aspiration/biopsy
  - Not necessary for diagnosis in children (1)[B] and adults (1),(2)[C]
  - Can be considered for a patient with atypical symptoms, such as fever and weight loss and multiple abnormalities in blood count

Test Interpretation

- Peripheral smear: normal red and white cells with large or giant platelets but diminished in number
- Marrow reveals normal to abundant megakaryocytes with normal erythroid and myeloid precursors.

TREATMENT

GENERAL MEASURES

- Management is based on both platelet count and hemorrhagic manifestations.
- Current evidence-based guidelines recommend treatment should be administered for newly diagnosed patients with a platelet count <30 × 10⁹/L (1),(2)[C].
- The main goal is to achieve a platelet count associated with adequate
hemostasis, rather than a normal count (1).

- Outpatient management unless patient has platelet count <20 × 10⁹/L and is at risk for bleeding
- Admit patients with active bleeding.

**MEDICATION**

**First Line**

- **Pediatric**
  - First-line treatment:
    - For children with no or mild bleeding (bruising and petechiae only with no mucosal bleeding), observation alone regardless of platelet count (1) [B]
    - For children with significant bleeding
      - Single-dose intravenous immunoglobulin (IVIG) 0.8 to 1.0 g/kg, especially when a more rapid increase in platelet count is desired (1) [B]. Do not administer in patients with IgA deficiencies because of anaphylaxis risk.
      - A short course of corticosteroids (e.g., PO prednisone 2 mg/kg/day for 2 weeks with 3 weeks taper) (1)[B]
      - Single dose of anti-Rho(D) immunoglobulin (anti-D), 50 to 75 g/kg for nonsplenectomized children who are Rh-positive, with negative direct antiglobulin test (1),(2)[B]. Do not use in children with low hemoglobin or evidence of hemolysis (1)[C].
  - Second and other treatments for pediatric and adolescent with ITP
    - Splenectomy for chronic or persistent ITP (1)[B]
    - Rituximab (Rituxan) 375 mg/m² weekly for 4 weeks (1),(2)[C]
    - High-dose dexamethasone 0.6 mg/kg/day for 4 days every 4 weeks (1), (2)[C]
    - Others without adequate data: azathioprine, cyclosporin A, danazol, mycophenolate mofetil, anti-CD52 monoclonal antibody, and interferon

- **Adult**
  - First line, adult ITP
    - Treatment is recommended for newly diagnosed patients with platelet count <30 × 10⁹/L (1),(2)[C].
    - Longer courses of steroids are preferred over shorter courses of steroids or IVIG (4).
    - If corticosteroids are contraindicated:
      - IVIG: 1 to 2 g/kg once, repeating as necessary (1),(2)[C]
- OR anti-D: 50 to 75 μg/kg once, repeating as necessary for Rh+ nonsplenectomized patients. Do not use anti-D in patients with low hemoglobin or evidence of hemolysis (1),(2)[C].
  - Second line, adult ITP
    - Splenectomy for patients who failed corticosteroid therapy (1)[B]
    - For patients for whom splenectomy is contraindicated and have risk of bleeding, thrombopoietin receptor agonists (1)[B]: eltrombopag (Promacta), 50 mg/day PO OR romiplostim (Nplate), 1 μg/kg SC weekly
    - Rituximab, 375 mg/m² IV weekly for 4 weeks, for patients at high risk of bleeding who have failed one line of therapy or post splenectomy (1),(2)[C]
    - Others to consider: azathioprine, cyclosporine A, cyclophosphamide, danazol, dapsone, mycophenolate mofetil, and vincristine
    - Asymptomatic patients after splenectomy, with platelet counts >30 × 10⁹/L, do not require treatment (1)[C].

- ITP in pregnancy
  - Preeclampsia or gestational thrombocytopenia may cause thrombocytopenia unrelated to ITP.
  - Corticosteroids or IVIG are considered safe and are considered first line (1)[C].
  - Do not use danazol or cyclophosphamide.
  - ITP management at time of delivery is based on maternal bleeding risks, and mode of delivery should be based on obstetric indications (1),(2)[C]. Platelet autoantibodies can cross the placenta and cause neonatal thrombocytopenia.
  - Caesarean section can be considered if platelet count >50 × 10⁹/L.
  - Prednisone and/or IVIG may be considered 2 to 3 weeks prior to delivery.

- ITP secondary to HIV
  - Antivirals should be considered before other treatment (1)[A].
  - If treatment is required, corticosteroids, IVIG, or anti-D are first-line options; and splenectomy is a second-line option (1),(2)[C].

- ITP secondary to HCV
  - Antivirals should be considered before other treatment (1),(2)[C].
  - If treatment required, IVIG is initial treatment (1),(2)[C].
  - Based on recent studies, TPO mimetics are approved for HCV-related ITP, because they increase platelets to a level required to initiate antiviral therapy (5).

- ITP and H. pylori
– Screen for *H. pylori* in patients in whom eradication therapy would be considered if result is positive (1),(2)[C].

**Emergency treatment**
– Patients with intracranial or GI bleeding, massive hematuria, internal hematoma, or who need emergent surgery

– IV corticosteroids (e.g., IV methylprednisolone, 1 g/day for 3 doses) (1)[B] with caution in patients with GI bleeding and/or IVIG 1 g/kg; repeat following day for count <50 × 10⁹/L (1)[B].

– Platelet transfusions with IVIG may also be considered for significant bleeding (1)[C].

– Other agents that may be considered: Recombinant factor VIIa (1)[C] not only promotes hemostasis but also increases risk of thrombosis. Efficacy of antifibrinolytic agents, aminocaproic acid, and tranexamic acid, is unproved in randomized trials; they may be used as adjunctive treatments only. Emergent splenectomy has been reported.

**ISSUES FOR REFERRAL**
Hematology consultation is recommended for acute bleeding or for those who fail to respond to first-line therapies.

**SURGERY/OTHER PROCEDURES**
**Splenectomy**

– Mortality rate is very low (<1%) even in patients with severe thrombocytopenia.

– Necessary vaccinations prior to splenectomy: polyvalent pneumococcal vaccine and quadrivalent meningococcal vaccine every 3 to 5 years and one-time *Haemophilus influenzae* B (Hib)

– Consider lifelong prophylactic antibiotics with penicillin or erythromycin.

– Should raise the platelet count to at least 20 × 10⁹/L prior to surgery

– Reported 5- to 10-year efficacy is ~65% for all patients.

– Laparoscopic splenectomy has similar long-term outcomes compared to open splenectomy and has better short-term outcomes, in medically suitable patients (1)[C].

**ONGOING CARE**
**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Platelet counts weekly for patients on prednisone and monthly for stable patients are reasonable.

**DIET**
- Evidence demonstrating benefit of an anti-inflammatory diet in ITP is lacking.
- The following foods and supplements can cause significant bleeding: garlic, ginger, Ginkgo biloba, and saw palmetto.
- Some foods and supplements that may inhibit platelets: evening primrose oil, fish oil, feverfew, ginseng, licorice, soy, vitamin C, vitamin E, and wintergreen.
- Partial list of foods and supplements with coumarin or salicylate components: alfalfa, angelica, anise, asafetida, aspen bark, birch, black cohosh, celery, chamomile, cinnamon, dandelion, fenugreek, heartsease, horse chestnut, meadowsweet, poplar, prickly ash, Quassia, sarsaparilla, sweet birch, sweet clover, and willow bark.

**PATIENT EDUCATION**
- Modified activity to prevent injury or bruising; avoid contact sports.
- Avoid anticoagulants, aspirin and other platelet-inhibiting drugs, and NSAIDs.

**PROGNOSIS**
- Acute ITP
  - ~80–85% of patients completely recover within 2 months.
  - 15% proceed to chronic ITP.
- Chronic ITP
  - ~10–20% of the patients recover spontaneously.
  - Remainder with diminished platelets for months to years
  - May see spontaneous remissions (5%) and relapses
  - ~10% are refractory (fail medical therapy and splenectomy).

**COMPLICATIONS**
- Related to thrombocytopenia: 1% mortality due to intracranial hemorrhage and severe blood loss.
- Related to treatment: for example, corticosteroid adverse effects, anaphylaxis and renal failure with IVIG, hepatotoxicity with eltrombopag, reports of progressive multifocal leukoencephalopathy with rituximab, hemolysis with anti-D, and septicemia for splenectomized patients.
REFERENCES

CODES

**ICD10**
D69.3 Immune thrombocytopenic purpura

CLINICAL PEARLS

- ITP: platelet counts of <100 × 10⁹/L caused by accelerated destruction and/or impaired thrombopoiesis by antiplatelet antibodies
- Pediatric ITP: relatively common, with spontaneous remission in 2 months
- Adult ITP: usually persistent; requires treatment, with rare spontaneous remission
- Goal of treatment is to achieve adequate hemostasis.
IMPETIGO
Elisabeth L. Backer, MD

BASICS
DESCRIPTION
- A contagious, superficial, intraepidermal infection occurring prominently on exposed areas of the face and extremities, most often seen in children
- Primary impetigo (pyoderma): invasion of previously normal skin
- Secondary impetigo (impetiginization): invasion at sites of minor trauma (abrasions, insect bites, underlying eczema)
- Infected patients usually have multiple lesions.
- Cultures are positive in >80% cases for Staphylococcus aureus either alone or combined with group A β-hemolytic streptococci; S. aureus is the more common pathogen since the 1990s.
- Nonbullous impetigo: most common form of impetigo. Formation of vesiculopustules that rupture, leading to crusting with a characteristic golden appearance; local lymphadenopathy may occur.
- Bullous impetigo: staphylococcal impetigo that progresses rapidly from small to large flaccid bullae (newborns/young children) caused by epidermolytic toxin release; less lymphadenopathy; trunk more often affected; <30% of patients
- Folliculitis: considered by some to be S. aureus impetigo of hair follicles
- Ecthyma: a deeper, ulcerated impetigo infection often with lymphadenitis
- System(s) affected: skin/exocrine
- Synonym(s): pyoderma; impetigo contagiosa; impetigo vulgaris

EPIDEMIOLOGY
Incidence
- Predominant sex: male = female
- Predominant age: children ages 2 to 5 years

Prevalence
In the United States: not reported but common

Pediatric Considerations
Poststreptococcal glomerulonephritis may follow impetigo (in young children).
Impetigo neonatorum may occur due to nursery contamination.

ETIOLOGY AND PATHOPHYSIOLOGY
- Coagulase-positive staphylococci: pure culture ~50–90%; more contagious via contact
- β-Hemolytic streptococci: pure culture only ~10% of the time (primarily group A)
- Mixed infections of streptococci and staphylococci are common; data suggest increasing importance of staphylococci over the past decades.
- Direct contact or insect vector
- Can result from contamination at trauma site
- Regional lymphadenopathy

RISK FACTORS
- Warm, humid environment
- Tropical or subtropical climate
- Summer or fall season
- Minor trauma, insect bites, breaches in skin
- Poor hygiene, poverty, crowding, epidemics, wartime
- Familial spread
- Poor health with anemia and malnutrition
- Complication of pediculosis, scabies, chickenpox, eczema/atopic dermatitis
- Contact dermatitis (Rhus spp.)
- Burns
- Contact sports
- Children in daycare
- Carriage of group A Streptococcus and Staphylococcus aureus

GENERAL PREVENTION
- Close attention to family hygiene, particularly hand washing among children
- Covering of wounds
- Avoidance of crowding and sharing of personal items
- Treatment of atopic dermatitis

COMMONLY ASSOCIATED CONDITIONS
- Malnutrition and anemia
Crowded living conditions
Poor hygiene
Neglected minor trauma
Any chronic/underlying dermatitis

DIAGNOSIS

HISTORY
Lesions are often described as painful.
May be slow and indolent or rapidly spreading
Most frequent on face around mouth and nose or at site of trauma

PHYSICAL EXAM
Tender red macules or papules as early lesions (contact dermatitis presents with pruritic lesions)
Thin-roofed vesicles to bullae: usually nontender
Pustules
Weeping, shallow, red ulcers
Honey-colored crusts
Satellite lesions
Often multiple sites
Bullae on buttocks, trunk, face

DIFFERENTIAL DIAGNOSIS
Nonbullous
– Contact dermatitis
– Chickenpox
– Herpes
– Folliculitis
– Erysipelas
– Insect bites
– Severe eczematous dermatitis
– Scabies
– Tinea corporis
Bullous
– Burns
– Pemphigus vulgaris
– Bullous pemphigoid
● Stevens-Johnson syndrome

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- None usually necessary in typical presentations; cultures of pus/bullae fluid may be helpful if no response to empiric therapy.
- Culture: taken from the base of lesion after removal of crust; will grow both staphylococci and group A streptococci
- Antistreptolysin-O (ASO) titer: can be weak positive for streptococci but overall not useful
- Antideoxyribonuclease B (anti-DNase B) and antihyaluronidase (AHT) response more reliable than ASO response
- Streptozyme: positive for streptococci

- Disorders that may alter lab results: Streptococcal pharyngitis will alter streptococcal enzyme tests.

**Follow-Up Tests & Special Considerations**

- Monitor for spread of disease and systemic manifestations.
- Serologic testing is helpful in context of impetigo with subsequent poststreptococcal glomerulonephritis.

**TREATMENT**

**GENERAL MEASURES**

- Treatment speeds healing, improves cosmetic appearance, and avoids spread of disease.
- Prevent with mupirocin ointment TID to sites of minor skin trauma.
- Remove crusts; clean with gentle washing 2 to 3 times daily; and clean with antibacterial soap, chlorhexidine, or Betadine.
- Washing of entire body may prevent recurrence at distant sites.

**MEDICATION**

- In 2005, the Infectious Diseases Society of America (IDSA) recommended topical treatment for limited lesions and oral medication when the disease is more severe/extensive (1)[A].
- Optimal treatment is unclear due to limited quality of evidence. Treatment
reduces spread of infection and enhances resolution (2)[C].

- Penicillin and macrolide therapy is no longer recommended. Fluoroquinolones are not indicated due to resistance patterns.
- Consult the local hospital or health department for microbial resistance information.
- Nonbullous (minor spread, treat 7 days; widespread, treat 10 days); bullous (treat 10 days)
  - Retapamulin 1% ointment to be applied BID for 5 days
  - Mupirocin (Bactroban) 2% topical ointment applied TID for 5 to 7 days (nonbullous only); not as effective on scalp as around mouth
  - Dicloxacillin: adult 250 mg PO QID; pediatric <40 kg: 12 to 25 mg/kg/day divided q6h; >40 kg: 125 to 250 q6h

- Dicloxacillin, cephalaxin, topical mupirocin, and fusidic acid are effective unless local staphylococcal strains are resistant. (For methicillin-resistant S. aureus [MRSA] infections, treatment options include clindamycin, tetracyclines, or trimethoprim-sulfamethoxazole.) Oral doses given for 7 days are usually sufficient (3)[C].

- 1st-generation cephalosporins
  - Children
    - Cephalexin 25 to 50 mg/kg/day divided, q6–12h
    - Cefaclor 20 to 40 mg/kg/day divided q8h
    - Cephradine 25 to 50 mg/kg/day divided q6–12h
    - Cefadroxil 30 mg/kg/day divided BID
  - Adults
    - Cephalexin 250 mg up to QID
    - Cefaclor 250 mg TID
    - Cephradine 500 mg BID
    - Cefadroxil 1 g/day in divided doses

- Clindamycin 300 mg q6–8h
- Severe bullous disease may require IV therapy such as nafcillin or cefazolin.

**ISSUES FOR REFERRAL**

If resistant or extensive infections occur, especially in immunocompromised patients

**ADDITIONAL THERAPIES**

Monitor for microbial resistance patterns.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Athletes are restricted from contact sports.
- School and daycare contagious restrictions
- Children can return to school 24 hours after initiation of antimicrobial treatment.

Patient Monitoring
If not clear within 7 to 10 days, culture the lesions.

PATIENT EDUCATION
Avoidance of infection spread is the key; hand washing is vital, especially for reducing spread in children.

PROGNOSIS
- Complete resolution in 7 to 10 days with treatment
- Antibiotic treatment will not prevent or halt glomerulonephritis, as it will in rheumatic fever.
- If not clear within 7 to 10 days, culture is necessary to find resistant organism.
- Recurrent impetigo: Evaluate for carriage of S. aureus in nares (also perineum, axillae, toe web). Apply mupirocin ointment to nares BID for 5 days for clearance/decolonization.

COMPLICATIONS
- Ecthyma
- Erysipelas
- Poststreptococcal acute glomerulonephritis
- Cellulitis
- Bacteremia
- Osteomyelitis
- Septic arthritis
- Pneumonia
- Lymphadenitis

REFERENCES

ADDITIONAL READING

SEE ALSO

Algorithm: Rash

CODES

ICD10
- L01.00 Impetigo, unspecified
- L01.01 Non-bullous impetigo
- L01.03 Bullous impetigo

CLINICAL PEARLS
- Superficial, intraepidermal infection
- Predominantly staphylococcal in origin
- Microbial resistance patterns need to be monitored.
- Topical treatment is recommended for limited lesions and oral medication only when the disease is more severe/extensive.
INCONTINENCE, FECAL

Kalyanakrishnan Ramakrishnan, MD

BASICS
Defined as continuous or recurrent involuntary passage of fecal material through the anal canal for >1 month in an individual at least 4 years of age

- Involves recurrent, involuntary loss of solid/liquid stool
- Requires careful rectal exam to assess rectal tone, voluntary squeeze, and rule out overflow incontinence from fecal impaction
- Endorectal ultrasound (EUS) is the simplest, most reliable, and least invasive method to detect anatomic anal sphincter defects.
- The goal of treatment is to restore continence and/or improve quality of life.

DESCRIPTION
Major incontinence is the involuntary evacuation of feces. Minor incontinence (fecal soilage) includes incontinence to flatus and occasional seepage of liquid stool.

Geriatric Considerations
- The prevalence of fecal incontinence increases with age. It is an important cause for nursing home placement among the elderly.
- Idiopathic fecal incontinence is more common in older women.

EPIDEMIOLOGY
Incidence
Patients often do not report fecal incontinence unless specifically queried (“silent affliction”). The number of affected patients is likely significantly underestimated.

Prevalence
- Women > men
- 7% of adults; 15% of adults age >90 years
- 56–66% of hospitalized older patients and >50% of nursing home residents
- 50–70% of patients who have urinary incontinence also suffer from fecal incontinence.
**Pregnancy Considerations**
Obstetric injury to the pelvic floor may result in either temporary or persistent incontinence.

**Geriatric Considerations**
- Fecal impaction and overflow diarrhea leading to fecal incontinence is common in older patients.
- Surgical history—particularly anal surgery, including hemorrhoidectomy, anal fissure repair (sphincterotomy), anal dilatation, or prior pelvic floor surgeries

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Continence requires the complex orchestration of pelvic musculature, nerves, and reflex arcs.
- Stool volume and consistency, colonic transit time, anorectal sensation, rectal compliance, anorectal reflexes, external and internal sphincter muscle tone, puborectalis muscle function, and mental capacity each plays a role in maintaining fecal continence.
- Disease processes or structural defects impacting any of these factors may contribute to incontinence.
- Diabetes is the most common metabolic disorder leading to fecal incontinence through pudendal nerve neuropathy.
- Congenital: spina bifida and myelomeningocele with spinal cord damage
- Trauma: anal sphincter damage from vaginal delivery or surgical procedures
- Medical: diabetes mellitus, stroke, spinal cord trauma, degenerative disorders of the nervous system, inflammatory bowel disorders, rectal neoplasia

**RISK FACTORS**
- Poor functional status—older age, female sex, obesity, limited physical activity contributory
- Neuropsychiatric conditions (dementia, depression)
- Multiple sclerosis, spinal cord injury, stroke, diabetic neuropathy
- Prostatectomy, radiation
- Trauma: Risk factors for perineal trauma at the time of vaginal delivery include occipitoposterior presentation, prolonged second stage of labor, assisted vaginal delivery (forceps or vacuum-assist), and episiotomy.
- Diarrhea, inflammatory bowel disease (IBD), irritable bowel syndrome (IBS), menopause, smoking, constipation
- Potential association with child abuse and sexual abuse
● Congenital abnormalities, such as imperforate anus/rectal prolapse
● Fecal impaction

GENERAL PREVENTION
● Behavioral and lifestyle changes: Obesity, limited physical activity/exercise, poor diet, and smoking are modifiable risk factors.
● Postmeal bowel regimen—defecate regularly after meals to maximize effect of gastrocolic reflex.
● Pelvic floor muscle training during and after pregnancy and pelvic surgery
● Increase fiber intake (>30 g/day)

COMMONLY ASSOCIATED CONDITIONS
● Increasing age (>65 years)
● Urinary incontinence/pelvic organ prolapse
● Chronic medical conditions—diabetes mellitus, dementia, stroke, spinal cord compression, depression, immobility, chronic obstructive pulmonary disease, IBS, and IBD
● Perineal trauma (obstetric)
● Anorectal surgery
● History of pelvic/rectal irradiation

DIAGNOSIS
Diagnosis is based on history and physical findings.

HISTORY
● Patients seldom volunteer information about fecal incontinence. Direct questioning is important.
● Problem-specific history includes (1)[C]:
  – Severity of soiling by liquid stool or gross incontinence of solid stool
  – Onset and duration (recent onset vs. chronic)
  – Frequency, presence of constipation/diarrhea
● Medication review
● Review diet, medical and obstetric history, lifestyle, and mobility.
● Evaluate for social withdrawal and depression.

PHYSICAL EXAM
● Inspect the perineum for chemical dermatitis, hemorrhoids, fistula, surgical
scars, skin tags, rectal prolapse, soiling, and ballooning of the perineum (sarcopenia of pelvic musculature).

- A patulous anal orifice may indicate myopathy or a neurologic disorder.
- Evaluate the external sphincter response to perineal skin stimulation (anal wink). Absence suggests neuropathy.
- Ask the patient to bear down, preferably in standing position, to assess for rectal prolapse.
- Digital rectal exam to assess anal canal pressure sphincter tone, rectal bleeding, hemorrhoids, neoplasm, fecal consistency, and diarrhea/distal fecal impaction
- General neurologic examination, including perianal sensation (1)[C]
- Evaluate mental status.

**DIFFERENTIAL DIAGNOSIS**

- Anorectal disorders
  - Inflammatory/infectious gastrointestinal disorders
  - Bowel neoplasms, radiation proctitis, ischemic colitis, fistulas
  - Prolapsed internal hemorrhoids; rectal prolapse
  - Trauma: obstetric, surgical, radiation, accidental, sexual
- Neurologic disorders
  - Stroke, dementia, neoplasms, spinal cord injury, and/or diseases causing altered level of consciousness
  - Pudendal neuropathy, neurosyphilis, multiple sclerosis, diabetes mellitus
- Miscellaneous causes
  - Infectious diarrhea, fecal impaction and overflow, IBS, laxative abuse, IBD, short bowel syndrome, myopathies, senescence and frailty, collagen vascular disease, psychological and behavioral problems

**DIAGNOSTIC TESTS & INTERPRETATION**

The approach to fecal incontinence in older patients should be individualized, minimally invasive, and practically feasible. History and physical examination are generally sufficient for diagnosis. If uncertainty remains, consider the following:

- EUS is the most reliable and least invasive test for defining anatomic defects in the external and internal anal sphincters, rectal wall, and the puborectalis muscle (1)[B]. EUS can reliably predict therapeutic response to sphincteroplasty.
- Plain abdominal x-ray (fecal impaction, constipation)
Sigmoidoscopy/anoscopy/colonoscopy (hemorrhoids, colitis, neoplasm)

**Initial Tests (lab, imaging)**
- If history of travel, antibiotics, tube feedings, or signs and symptoms of sepsis, consider stool studies:
  - Culture
  - Ova and parasites
  - *Clostridium difficile* toxin assay
- Thyroid-stimulating hormone (TSH), electrolytes, and BUN in elderly patients
- EUS may demonstrate structural abnormalities of the anal sphincters, rectal wall, or puborectalis muscle.
- EUS may detect a sphincter injury in over 1/3 of primiparous vaginal deliveries and nearly half of multiparous vaginal deliveries.

**Follow-Up Tests & Special Considerations**
- Defecography can measure the anorectal angle, evaluate pelvic descent, and detect occult/over rectal prolapse.
- MRI defecography (dynamic MRI) can further define pelvic floor anatomy.
- Anorectal manometry measures parameters such as maximal resting anal pressure, amplitude and duration of squeeze pressure, the rectoanal inhibitory reflex, threshold of conscious rectal sensation, rectal compliance, and anorectal pressures during straining.
- Pudendal nerve terminal motor latency (PNTML) measures neuromuscular integrity between the pudendal nerve and the anal sphincter; is operator-dependent and has poor correlation with clinical and histologic findings
- Electromyography can assess neurogenic/myopathic damage.

**TREATMENT**

**GENERAL MEASURES**
- In ambulatory patients, scheduled (or prompted) defecation is effective, particularly in those with overflow incontinence.
- Kegel exercises to strengthen pelvic floor
- If bed-bound, scheduled osmotic or stimulant laxatives for constipation
- Enemas, laxatives, and suppositories may help promote more complete bowel emptying in impacted patients and minimize postdefecation leakage.
- Use of stool deodorants (Peri-Wash, Derifil, Devrom)
MEDICATION

Limited evidence that antidiarrheals (loperamide, codeine) and drugs enhancing sphincter tone (phenylephrine gel, sodium valproate) are of benefit \( ^2[B] \). Cholestyramine, colestipol useful in diarrhea following malabsorption or cholecystectomy; alosetron in diarrhea due to IBS, amitriptyline in idiopathic fecal incontinence

First Line

Specific treatment of underlying disorder (e.g., infectious diarrhea/IBD) may improve fecal continence.

Second Line

- Increasing dietary fiber in milder forms of fecal incontinence reduces symptoms \( ^1[B] \). Stool-bulking agents include high-fiber diet, psyllium products, or methylcellulose.
- Antidiarrheal agents, such as adsorbents or opium derivatives, may reduce diarrhea-associated incontinence \( ^1[C] \).
- Disimpacting patients with fecal impaction and overflow incontinence and treating with a bowel regimen to prevent recurrence

ADDITIONAL THERAPIES

- Biofeedback: initial treatment modality in motivated patients with some voluntary sphincter control \( ^1[C] \); teaches patients to recognize rectal distension and contract the external anal sphincter while keeping intra-abdominal pressure low
- Biofeedback plus electrical stimulation of the anal sphincters is more effective than either alone.
- Patients with systemic neurologic disorders, anal deformities, or frequent episodes of incontinence respond poorly.

SURGERY/OTHER PROCEDURES

- Surgery should be considered only when nonsurgical approaches have failed.
- Sphincter repair should be offered for highly symptomatic patients with well-defined defect of external anal sphincter \( ^1[A] \).
- Injectable therapy (tissue-bulking agent injected into the anorectal submucosa or the intersphincteric space) appears safe and effective (40% efficacy) for patients with internal anal sphincter dysfunction \( ^3[A] \).
- Artificial anal sphincter implantation/dynamic graciloplasty (where gracilis...
muscle transposed into anus as modified sphincter) considered in patients with severe fecal incontinence and irreparable sphincter damage (4)[B]

- Stoma (colostomy/ileostomy) creation may be appropriate in patients with disabling fecal incontinence when other available therapeutic options have failed or if preferred by patient (1)[B]. A continent stoma created using the appendix or the cecum as the point of entry is a less radical option and enables using antegrade continence enema to flush the colon in these patients.

- Anal plugs minimize fecal leakage in patients who do not benefit from other treatment modalities, especially immobilized, institutionalized, or neurologically disabled patients; plugs often poorly tolerated (1)[C]

- Sacral nerve stimulation (neuromodulation) via implantation of SC electrodes delivering low-amplitude electrical stimulation to sphincter muscles improves overall rectal tone, especially in patients with a coexistent sphincter defect (5)[B].

- SECCA procedure (radiofrequency anal sphincter remodeling)—temperature-controlled radiofrequency energy delivered to the anorectal junction distal to the dentate line causing tissue damage, scarring, and anal canal narrowing. Minimally invasive, ambulatory procedure useful in mild-to-moderate fecal incontinence (1)[C].

- Magnetic anal sphincter (MAS) devices—series of interlinked titanium beads (14 to 20) with internal magnetic cores placed to form a flexible ring that encircles the external anal sphincter 3 to 5 cm from the anal verge. During expulsion of feces, the beads separate allowing evacuation. After evacuation, the beads approximate closing the canal (5)[C]; useful in moderate and severe incontinence

- A vaginally placed bowel control device that the patient inflates to control leakage and deflates to defecate is well tolerated and effective in 86% (5)[B].

- Percutaneous posterior tibial nerve stimulation at the ankle for 30 minutes weekly for 12 weeks (50% efficacy) and the TOPAS pelvic floor repair system (self-fixating polypropylene mesh placed behind the anorectum to support the puborectalis) (55% efficacy) are other recent advances in controlling fecal incontinence (5)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- If secondary to fecal impaction, manual evacuation of fecal mass (after lubrication with lidocaine jelly)

- Avoid catharsis.
No hot water, soap, or hydrogen peroxide enemas
Outpatient care

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Periodic rectal exam

Patient Monitoring
Consider impaction if there is <1 bowel movement every other day in patients with fecal incontinence.

DIET
- High fiber (20 to 30 g/day) and at least 1.5 L fluid daily
- Avoid precipitants (caffeine).

PATIENT EDUCATION
Kegel/sphincter training exercises are helpful but not sufficient for treating fecal incontinence.

PROGNOSIS
- Reimpaction likely if bowel regimen discontinued
- 50% failure rate over 5 years following overlapping sphincteroplasty

COMPLICATIONS
- Depression and social isolation
- Skin ulcerations
- Artificial bowel sphincter: infection, erosion, mechanical failure

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**
- R15.9 Full incontinence of feces
- R15.2 Fecal urgency
- R15.0 Incomplete defecation

**CLINICAL PEARLS**

- Scheduled defecation after meals, bulking agents, and scheduled enemas minimize impaction and are helpful in mild/moderate fecal incontinence.
- Differentiate true incontinence from pseudoincontinence (overflow or functional incontinence).
- New onset fecal incontinence may indicate spinal cord compression if accompanied by other neurologic signs or symptoms.
INCONTINENCE, URINARY ADULT FEMALE

Cara Marshall, MD • Azmina A. Bhayani, MD, MPH • Roopa L. Chari, MD

BASICS

DESCRIPTION

- Urinary incontinence: involuntary loss of urine
- Stress incontinence: associated with increased intra-abdominal pressure, such as coughing, laughing, sneezing, or exertion
- Urge incontinence: sudden uncontrollable loss of urine, preceded or accompanied by urgency, or a sudden compelling desire to urinate that is difficult to delay. Urge incontinence may be associated with overactive bladder or detrusor overactivity.
- Mixed incontinence: loss of urine from a combination of stress and urge incontinence
- Overflow incontinence: high residual or chronic urinary retention leading to urinary spillage from an overdistended bladder
- Functional incontinence: loss of urine due to deficits of cognition and/or mobility
- Total incontinence: continuous leakage of urine; leakage without awareness

EPIDEMIOLOGY

- Affects 25% of young women and up to 57% of women aged 40 to 60 years. Women 19 to 64 years of age have predominantly stress incontinence (12–28%), followed by mixed (7–12%), and urge (5–10%) incontinence.
- Prevalence in women >75 years is 75%, and 6% of nursing home admissions are directly attributable to incontinence (1).

ETIOLOGY AND PATHOPHYSIOLOGY

- Stress incontinence: occurs with increased intra-abdominal pressure. Two types:
  - Anatomic: due to urethral hypermobility from lack of pelvic support
  - Intrinsic sphincter deficiency (ISD): impaired closure of urethra. Urethral
mucosal seal and inherent closure from collagen, fibroelastic tissue, and smooth and striated muscles may be lost secondary to surgical scarring, radiation, or hormonal and age-related changes.

- Urge incontinence: may be due to detrusor overactivity or may be idiopathic
- Overflow incontinence: urinary retention (usually from neurogenic bladder)
- Total incontinence: constant loss of urine. Ectopic ureters in females usually open in the urethra distal to the sphincter or in the vagina, causing continuous leakage; may also occur with fistulous connections between bladder, ureters, or urethra and vagina or uterus
- Women with urge urinary incontinence report poorer quality of life than those with stress incontinence (2).

RISK FACTORS
Advanced age, impaired functional status, obesity (BMI >30), history of gestational diabetes, pregnancy, vaginal childbirth, pelvic surgery or radiation, urethral diverticula, genital prolapse, smoking, chronic obstructive pulmonary disease (COPD), cognitive impairment, constipation, caffeine, and pelvic floor dysfunction

GENERAL PREVENTION
Obesity and caffeine avoidance, smoking cessation, high-fiber diet to reduce constipation

COMMONLY ASSOCIATED CONDITIONS
Pelvic organ prolapse, UTI, COPD, diabetes mellitus, neurologic disease, obesity, chronic constipation, depression, low libido, dyspareunia, and any disease that results in chronic cough

DIAGNOSIS

HISTORY
- Important to screen for symptoms, as only 55% of women who reported at least twice weekly urine leakage on a U.S. survey sought care for their symptoms (2)
- Age: Stress incontinence is more common in women aged 19 to 64 years, whereas mixed incontinence is more common in women >65 years. Onset from childhood indicates congenital causes (e.g., ectopic ureter).
- Amount and frequency of leakage; pad usage
- Stress incontinence: occurs in small spurts; patients typically remain dry at night in bed.
- Urge incontinence: sudden urge followed by leakage of large amounts, usually associated with frequency and nocturia. Sensory stimuli may trigger (e.g., cold).
- Continuous slow leakage in between regular voiding indicates ectopic ureter, urinary fistula, and so forth.
- Pain: Suprapubic pain with dysuria implies urinary infection or interstitial cystitis.
- Medical history
  - Neurologic conditions or suggestive symptomatology: cerebrovascular accident, parkinsonism, multiple sclerosis, myelodysplasia, diabetes, spinal cord injury
  - Radiation to pelvic and vaginal areas: causes ISD, overactive bladder, fibrotic changes of pelvic floor musculature, and low bladder compliance
  - Obstetrical history: Weakness of the pelvic floor is more likely in multiparous women.
  - History of smoking and COPD with a chronic cough can aggravate incontinence.
  - Constipation can aggravate incontinence.
  - Surgical history: Pelvic surgery, including gynecologic and bowel surgery, can injure the pelvic floor musculature and affect neurologic function.
- Medications
  - Sympatholytic α-blockers (terazosin, prazosin, doxazosin, tamsulosin, alfuzosin, silodosin) can cause or worsen incontinence.
  - Sympathomimetic agents, tricyclic antidepressants, anticholinergics, and opioids can cause retention with overflow incontinence.
- International Consultation of Incontinence Modulator Questionnaire (ICIQ) is highly recommended for assessment of patient’s perspective of symptoms of incontinence and his or her impact on quality of life.
- Can use 3-day voiding diary to evaluate fluid intake, caffeine intake, timing of leakage, and patient habits

**PHYSICAL EXAM**
- General status
  - Obesity (BMI)
- General neurologic examination
  - Mental status, speech, intellectual performance
– Motor status: gait, generalized or focal weakness, rigidity, tremor
– Sensory status: impairment of perineal–sacral area sensation

● Urologic examination
  – Abdomen: masses, incisional scars of previous surgeries
  – Suprapubic tenderness: may indicate cystitis
  – Palpable, distended bladder: chronic urinary retention

● Pelvic examination
  – Examination of the perineum and external genitalia, including tissue quality and sensation
  – Vaginal (half-speculum) examination for prolapse
  – Bimanual pelvic and anorectal examination for pelvic masses, fecal impaction, pelvic floor function, and so forth
    ● Assessment of pelvic floor resting tone and function (ability to isolate and contract pelvic floor musculature) (3)[C]; can use Oxford scale to grade strength
  – Urethral mobility (cotton swab test): displacement angle of urethra-bladder neck at least 30 degrees from horizontal with Valsalva (recommended by ACOG but not AUA) (2,4)[C]
  – Stress test: positive with involuntary loss of urine from urethral meatus with cough or Valsalva maneuver. If test is negative in supine position, can try in standing position. Ensure that patient has a comfortably full bladder (4). Test has 98% positive predictive value for SUI (3).
  – Cystocele: if evident, stage (grade 0 to 4)
  – Rectocele: if evident, stage (stage 0 to IV)

DIFFERENTIAL DIAGNOSIS
● Nocturnal enuresis: idiopathic, detrusor overactivity, neurogenic, cardiogenic, or sleep apnea
● Continuous leakage: ectopic ureter, urinary fistulas
● Postvoid dribbling: urethral diverticulum, idiopathic, iatrogenic, surgical
● Pelvic pain/dyspareunia: interstitial cystitis, STI
● Pelvic organ prolapse
● Hematuria/recurrent UTI/pelvic mass: malignancy (5)

DIAGNOSTIC TESTS & INTERPRETATION
● Urinalysis and urine culture
● Renal function assessment: recommended if renal impairment is suspected
**Initial Tests (lab, imaging)**
- Unnecessary in uncomplicated patients
- Bladder scan to evaluate postvoid residual (PVR) if overflow suspected (<50 mL age <65 years, <100 mL if ≥65) (5)
- TSH if constipation is present
- Upper tract imaging if upper tract involvement is suspected: renal ultrasound

**Follow-Up Tests & Special Considerations**
Asymptomatic bacteriuria is common. With a positive urine culture, initial treatment is indicated.

**Diagnostic Procedures/Other**
- Urodynamic studies and cystoscopy are not indicated in initial workup and should only be performed after failing conservative treatment; this includes cystometric study of detrusor function and pressure flow studies looking at bladder emptying.
- Cystoscopy may be helpful in women with recurrent UTI or in microscopic hematuria workup.
- Results of urodynamic testing are not predictive of treatment success (2)[A], and are not necessary prior to surgery for uncomplicated patients with known SUI (3)[C].

---

**TREATMENT**

**GENERAL MEASURES**
- Treat correctable causes (e.g., UTI).
- Encourage weight loss in obese patients.
- Aggressively correct constipation.
- Treat mixed for primary symptom type (5)[C].

**MEDICATION**

**First Line**
- Lifestyle changes:
  - Reduce BMI to <25; can reduce weekly incontinence episodes by 28–47% (2)[A]. Even moderate weight loss (5–10%) can help (6)[A].
  - Bladder diaries (fluid intake, voids, leakage)
– Decrease fluid intake before bedtime.
– Reduce caffeine to <1 cup coffee/day (2)[B].
– Aggressive treatment of constipation: Limit medications that may induce constipation. Treat constipation with polyethylene glycol 3350 (PEG 3350), increased fluid intake, and so forth.

- Pelvic floor muscle training with Kegel exercises may be used alone or in combination with bladder training, biofeedback, or electrical stimulation (2).
  – Proper technique should be confirmed on exam by trained physical therapists.
  – 5 times as effective as placebo (1)[A]

- Bladder training:
  – Scheduled voiding, urge suppression between voids

- No differences in treatment efficacy by type of incontinence so reasonable to start with lifestyle changes in all types (2)[A]

**Second Line**

- Stress incontinence
  – Surgical management for stress incontinence
    - Mesh midurethral sling (most common, most studied surgical intervention) (2)[C],(4)[A]
    - Women with moderate to severe stress incontinence have better outcomes at 1 year with midurethral slings than pelvic floor muscle training (2)[A].
    - Two main approaches with similar effectiveness: retropubic (more perioperative complications) versus transobturator (more groin pain) (4)[A]

- Autologous fascial bladder neck slings should be considered in severe incontinence and fixed urethra, urethral diverticula or fistula, or with complications from previously placed mesh (2)[C].

- Pelvic organ prolapse may unmask incontinence in up to 40% of women; consider repair of both during same surgery (2)[A].
- Periurethral bulking agents (silicone polymers, collagen) can increase periurethral resistance in women who have recurrent symptoms after surgery, or who cannot tolerate surgery. However, they are 2 to 5 times less effective than surgery and often require repeat injections (2)[A]. Occlusive and supportive devices (e.g., cones, pessaries, and super tampons) may have high satisfaction rates and are an alternative to surgery (6).

- Urge incontinence: anticholinergic agents (inhibit involuntary detrusor
contractions) (1)[A]

- Tolterodine (Detrol LA): 2 to 4 mg/day PO
- Oxybutynin (Ditropan XL): 5 to 30 mg/day PO
- Solifenacin (VESIcare): 5 to 10 mg/day PO
- Darifenacin (Enablex): 7.5 to 15 mg/day PO
- Trospium chloride (Sanctura XR): 60 mg/day PO—does not cross blood–brain barrier (3)
- Transdermal oxybutynin gel (Gelnique): 10% applied daily
- Transdermal oxybutynin patch (Oxytrol): twice weekly—available over the counter (OTC)
- Fesoterodine (Toviaz): 4 to 8 mg/day PO
- Fesoterodine may be more effective than tolterodine, at the expense of greater adverse effects (1)[B].

- No single agent has been shown to be overall superior (5).
- Extended-release and transdermal medications cause fewer side effects (2)[B].

- Dry mouth, dry eyes, constipation, impaired cognitive function, and other anticholinergic side effects can limit use.
- Avoid with narrow-angle glaucoma, urinary retention (PVR >250 mL), impaired gastric emptying, and frail elders (3).

**Geriatric Considerations**

Anticholinergics (oxybutynin, in particular) can worsen cognition and delirium; the effects are cumulative and increase with length of exposure (5).

- β-3 Agonist (leads to detrusor muscle relaxation and increased bladder capacity): mirabegron (Myrbetriq ER): 25 to 50 mg/day PO (1)[B]; onset of action delayed ~8 weeks; increases BP (avoid use in those with uncontrolled HTN, end-stage renal disease, or significant liver impairment); safe in geriatric patients (5); recommend BP check 2 weeks after starting (3)[C].
- Can consider dual therapy with mirabegron and low-dose anticholinergics (3,5)

**Third Line**

- Stress incontinence
  - Duloxetine (Cymbalta) 40 mg BID may have some limited efficacy (1)[C] but with GI and CNS side effects (5).
  - Estrogen may be beneficial in topical form for symptoms of urgency and frequency in postmenopausal women with vaginal atrophy, but transdermal
or PO estrogen may worsen symptoms (1)[B],(2)[C].

– Acupuncture

– Urge incontinence
  – Intradetrusor onabotulinumtoxinA 100 to 200 U (urinary retention common, temporary self-catheterization may be needed) (5)[A]
  – Sacral nerve stimulation: 50% reduction in episodes in 2/3 of patients who have failed other treatments; invasive with frequent complications (5)[B]
  – Posterior tibial nerve stimulation: office-based therapy, requires frequent visits (3)
  – Bladder augmentation (5)[C]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Periodic long-term follow-up with outcome-based questionnaire surveys

PATIENT EDUCATION
Instructions on self-care and warning signs are available at PubMed Health:

PROGNOSIS
Significant improvements are usually obtained with most patients.

COMPLICATIONS

• Prolonged exposure to urine causes skin breakdown and dermatitis, which may lead to ulceration and secondary infection.
• Inability to self-care is the precipitating factor for many nursing home admissions.
• Social isolation/depression
• Weight gain (due to self-limiting exercise from fear of leakage)
• Impaired sexual function
• Impaired quality of life

REFERENCES

**ADDITIONAL READING**

**CODES**

ICD10
- R32 Unspecified urinary incontinence
- N39.3 Stress incontinence (female) (male)
- N39.41 Urge incontinence

**CLINICAL PEARLS**

- Rule out UTI or STI by culture.
- Aggressively treat constipation.
- Try lifestyle changes first for all types of urinary incontinence.
- If lifestyle changes do not work for stress incontinence, mesh midurethral sling surgery has high success rates.
- If lifestyles changes do not work for urge incontinence, anticholinergic medications and mirabegron should be trialed.
INCONTINENCE, URINARY ADULT MALE

William Dabbs, MD • Justin Jenkins, DO, MBA • Taylor Wright, MD

BASICS
DESCRIPTION

- Urinary incontinence (UI) is a pathologic condition of an acute or chronic nature that refers to the involuntary loss of urine leading to medical, financial, social, or hygienic problems. Five main types of UI have been described: stress, urge, mixed, overflow (urinary retention), and functional UI (1).
- Stress incontinence: involuntary urine leaks secondary to increased intra-abdominal pressure being greater than the sphincter can control; may be precipitated by sneezing, laughing, coughing, exertion
- Urge incontinence: Involuntary leakage of urine associated with urgency is believed to be secondary to uncontrolled contraction of the urinary bladder. It is also called detrusor overactivity.
- Mixed incontinence: involuntary leakage of urine with urgency and with stress, such as sneezing, laughing, coughing, exertion
- Overflow incontinence: also known as urinary retention; this occurs with bladder overdistention due to impaired detrusor contraction or bladder outlet obstruction (due to benign prostatic hyperplasia [BPH], bladder stones, bladder tumors, pelvic tumors, urethral strictures, or spasms).
- Functional UI: urine leakage variable, often due to environmental or physical barriers to toileting (i.e., reduced mobility)
- Polyuria is defined by excessive amounts of urine (≥2.5 to 3.0 L) > 24 hours.
- Nocturnal polyuria is where >33% of total daily urine output occurs during sleeping hours.

EPIDEMIOLOGY

- Stress incontinence in men is rare and is often attributable to prostate surgery, neurologic disease, or trauma.
- Involuntary detrusor overactivity may be spontaneous or provoked and may be neurogenic or idiopathic in cause.
Reported rates of incontinence range from 1% after transurethral resection to 2–66% after radical prostatectomy and 1–15% following transvesical prostatectomy, although rates decline with time (1).

**Prevalence**
- 12.4% prevalence of UI in community-dwelling adult men in the United States as based on the National Health and Nutrition Examination Survey (NHANES) as of 2008.
- 4.5% reported moderate to severe UI, of which 48.6% experienced urge, 23.5% experienced other UI, 15.4% experienced mixed, and 12.5% experienced stress incontinence as per the NHANES report in 2010.
- UI is common in nursing home patients, with a prevalence of about 70% in the Southeastern United States from 1999 to 2002.
- Incontinence in men of all ages is approximately half as prevalent as it is in women; however, after 80 years of age, both sexes are affected equally (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Incontinence secondary to bladder abnormalities
  - Detrusor overactivity results in urge incontinence.
  - Detrusor overactivity commonly is associated with bladder outlet obstruction from BPH.
- Incontinence secondary to outlet abnormalities
  - Sphincteric damage secondary to pelvic surgery or radiation
  - Sphincteric dysfunction secondary to neurologic disease
  - Commonly associated with BPH due to compression of the urethra, affecting urinary flow
- Mixed incontinence is caused by abnormalities of both the bladder and the outlet overflow or by enlarged prostate/bladder neck contracture from prostate surgery.
- Stress incontinence is caused by weakened urethral sphincter and/or pelvic floor weakness.

**RISK FACTORS**
- Age
- Diabetes
- Hypertension
- History of urinary tract infections
- Major depression
• Neurologic disease
• Pelvic trauma
• Polypharmacy
• Prostate surgery

GENERAL PREVENTION
Proper management of conditions, such as symptomatic bladder outlet obstruction caused by BPH early in the course, may prevent continence problems later in life; no evidence for screening in men unless patient is experiencing symptoms using The 3 Incontinence Questions tool to evaluate the type of UI (2).

COMMONLY ASSOCIATED CONDITIONS
• Benign prostatic hypertrophy
• Neurologic disease (cerebrovascular accident, parkinsonism, multiple sclerosis, myelodysplasia, spinal cord injury, normal pressure hydrocephalus, and cognitive impairment)
• Major depression
• Pelvic surgery, radiation, or trauma

DIAGNOSIS

HISTORY
• Voiding symptoms
  – Duration and characteristics of incontinence
  – Precipitants, severity, timing, and associated symptoms
  – Use of pads, briefs, diapers
  – Fluid intake
  – Alteration in bowel habits
  – Previous treatments and effect on incontinence
  – BPH symptoms
• Associated conditions, such as diabetes mellitus, neurologic disease, cardiopulmonary disorders, renal disorders, sleep disturbance, mental health or cognitive impairment, erectile dysfunction
• Transient causes: UTI, delirium, medications, constipation, immobility
• Geriatric patients: Assess cognitive levels (dementia/delirium), psychological disorders, mobility problems.
- Medication use: diuretics, drugs for BPH, opioids, muscle relaxants, anticholinergics, antidepressants
- Alcohol and drug use, including caffeine
- Surgery
  - Pelvic surgery or radiation
  - Bowel, back, genitourinary procedures
  - Abdominoperineal resection
  - Prostatectomy: radical for cancer, open/transurethral for benign disease
- **Red flag symptoms** requiring rapid referral to specialist management
  - Pain, hematuria, recurrent UTI, history of prostate irradiation, history of radical pelvic surgery (i.e., prostate surgery), constant leakage suggesting fistula, voiding difficulty, suspected neurologic disease

**PHYSICAL EXAM**
- Cardiovascular
  - Look for signs of volume overload.
- Abdominal examination
  - Suprapubic mass suggests retention.
  - Suprapubic tenderness suggests UTI.
  - Surgical scars suggesting pelvic surgery
  - Skin lesions associated with neurologic disease (e.g., neurofibromatosis and café au lait spots)
- Genitourinary examination
  - External genitalia
  - DRE
  - Prostate
- Musculoskeletal (look for neurogenic or functional causes)
  - Extremities
  - Spine/back
  - Skeletal deformities
  - Scars from previous spinal surgery
  - Sacral abnormalities may be associated with neurogenic bladder dysfunction.
- Neurologic
  - Motor
  - Sensory
  - Reflexes

**DIFFERENTIAL DIAGNOSIS**
• Transient (infections, meds, constipation, etc.)
• Chronic
  – Urge incontinence
  – Stress incontinence
  – Mixed incontinence
  – Overflow incontinence
  – Functional UI

**DIAGNOSTIC TESTS & INTERPRETATION**

- Urinalysis and urine culture to check for glucosuria, pyuria, proteinuria, and/or blood
- Voiding diary, The 3 Incontinence Questions (1)[C]
- Pad test if quantity of leakage or objective outcome measure is desired
- Do not routinely perform urodynamics before conservative treatment for UI (3)[B].
- Postvoid residual (PVR) volume if difficulty voiding or other lower urinary tract symptoms using ultrasound (US) to measure PVR: PVR persistently ≥100 mL indicates voiding dysfunction (1)[C].
- Uroflowmetry
- PSA only if diagnosis of prostate cancer will influence treatment or if levels can help decision making for patients at risk for BPH
- Renal function if renal impairment or hydronephrosis is suspected or if considering surgical treatment for lower urinary tract symptoms
- Voiding cystogram in select cases

**Diagnostic Procedures/Other**

- Urodynamics is useful for confirming bladder outlet obstruction as a possible cause of detrusor overactivity (3)[B].
- Prostate US and biopsy if indicated by physical exam or PSA
- Urethrocystoscopy to exclude suspected bladder or urethral pathology or before invasive therapies if findings might influence treatment
- Imaging of upper and lower urinary tract is not routinely indicated as part of UI assessment.
- Consider US (preferred) or MRI of lower urinary tract if indicated.
  – US is rarely required to diagnose or rule out BPH in patients with UI as DRE can diagnose and guide treatment in most patients.
  – Consider US of prostate if it assists with choice of drug therapy for lower urinary tract symptoms.
– Consider US of prostate to assess for intravesical prostatic protrusion (IPP) if considering surgical treatment.
– Consider US of upper urinary tract in patients with large PVR, hematuria, or history of urolithiasis.

**TREATMENT**

Conservative, nonmedication interventions, such as behavioral modification, timed voiding, bladder training, and pelvic floor muscle training, should be considered *first-line therapy*, prior to initiating any pharmacologic therapy.

**GENERAL MEASURES**

- Bladder diaries are invaluable in helping patients understand patterns of incontinence (2)[A].
- Patients with underlying or associated disease states should have appropriate medical therapy for those diseases (4)[A].
- Constipation is associated with UI (4), but treatment for constipation has not been shown to improve UI (3)—patients with UI and constipation should be given appropriate medical therapy for constipation (3)[C].
- Pads may be used for urine containment in UI as well as external sheaths (1)[B]—external sheaths may have similar rates of UTIs with indwelling catheters but result in better QoL.
- Reduction in caffeine intake does not improve UI but may improve urgency and frequency, although there is conflicting evidence on whether fluid intake modification helps decrease UI (2)[B].
- Stopping smoking has not been shown to reduce UI, but patients should all be counseled to quit (3)[A].
- Bladder training and prompted voiding are effective (3)[A].
- Pelvic floor muscle training speeds recovery of continence following radical prostatectomy, but preoperative PFMT does not seem to confer benefit (3)[B].

**MEDICATION**

*First Line*

- **Urge incontinence**: There is no consistent evidence that drug therapy is better than behavioral therapy in UUI (1)[B], and behavioral therapy results in higher patient satisfaction (1)[B].
- Antimuscarinic agents are first-line drug therapy in UUI (1)[B], and there is
no evidence that any one agent is superior for UUI (1)[A].

- Caution in those with bladder outlet obstruction and PVR >250 to 300 mL: In men with urgency associated with BPH, consider α-blockers (i.e., tamsulosin, alfuzosin, silodosin) as monotherapy or in combination with antimuscarinic for residual overactive bladder (4).
- Review efficacy and side effects 4 to 6 weeks after treatment initiation.
- Most patients will stop antimuscarinic therapy within 3 months due to adverse effects, nonefficacy, or cost (2).

Antimuscarinics should be used with caution in the elderly due to risk of worsened cognition (3)[B].
- Oxybutynin (Ditropan XL) 5 to 15 mg PO every day
- Tolterodine (Detrol LA) 2 to 4 mg PO every day
- Darifenacin (Enablex) 7.5 to 15.0 mg PO every day
- Solifenacin (Vesicare) 5 to 10 mg PO every day
- Trospium chloride (Sanctura XR) 60 mg PO every day
- Transdermal oxybutynin (Gelnique) 10% apply daily (EAU Grade B)—no dry mouth
- Fesoterodine (Toviaz) 4 to 8 mg PO every day

Stress incontinence
- No generally accepted drug therapy
- Mixed stress and urge incontinence; ER formulations are preferred due to reduced side effects.

Second Line
- Urge incontinence
- Tricyclic antidepressants
  - Imipramine 10 to 25 mg PO BID/TID
- Desmopressin (DDAVP) for occasional short-term relief of UI
  - 25 to 50 μg PO or intranasal at bedtime
- Intradetrusor botulinum toxin injections 100 U intravesical injections (not FDA approved)
- Mirabegron (Myrbetriq): new β3 agonist (FDA approved) 25 to 50 mg PO daily. Caution: HTN
- Duloxetine for temporary improvements of incontinence with dose titration (mixed stress/urge)

Geriatric Considerations
- Anticholinergics and tricyclics may result in significant cognitive impairment
in elderly patients.

- DDAVP should be avoided in patients with known/potential cardiac disease.

**ADDITIONAL THERAPIES**

- Pelvic floor rehabilitation (Kegel exercises) may significantly reduce both stress and urge incontinence in male patients and should be considered a part of initial management for stress UI.
- Timed voiding is a useful therapy for patients with urge incontinence.
- Overflow incontinence is usually caused by poor bladder contractility with urinary retention.
  - Indwelling catheter
  - Intermittent catheterization
  - Evaluate for outlet obstruction.

**SURGERY/OTHER PROCEDURES**

- Urge incontinence
  - Sacral nerve stimulation with behavioral therapy
  - Augmentation cystoplasty and urinary diversion
  - Botulinum toxin injection via cystoscopy

- Stress incontinence (3)[B]
  - Urethral bulking agents: modest success rates with low cure rates
  - Male sling procedures: promising short-term and intermediate results but no long-term studies
  - Artificial urinary sphincter implant has excellent long-term continence rates and is considered gold standard (5).

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Acupuncture in selected cases
- Physical therapy in selected cases

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*

Must monitor residual volume after voiding in patients taking anticholinergic
medications; monitor side effects.

PROGNOSIS
Continence can be improved in almost all patients.

COMPLICATIONS
- Dermatitis
- Candidiasis
- Skin breakdown
- Social isolation
- Avoidance of sex
- Weight gain

REFERENCES

CODES

ICD10
- R32 Unspecified urinary incontinence
- N39.3 Stress incontinence (female) (male)
- N39.41 Urge incontinence

CLINICAL PEARLS
- Think “outside” the lower urinary tract: Comorbid medical illness and impairments are independently associated with UI; treat contributing comorbidities and rule out secondary causes.
- Always check PVR to rule out overflow incontinence.
- Have patient complete the International Prostate Symptom Score and do uroflow, PSA if indicated.
- Urodynamics if conservative management fails
- Pelvic floor rehabilitation handouts may have a significant effect for male patients than physical therapy–mediated pelvic floor rehabilitation.
INFECTIOUS MONONUCLEOSIS, EPSTEIN-BARR VIRUS INFECTIONS

Dennis E. Hughes, DO, FAAFP, FACEP

BASICS

DESCRIPTION

- Epstein-Barr virus (EBV) is a member of the herpes virus family: human herpes virus 4 (1)
  - Two subtypes: ST1 predominates in Western Hemisphere, Southeast Asia;
    ST1 and ST2 equally prevalent in Africa
- Primary infection typically occurs in childhood; responsible for infectious mononucleosis (IM) (most common disease association); linked to numerous cancers
- WHO classified EBV as “tumor virus” (Group I carcinogen) due to cancer association (1).

EPIDEMIOLOGY

Prevalence
Worldwide, infects >90% of people (antibody-positive)

Incidence
- Military, college students, and others living in cloistered and crowded populations have highest infection rate. Overall rate in United States is 500/100,000 (2).
- Predominant age of primary infection is 10 to 19 years; 200 to 800/100,000 affected (2)
  - Primary clinical manifestation is IM.
  - Early childhood infections are usually asymptomatic.
- Seroconversion occurs later in childhood in developed countries; there is suggestion of race/ethnicity disparity in the United States with higher seroprevalence in non-Hispanic black, Asian, and Hispanic populations (2).

ETIOLOGY AND PATHOPHYSIOLOGY
- After inoculation, the virus replicates in the nasopharyngeal epithelium with
resulting cell lysis, virion spread, and viremia. The reticuloendothelial system is affected, resulting in a host response and the appearance of atypical lymphocytes in the peripheral blood. Viral genome can be detected in the oral cavity 1 week prior to displaying symptoms.

- A polyclonal B-cell proliferative response follows. Relatively few (<0.1%) of the circulating lymphocytes are infected by EBV in the acute illness.
- A persistent (asymptomatic) state ensues with the EBV genome invisible to the immune system.
- A subsequent coinfection increases risk for an EBV-associated condition (e.g., malignancy).
- Either through B-cell stimulation or diminished EBV-specific immune modulation, the previously latent EBV-infected B cells replicate, allowing clinical expression of the EBV genome. The proteins produced may either modify host response to or contribute directly to subsequent malignancy (1,3).
- Immunosuppression (organ transplant/acquired immune deficiency) can result in transformation and lymphoproliferative disorders.

**RISK FACTORS**

- Age (highest incidence in adolescent, young adults)
- Socio-hygienic level (“crowed conditions”)
- Geographic location
- Close, intimate contact; especially “deep kissing” in adolescents and young adults (4)
- Immunosuppression

**GENERAL PREVENTION**

- Avoid close physical contact with symptomatic EBV/IM patients.
- Good hand washing and hygiene
- General precautions with potential blood exposure (EBV can be transmitted via blood contamination, as well as hematopoietic cell and solid organ transplant)
- EBV vaccines are undergoing study but have had limited efficacy in small studies.

**COMMONLY ASSOCIATED CONDITIONS**

- IM: Symptomatic primary EBV infection is common in otherwise healthy adolescents, and young adults.
  - Clinical features vary in severity and duration: In children age <10 years,
generally mild; in adolescents and adults, symptoms can be more severe and protracted.
– Incubation period is 30 to 50 days.
● X-linked lymphoproliferative syndrome (XLP-rare inherited extreme vulnerability to EBV infection)
● Lymphoproliferative syndromes due to EBV infections in transplant recipients
● Lymphomas (B-cell lymphoblastic, T-cell)
● Lymphocytic interstitial pneumonitis
● Hairy leukoplakia of the tongue, leiomyosarcoma, and CNS lymphomas in patients with AIDS
● Burkitt lymphoma (most common childhood tumor in Africa and Papua New Guinea where malaria is also endemic and may be a cofactor)
● Nasopharyngeal carcinoma (particularly in Southeast China)
● Parotid carcinoma
● Hodgkin lymphoma (most common EBV-associated malignancy in United States, European Union)
● Postulated to be associated with multiple sclerosis (2 to 3 times incidence in EBV-positive individuals)
● Chronic active Epstein-Barr virus (CAEBV) due to loss of host control of viral replication

**DIAGNOSIS**

**HISTORY**
● May begin abruptly or insidiously
● Syndrome of fatigue, malaise, and sore throat
● In adults, temperature may rise to 103°F (39.4°C) and gradually fall over a variable period of 7 to 10 days; in severe cases, temperature elevations of 104–105°F (40.0–40.6°C) may persist for 2 weeks.
● Children typically have low-grade fever or are afebrile.
● Rash
● Chest pain (myocarditis and pericarditis)

**PHYSICAL EXAM**
● Fever, lymphadenopathy, pharyngitis in >50%, with palatal petechiae and hepatosplenomegaly in ~10%
● Diffuse hyperemia and hyperplasia of oropharyngeal lymphoid tissue
• Gelatinous, grayish-white exudative tonsillitis persists for 7 to 10 days in 50%.
• Petechiae develop at border of hard and soft palates in 60%.
• Axillary, epitrochlear, popliteal, inguinal, mediastinal, and mesenteric lymphadenopathy (95% of patients)
• Lymph node enlargement subsides over days/weeks
• Tender lymphadenopathy (cervical nodes are most commonly enlarged)
• Splenomegaly in 50%
• Skin manifestations in 3–16%
  – Erythematous macular/maculopapular rash
  – Petechial and purpuric exanthems reported
  – Rash typically on trunk and upper arms; occasionally, the face and forearms are involved.

DIFFERENTIAL DIAGNOSIS
• Streptococcal pharyngitis and tonsillitis
• Diphtheria
• Blood dyscrasias
• Rubella
• Measles
• Viral hepatitis
• Cytomegalovirus
• Toxoplasmosis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• CBC with differential
• Lymphocytes and atypical lymphocytes
  – Increased numbers of lymphocytes (especially atypical lymphocytes; may be up to 70% of leukocytes) in peripheral blood
  – In 1st week after onset, WBC count is normal/moderately decreased.
    • By week 2, atypical lymphocytosis develops.
  – During early illness, atypical lymphocytes are B cells transformed by the EBV; later, atypical cells are activated CD8T lymphocytes (4).
• Antibodies
  – Heterophile antibodies in 80–90% of adults
  – Heterophile antibody is an IgM response, which appears during the 1st/2nd week of illness and disappears in 4 to 6 weeks.
– In general, agglutinin titer is higher in IM than other disorders; an unabsorbed heterophile titer >1:128 and ≥1:40 is significant.

- Specific antibodies to EBV-associated antigens
  - Develop regularly in IM
  - Viral capsid-specific IgM and IgG are present early in illness.
  - Viral capsid-IgM disappears after several weeks; viral capsid-IgG persists for life.

- Liver tests: Transaminitis, hyperbilirubinemia are common; jaundice is rare.

- Atypical lymphocytes are not specific for EBV infections and may be present in other clinical conditions, including rubella, infectious hepatitis, allergic rhinitis, asthma, and atypical pneumonia.

- Abdominal ultrasound to routinely monitor for splenic enlargement is not necessary.

- Consider ultrasound for those wishing to return to strenuous activity/contact sports at day 21 of illness to ensure resolution of splenomegaly.

**Follow-Up Tests & Special Considerations**

- Abnormal hepatic enzymes persist in 80% of patients for several weeks; hepatomegaly in 15–20%
- In transplant recipients, quantitative polymerase chain reaction (PCR) used to monitor EBV loads

**Diagnostic Procedures/Other**

- Chest x-ray
  - Hilar adenopathy may be observed in IM with extensive lymphoid hyperplasia.

**Test Interpretation**

- Mononuclear infiltrations involve lymph nodes, tonsils, spleen, lungs, liver, heart, kidneys, adrenal glands, skin, and CNS.
- Bone marrow hyperplasia with small granulomas formation may be present; these findings are nonspecific and have no prognostic significance.

**TREATMENT**

- Treatment is mostly supportive.
- NSAIDs or acetaminophen
During acute stage, limit activity for 4 weeks to reduce potential complications (e.g., splenic rupture).

Transplant recipients who develop EBV infection may require reduction in immunosuppression and administration of monoclonal anti-CD20 (rituximab).

**MEDICATION**

In primary infections:

- Antimicrobial agents (usually penicillin) only if throat culture is positive for group A β-hemolytic streptococci. Previously, ampicillin rash in presumed group B *Streptococcus* (GBS) was thought to be highly suggestive of IM. Incidence of rash is much lower than historically thought (4)[B].

- Warm saline gargles for oropharyngeal pain
- Corticosteroids
  - May provide some symptomatic relief but no improvement in resolution of illness
  - Consider in severe pharyngotonsillitis with oropharyngeal edema and airway encroachment. Dexamethasone 0.3 mg/kg/day may be used for 1 to 3 days.
  - Also for patients with marked toxicity/major complications (e.g., hemolytic anemia, thrombocytopenic purpura, neurologic sequelae, myocarditis, pericarditis) (5)[B]

Antiviral medications (acyclovir) have been found to shorten recovery time and improve subjective symptoms in acute EBV infection in small studies.

**ISSUES FOR REFERRAL**

Most cases can be managed as an outpatient without the need for specialty referral. Consider referral for complications such as oropharyngeal edema with airway compromise.

**SURGERY/OTHER PROCEDURES**

- Splenectomy may be necessary with profound thrombocytopenia that is refractory to corticosteroids
- Only current effective treatment for XLP is hematopoietic stem cell transplantation.
- Splenic rupture
ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

ALERT
Rupture of the spleen may be fatal if not recognized; it requires blood transfusions, treatment for shock, and splenectomy. Occurrence is estimated at 0.1%.

Patient Monitoring
- Avoid contact sports, heavy lifting, and excess exertion until spleen and liver have returned to normal size (ultrasound can verify). Current consensus is that if after 3 weeks and normal exam, no fever, and no constitutional symptoms, one may return to contact sport play.
- Eliminate alcohol/exposure to other hepatotoxic drugs until LFTs return to normal.
- Monitor patients closely during the first 2 to 3 weeks after the onset of symptoms as rates of complications are highest during this period.
- Alert patients that symptoms (malaise, fatigue, intermittent sore throat, lymphadenopathy) may persist for months.

DIET
No restrictions. Hydration is important.

PROGNOSIS
- Most recover in ~4 weeks.
- Fatigue may persist for months.

COMPLICATIONS
- Neurologic (rare)
  - Aseptic meningitis, meningoencephalitis
  - Bell palsy, Guillain-Barré syndrome
  - Transverse myelitis
  - Cerebellar ataxia
  - Acute psychosis
- Hematologic (rare)
  - Thrombocytopenia, early in illness
- Hemolytic anemia with neutropenia (early)
- Hemophagocytic syndrome (splenomegaly, fever, cytopenia)
- Agammaglobulinemia

- Pneumonitis
- Airway obstruction
- Splenic rupture
  - Rare, but most often occurs in first 21 days of illness

REFERENCES

ADDITIONAL READING

CODES

ICD10

- B27.00 Gammaherpesviral mononucleosis without complication
- B27.09 Gammaherpesviral mononucleosis with other complications
- B27.01 Gammaherpesviral mononucleosis with polyneuropathy
CLINICAL PEARLS

- 98% of patients with acute IM manifest with a combination of fever, sore throat, cervical node enlargement, and tonsillar hypertrophy.
- False-negative monospot (heterophile antibody) is common in the first 10 to 14 days of illness. 90% will have heterophile antibodies by week 3 of illness.
- Lymphocytosis (not monocytosis) is common in IM.
INFERTILITY
Sharon L. Koehler, DO, FACS • Sonia Rivera-Martinez, DO, FACOFP

BASICS
DESCRIPTION
Definition: failure of a couple to conceive after ≥12 months of regular unprotected intercourse or after ≥6 months if the woman is ≥35 years. Primary: Couple has never been pregnant. Secondary: Couple has been pregnant. Fecundability: the probability of achieving pregnancy in one menstrual cycle.

EPIDEMIOLOGY
Incidence
Incidence is the probability of achieving a pregnancy within 1 year. ~85% of couples will conceive within 12 months of unprotected intercourse.

Prevalence
- In the United States, 5–15% of women currently trying to conceive are infertile.
- ~11.5% of married couples between ages 15 and 34 years and 42% between ages 35 and 44 years meet the criteria for being infertile.
- May increase as more women delay childbearing; 20% of women in the United States have their first child >35 years.

ETIOLOGY AND PATHOPHYSIOLOGY
- Most cases multifactorial: Approximately 50% of cases due to female factors (of which 20% are due to ovulatory dysfunction and 30% due to tubal and pelvic pathology); 30% due to male factors; and 20% are of unknown etiology.
- Acquired: Most common cause of infertility in the United States is pelvic inflammatory disease (PID) secondary to chlamydia (1), endometriosis, polycystic ovary syndrome (PCOS), premature ovarian failure, and increased maternal age.
- Diminished ovarian reserve (DOR): low fertility due to low quantity or...
functional quality of oocytes
• Congenital: anatomic and genetic abnormalities

**Genetics**
• Higher incidence of genetic abnormalities among infertile population, including Klinefelter syndrome (47XXY), Turner syndrome (45X or mosaic), and fragile X syndrome
• Y chromosomal microdeletions are associated with isolated defects of spermatogenesis → found in 16% of men with azoo-/severe oligospermia.
• Cystic fibrosis transmembrane conductance regulator (CFTR) gene mutation causing congenital bilateral absence of vas deferens (CBAVD)

**RISK FACTORS**
• Female
  – Gynecologic history: irregular/abnormal menses, sexually transmitted infections (STIs), dysmenorrhea, fibroids, prior pregnancy
  – Medical history: endocrinopathy, autoimmune disease, undiagnosed celiac disease, collagen vascular diseases, thrombophilia, obesity, and cancer
  – Surgical history: appendicitis, pelvic surgery, intrauterine surgery, tubal ligation
  – Social history: smoking, alcohol/substance abuse, eating disorders, exercise, advanced maternal age
• Male
  – Medical history: STI, prostatitis, medication use (i.e., β-blockers, calcium channel blocker, antulcer medication), endocrinopathy, cancer
  – Surgical history: orchiopexy, hernia repair, vasectomy with/without reversal
  – Social: smoking, alcohol/substance abuse, anabolic steroids, environmental exposures, occupations leading to increased scrotal temperature

**GENERAL PREVENTION**
Normal diet and exercise, avoid smoking and other substance abuse, prevention of STIs

**COMMONLY ASSOCIATED CONDITIONS**
• Sexual behavior increasing risk for STIs
• Pelvic pathology: endometriosis, ovarian cysts, endometrial polyps, and uterine fibroids
• Endocrine dysfunction (thyroid, glucose metabolism, menstrual cycle
abnormalities, prolactin)

- Anovulation is commonly associated with hyperandrogenism and PCOS.

**DIAGNOSIS**

**HISTORY**

- Complete reproductive history:
  - Age at menarche, regularity of menstrual cycle, physical development, previous methods of contraception, history of abnormal Pap smears and treatment
  - History of abortion, D&Cs, bilateral tubal ligation, vasectomy, or other pelvic/abdominal surgery
- Frequency of intercourse and sexual dysfunction
- Abdominal pain or other abdominal symptoms
- History of STI
- History of endocrine abnormalities
- History of malignancy or chronic illness
- Family history: close relatives with congenital abnormalities or mental retardation; infertility or early menopause in close relatives of female partner
- Medications: drug abuse, allergies, occupation, and exposure to environmental hazards

**PHYSICAL EXAM**

- BMI, distribution of body fat, and waist circumference
- Female
  - Pubertal development with Tanner staging
  - Signs of PCOS: androgen excess, obesity, signs of insulin resistance
  - Breast exam: galactorrhea
  - Vaginal exam: Describe rugation, discharge, anatomic variation.
  - Uterine size/shape, mobility, tenderness
  - Adnexal tenderness infection or mass
- Male
  - Abnormalities of the penis or urethral meatus
  - Testes: volume, symmetry, masses (varicocele, hydrocele), presence/absence of vas deferens

**DIAGNOSTIC TESTS & INTERPRETATION**
Initial Tests (lab, imaging)
Evaluation is directed by history:

- Assessment of ovulation
  - Irregular or infrequent menses, not accompanied by consistent premenstrual or moliminal characteristics, which are inconsistent in flow and duration, are indicative of ovulatory dysfunction.
  - Luteal-phase progesterone ≥3 ng/mL confirms ovulation has recently occurred but does not indicate when it occurred.
  - Luteinizing hormone (LH) testing kit: identifies midcycle LH surge, which occurs approximately 14 to 26 hours prior to ovulation. Greatest fertility on day of LH surge until 2 days after; predicts time of ovulation in advance so couples can time intercourse
  - Basal body temperature (BBT): ~1 degree increase in BBT taken upon wakening indicates ovulation has occurred: Greatest fertility spans 7 days PRIOR to rise in BBT; not preferred

- Assessment of ovarian reserve
  - Follicle-stimulating hormone (FSH)/estradiol (E₂): FSH and E₂ levels on cycle days (CD) 2 to 5 are used to predict response to ovulation induction and pregnancy. High FSH levels (>10 mIU/mL) and high estradiol (>80 pg/mL) indicate a low chance of pregnancy with in vitro fertilization (IVF).
  - Anti-müllerian hormone (AMH) and antral follicle counts (AFCs): The number of antral follicles measured by transvaginal ultrasound (US) at any one time in the ovary is termed the “antral follicle count.” AMH is secreted by the granulosa cells of the antral follicles and decreases as a woman approaches menopause. AMH <0.7 μ/dL and total AFC <10 between both ovaries during the follicular phase indicate DOR.
  - Clomiphene challenge test: Measure FSH on CD 3; administer 100-mg clomiphene CDs 5 to 9; recheck FSH on CD 10. FSH ≥10 mIU/mL on CDs 3 or 10 indicates DOR; may increase the sensitivity of the standard day 3 FSH test

- Semen analysis
  - Warranted in all infertile couples. Semen analysis alone is not used to predict male fertility potential: normal results in 6–27% of infertile males, abnormal results in fertile males
  - Semen collection: collected after 2 to 5 days of abstinence. Repeat test 2 to 3 times due to inherent variability within the same individual.
  - Parameters for male subfertility: sperm concentration <13.5 million/mL, sperm motility <32%, sperm morphology <9% normal
Additional labs
- Prolactin, thyroid-stimulating hormone, 17-hydroxyprogesterone, androgen levels
- HIV, HSV 1 and 2, chlamydia gonorrhea antibody, RPR, hepatitis B and C, CMV
- Genetic testing based on family history
Transvaginal US for anatomic abnormality
Hysterosalpingogram (HSG) to evaluate patency of tubes and contour of the cavity; may be both diagnostic and therapeutic
Sonohysterography (SHG) may provide a more detailed evaluation of the uterine cavity, if indicated.

**Follow-Up Tests & Special Considerations**
- Abnormal lab values warrant reevaluation/referral.
- Abnormal imaging may require surgical evaluation.

**Diagnostic Procedures/Other**
- Hysteroscopy: gold standard, used to directly visualize the endometrial cavity; may be indicated to evaluate filling defects on HSG or SHG
- Laparoscopy: used to directly visualize the peritoneal cavity and may be indicated to evaluate abnormal findings on HSG. Laparoscopy is the only way to definitively diagnose endometriosis.

**TREATMENT**

**GENERAL MEASURES**
- Be aware of insurance coverage for each patient. Be mindful of the couple’s emotional state: Depression, anger, anxiety, and marital discord are common. Many patients benefit from counseling and support measures.
- All female fertility patients should be given folate supplementation 1 mg/day by mouth.
- New evidence is suggesting beneficial effects of antioxidants in decreasing time to pregnancy. Additionally, dietary carotenoids in males may improve sperm quality (2,3).
- IVF is the most effective infertility treatment available:
  - Eggs are removed from the female and fertilized outside the body. The embryo is monitored for 3 to 5 days and then implanted into the uterus on
day 3 or day 5.

- Anatomic causes should be referred immediately for IVF, although surgical consult may be required.

- Fewer complications have been reported for individuals undergoing IVF for anatomic causes rather than ovulatory dysfunction (low APGAR scores, DM) (4)[A].

- Donor eggs may be obtained.

- Male factor

  - Consider lifestyle changes.

  - Intrauterine insemination (IUI): Sperms are placed via a catheter directly in the uterus. IUI effectively increases the sperm count.

  - Intracytoplasmic sperm injection (ICSI) is performed in conjunction with IVF for males with severe abnormalities (i.e., <5 million sperm) or those who have failed to conceive with IUI. A single sperm is injected directly into the cytoplasm of the egg. Fertilization occurs ~70% of the time.

  - Donor sperm may be obtained.

**MEDICATION**

**First Line**

- Treatment of infertility depends on the etiology.

- Anovulation: must determine if HYPOgonadotropic or NORMOgonadotropic

  - Hypogonadotropic patients: Standard treatment to induce ovulation consists of daily injections of both FSH and LH, which need to be carefully monitored to avoid overstimulation, resulting in ovarian hyperstimulation syndrome (OHSS).

  - Normogonadotropic patients: most commonly due to PCOS. Ovulation induction with clomiphene citrate (Clomid). Regimen: 50 mg/day for 5 days beginning typically on CD 5 after spontaneous or progestin-induced withdrawal bleed. If no ovulation, increase dose to 100 mg/day in subsequent cycles; maximum 150 mg/day. Some will increase dose with ovulation but no pregnancy; most effective with ~10% body weight loss if obese

- Unexplained infertility: IVF most effective; IUI, clomiphene, or LH/FSH yield minor improvements; better outcomes in combination

- Coital or cervical problems: IUI

- Endometriosis: either IVF or surgery; medical therapy does not increase pregnancy rates.
Second Line

- If clomiphene fails to induce ovulation:
  - Aromatase inhibitors (i.e., letrozole) may produce a better response.
  - Metformin beneficial in anovulatory women with PCOS; initiate with 500 mg daily and increase to ~1,500 mg/day; monitor renal function. Metformin may take up to 3 months to be effective. Consider also oral contraceptive pills (OCPs) for ≥2 cycles and then retry the clomiphene immediately after stopping the OCPs.
- Generally in subspecialty care: Gonadotropin therapies (injectable FSH or FSH + LH) are effective but riskier, treatments for infertility. They are effective for hypothalamic dysfunction for which clomiphene generally is not.

ISSUES FOR REFERRAL
Reproductive endocrinology and/or urology: Specialized lab prep is needed for IUI. FSH + LH therapies and IVF warrant referral in most cases.

ADDITIONAL THERAPIES
Consider using surrogate pregnancy if female cannot conceive.

SURGERY/OTHER PROCEDURES
Reproductive surgery may be necessary in those with anatomic causes of infertility. Polypectomy could be beneficial for large polyps obstructing the lumen of the uterus. Myomectomy may increase pregnancy success rates for intramural fibroids that obstruct or distort the uterine cavity. Salpingectomy is recommended and increases fertility in those with hydrosalpinx.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture may increase live birth rates with IVF.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Rarely needed; however, may be needed occasionally for problems in early pregnancy and OHSS
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patients should be referred to a specialist and consider more aggressive options if not successful after 3 to 6 cycles of oral ovulation induction.

Patient Monitoring
Cycle monitoring may decrease risks. US can show the number of developing follicles per cycle, which may help to predict OHSS and risk of multiple gestations.

DIET
A diet with sufficient calories to maintain a BMI permissible for ovulation. If obese, weight loss is recommended.

PATIENT EDUCATION
- Knowledge of women of reproductive age is lacking regarding the adverse effects of STI, irregular menses, and obesity on reproduction. Infertility treatment should focus on patient education (5)[A].
- American Society for Reproductive Medicine (http://www.asrm.org)
- Resolve: patient advocacy group (http://www.resolve.org)

PROGNOSIS
Most couples will achieve a pregnancy. Without therapy, ~50% of couples not yet pregnant will conceive during the 2nd and 3rd years of trying.

COMPLICATIONS
Anxiety (stress levels are high during treatment), multiple pregnancy (rates increase with all medical ovulation induction therapies and IVF), OHSS (very rare with oral medications but more common with FSH treatments). Couples with infertility may have a slightly increased risk of congenital abnormalities in offspring.

**SEE ALSO**

- Amenorrhea; Endometriosis; Infertility; Metabolic Syndrome; Polycystic Ovarian Syndrome (PCOS)
- Algorithm: Infertility
CODES

ICD10
- N97.9 Female infertility, unspecified
- N46.9 Male infertility, unspecified
- N97.1 Female infertility of tubal origin

CLINICAL PEARLS
- Women <35 years of age should be evaluated for infertility after failing to conceive after 1 year of unprotected intercourse; those ≥35 years should receive evaluation after 6 months; and those ≥40 years should receive assistance immediately.
- Medical therapy for endometriosis does not increase pregnancy rates, but surgical treatment does.
INFLUENZA

Katherine M. Tromp, PharmD • Hershey S. Bell, MD, MS, FAAFP

BASICS

DESCRIPTION
- Acute, typically self-limited, febrile infection caused by orthomyxovirus influenza types A and B
- Marked by inflammation of nasal mucosa, pharynx, conjunctiva, and respiratory tract
- Outbreaks have varying degrees of severity and generally peak in winter.
- Influenza virus can undergo antigenic shift (abrupt change) leading to viral strains with little immunologic resistance in a population. This can result in pandemic outbreaks. Minor seasonal variations are called antigenic drift.
- System(s) affected: typical cases: head/eyes/ears/nose/throat; pulmonary; complicated cases: cardiac and CNS involvement
- Synonym(s): flu; grippe; acute catarrhal fever

EPIDEMIOLOGY
- Predominant age: children (3 months to 16 years) and young adults
  - Morbidity: seasonal morbidity and rates of hospitalization highest in very young (preschool), elderly (>75 years of age), and individuals with comorbid illness (lung disease, malignancy)
- Predominant sex: male = female

Incidence
- Seasonal influenza in preuniversal vaccination: 95 million cases per year, typically fall/winter
- Attack rates in healthy children: 10–40% each year, prior to routine influenza vaccination
- Weekly reports: http://www.cdc.gov/flu/weekly

ETIOLOGY AND PATHOPHYSIOLOGY
Orthomyxovirus (influenza types A [majority] and B); influenza A virus subtypes HxNx based on hemagglutinin and neuraminidase
Incubation is 1 to 4 days; infected persons are most contagious during peak symptoms.
Spread by aerosolized droplets or contact with respiratory secretions
Hemagglutinin binds to columnar respiratory epithelium where replication occurs, and neuraminidase protein facilitates spread along respiratory epithelium.

RISK FACTORS
For contracting disease
- Crowded environments such as nursing homes, barracks, schools, and correctional facilities
For complications
- Neonates, infants, elderly
- Pregnancy, especially in 3rd trimester
- Chronic pulmonary diseases
- Cardiovascular diseases, including valvular problems and congestive heart failure (CHF)
- Metabolic disease, morbid obesity
- Hemoglobinopathies
- Malignancy; immunosuppression
- Neuromuscular diseases that limit respiratory function and ability to handle secretions
- Patients <19 years of age who are on long-term aspirin therapy

GENERAL PREVENTION
Vaccination: All persons >6 months should be vaccinated annually unless contraindication present.
- Inactivated influenza vaccine (IIV) is available with either 3 (IIV3) or 4 (IIV4) strains of influenza. IIV also is available as high-dose, intradermal, cell culture-based (ccIV3), MF59-adjuvanted (aIIV3), and recombinant hemagglutinin vaccine (RIV3).
- Live attenuated influenza vaccine (LAIV) is an intranasal quadrivalent vaccine.
IIV recommended annually for the following:
- All persons aged ≥6 months
- Vaccine should be administered annually as soon as the vaccine is available.
- Protection occurs 1 to 2 weeks after immunization.
- Typically mild side effects include low-grade fever and local reaction at vaccination site.
– Inactivated IM dose: ≥3 years of age: 0.5 mL; children 6 to 35 months of age: 0.25 mL
– Intradermal formulation for 18- to 64-year-olds uses a short 30-gauge needle in a single-use prefilled syringe with 0.1 mL vaccine; somewhat higher local reactions when given intradermal
– Single annual dose except for children <9 years of age, who should receive 2 doses (4 weeks apart) the first year they receive influenza vaccine.
– Vaccine contraindication: Severe allergy such as anaphylaxis to IIV components, hives from eggs are not considered a contraindication; observe all patients for 15 minutes after vaccination; no skin testing with influenza vaccine is needed in egg-allergic patients. RIV is safe in patients with an egg allergy.
– Precaution: Guillain-Barré syndrome within 6 weeks after a previous dose of influenza vaccine

* LAIV is not recommended for the 2017 to 2018 influenza season.
* IIV-HD: high-dose quadrivalent IIV
  – Contains 4 times the antigen concentration of IIV
  – Licensed for persons ≥65 years of age
  – Results in higher antibody levels but somewhat higher rates of local reactions
  – Advisory Committee on Immunization Practices does not express a preference for/against IIV-HD.
* Antiviral prophylaxis depends on current resistance patterns each year; see [http://www.cdc.gov/flu/](http://www.cdc.gov/flu/) for current patterns or check with local health department.

  – In high-risk groups that have not been vaccinated or need additional control measures during epidemics; *not* a substitute for vaccination unless vaccine is contraindicated
  – During influenza season, for those with contraindications to vaccine who have been exposed to the virus

  For staff and residents in nursing home outbreaks
  – For immune-deficient persons who are expected not to respond to vaccination after viral exposure

**Pediatric Considerations**

* Vaccinate children 6 months and older annually.
* For prophylaxis, oseltamivir dosage varies by weight and is recommended by the CDC for prophylaxis for children ≥3 months; zanamivir is approved for prophylaxis for children ≥5 years of age at a dosage of 2 inhalations per day.
Prophylaxis treatment duration is 7 days. For prophylaxis, the dosage of amantadine and of rimantadine is 5 mg/kg/day up to 150 mg in 2 divided doses. Currently, amantadine and rimantadine are not recommended due to resistance.

**Pregnancy Considerations**
- The CDC recommends vaccinating all women who will be pregnant during influenza season.
- If unvaccinated at the time of flu season, pregnant women should receive IIV or RIV.
- Oseltamivir, zanamivir, peramivir, rimantadine, and amantadine are pregnancy Category C.

**COMMONLY ASSOCIATED CONDITIONS**
Bacterial pneumonia

**DIAGNOSIS**

Look for:
- Systemic symptoms
- Cough
- Not being able to cope with daily activities
- Being confined to bed

**HISTORY**

Sudden onset of:
- Fever (37.7–40.0°C), especially within 3 days of illness onset
- Anorexia
- Chills, sweats, malaise, myalgia, arthralgia
- Headache
- Sore throat/pharyngitis
- Nonproductive cough
- Rhinorrhea, nasal congestion

**PHYSICAL EXAM**
- Physical exam is not specific for influenza.
- Physical examination should exclude complications such as otitis media,
pneumonia, sinusitis, and tracheobronchitis.

**DIFFERENTIAL DIAGNOSIS**

- Respiratory viral infections including respiratory syncytial virus, parainfluenza, adenovirus, enterovirus (“influenza-like illness”)
- Infectious mononucleosis
- Coxsackievirus infections
- Viral or streptococcal tonsillitis
- Atypical mycoplasmal pneumonia
- *Chlamydia pneumoniae*
- Q fever
- Less likely possibilities include severe acute respiratory syndrome, primary HIV infection, acute myeloid leukemia, tuberculosis, anthrax, and malaria.

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- During influenza season, diagnosis is based solely on clinical findings. If additional testing is needed:
  - Viral culture is gold standard for diagnosis but is of limited practical value due to time it takes for results to become available.
  - Reverse transcription polymerase reaction (RT-PCR) from nasopharyngeal swab or aspirate is the test of choice for diagnostic confirmation.
  - CBC: typically shows normal WBC count or mild leukopenia. Leukocytosis may indicate bacterial complications.
  - Direct fluorescent antibody or indirect fluorescent antibody staining for influenza antigen; results available in hours (dependent on lab expertise)
  - Commercial rapid enzyme-linked immunosorbent assay antigen tests are available. Some rapid tests diagnose influenza A, whereas others diagnose A and B. Sensitivity and specificity vary by manufacturer, strain of influenza, and age of patient. False-negative results are fairly common particularly during peak influenza activity.
  - Viral isolation is not particularly useful except in periods of low influenza activity when making the correct diagnosis is critical.

- Imaging
  - Chest x-ray if pneumonia is suspected
TREATMENT

- Symptomatic treatment is typically all that is required (saline nasal spray, analgesic gargle, antipyretics, analgesics).
- Cool-mist or ultrasonic humidifier to increase moisture of inspired air
- Droplet precautions: see http://www.cdc.gov/HAI/settings/outpatient/basic-infection-control-prevention-plan-2011/transmission-based-precautions.html#c
- 5 days is the average period of viral shedding in immunocompetent hosts.
- Hospitalized patients may require oxygen or ventilatory support.
- Tobacco cessation

MEDICATION

- Antiviral treatment depends on yearly resistance patterns; check http://www.cdc.gov/flu/ or with local health department. Antivirals are most effective if administered within first 48 hours in laboratory-confirmed (or highly suspected based on clinical findings) influenza cases.
- Antivirals within 48 hours of symptom onset are recommended for patients at risk of complications (i.e., diabetes, CHD, COPD, asthma, etc.) (1)[A].
- Antivirals are recommended if hospitalized (2)[A].
- Antivirals include oseltamivir, zanamivir, and peramivir. Amantadine and rimantadine currently are not recommended due to resistance.
- Consider antivirals for persons whose onset of symptoms is within the past 48 hours and who wish to shorten the duration of illness and further reduce their relatively low risk of complications (1)[A].
- Symptomatic treatment is preferred for those patients without risk factors and without signs of lower respiratory tract infection (2)[A].
- Effect is 24-hour reduction of symptoms and a reduction in complication rates.
  - Zanamivir dose: 2 inhalations BID for 5 days (age ≥7 years)
  - Oseltamivir dose: 75 mg PO BID for 5 days (age ≥13 years)
  - If severe renal impairment, 75 mg/day PO
  - Oseltamivir for children ≥1 year of age
    o <15 kg, 30 mg BID
    o >15 to 23 kg, 45 mg BID
    o >23 to 40 kg, 60 mg BID
    o >40 kg, 75 mg BID
  - Oseltamivir for children <1 year of age: 3 mg/kg/dose BID
– Peramivir dose: 600 mg IV infusion over 15 to 30 minutes for adults ≥18 years of age

● Antipyretics
  – Acetaminophen: in children

● Precautions
  – Zanamivir may cause bronchospasm if the patient has COPD or asthma; the patient should have a bronchodilator available.
  – Amantadine has anticholinergic properties and should be used with caution in those with psychiatric, addiction, or neurologic disorders, as it may increase risk for suicide attempts or increase neurologic symptoms.
  – Rimantadine may increase the risk of seizures in those with an underlying seizure disorder.
  – Oseltamivir may cause nausea and vomiting; may be less severe if taken with food
  – Peramivir may cause serious skin reactions.

● Decrease dose of certain antivirals if creatinine clearance <60 mL/min.
● Ibuprofen or other NSAIDs for symptomatic relief
● Aspirin: should not be used in children <16 years due to risk of Reye syndrome
● Outpatient treatment is sufficient except for cases with severe complications or in high-risk groups.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

● Mild cases: Usually, no follow-up is required.
● Moderate or severe cases: Follow up until symptoms and any secondary sequelae resolve.

DIET
Increase fluid intake.

PATIENT EDUCATION
CDC: http://www.cdc.gov/flu/

PROGNOSIS
Good
COMPLICATIONS

- Otitis media; acute sinusitis
- Croup; bronchitis
- Pneumonia (primary viral or secondary bacterial)
- Apnea in neonates
- Reye syndrome
- Rhabdomyolysis/myositis
- Postinfluenza asthenia
- COPD or CHF exacerbation
- Encephalopathy, death

**Geriatric Considerations**
Complications requiring hospitalization are more likely in elderly patients.

REFERENCES

1. Centers for Disease Control and Prevention. Influenza antiviral medications: summary for clinicians.

ADDITIONAL READING

- Centers for Disease Control and Prevention. Influenza (flu).

CODES

**ICD10**

- J11.1 Influenza due to unidentified influenza virus with other respiratory manifestations
CLINICAL PEARLS

- Influenza is an acute, (typically) self-limited, febrile infection caused by influenza virus types A and B.
- With rare exceptions, all persons >6 months should be vaccinated against influenza on an annual basis.
- Complications from influenza are most common in the very young, very old, and individuals with comorbid disease.
- Hand hygiene either with soap and water (slightly superior) or with alcohol-based hand rubs and covering coughs are simple ways to reduce the spread of influenza.
INGROWN TOENAIL
Sally-Ann L. Pantin, MD, FAAFP • Thomas A. Waller, MD

BASICS
DESCRIPTION
- In an ingrown toenail, the distal margin of the nail plate grows into the lateral nail fold, causing irritation, inflammation, and sometimes bacterial or fungal infection:
  - Stage 1 (inflammation): erythema, edema, tenderness to palpation of lateral nail fold
  - Stage 2 (abscess): increased pain, erythema, and edema as well as drainage (purulent or serous)
  - Stage 3 (granulation): Chronic inflammation leads to further erythema, edema, and pain, often with granulation tissue growing over the nail plate and significant nail fold hypertrophy.
- Can reoccur
- Synonym(s): onychocryptosis, unguis incarnatus

EPIDEMIOLOGY
- Great toenail is most often affected.
- Lateral edge of nail is more commonly affected than the medial edge.
- Most common in males aged 14 to 25 years
- Infrequent, but more often in elderly females than in elderly males
- More common in those with lower incomes

Prevalence
- 24.5/1,000 overall
- 50/1,000 ≥65 years

ETIOLOGY AND PATHOPHYSIOLOGY
- Nail plate penetrates the nail fold causing a foreign body reaction (inflammation).
- Bacteria or fungi may enter through the opening in the nail fold, causing infection and abscess formation.
The inflamed and infected area leads to granulation tissue and hypertrophy of the nail fold.

**RISK FACTORS**

- Genetic factors
  - Increased nail fold width
  - Decreased nail thickness
  - Medial rotation of the toe
- Many others proposed; none proven, including the following:
  - Distorted, thickened nail (onychogryphosis)
  - Fungal infection (onychomycosis)
  - Hyperhidrosis
  - Improper trimming of the lateral nail plate
  - Poorly fitting shoes
  - Trauma to nail or nail fold
  - Conditions that predispose to pedal edema (i.e., thyroid dysfunction, diabetes, obesity, heart failure, renal disease)

**GENERAL PREVENTION**

- Properly fitting shoes
- Proper nail trimming (see “Patient Education”)

**DIAGNOSIS**

**HISTORY**

- Patients most often present with pain, redness, and swelling in the toe along one or both sides of the nail.
- Drainage can occur as inflammation and/or infection develop.

**PHYSICAL EXAM**

- Nail fold tenderness
- Erythema and edema
- Drainage (serous or purulent)
- Granulation tissue
- Lateral nail fold hypertrophy

**DIFFERENTIAL DIAGNOSIS**
- Cellulitis
- Felon (pulp abscess on plantar aspect of toe)
- Onychogryphosis (gross thickening and hardening of the nail)
- Onycholysis (separation of nail from nail bed)
- Onychomycosis (fungal infection of the nail)
- Osteomyelitis
- Paronychia (infection or inflammation around the nail fold)
- Subungual exostosis (bony projection from distal phalanx)
- Subungual osteochondroma (benign bone tumor)

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

None usually needed
- Consider MRI, x-ray, or bone scan if osteomyelitis is suspected.
- Consider x-ray if subungual exostosis or osteochondroma is suspected.

**TREATMENT**

*GENERAL MEASURES*
- Majority of cases respond to conservative therapy.
- Warm, soapy water or Epsom salt soaks for 10 to 20 minutes 3 times per day until symptoms resolve (1)
- Bluntly insert a cotton wisp or dental floss underneath the ingrown portion of the nail. The patient can continue to replace the insert until the nail grows beyond the fold.
- Use tape to pull the lateral nail fold away from the nail plate until the nail grows beyond the fold.
- Stage 2 ingrown nails often respond to conservative treatment, as above, especially cotton wool, or a trial of cryotherapy.

*MEDICATION*
- NSAIDs are usually adequate for analgesia.
- Topical antibiotic can be applied after soaking (1).
- Neither oral nor topical antibiotics are useful as an adjunct to surgical treatment.
SURGERY/OTHER PROCEDURES

- Surgical interventions are more effective than nonsurgical interventions in preventing recurrence (2,3)[A].
- Nail avulsion techniques are more effective than nail fold debulking techniques (not described in this topic) (3)[A].
  - Partial avulsion of the nail with phenol nail matrix ablation
    o Obtain surgical consent after explaining the risks, benefits, and alternatives.
    o Achieve local anesthesia with a digital wing or ring block.
    o May consider placing a tourniquet around the base of the toe to assist with hemostasis (caution in patients with diabetes or peripheral vascular disease)
    o Elevate the ingrown part of the nail from the nail bed with a periosteal (Freer) elevator or hemostat.
    o Incise the nail longitudinally with scissors or a nail splitter a few millimeters from the ingrown border, starting at the distal edge and proceeding to the matrix.
    o Grasp, down to the cuticle, the avulsed fragment with a hemostat and pull this portion gently out with a hemostat, utilizing longitudinal traction, as well as rotation to the lateral nail fold if needed.
    o Remove the tourniquet once hemostasis is attained.
    o Dip a urethral swab in 80–88% phenol solution (phenol use is contraindicated in pregnancy).
    o Apply the phenol 3 times for 30 seconds to the nail matrix under the proximal nail fold. Wash the area with 70% isopropyl (rubbing) alcohol to neutralize phenol.

- Nonsurgical interventions, such as a flexible gutter splint, are another option for treatment of stage 2 or 3 ingrown nails (4,5)[B].
  - J Flexible gutter splint
    o Cut a 1- to 2-cm long piece of sterilized plastic tube, such as IV tubing, 2 to 3 mm in diameter (alternatively, you may use a cap from a 29-gauge needle).
    o Make a slit in the tubing lengthwise and cut the end off at an angle.
    o Apply local anesthesia with a digital wing or ring block.
    o Release the ingrown edge of the nail from the nail fold with a hemostat.
    o Slide the tube, angled end first, along the ingrown edge of the nail.
    o Consider fixing the tube in place with self-curing formable acrylic resin (used for dentures and sculptured nails), tape, or a single suture through
the nail plate.
  - Leave the tube in place until nail has grown beyond the nail fold.
- Bilateral partial matricectomy should be considered in patients with severe ingrown toenail or recurrence.
- Permanent destruction of the germinal matrix can be used to prevent recurrence. The use of phenol for nail bed ablation is probably more effective than nail avulsion alone in preventing recurrence (2,3)[A].
  - Other options for nail bed ablation:
    - Sodium hydroxide (NaOH)
    - Cryotherapy
    - Electrocautery with a special flattened tip coated with Teflon on one side to protect the proximal nail fold
    - Carbon dioxide laser
    - Surgical excision of the nail matrix

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Dress with antibiotic ointment or sterile petroleum jelly; cover with sterile gauze and tube gauze.
- Postop instructions should include the following:
  - Rest and elevate the foot for 12 to 24 hours.
  - Take NSAIDs for discomfort.
  - Change dressing and wash with soap and water at least daily for 1 to 2 weeks following procedure.
  - Expect a sterile exudate for 2 to 6 weeks.
  - Avulsed nails may take 6 to 12 months to grow completely out (if no matrix ablation).
  - Call for increasing pain, redness, or swelling.
  - Average time to return to normal activities is 2 weeks.
- Patients treated conservatively should be followed up in the office every 7 to 10 days until marked improvement is noted.

**PATIENT EDUCATION**
- Trim nails straight across perpendicular to long axis of the nail (do not round corners) and not too short.
- Wear properly fitting, comfortable shoes.
COMPLICATIONS

- Cellulitis after surgical procedure (uncommon)
- Damage to fascia or periosteum from overly aggressive matrix ablation
- Damage to nail bed
- Distal toe ischemia due to prolonged use of a tourniquet during surgery (rare)
- Nail plate deformity (due to nail matrix damage)
- Osteomyelitis (rare)
- Permanent narrowing of nail (if partial matrix ablation is performed)
- Persistent postoperative wound drainage particularly with excessive phenolization of adjacent tissues
- Recurrence (40–80% with avulsion alone, 0.6–14% with matrix ablation, 6–13% with gutter splint)

**CODES**

**ICD10**

L60.0 Ingrowing nail

**CLINICAL PEARLS**

- The best treatment for a stage 1 ingrown toenail is to insert a wisp of cotton or dental floss between the nail plate and lateral nail fold.
- The best treatment for a stage 3 ingrown toenail is partial nail avulsion with phenol matrix ablation.
- Patients can prevent ingrown toenails by trimming nails properly and wearing properly fitting shoes.
- Oral and topical antibiotics are not useful in the treatment of ingrown nails in conjunction with surgical treatment.
INJURY AND VIOLENCE

Jonathan R. Ballard, MD, MPH, MPhil • Charity F. Kranz, DO • Tisha K. Johnson, MD, MPH

BASICS

DESCRIPTION

• Injury, intentional or not, is often predictable and preventable.
• Unintentional injuries are no longer considered “accidents” given that most injuries are preventable.
• As of 2015, unintentional injury is the fourth leading cause of death, and intentional self-harm is the 10th leading cause of death in the United States.
• Injury is the leading cause of death of people aged 1 to 44 years and a leading cause of disability for people of all ages, regardless of sex, race/ethnicity, or socioeconomic status.
• Violence-related deaths accounted for 62,516 deaths in the United States in 2015 (71% suicide, 28% homicide, and 1% undetermined).

Source: Centers for Disease Control and Prevention (CDC) Web-based Injury Statistics Query and Reporting System (WISQARS)

• Children mostly die of unintentional injuries: (in rank order) motor vehicle accidents (MVAs), drowning, fire/burn, and suffocation.
• MVAs are the most common type of unintentional injury deaths in adolescents, followed by firearm-associated injury deaths.

ALERT

Poisoning, which includes drug overdose, has been the leading cause of injury
deaths overall since 2011 and is particularly deadly for persons ages 15 to 64 years, as the leading cause of injury deaths among 25 to 64 years and the second leading cause of unintentional injury deaths for 15 to 24 years.

- All forms of violence combine to cause >1.3 million deaths worldwide, 2.5% of global mortality (World Health Organization [WHO]).
- Since 2000, suicide has been increasing among those 10 to 74 years, especially in nonurban areas, and it is the second leading cause of death for 15 to 34 years.
- Among leading causes of injury deaths, firearms (related suicide, homicide unintentional injury deaths combined) rank third overall, second in 10 to 44 years, third in 45 to 65+ years, and fourth in 5 to 9 years of age.
- Homicide is the third leading cause of death in 2015 for persons between ages 1 to 4 years and 15 to 34 years in the United States.

**ALERT**

*Consider homicide as cause of unexplained death in young children.*

**ETIOLOGY AND PATHOPHYSIOLOGY**

*Multifactorial*

**RISK FACTORS**

- **MVAs:**
  - MVAs accounted for 36,161 deaths in 2015 with an age-adjusted rate of 10.3 deaths per 100,000 persons.
  - 2.5 million adult drivers and passengers were treated in emergency departments (EDs), and ~200,000 patients were hospitalized as a result of MVAs in 2012.
  - Young adults (20 to 24 years old) have the highest crash-related injury rates.
  - Motorcyclists are 29 times more likely to die in a motor vehicle crash than car occupants and 5 times more likely to be injured per mile traveled.
  - Risk factors for involvement in an MVA include high speed, teenage drivers, consumption of alcohol or drugs affecting the central nervous system, fatigue, distracted driving (hand-held mobile phones and inadequate visibility).
  - Increased risk of death by MVA: male driver, inexperience, nighttime driving, speeding, tailgating, driving with other teenagers, cell phone use, unrestrained occupants, use of older cars, nonuse of crash helmets, alcohol,
and drug use. In elderly, poor vision, medical conditions, and comorbidities increase risk of death by an MVA (CDC, National Center for Injury Prevention and Control [NCIPC], and WHO).

- **Pedestrians:**
  - 5,376 pedestrians were killed by motor vehicles and nearly 129,000 were treated in EDs for nonfatal injuries (2015; CDC, NCIPC).

- **Bicycles (WHO):**
  - Risk of death from crash with motor vehicle increases if speed >30 km/hr (~18 mph) and if there is impact with front of vehicle.
  - Risk factors for cyclist injury include alcohol consumption, shared use motorways, poor visibility, lack of understanding of road safety, and design/type of impacting vehicle.

- **Sports and recreation-related injury (CDC):**
  - >2.6 million children (0 to 19 years) treated in EDs each year; males, deconditioned adults, and athletes playing collision or contact sports are at also increased risk.

- **Drowning:** a leading cause of unintentional injury death among all children, particularly 1 to 4 years of age; children at increased risk include African Americans and those unattended in bathtubs, swimming pools, and recreational water activities (CDC, NCIPC).

- **Suffocation:** increased risk for children <1 year, unsafe sleeping environments (CDC)

- **Falls (CDC, NCIPC):**
  - The leading cause of nonfatal injuries and most common cause of traumatic brain injuries (TBIs)
  - Poor vision, psychotropic medications and diuretics, arthritis, impaired mobility, inappropriate footwear and walking aids, cognitive impairment, gait imbalance, environmental risk factors (1)

- **Violence:** risk factors: adverse childhood exposures (ACEs); lack of access to social capital, community organization, and economic resources; familial instability; community and family violence; access to firearms; mental health; personal or household member alcohol and drug use; exposure to suicidal behavior; history of aggressive behavior; cognitive deficits; poor supervision; poor peer-to-peer interaction; academic failure; poverty; lower socioeconomic class (CDC)

- **Homicide:** third leading cause of death for children 1 to 4 years and adolescents and young adults ages 15 to 34 years (CDC). Most common victims are young males. Firearms are used in 1 out of 2 homicides (WHO).

- **Suicide:** Females are more likely to have suicidal thoughts, but males are 4
times more likely to complete suicide. Most common methods are firearms for males and poisoning for females (CDC, NCIPC).

- Adolescent violence (CDC):
  - 23% of students are involved in fights annually; 8% of students participated in ≥1 fights at school in the last year.
  - 16% of students have carried a weapon in the last 30 days; 4% of students have carried a weapon to school; 6% of students have been threatened or injured by a weapon at school.

- Bullying (CDC):
  - 20% of 9th- to 12th-grade students bullied on school property in the last year
  - 15% of students report cyberbullying.
  - Bullying is associated with social, emotional, and academic difficulties.

- Interpersonal and intimate partner violence (IPV):
  - WHO reports about 38% of female and 6% of male homicides were killed by partners.
  - Nearly 27% of women and 11% of men report having some form of IPV in their lifetime (CDC).
  - Dating violence: Of 9th- to 12th-grade students dating in the previous 12 months, 10% experienced physical violence and 11% experienced sexual violence (CDC).
  - Increased risk for female, young (12% of rapes occur prior to 12 years of age; 40% by 18 years), history of IPV or sexual assault or child abuse, alcohol or drugs, marital difficulties, unemployment, emotional or mental health problems, income or educational disparity, poverty

**ALERT**

**Poisonings (CDC):**

- The United States’ epidemic of drug overdoses (poisonings) includes more than half a million deaths from 2000 to 2015, mainly from opioids (6 out of 10, ~91 deaths per day).
- Since 1999, prescription opioids sold in the United States have almost quadrupled, and deaths from prescription opioids have more than quadrupled.
- >33,000 people died from opioid overdoses in 2015; a 15% increase in opioid-death rates from 2014 to 2015 is likely due to illicit opioids, including synthetic-opioids (72%) such as fentanyl and heroin (20%).
- Overlapping prescriptions of pain relievers or other sedating drugs; high doses, history of mental illness or substance abuse, uninsured or Medicaid,
low income increase risk for overdose deaths.
- Consider opioid-induced poisonings in unexplained altered mental status.

**DIAGNOSIS**

**HISTORY**

- Mechanism, timing, and location of injury:
  - Blunt versus penetrating; intentional versus unintentional; others injured versus isolated injury; circumstances (weather, substance use, restrained vs. unrestrained)
  - Does history correlates with level of injury (i.e., level of suspicion for abuse [elderly, child, or partner])?
  - Is further evaluation required (blood and/or urine testing, response to opioid receptor antagonists, imaging)?
- IPV: neurologic deficits, seizures, chronic pain, GI, STI, pregnancy, psychiatric presentations
  - Screen women of childbearing age for IPV and intervene if screening results are positive.

**TREATMENT**

- Prevention: The primary focus for reducing injury and violence is individually tailored prevention based on risk factors combined with population-level prevention (2). The “three Es”: education, engineering strategies, and enforcement of laws (2). The “Haddon Matrix” describes injury events in terms of three influencing factors (host, agent/vector, environment) and three phases (preevent, event, postevent) (1,2).
- Primary (i.e., prevent crash), secondary (i.e., prevent injury from crash), and tertiary (i.e., prevent poor outcomes from injury) prevention (1,2)[C]
- Acute setting: Follow basic life support (BLS), advanced trauma life support (ATLS), advanced cardiovascular life support (ACLS), and pediatric advanced life support (PALS) guidelines (2,3)[A].
- Motor vehicle injuries (CDC):
  - Infants, toddlers, and children: age-appropriate child safety seats and passenger restraints with distribution programs, education programs for parents and caregivers, safety seat checkpoints, penalties for drivers
transporting children under the influence of drugs and/or alcohol, legislation regarding restraint of motor vehicle occupants (1)[A]

- Adolescents and adults: seat belts, air bags, graduated driver licensing programs, blood alcohol concentration laws, minimum drinking age laws, sobriety checkpoints, ignition interlocks, programs for alcohol servers, zero-alcohol tolerance laws for young drivers, school-based education programs on drinking and driving. Emergency medical services (EMS) response times, engineering cars for rapid extraction, organized trauma systems; collapsible automobile steering columns have been shown to decrease injury mortality and morbidity; texting and driving penalties (1)[B]
- Older adults: alternative transportation programs, screening for high-risk drivers, gradual curtailment of driving privileges, more frequent license renewal process (1)[B]
- Bicycle helmets can reduce risk of head injury by 63–88%. Canadian helmet legislation decreased mortality by 52% (1)[B].
- Pedestrian injury: pedestrian safety education, reflective clothing, use of crosswalks, limit mobile phone use while crossing roads (1)[B], street lighting for pedestrians (1)[A], fluorescent clothing for pedestrians and cyclists (1)[A]
- Cyclists injury: flashing lights and reflectors at night (2)[B], helmet use and laws (1)[A], cyclists separation for motor vehicles (1)[B]

- Sports-related injuries:
  - Proper equipment: Helmets can prevent bicyclist head injuries and mortality (1)[A].
  - Plan of action for dealing with concussion and head injury in young athletes, with guidelines regarding if or when it is safe to return to play (CDC)(A)

- Drowning:
  - Improved supervision of young children, especially for those with epilepsy; swimming lessons in those >4 years; trained lifeguard supervision; fencing; locked gates and pool alarms; no use of alcohol in recreation aquatic activities; personal flotation devices and boating safety awareness; parental and caregiver certification in CPR (1)[B]

- Falls:
  - Home safety assessments, installation of handrails and grab bars, removal of tripping hazards, nonslip mats, exercise programs such as Tai Chi to improve strength and balance, night lights, cataract surgery, gradual withdrawal of psychotropic medication (1)[B]
– In May 2012, USPSTF recommended exercise or physical therapy and vitamin D supplementation to prevent falls in community-dwelling adults aged 65 years or older who are at increased risk for falls (4)[B].

Violence (homicide, suicide, assaults) (CDC):
– Primary prevention: Most effective strategies focus on younger age groups to change individual attitudes and behaviors (1)[C].
– Secondary prevention: Detect and identify violence in early stages (1)[B]. The USPSTF recommends that clinicians screen women of childbearing age for IPV, such as domestic violence, and provide or refer women who screen positive to intervention services (4)[B].
– Tertiary prevention: IPV reduced by alcoholism treatment for partner; intense advocacy interventions of >12 hours (1)[A]
– Suicide: access to mental health services, improved family and community support, development of healthy coping and problem-solving skills (CDC) [B]
– USPSTF recommends screening adults for depression when depression care supports are in place to assure accurate diagnosis, effective treatment, and follow-up (4)[B].
– Dating violence: self-reported dating violence reduced by school- and community-based programs for prevention of dating violence (1)[A]

ALERT
Poisonings (CDC): In response to the opioid epidemic, the CDC Guideline for Prescribing Opioids for Chronic Pain—United States, March 2016 was released to improve prescribing practices, to aid in early identification of those at high risk for addiction, and to prevent opiate and heroin addiction and deaths.

– Prevent and treat opioid abuse: prescription drug monitoring programs; state prescription drug laws; insurance strategies (prior authorization, quantity limits, drug utilization review); prescribing practice quality improvement programs; substance abuse counseling and medication-assisted treatment.
– Consider use of naloxone to counter the effects of opioid overdose.
– Multiple doses of naloxone may be required, as the duration of many opioids is greater than that of naloxone.
– Follow acute care guidelines and call 911; may contact Poison Control Center hotline after discovered ingestion of toxin for recommendations (5)[A]
ONGOING CARE

COMPLICATIONS

Social burden of injury: loss of productivity, emotional loss, nonmedical expenditures, reduced quality of life, litigation, rehabilitation, mental health costs, altered family and peer relationships, chronic pain, substance use and abuse, changes in lifestyle (1,CDC)

REFERENCES

ADDITIONAL READING

- National Center for Injury Prevention and Control: https://www.cdc.gov/injury

CODES

mebooksfree.com
ICD10
- T14.90 Injury, unspecified
- T14.8 Other injury of unspecified body region
- R29.6 Repeated falls

CLINICAL PEARLS
- Injury and violence are predictable and preventable.
- Unintentional injury is a leading cause of death in the United States.
- Injury is the primary source of lost years of productive life for individuals age <44 years.
- MVAs cause most deaths in children and adolescents.
- Nearly 31% of women and 26% of men report having some form of IPV in their lifetime.
- Opioid overdose is increasing as a serious cause of unintentional injury and death.
INSOMNIA

Susanne Wild, MD

BASICS

DESCRIPTION
- Difficulty initiating or maintaining sleep or nonrestorative sleep despite adequate opportunity and circumstances for sleep
- Causes at least one of the following forms of daytime impairment related to nighttime sleep difficulty:
  - Fatigue or malaise
  - Attention, concentration, or memory impairment
  - Social or vocational dysfunction or poor school performance
  - Mood disturbance or irritability
  - Daytime sleepiness
  - Motivation, energy, or initiative reduction
  - Proneness for errors or accidents at work or while driving
  - Tension, headaches, or GI symptoms in response to sleep loss
  - Concerns or worries about sleep

EPIDEMIOLOGY
- Predominant age: increases with age
- Predominant sex: female > male (5:1)

Prevalence
- Insomnia (transient and chronic): 5–35% of the population; 10–15% associated with daytime impairment
- Chronic insomnia: 10% middle-aged adults; 1/3 of people >65 years

ETIOLOGY AND PATHOPHYSIOLOGY
- Transient/intermittent (<30 days)
  - Stress/excitement/bereavement
  - Shift work
  - Medical illness
  - High altitude
- Chronic (>30 days)
– Medical: gastroesophageal reflux disease, sleep apnea, chronic pain, congestive heart failure, Alzheimer disease, Parkinson disease, chronic fatigue syndrome, irritable bowel syndrome
– Psychiatric: mood, anxiety, psychotic disorders
– Primary sleep disorder: idiopathic, psychophysiological (heightened arousal and learned sleep-preventing associations), paradoxical (sleep state misperception)
– Circadian rhythm disorder: irregular pattern, jet lag, delayed/advanced sleep phase, shift work
– Environmental: light (liquid crystal display [LCD] clocks), noise (snoring, household, traffic), movements (partner/young children/pets)
– Behavioral: poor sleep hygiene, adjustment sleep disorder
– Substance induced
– Medications: antihypertensives, antidepressants, corticosteroids, levodopa-carbidopa, phenytoin, quinidine, theophylline, thyroid hormones

**Pregnancy Considerations**
Transient insomnia occurs secondary to change of sleep position, nocturia, gastritis, back pain, anxiety.

**RISK FACTORS**
- Age
- Female gender
- Medical comorbidities
- Unemployment
- Psychiatric illness
- Impaired social relationships
- Lower socioeconomic status
- Shift work
- Separation from spouse or partner
- Drug and substance abuse

**GENERAL PREVENTION**
- Practice consistent sleep hygiene:
  – Fixed wake-up times and bedtimes regardless of amount of sleep obtained (weekdays and weekends)
  – Go to bed only when sleepy.
  – Avoid naps.
– Sleep in a cool, dark, quiet environment.
– No activities or stimuli in bedroom associated with anything but sleep or sex
– 30-minute wind-down time before sleep
– If unable to sleep within 20 minutes, move to another environment and engage in quiet activity until sleepy.

● Limit caffeine intake to mornings.
● No alcohol after 4 PM
● Fixed eating times
● Avoid medications that interfere with sleep.
● Regular moderate exercise

COMMONLY ASSOCIATED CONDITIONS

● Psychiatric disorders
● Painful musculoskeletal conditions
● Obstructive sleep apnea
● Restless leg syndrome
● Drug or alcohol addiction/dependence

DIAGNOSIS

HISTORY

● Daytime sleepiness and napping
● Unintended sleep episodes (driving, working)
● Insomnia history
  – Duration, time of problem
  – Sleep latency, difficulty in maintaining sleep (repeated awakening), early morning awakening, nonrestorative sleep, or patterns (weekday vs. weekend, with or without bed partner, home vs. away)
● Sleep hygiene
  – Bedtime/waking time
  – Physical environment of sleep area: LED clocks, TV, room lighting, ambient noise
  – Activity: nighttime eating, exercise, sexual activity
  – Intake: caffeine, alcohol, herbal supplements, diet pills, illicit drugs, prescriptions, over-the-counter (OTC) sleep aids
● Symptoms or history of depression, anxiety, obsessive-compulsive disorder, or
other major psychological symptomatology

- Symptoms of restless leg syndrome and periodic limb movement disorder
- Symptoms of heightened arousal
- Snoring and other symptoms of sleep apnea
- Symptoms or history of drug or alcohol abuse
- Current medication use
- Chronic medical conditions
- Acute change or stressors such as travel or shift work
- Sleep diary: sleep log for 7 consecutive days

DIFFERENTIAL DIAGNOSIS

- Sleep-disordered breathing such as obstructive sleep apnea
- CNS hypersomnias (e.g., narcolepsy)
- Circadian rhythm sleep disturbances
- Sleep-related movement disorders (e.g., restless leg syndrome)
- Substance abuse
- Insomnia due to medical or neurologic disorder
- Mood and anxiety disorders such as depression or anxiety

DIAGNOSTIC TESTS & INTERPRETATION

- Diagnostic testing usually not required; consider polysomnography if sleep apnea or periodic limb movement disorder is suspected (1)[C].

Primary insomnia
- Symptoms for at least 1 month: difficulty in initiating/maintaining sleep or nonrestorative sleep
- Impairment in social, occupational, or other important areas of functioning
- Does not occur exclusively during narcolepsy, breathing-related sleep disorder, circadian rhythm sleep disorder, or parasomnia
- Does not occur exclusively during major depressive disorder, generalized anxiety disorder, delirium
- Is not secondary to physiologic effects of substance or general medical condition
- Sleep disturbance (or resultant daytime fatigue) causes clinically significant distress.

Secondary insomnia
- Due to substance abuse, medication induced (diuretics, stimulants, etc.), primary depressive disorder, generalized anxiety disorder or phobias, acute situational stress, posttraumatic stress disorder, pain
Initial Tests (lab, imaging)
Testing to consider based on history and physical exam:
- Thyroid-stimulating hormone
- Urine toxicology

Diagnostic Procedures/Other
Polysomnography or multiple sleep latency test not routinely indicated but may be considered if
- Initial diagnosis is uncertain.
- Treatment interventions have proven unsuccessful.

TREATMENT
- Transient insomnia
  - May use medications for short-term use only; hypnotic sedatives favored
  - Self-medicating with alcohol can increase awakenings and sleep-stage changes.
- Chronic insomnia
  - Treatment of underlying condition (major depressive disorder, generalized anxiety disorder, medications, pain, substance abuse)
  - Advise good sleep hygiene.
  - Cognitive-behavioral therapy is first-line treatment for chronic insomnia, especially in >60 years population, especially when sedatives are not advantageous (2)[A].
  - Behavioral therapy is an effective treatment for insomnia and a potentially more effective long-term treatment than pharmacotherapy (3)[B].
  - Ramelteon is the only agent without abuse potential (4)[B].

MEDICATION
- Reserved for transient insomnia such as with jet lag, stress reactions, transient medical condition
- Nonbenzodiazepine hypnotics
  - Act on benzodiazepine receptor, so have abuse potential
    - Zaleplon (Sonata) 5 to 20 mg; half-life 1 hour
    - Zolpidem (Ambien) 5 to 10 mg (males); 5 mg (females); half-life 2.5 to 3 hours
    - Zolpidem (Ambien CR) 6.25 to 12.50 mg (males); 6.25 mg (females);
half-life 2.5 to 3 hours
  - Eszopiclone (Lunesta) 1 to 3 mg; half-life 6 hours

- Benzodiazepine hypnotics
  - Short acting
    - Triazolam (Halcion) 0.25 mg; half-life 1.5 to 5.5 hours
  - Intermediate acting
    - Temazepam (Restoril) 7.5 to 30.0 mg; half-life 8.8 hours
    - Estazolam (Prosom) 1 to 2 mg; half-life 10 to 24 hours
  - Long acting
    - Flurazepam (Dalmane) 15 to 30 mg; half-life 40 to 100 hours

- Contraindications/precautions are as follows:
  - Not indicated for long-term treatment due to risks of tolerance, dependency, daytime attention and concentration compromise, incoordination, rebound insomnia
  - Long-acting benzodiazepines associated with higher incidence of daytime sedation and motor impairment
  - Avoid in elderly, pregnant, breastfeeding, substance abusers, and patients with suicidal or parasuicidal behaviors.
  - Avoid in patients with untreated obstructive apnea and chronic pulmonary disease.
  - No good evidence for benzodiazepines for patients undergoing palliative care (4)[A]
  - Nonbenzodiazepine receptor agonists may occasionally induce parasomnias (sleepwalking, sleep eating, sleep driving).

- Melatonin receptor agonist
  - Ramelteon (Rozerem) 8 mg; half-life 1 to 2.6 hours
    - Recommended as first-line pharmacologic treatment option per AASM consensus
    - Effective to reduce sleep time onset for short- and long-term use in adults, without abuse potential; no comparative studies with older agents have been completed. Onset of effect may take up to 3 weeks.

- Sedating antidepressants
  - Doxepin (Silenor) 10 to 50 mg; half-life 15 hours
    - Only antidepressant with FDA approval for insomnia
    - New formulation of medication is available at dosage 3 to 6 mg QHS.
  - Trazodone (Oleptro) 25 to 200 mg; half-life 3 to 9 hours
  - Mirtazapine (Remeron) 7.5 to 15.0 mg; half-life 20 to 40 hours
  - Amitriptyline (Elavil) 25 to 100 mg; half-life 10 to 26 hours

- Orexin receptor agonists
Suvorexant (Belsomra) 10 to 20 mg; half-life 12 hours

Sedating antihistamines are not recommended and should be used conservatively for insomnia due to insufficient evidence of efficacy and significant concerns about risks of these medications.

**Geriatric Considerations**
Caution (risk of falls and confusion) when prescribing benzodiazepines or other sedative hypnotics; if absolutely necessary, use short-acting nonbenzodiazepine agonists at half the dosage or melatonin agonists for short-term treatment.

**ADDITIONAL THERAPIES**
Associated with hypertension, congestive heart failure, anxiety and depression, and obesity; management of these chronic conditions will help with incidence and symptoms of insomnia.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Melatonin: decreases sleep latency when taken 30 to 120 minutes prior to bedtime, but there is no good evidence for efficacy in insomnia, and long-term effects are unknown (5)[B]
- Valerian: Inconsistent evidence supporting efficacy and its slow onset of action (2 to 3 weeks) makes it unsuitable for the acute treatment of insomnia.
- Acupuncture: insufficient evidence on effect of needle acupuncture and its variants
- Antihistamines: insufficient evidence; should not be recommended for use
- Cognitive-behavioral therapy (including relaxation therapy): effective and considered more useful than medications; recommended initial treatment for patients with chronic insomnia; no improvement of efficacy when combined with medication
- Mindfulness awareness practices: improved sleep quality and sleep-related daytime impairment for older adults per small randomized trial

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Daily exercise improves quality of sleep and may be more effective than medication.
Avoid exercise within 4 hours of bedtime.

**Patient Monitoring**
- Reassess need for medications periodically; avoid standing prescriptions.
- Caution patients that nonbenzodiazepine agonists (zolpidem, zaleplon, eszopiclone), as well as benzodiazepines, can be habit forming.
- Studies suggest an association between receiving a hypnotic prescription and a >3-fold increase in hazards of death, even when prescribed <18 pills per year (6)[B].

**Diet**
- Avoid caffeine or reserve for morning only.
- Avoid heavy late-night snacks (light snack at bedtime may help).
- Avoid alcohol within 6 hours of bedtime.

**Prognosis**
- Situational insomnia should resolve with time.
- Treatment of underlying etiology and consistent sleep hygiene are the mainstays of treatment.

**Complications**
- Transient insomnia can become chronic.
- Daytime sleepiness, cognitive dysfunction
- Pulmonary hypertension if chronic sleep apnea left untreated
- Sleep apnea may lead to hypertension, stroke, or cardiac ischemia.

**References**

**ADDITIONAL READING**

**SEE ALSO**

- Anxiety (*Generalized Anxiety Disorder*); Depression; Fibromyalgia; Sleep Apnea, Obstructive
- Algorithms: Anxiety; Insomnia, Chronic; Restless Legs Syndrome

**CODES**

**ICD10**

- G47.00 Insomnia, unspecified
- F51.02 Adjustment insomnia
- F51.01 Primary insomnia

**CLINICAL PEARLS**

- Treatment of underlying etiology of the insomnia and consistent sleep hygiene are key.
- Most medications are indicated for short-term use only.
- Sedative hypnotics are not recommended in the elderly because risks may outweigh benefits.
- Patients with chronic insomnia benefit from sleep hygiene education and cognitive-behavioral therapy.
INTELLECTUAL DISABILITY
(INTELLECTUAL DEVELOPMENTAL DISORDER)

Jennifer L. Ayres, PhD

BASICS

- A global deficit in cognitive functioning evidenced by a significant difference in mental and chronologic ages (intelligence quotient [IQ]) and significantly impaired adaptive functioning (1)
- Although cognitive issues typically have a pervasive impact, patients with ID display highly variable levels of functioning and subsequent service needs.
- Evaluation and treatment plans must be tailored to individual needs.
- The term mental retardation was deleted from the DSM-5 and replaced with “intellectual disability” (ID) or “intellectual developmental disorder.” The term “mental retardation” is pejorative and insensitive.

DESCRIPTION

- ID is defined as an IQ ≤70 + 5 and a significant impairment in intellectual functioning, including verbal and nonverbal reasoning, planning, academic learning, problem solving, and experiential learning. Intellectual function is confirmed by IQ testing and clinical assessment (1).
- A diagnosis of ID also requires deficits in adaptive functioning, such as communication, socialization, and independent living (1).
- By definition, ID is a neurodevelopmental disorder that is typically present from birth or recognized during early childhood (1).
- ID is currently subgrouped according to adaptive function and level of needed support: mild (typical development in some domains, mild impairment in others), moderate (skills are markedly behind same-age peers), severe (skills quite limited compared to peers), profound (limited awareness of concepts, language; dependent on others for adaptive functioning) (1).
- The three most common causes of ID are Down syndrome, fragile X syndrome, and fetal alcohol syndrome (FAS).
- If ID reflects a loss of previously acquired intellectual skills, consider a comorbid neurocognitive disorder.
• Previous stereotypes of people with ID (e.g., always happy, poor prognosis, unable to function independently) have been refuted. People with ID are showing a level of functioning variability that parallels what is found in the non-ID population.
• Under the Individuals with Disabilities Education Act (IDEA), caregivers should be encouraged to familiarize themselves with their child’s legal rights to facilitate coordination of services with the school district.
• Under the Americans with Disabilities Act (1990), people with ID cannot be discriminated against based on their disability, and employers are legally required to ensure that appropriate accommodations are in place.

**ALERT**
For some causes of ID, prenatal testing is available.

**EPIDEMIOLOGY**

**Incidence**
• 1 of 6 children (2)
• Predominant sex: male > female: 1.6:1 for mild ID, 1.2:1 for severe ID (1)

**Prevalence**
In the United States, 1% of the general population. The prevalence of severe ID is 6/1,000 (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**
• Causes:
  – Maternal substance abuse (e.g., alcohol); FAS is a leading environmental cause of ID.
  – Maternal infections: TORCH viruses (toxoplasma, other infections, rubella, cytomegalovirus, and herpes simplex virus)
  – Down syndrome
  – Sex chromosome abnormalities: fragile X, Turner syndrome, Klinefelter syndrome
  – Autosomal dominant conditions: neurocutaneous syndromes (e.g., neurofibromatosis, tuberous sclerosis)
  – Autosomal recessive conditions:
    o Amino acid metabolism (e.g., phenylketonuria, maple syrup urine disease)
    o Carbohydrate metabolism (e.g., galactosemia, fructosuria)
- Lipid metabolism
- Tay-Sachs disease
- Gaucher disease
- Niemann-Pick disease; mucopolysaccharidosis
- Purine metabolism (e.g., Lesch-Nyhan disease)
- Other (e.g., Wilson disease)

- Maternal use of prescription medications (e.g., Accutane, Dilantin)
- Perinatal factors:
  - Prematurity
  - Birth injuries
  - Perinatal anoxia
- Postnatal factors:
  - Childhood diseases (e.g., meningitis, encephalitis, hypothyroidism, seizure disorders)
  - Trauma (e.g., accidents, physical abuse, hypoxia)
  - Severe deprivation
  - Poisoning (e.g., lead, carbon monoxide, household products)

**Genetics**
A number of genetic and epigenetic causes are known, and more are under investigation (3).

**RISK FACTORS**
- Maternal substance abuse during pregnancy
- Maternal infection during pregnancy
- For some causes, family history

**GENERAL PREVENTION**
- Public health efforts to reduce alcohol and drug use by pregnant women
- Prenatal folic acid supplementation

**COMMONLY ASSOCIATED CONDITIONS**
- Seizures
- Mood disorders
- Behavioral disorders
- Constipation
**DIAGNOSIS**

The diagnosis of ID requires a thorough assessment conducted by an appropriately credentialed mental health provider who is formally trained and licensed to conduct appropriate psychodiagnostic testing.

**HISTORY**
- Children with profound/severe ID are typically diagnosed at birth or during the newborn period. They may have pathognomonic dysmorphic features.
- Children with ID are often identified because they fail to meet motor/language milestones.

**PHYSICAL EXAM**
Certain morphologic features suggest a specific etiology for ID (e.g., microcephaly) (4).

**DIFFERENTIAL DIAGNOSIS**
- Brain tumors
- Auditory, visual, and/or speech/language impairment
- Autism spectrum disorder (language and social skills are more affected than other cognitive abilities); however, 75% of individuals with an autistic disorder may meet criteria for a comorbid diagnosis of ID.
- Expressive/receptive language disorders
- Cerebral palsy
- Emotional/behavioral disturbance
- Learning disorders (reading, math, written expression)
- Auditory/sensory processing difficulties
- Lack of environmental opportunities for appropriate development

**DIAGNOSTIC TESTS & INTERPRETATION**
- Visual and hearing tests to rule out these etiologies as the cause of impairment and provide an assessment of visual and auditory functioning (often impaired in children and adults with ID)
- Formal testing of intellectual and adaptive functioning:
  - A child’s communication skills must be considered in test selection. For example, a patient with auditory processing issues/limited expressive/receptive language skills may need to be assessed using a nonverbal IQ test, such as the Leiter-R, *Test of Nonverbal Intelligence*, or
other nonverbal measures.

- Commonly used intelligence tests (e.g., Bayley Scales of Infant Development, Stanford-Binet Intelligence Scale, Wechsler Intelligence Scales) are determined by age/developmental level.
- Common tests of adaptive functioning include the *Vineland Adaptive Behavior Scales, 2nd ed.* and *Adaptive Behavior Assessment System, 2nd ed.* These tests assess areas of functioning such as age-appropriate communication, social skills, activities of daily living, and motor skills.

Metabolic screening is not routine unless suggested by history and physical exam or no newborn screening was performed (5).

**Initial Tests (lab, imaging)**

- Lead (5)[B]
- Thyroid-stimulating hormone if systemic features present or no newborn screening was done (5)[B]
- Routine cytogenetic testing (karyotype) (5)[B]:
  - Fragile X screening (FMR1 gene), particularly with a family history of ID
  - Rett syndrome (MECP2 gene) in women with unexplained moderate to severe ID (5)
- Molecular screening (e.g., array comparative genomic hybridization) is increasing in use (4)[B].
- Neuroimaging (MRI more sensitive than CT) is routinely recommended. The presence of physical findings (microcephaly, focal motor deficit) increase yield (5)[B].
- MRI may show mild cerebral abnormalities but is unlikely to establish etiology of ID (4).

**Follow-Up Tests & Special Considerations**

Electroencephalogram not routinely used unless a specific epileptiform diagnosis is present (5)[C]

**TREATMENT**

- Tailor early intervention services to individual needs.
- Caregiver support, including:
  - Train caregiver(s) to address behavioral issues, discipline, and social development.
  - Encourage caregivers to create a structured home environment based on the
child’s developmental level and specific needs rather than routine age-appropriate expectations.

– Offer caregiver(s) an opportunity to address their reactions to the diagnosis and their child’s special needs.
– Inform caregivers about advocacy groups and available community, state, and national resources (6).
– Encourage caregiver(s) to seek social support to increase their own overall sense of well-being.
– Encourage caregivers to intermittently seek respite care to promote self-care.

● Individualized education plans, social skills, and behavioral plans/training
● Refer to job training programs and independent living opportunities, if appropriate.
● Notice all changes in behavior, which may be indicative of pain/illness, particularly in individuals with limited communication skills.
● Assess for abuse and neglect.

MEDICATION
Medication may be appropriate for comorbid conditions (e.g., anxiety, ADHD, depression).

ONGOING CARE
Match provider communication of procedures, results, and treatment recommendations to patient level of cognitive functioning and receptive language skills.

● Most patients with mild ID are fully capable of understanding information when provided at the appropriate level.
● Provide oral and written explanations directly to the patient instead of solely to caregivers. Respect patient dignity at all times. Provide honest information, respond to patient’s questions with respect, and do not infantilize the patient due to their ID.

FOLLOW-UP RECOMMENDATIONS
Link to community-based resources for job training, independent living, caregiver support, school-based services
**Patient Monitoring**

- A quality of life assessment provides information about a patient’s general sense of well-being and life satisfaction. Quality of life may be difficult to assess when significant behavioral issues confound an individual’s self-report and socialization.
- Vision testing at least once before age 40 years (age 30 years in Down syndrome) and every 2 years thereafter
- Hearing evaluations every 5 years after age 45 years (every 3 years throughout life in Down syndrome)
- Screen for sexual activity and offer contraception and testing for STIs as appropriate.
- Abuse and neglect of people with ID are common. Screen at least annually and if behavior change is noted. Report abuse/neglect to appropriate protective agencies.
- Dysphagia and aspiration are common; consider speech pathology evaluation and swallowing study (7)[B].

**DIET**

No restrictions, except in cases of metabolic and storage disorders (e.g., phenylketonuria)

**PATIENT EDUCATION**

- The Arc of the United States (The Arc): [www.thearc.org](http://www.thearc.org)
- American Association of Intellectual and Developmental Disabilities: [www.aaid.org](http://www.aaid.org)
- Family support groups (Parent to Parent, local Down Syndrome, or Autism Association)
- Special Olympics: [www.specialolympics.org](http://www.specialolympics.org)

**PROGNOSIS**

- Although ID is a lifelong diagnosis, individuals with ID can (and should) live fulfilling, purposeful lives that include career, independent living, marrying/participating in a committed relationship, and becoming a parent.
- The level of severity and support needed may vary over the course of the individual’s life.

**COMPLICATIONS**

- Constipation is a commonly overlooked problem and can lead to significant
morbidity.

- Polypharmacy, often associated with psychotropic medication use to control behaviors, should be addressed to minimize adverse side effects.

REFERENCES

CODES

ICD10

- F79 Unspecified intellectual disabilities
- F70 Mild intellectual disabilities
- F71 Moderate intellectual disabilities

CLINICAL PEARLS

- “Mental retardation” is an insensitive and disrespectful term that should not be used. ID or intellectual developmental disorder is preferred.
• Multiple factors (including appropriateness of school placement/special education services, exposure to early intervention, behavioral therapy, parent training, self-esteem, and social skills) influence overall functional ability for individuals with ID.

• Children with developmental disabilities are at higher risk of abuse.

• The diagnosis of ID should be confirmed through psychodiagnostic testing by an appropriately licensed professional.
INTERSTITIAL CYSTITIS
Rebecca R. Yeager, MD • Montiel T. Rosenthal, MD

BASICS

DESCRIPTION
- A condition of pain or discomfort in the bladder associated with a need to urinate frequently and urgently
- A disease of unknown cause, probably representing a final common pathway from several etiologies
- Likely, pathogenesis is disruption of urothelium, impaired lower urinary tract defenses, and loss of bladder muscular wall elasticity. The symptoms in many patients are insidious, and the disease progresses for years before diagnosis is established.
- Newer research implicates urine and serum inflammatory proteins antiproliferative factor, epidermal growth factor, heparin-binding epidermal growth factor, glycosaminoglycans, and bladder nitric oxide as contributing factors.
- Mild: normal bladder capacity under anesthesia; ulceration, cracking, or glomerulation of mucosa (or not) with bladder distention under anesthesia; no incontinence symptoms wax and wane and may not progress. Interstitial cystitis is a bladder sensory problem.
- Severe: progressive bladder fibrosis; small true bladder capacity under anesthesia; poor bladder wall compliance. In 5–10% of cases, Hunner ulcers present at cystoscopy; may have overflow incontinence and/or chronic bacteriuria unresponsive to antibiotics
- System(s) affected: renal/urologic
- Synonym(s): urgency frequency syndrome; IC/bladder pain syndrome (BPS)

Pregnancy Considerations
Unpredictable symptom improvement or exacerbation during pregnancy; no known fetal effects from interstitial cystitis; usual problems of unknown effect on fetus with medications taken during pregnancy

EPIDEMIOLOGY
- Occurs predominantly among whites
Predominant sex: female > male (10:1)
Patients <30 years have predominant symptoms: dysuria, frequency, urinary urgency, pain in external genitals, and dyspareunia, and those >60 years more commonly have nocturia, urinary incontinence, or Hunner ulcer disease.

Predominant age
– Mild: 20 to 40 years
– Severe: 20 to 70 years

Pediatric considerations
– <10 years old and again at 13 to 17 years
– Daytime enuresis, dysuria without infection

**Prevalence**
In the United States:
– Up to 1 million affected, but many cases likely are unreported
– 0.052% but may be higher up to 10%

**ETIOLOGY AND PATHOPHYSIOLOGY**
– Unknown but is not primarily psychosomatic
– Possible causes
  – Subclinical urinary infection
  – Damage to glycosaminoglycan mucus layer increasing bladder wall permeability to irritants such as urea
  – Autoimmune
  – Mast cell histamine release
– Neurologic upregulation/stimulation

**RISK FACTORS**
Unknown

**COMMONLY ASSOCIATED CONDITIONS**
– Fibromyalgia
– Allergies
– Chronic fatigue syndrome
– Depression
– Vulvodynia
– Sexual dysfunction
– Sleep disturbance
– Migraines
- Syncope
- Dyspepsia
- Chronic prostatitis
- Chronic pelvic pain
- Irritable bowel syndrome
- Anal/rectal disease

**DIAGNOSIS**
- Frequent, urgent, relentless urination day and night; >8 voids in 24 hours
- Pain with full bladder that resolves with bladder emptying (except if bacteriuria is present)
- Urge urinary incontinence if bladder capacity is small
- Sleep disturbance
- Dyspareunia, especially with full bladder
- Secondary symptoms from chronic pain and sleeplessness, especially depression

**HISTORY**
- Pelvic Pain and Urgency/Frequency Patient Symptom Scale: self-reporting questionnaire for screening potential interstitial cystitis patients (1)[B] (http://www.wgcaobgyn.com/files/urgency_frequency_pt_symptom_scale.pdf)
- Frequent UTIs, vaginitis, or symptoms during the week before menses

**PHYSICAL EXAM**
- Perineal/prostatic pain in men
- Anterior vaginal wall pain in women

**DIFFERENTIAL DIAGNOSIS**
- Uninhibited bladder (urgency, frequency, urge incontinence, less pain, symptoms usually decrease when asleep)
- Urinary infection: cystitis, prostatitis
- Bladder neoplasm
- Bladder stone
- Neurologic bladder disease
- Nonurinary pelvic disease (STIs, endometriosis, pelvic relaxation)
**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Urinalysis: normal except with chronic bacteriuria (rare)
- Urine culture from catheterized specimen: normal except with chronic bacteriuria (rare) or partial antibiotic treatment
- Urine cytology
  - Normal: reserve for men >40 years old and women with hematuria

**Diagnostic Procedures/Other**
- Cystoscopy (especially in men >40 years old or women with hematuria)
  - Bladder wall visualization
  - *Hydraulic distention: no improved diagnostic certainty over history and physical alone*
  - No role for urodynamic testing
- Intravesical lidocaine can help to pinpoint the bladder as the source of pain in patients with pelvic pain; this can be both diagnostic and therapeutic.
- Potassium sensitivity test
  - *Insert catheter, empty bladder, instill 40 mL H₂O over 2 to 3 minutes, rank urgency on scale of 0 to 5 in intensity, rank pain on scale of 0 to 5 in intensity, drain bladder, instill 40 mL potassium chloride (KCl) 0.4 mol/L solution:*
  - If immediate pain, flush bladder with 60 mL H₂O and treat with bladder instillations.
    - If no immediate pain, wait for 5 minutes and rate the urgency and pain.
- If urgency or pain >2, treat as above.
- Pain or urgency >2 is considered a positive test and strongly correlates with interstitial cystitis if no radiation cystitis or acute bacterial cystitis is present.

**Test Interpretation**
- Nonspecific chronic inflammation on bladder biopsies
- Urine cytology negative for dysplasia and neoplasia
- Possible mast cell proliferation in mucosa

---

**TREATMENT**

**GENERAL MEASURES**
Appropriate health care: outpatient
Self-care (eliminate foods and liquids that exacerbate symptoms on individual basis, fluid management) (2)[C]
Biofeedback bladder retraining (2)[C]

**MEDICATION**
Randomized controlled trials of most medications for interstitial cystitis demonstrate limited benefit over placebo; there are no clear predictors of what will benefit an individual. Prepare the patient that treatment may involve trial and error.

Behavioral therapy combined with oral agents found improved outcomes compared to medications alone.
Intravesical injections of botulinum toxin are not effective in the treatment of ulcer-type interstitial cystitis.

**First Line**
Note: AUA consensus states medicines should be considered second-line therapy after patient education, stress reduction, behavior modification, and self-care (2)[C].
Pentosan polysulfate (Elmiron) 100 mg TID on empty stomach; may take several months (3 to 6) to become effective; rated as modestly beneficial in systematic drug review (only FDA-approved treatment for interstitial cystitis)

Amitriptyline: most effective at higher doses (≥50 mg/day); however, initiate with lower doses to minimize side effects (3)[B].
Hydroxyzine 25 to 50 mg HS
Sildenafil 25 mg/day (4)[B]
Cimetidine 400 mg BID (2)[C]
Triple-drug therapy: 6 months of pentosan, hydroxyzine, doxepin
Antibacterials for bacteriuria
Oxybutynin, hyoscyamine, tolterodine, and other anticholinergic medications decrease frequency.
Prednisone (only for ulcerative lesions)
Montelukast has shown some benefit.
NSAIDs for pain and any inflammatory component
Bladder instillations
– Lidocaine, sodium bicarbonate, and heparin or pentosan polysulfate sodium
– Dimethyl sulfoxide (DMSO) every 1 to 2 weeks for 3 to 6 weeks and then PRN
– Heparin sometimes added to DMSO
– Intravesical liposomes
– Other agents: steroids, silver nitrate, oxychlorosene (Clorpectin)
– Contraindication
– No anticholinergics for patients with close-angle glaucoma
– Significant possible interaction
– Refer to manufacturer’s profile of each drug.

**Second Line**
- Phenazopyridine, a local bladder mucosal anesthetic, usually is not very effective.
- Intravesicular injection of botulinum type A for nonulcer interstitial cystitis
- Cyclosporin A (2)[C]
- Hyaluronic acid instillations (5)[C]
- Chondroitin sulfate instillations (single or in combination with hyaluronic acid) have shown mixed results (5)[C]

**ISSUES FOR REFERRAL**
- Need for clarity with respect to diagnosis
- Surgical intervention

**ADDITIONAL THERAPIES**
Myofascial physical therapy (targeted pelvic, hip girdle, abdominal trigger point massage) (6)[B]

**SURGERY/OTHER PROCEDURES**
- Hydraulic distention of bladder under anesthesia: symptomatic but transient relief
- Cauterization of bladder ulcer
- Augmentation cystoplasty to increase bladder capacity and decrease pressure with or without partial cystectomy. Expected results in severe cases: much improved, 75%; with residual discomfort, 20%; unchanged, 5%
- Urinary diversion with total cystectomy only if disease is completely refractory to medical therapy
- Sacral neuromodulation
- Transurethral electro- or laser fulguration (effective for Hunner lesions). Pain relief may persist from several months to 2 years (5)[C].
COMPLEMENTARY & ALTERNATIVE MEDICINE
Guided imagery

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Not specifically needed unless symptoms are unresponsive to treatment

DIET
• Variable effects from person to person
• Common irritants include caffeine, chocolate, citrus, tomatoes, carbonated beverages, potassium-rich foods, spicy foods, acidic foods, and alcohol.

PATIENT EDUCATION

PROGNOSIS
• Mild: exacerbations and remissions of symptoms; may not be progressive; does not predispose to other diseases
• Severe: progressive problems that usually require surgery to control symptoms

COMPLICATIONS
Severe, with long-term, continuous high bladder pressure could be associated with renal damage.

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

- Urinary Tract Infection (UTI) in Females
- Algorithm: Pelvic Girdle Pain (Pregnancy or Postpartum Pelvic Pain)

**CODES**

**ICD10**

- N30.10 Interstitial cystitis (chronic) without hematuria
- N30.11 Interstitial cystitis (chronic) with hematuria

**CLINICAL PEARLS**

- The potassium sensitivity test has been the most useful in confirming an initial diagnosis of interstitial cystitis.
Potassium sensitivity test

- *Insert catheter, empty bladder, instill 40 mL H\textsubscript{2}O over 2 to 3 minutes; rank urgency on scale of 0 to 5 in intensity; rank pain on scale of 0 to 5 in intensity; drain bladder; and instill 40 mL KCl 0.4 mol/L solution.*
- Submucosal petechial hemorrhages and/or ulceration at the time of bladder distention and cystoscopy further support the diagnosis.

At present, there is no definitive treatment for interstitial cystitis.

Most patients with severe disease receive multiple treatment approaches. Regular multidisciplinary follow-up, pharmacologic therapy, avoidance of symptom triggers, and psychological and supportive therapy are all important because this disease tends to wax and wane. Monitor patients for comorbid depression.

Empowering patients to manage their symptoms, communicate regularly with their physicians, and learn as much as they can about this disease which may help them to optimize their outcome.
INTERSTITIAL NEPHRITIS
Roger P. Holland, MD, PhD

BASICS

DESCRIPTION

- Acute and chronic tubulointerstitial diseases result from the interplay of renal cells and inflammatory cells and their products. Lethal or sublethal injury to renal cells leads to expression of new local antigens, inflammatory cell infiltration, and activation of proinflammatory and chemoattractant cytokines. These cytokines are produced by macrophages and lymphocytes and also by the renal cells (i.e., proximal tubule, vascular endothelial cells, interstitial cells, fibroblasts). The outcome can be acute interstitial nephritis (AIN) or chronic interstitial nephritis (CIN).
- AIN presents as acute kidney injury (AKI) after the use of offending drugs or agents (OFA) and is associated with typical findings of proteinuria, hematuria, and white cell casts. Less frequently, AIN is secondary to infection or systemic diseases (e.g., sarcoidosis, mixed connective tissue disease [MCTD], SLE, Sjögren syndrome).
- System(s) affected: renal/urologic, endocrine/metabolic, immunologic
- Synonym(s): acute interstitial allergic nephritis

EPIDEMIOLOGY

Pediatric Considerations

- Children with history of lead poisoning are more likely to develop CIN as young adults.
- Tubulointerstitial nephritis with uveitis (TINU) presents in adolescent females.

Incidence

- AIN and CIN account for 10–15% of kidney disease.
- Peak incidence in women 60 to 70 years of age

Geriatric Considerations

The elderly (≥65 years) have more severe disease and increased risk of permanent damage due to their increased use of OFA, specifically more drug-
ETIOLOGY AND PATHOPHYSIOLOGY

- **AIN**
  - Delayed drug hypersensitivity reactions
  - Causes AKI
  - Renal dysfunction generally is usually partially or completely reversible, possibly reflecting the regenerative capacity of tubules with a preserved basement membrane.
  - Hypersensitivity to drugs (75%): not dose dependent. The three top drug causes were omeprazole (12%), amoxicillin (8%), and ciprofloxacin (8%) in a recent case series (2)[C].
    - Antibiotics (e.g., penicillins, cephalosporins, sulfonamides, tetracycline, vancomycin, fluoroquinolones, macrolides, TB meds)
    - Proton pump inhibitors
    - Antivirals (indinavir)
    - NSAIDs (all, including Cox-2 inhibitors)
    - Diuretics (thiazide, loop, and triamterene)
    - Miscellaneous (allopurinol, H₂ blockers, diphenylhydantoin, and 5-aminosalicylates such as Azulfidine and mesalamine)
  - Autoimmune disorders (e.g., SLE, Sjögren syndrome, sarcoidosis, Wegener granulomatosis, cryoglobulinemia) (10–15%)
  - Toxins (e.g., snake bite venom)
- **CIN**
  - Follows long-term exposure to OFA (e.g., heavy metals, especially lead)
  - Often found on routine labs or evaluation for hypertension (HTN)
  - Characterized by interstitial scarring, fibrosis, and tubular atrophy, resulting in progressive chronic kidney disease (CKD)

GENERAL PREVENTION

- Early recognition and prompt discontinuation of OFA
- Avoid further nephrotoxic substances.

COMMONLY ASSOCIATED CONDITIONS
CIN
- Chronic pyelonephritis
- Abuse of analgesics
- Lithium use
- Gout and gout therapy
- Immune disorders
- Malignancy (lymphoma, multiple myeloma)
- Amyloidosis
- Exposure to heavy metals (e.g., lead, cadmium)
- Renal papillary necrosis

**DIAGNOSIS**
- AIN: suspected in a patient who presents with nonspecific signs and symptoms of AKI (e.g., malaise, fever, nausea, vomiting) with an elevated serum creatinine and an abnormal urinalysis
  - AKI
    - Elevated creatinine, BUN, and electrolyte abnormalities (e.g., hyperkalemia, low serum bicarbonate)
    - Decreased urine output (oliguria in 51%)
    - Signs of fluid overload or depletion
  - Signs of systemic allergy (e.g., fever [27%], maculopapular rash [15%], peripheral eosinophilia [23%], arthralgias [45%] but less commonly found when NSAIDs are the OFA)
  - White cells, red cells, and white cell casts
- CIN
  - HTN
  - Decreased urine output or polyuria
  - Inability to concentrate urine
  - Polydipsia
  - Metabolic acidosis
  - Anemia
  - Fanconi syndrome

**HISTORY**
- Medications: Onset of AIN following drug exposure ranges from 3 to 5 days (as occurs with a second exposure to an OFA) to as long as several weeks to many months (the latter with NSAIDs, especially) [2][B].
Infections: may have symptoms related to an associated infection or systemic condition
TINU patients present with interstitial nephritis and uveitis and occasionally systemic findings.
Exposure to heavy metals
Postorgan transplant

**PHYSICAL EXAM**
- Increased BP
- Fluid retention/extremity swelling/weight gain
- Rash accompanying renal findings in acute AIN
- Lung crackles if fluid is overloaded
- Pericardial rub if uremic pericarditis

**DIFFERENTIAL DIAGNOSIS**
- AKI secondary to other causes:
  - Prerenal (e.g., hypovolemia, shock, sepsis, renal artery emboli)
  - Intrarenal (e.g., acute tubular injury, hypertensive nephropathy, DM nephropathy)
  - Postrenal (e.g., obstructive uropathy)
  - Some OFA that cause AIN can produce other forms of AKI as well:
    - NSAIDs can exacerbate prerenal disease.
    - Aminoglycosides can cause acute tubular injury.
- CKD secondary to long-standing HTN, diabetes, and chronic pyelonephritis

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Chemistry
  - Elevated plasma creatinine: seen in all patients, with 40% requiring dialysis
  - Hyperkalemia and acidosis
- CBC
  - Eosinophilia (80%): NSAID-induced AIN is only associated with eosinophilia in ~15% of cases.
  - Anemia
- Urinalysis with urine electrolytes
  - Hematuria (95%)
  - Mild and variable proteinuria: usually <1 g/24 hr, except in AIN associated with NSAIDs where it is significantly higher
– Urine sediment: white cells, red cells, white cell casts. Red blood cell casts are rare.
– Eosinophiluria but has no clinical utility specific for AIN (3)[C]
– Fractional excretion of sodium (FE\textsubscript{Na} >1%) indicative of tubular damage
– Normal urinalysis does not rule out AIN.

- CXR to evaluate for pulmonary tuberculosis, sarcoidosis, and other infections
- Serologic testing for immunologic disease (e.g., sarcoidosis, Sjögren syndrome, Wegener granulomatosis, Behçet syndrome) or infectious causes (e.g., histoplasmosis, coccidioidomycosis, toxoplasmosis, EBV)
– Serum levels of angiotensin-converting enzyme and serum Ca\textsuperscript{++} for sarcoidosis
– Antinuclear antibody (ANA) and dsDNA to exclude SLE
– Urinary antigen to exclude Legionella infection
– Anti-Ro/SSA, anti-La/SSB antibodies, CRP, and rheumatoid factor to exclude Sjögren syndrome

- Liver function tests: elevated serum transaminase levels in patients with associated drug-induced liver injury
- Renal US may demonstrate kidneys that are normal to enlarged in size with increased cortical echogenicity, but no US findings will reliably confirm or exclude AIN versus other causes of AKI.
- IV pyelography (IVP) and CT scans with contrast are relatively contraindicated because of the associated nephrotoxicity and limited diagnostic yield.

**Follow-Up Tests & Special Considerations**

Patients who do not recover renal function and those with CIN should receive long-term follow-up care to protect kidneys from further potentially nephrotoxic therapies.

**Diagnostic Procedures/Other**

- Renal biopsy is the definitive method of establishing the diagnosis of AIN. Ideally, it should be performed to:
  – Patients treated with an OFA known to cause AIN but have normal urinalysis
  – Patients who are being considered for steroid therapy
  – Patients who are not on glucocorticoid therapy initially and do not have spontaneous recovery following cessation of the OFA
  – Patients with advanced renal failure of recent onset (<3 months)
– Patients with any features (e.g., high-grade proteinuria) that makes the diagnosis of AIN uncertain

- Contraindications: Renal biopsy is contraindicated in bleeding diathesis, solitary kidney, end-stage renal disease (ESRD) with small kidneys, uncontrolled HTN and sepsis, or renal parenchymal infection.

**Test Interpretation**

- Acute
  – Marked interstitial infiltrate consisting of T lymphocytes and monocytes. Eosinophils, plasma cells, and neutrophils also may be found.
  – In general, the urinary findings will distinguish AIN from other causes (e.g., acute tubular injury, glomerulonephritis).

- Chronic: CIN is characterized by tubular atrophy, fibrosis, and cellular infiltration with mononuclear cells.

**TREATMENT**

For AIN, data on corticosteroids’ efficacy have been limited (4)[B].

**GENERAL MEASURES**

- Discontinue offending agent. If topical NSAIDs are in use, discontinue these as well.
- Reduce exposure to other nephrotoxic agents (e.g., furosemide, aminoglycosides).
- Supportive measures:
  – Maintain adequate hydration.
  – Symptomatic relief for fever, rash, and so forth
  – Control of BP and anemia
  – Correct acidosis and electrolyte imbalances.
  – Possible short-term dialysis until recovery of renal function

**MEDICATION**

- Mainstay of treatment is supportive therapy.
- If patient is taking multiple offending agents, a reasonable clinical approach should include substitution of the suspected drug with another medication.
- If AKI persists after removing the offending agent, attempt medication therapy.
First Line

- Optimal therapy of AIN is unknown because there are no randomized controlled trials (RCTs) or large observational studies.
- Immunosuppressive therapy employed if no subsequent improvement within 3 to 7 days after discontinuation of OFA.
- A renal biopsy is preferred to confirm AIN and to exclude other possible diseases or CIN, where immunosuppressive Rx not indicated.
- Prednisone 1 mg/kg/day PO or equivalent IV dose to a max of 40 to 60 mg/day for 1 to 2 weeks, beginning a gradual taper after serum creatinine has returned to near baseline for a duration of 2 to 3 months, followed by a gradual taper over 3 to 4 weeks (4)[B]. Complete recovery is noted in 49% and partial in 39% (1)[C].
  - Steroids started within 7 days of withdrawal of offending agent more likely to recover function than those who started later (odds ratio [OR] 6.6).

Second Line

- There is limited experience with treating AIN in patients who are steroid dependent (i.e., relapse during prednisone taper), steroid resistant (as with NSAID-induced disease), or cannot tolerate steroids.
- Mycophenolate mofetil may be considered in these patients who have biopsy-proven AIN. Rx may need to be continued for 1 to 3 years.
- Lead toxicity: Chelation may improve function.
  - Succimer 10 mg/kg (max 500 mg) PO q8h for 5 days, then q12h for 14 days, or
  - EDTA 2 g IV/IM; if IM, use with 2% lidocaine.
- SLE nephritis: steroids + cyclophosphamide or azathioprine
- Urate nephropathy: urate-lowering agents
  - Allopurinol starting at 100 mg/day, increasing to 300 mg/day to achieve serum urate level <6 mg/dL
  - Dose may need to be adjusted down depending on level of renal impairment.
  - Allopurinol itself can be a cause of AIN.
  - Discontinue thiazide.
- Lithium-induced nephritis: Use amiloride as adjunct.
- Indinavir-induced nephritis: Use probenecid as adjunct.

ISSUES FOR REFERRAL

Most patients presenting with AKI, proteinuria, and acid-base and/or electrolyte
disorders require consultation with a nephrologist.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Patients with AKI and/or with serious electrolyte or acid-base disorders may require inpatient care until stabilization or resolution.

- Admission criteria/initial stabilization
  - Persistent oliguria or anuria
  - Severe acidosis and/or electrolyte abnormalities
  - ECG changes
- Discharge criteria
  - Stable vitals; correction of all electrolyte imbalances, including magnesium; and resolution of acute ECG changes
  - Normal urine production

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

If patients must remain on nephrotoxic agents, measure renal function, electrolytes, and phosphorus frequently.

**DIET**

- Low potassium (<2 g/day)
- Low sodium
- Low protein

**PATIENT EDUCATION**

Printed materials for patients are available at the National Kidney Disease Education Program, (866) 4-KIDNEY, [http://www.niddk.nih.gov/health-information/health-communication-programs/nkdep/Pages/default.aspx](http://www.niddk.nih.gov/health-information/health-communication-programs/nkdep/Pages/default.aspx).

**PROGNOSIS**

- If the associated AIN is detected early (within 1 week of the rise in serum creatinine) and the offending agent is discontinued promptly, the long-term outcome is favorable for a return to baseline; however, it is often incomplete
with persistent serum creatinine noted in up to 40% of patients, especially in the instance of NSAID-induced AIN.

- Renal biopsy reveals extent of damage.
- AIN
  - Recovery within weeks to months
  - Acute dialysis is needed for 1/3 of patients before resolution.
  - Rarely progresses to ESRD
- CIN: can progress to ESRD
  - Renal disease may remit in 1 year if untreated.
  - TINU has relapsing course, requiring systemic corticosteroids.
- Untreated severe AKI has 45–70% mortality.

COMPLICATIONS

- Chronic tubulointerstitial disease may progress to ESRD, requiring dialysis or transplantation.
- Analgesics increase the risk of transitional cell cancers of the uroepithelium.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- N12 Tubulo-interstitial nephritis, not spcf as acute or chronic
- N10 Acute tubulo-interstitial nephritis
- N11.9 Chronic tubulo-interstitial nephritis, unspecified

CLINICAL PEARLS
- First step in treatment is to remove OFA.
- Most common OFA in elderly is PPIs and antibiotics.
- A renal biopsy is preferred to confirm AIN.
- Immunosuppressive therapy is employed if no subsequent improvement within 3 to 7 days after discontinuation of OFA.
IRRITABLE BOWEL SYNDROME
Mohamed Abdalaziz, MD • Naureen Rafiq, MBBS

BASICS
DESCRIPTION
● A gastrointestinal disorder characterized by
  – Chronic and/or recurrent abdominal pain or discomfort and alteration in bowel habits
● May be characterized as diarrhea-predominant or constipation-predominant; may alternate between
● Synonym(s): spastic colon; irritable colon

EPIDEMIOLOGY
Irritable bowel syndrome (IBS) accounts for up to 50% of visits to gastroenterologists:
● Second only to upper respiratory infection as cause of lost workdays

Prevalence
Pooled estimate of 11% IBS prevalence internationally; ranges from South Asia (7%) to South America (21%) (1)
● Predominant age: 20 to 39 years
● If age >50 years, consider other diagnoses.
● Predominant sex: in the United States, female > male (2:1)
● More common in low socioeconomic communities

ETIOLOGY AND PATHOPHYSIOLOGY
● The etiology is unknown, associated with intestinal motility abnormalities and enhanced sensitivity to visceral stimuli.
● The trigger may be luminal or environmental.
● Evidence for the role of small intestinal bacterial overgrowth (SIBO) in IBS and association with antibiotic therapy is controversial; older age and female gender are predictors of SIBO in IBS patients.

Genetics
Unknown but more common in families of IBS patients
**RISK FACTORS**
- Other family members with similar GI disorder
- History of childhood sexual abuse
- Sexual/domestic abuse (primarily in women)
- Depression
- Gastrointestinal infection

**Pregnancy Considerations**
No risk to mother or fetus

**GENERAL PREVENTION**
See “Diet.”

**COMMONLY ASSOCIATED CONDITIONS**
- Chronic migraine
- Fibromyalgia
- Chronic fatigue syndrome
- Sleep disorders
- Psychiatric disorders: major depression, anxiety, somatoform disorders, and posttraumatic stress
- Chronic pelvic pain
- Temporomandibular joint dysfunction

**DIAGNOSIS**

**HISTORY**
- Rome III criteria: recurrent pain or discomfort in the abdomen at least 3 days per month over the past 3 months associated with at least two other criteria:
  - Symptoms improve with defecation.
  - Onset is associated with a change in stool frequency.
  - Onset is associated with a change in the form or appearance of the stool.
- Symptoms can also include:
  - Mucus in stools
  - Constipation, bloating, diarrhea, abdominal distension
  - Upper abdominal discomfort after eating
  - Straining for normal consistency stools
  - Urgency of defecation
– Feelings of incomplete evacuation
– Abnormal stool form
– Nausea, vomiting (rarely)

• May have history of abuse or depression
• Patient may note worsening of symptoms with stress or around menses.
• IBS is unlikely in patients with a history of:
  – Weight loss
  – Bleeding
  – Nocturnal diarrhea
  – Fever
  – Anemia

PHYSICAL EXAM

• Important to conduct a complete exam to exclude other causes
• Vital signs and general exam are typically normal.
• There is typically an absence of jaundice and organomegaly, but there may be tenderness to palpation.

DIFFERENTIAL DIAGNOSIS

• Inflammatory bowel disease
• Lactose intolerance; fructose malabsorption
• Infections (Giardia lamblia, Entamoeba histolytica, Salmonella, Campylobacter, Yersinia, Clostridium difficile)
• Celiac sprue
• Microscopic colitis
• Laxative abuse
• Magnesium-containing antacids
• Hypo-/hyperthyroidism
• Pancreatic insufficiency
• Depression
• Small bowel bacterial overgrowth
• Somatization
• Villous adenoma
• Endocrine tumors
• Diabetes mellitus
• Radiation damage to colon or small bowel

DIAGNOSTIC TESTS & INTERPRETATION
• With a typical history and no warning signs (anemia or weight loss), obtain baseline labs to rule out other causes and begin treatment.
• In patients who do not respond to treatment, further evaluation with imaging and/or endoscopy is warranted to exclude organic pathology.

**Initial Tests (lab, imaging)**
Rule out pathology specific to the patient’s symptoms:
• Diarrhea-predominant: ESR, CBC, tissue transglutaminase, thyroid-stimulating hormone (TSH), and stool for ova and parasites
• Constipation-predominant: CBC, TSH, electrolytes, calcium (2)
• Abdominal pain: LFTs and amylase
• When obtained, abdominal CT scan and ultrasound are generally normal.
• Consider small bowel series or video capsule endoscopy to rule out Crohn disease (typically normal).
• Sitz marker study may be used to evaluate colonic transit in patients with constipation.

**Follow-Up Tests & Special Considerations**
Consider lactulose breath test to assess for small bowel bacterial overgrowth associated with IBS.

**Diagnostic Procedures/Other**
Sigmoidoscopy/colonoscopy may be used to rule out inflammatory bowel disease or microscopic colitis.

**ALERT**
Screen all persons >50 years for colorectal cancer.

**Test Interpretation**
None

**TREATMENT**
• Goals: Relieve symptoms, improve quality of life (2).
  – Determine if diarrhea-predominant, constipation-predominant, or mixed type.
• Lifestyle modification
- Exercise 3 to 5 times per week decreases severity (2).
- Food diary to determine triggers (2)

**Medications**

- Fiber supplementation (psyllium) increases stool bulk; does not typically relieve abdominal pain; may be used for all types (2)[B]

**Medications that improve abdominal pain, global symptoms, and symptom severity in all types:**
- Antispasmodics such as hyoscyamine 0.125 to 0.250 mg PO/SL q4h PRN and dicyclomine 20 to 40 mg PO BID can be used for all types but have adverse effects such as dry mouth, dizziness, and blurred vision (2).
- Probiotics such as *Lactobacillus, Bifidobacterium*, and *Streptococcus* (3)[C]

**Diarrhea-predominant**
- Antidiarrheal such as loperamide 4 to 8 mg/day orally divided 1 to 3 times per day as needed to decrease stool frequency and increase stool consistency; does not help with abdominal pain; may also use diphenoxylate and atropine (2)
- Antibiotics such as 2-week course of rifaximin improve bloating, pain, and stool consistency (4).
- Alosetron (Lotronex 0.5 mg orally twice a day), for women with severe symptoms; associated with ischemic colitis, constipation, and death in a small number of patients
- Ondansetron was found to reduce symptoms severity other than pain (5).

**Constipation-predominant**
- Laxatives such as polyethylene glycol (MiraLAX) may improve stool frequency but not pain.
- Antibiotics such as neomycin and selective chloride channel activators such as lubiprostone (Amitiza) 8 mg twice a day can improve global symptoms and severity (2)[B].
- Linaclotide (guanylate cyclase 2C agonist) has been shown to improve bowel function and reduces abdominal pain and overall severity in adults only (6).

**Mixed**
- Use medications to match symptoms (2).

**Treat underlying behavioral issues:**
- Tricyclic antidepressants can help control IBS symptoms in moderate to severe cases.
- Behavioral therapy helps reduce symptoms (4).

**ISSUES FOR REFERRAL**
• Behavioral health referral may help with management of affective or personality disorders.
• Gastroenterology referral for difficult to control cases

ADDITIONAL THERAPIES
Probiotics use may result in reducing IBS symptoms and decreasing pain and flatulence. There is no difference among *Lactobacillus*, *Streptococcus*, *Bifidobacterium*, and combinations of probiotics.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

*Patient Monitoring*
The IBS Severity Score is a validated measure to assess the severity of IBS symptoms and can help monitor response to treatment.

• IBS Severity Score:
  – How severe has your abdominal pain been over the last 10 days?
  – On how many of the last 10 days did you get pain?
  – How severe has your abdominal distension (bloating, swollen, or tight) been over the last 10 days?
  – How satisfied have you been with your bowel habit (frequency, ease, etc.) over the last 10 days?
  – How much has your IBS been affecting/interfering with your life in general over the last 10 days?

DIET

• **Low FODMAPs diet:** This diet contains fermentable oligosaccharides, disaccharides, and monosaccharides, and polyols that are carbohydrates (sugars) found in foods. FODMAPs are osmotic, so they may not be digested or absorbed well and could be fermented upon by bacteria in the intestinal tract when *eaten in excess*.

• A low FODMAP diet may help reduce symptoms, which will limit foods high in fructose, lactose, fructans, galactans, and polyols.
  – Increase fiber slowly to avoid excess intestinal gas production.
  – During initial evaluation, consider 2 weeks of lactose-free diet to rule out lactose intolerance.
– Avoid large meals, fatty foods, and caffeine, which can exacerbate symptoms.
– A gluten-free diet resolves symptoms for some patients (especially diarrhea-predominant IBS) despite negative testing for celiac disease.

PATIENT EDUCATION
IBS is not a psychiatric illness.

PROGNOSIS
• IBS is a disorder that reduces quality of life. Many patients have behavioral health issues. IBS does not increase mortality (1).
• Expect recurrences, especially when under stress.
• Evidence suggests that “symptom shifting” occurs in some patients, whereby resolution of functional bowel symptoms is followed by the development of functional symptoms in another system (1).

Algorithm: Diarrhea, Chronic
CODES

ICD10

- K58.9 Irritable bowel syndrome without diarrhea
- K58.0 Irritable bowel syndrome with diarrhea

CLINICAL PEARLS

- Use Rome III criteria to establish the diagnosis of IBS.
- Goals of treatment are to relieve symptoms and improve quality of life.
- If patient does not respond to initial treatment, consider further evaluation (including imaging and/or referral for endoscopy) to exclude organic pathology.
KAWASAKI SYNDROME
Scott P. Grogan, DO, MBA, FAAFP

BASICS
DESCRIPTION
- Kawasaki syndrome (KS) is a self-limited acute, febrile, systemic vasculitis of small- and medium-sized arteries that predominantly affects patients age 6 months to 5 years and is the most prominent cause of acquired coronary artery disease in pediatric populations.
  - Vasculitis of coronary arteries resulting in aneurysms/ectasia, further leading to myocardial infarction (MI)/ischemia or sudden death
- System(s) affected: cardiovascular, gastrointestinal, hematologic/lymphatic/immunologic, musculoskeletal, nervous, pulmonary, renal/urologic, skin/exocrine
- Synonym(s): mucocutaneous lymph node syndrome (MCLS), infantile polyarteritis, Kawasaki disease

ALERT
KS should be considered in any child with extended high fever unresponsive to antibiotics or antipyretics, rash, and nonexudative conjunctivitis.

EPIDEMIOLOGY
Incidence
- Worldwide: affects all races but most prevalent in Asia; Japan annual incidence rate 265/100,000 in children <5 years of age
- In the United States, the annual incidence in children <5 years is 19/100,000. In comparison to Caucasians, African Americans have a 1.5 times risk, and Asian Americans have a 2.5 times increased risk. Highest state incidence is in Hawaii.
- Leading cause of acquired heart disease in children in developed countries
  - Predominant age: 1 to 5 years
  - 85% of cases are children <5 years of age and 50% <2 years of age.
  - Male-to-female ratio = 1.5:1

Prevalence
- Highest to lowest prevalence: Asians > African Americans > Hispanics > Caucasians
- Seasonal variation: increased in winter and early spring in temperate places, summer in Asia, and outbreaks at 2- to 3-year intervals

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Acute KS causes a necrotizing arteritis in the smooth muscle layer of medium extraparenchymal arteries that destroys arterial walls into the adventitia, especially in coronary arteries.
- Inflammatory cells in the media secrete cytokines (TNF-α), interleukins 1 and 6, and matrix metalloproteases that cause fragmentation of the internal elastic lamina.
- A prominence of IgA plasma cells and IgA deposits are characteristic features and may be found in the lungs.
- As the acute process resolves, active neutrophilic inflammatory cells are succeeded by a subacute/chronic, lymphocytic vasculitis; fibroblasts and monocytes cause tissue repair/remodeling that may cause vascular fibrosis and stenosis.
- Unknown; believed to be an exaggerated immune response to infectious agent due to the acute, self-limited nature; community-wide outbreaks; age distribution; seasonality; and laboratory features indicating respiratory route of entry

**Genetics**
- Siblings of patients in Japan have a 10- to 30-fold increased risk, and >50% develop KS within 10 days of first case; increased occurrence of KS in children whose parents also had illness in childhood
- Populations at higher risk and family link suggest a genetic predisposition.
- Single-nucleotide polymorphisms in six different genes have been implicated in KS (Fcγ receptor 2A, CASP3, HLA class II, B-cell lymphoid kinase, IPTKC, CD40).
- Coronary aneurisms are associated with variants in TGF-β signaling pathways.

**GENERAL PREVENTION**
No preventive measures available
**DIAGNOSIS**

≥5 days of fever and ≥4 of the following 5 principal clinical features; or <4 features and presence of coronary artery disease on 2D echocardiography:

- Bilateral conjunctival injection with limbic sparing
- Erythematous mouth and pharynx, tongue, and lips
- A polymorphous, generalized, erythematous rash
- Changes in the skin of the peripheral extremities
- Cervical lymphadenopathy

**Pediatric Considerations**

- Prolonged fever without rash and treated with antibiotics may cause clinicians to believe that later rash development is due to a drug reaction.
- Can be diagnosed on day 4 of illness if ≥4 principal features are present
- Incomplete KS
  - ≥5 days of fever, 2 to 3 principal clinical features, labs indicating systemic inflammation, and exclusion of other diseases
  - Incomplete cases that exhibit <4 clinical criteria often occur in infants ≤6 months of age or older children/adolescents. The frequency of coronary artery aneurysms (CAAs) is often higher in patients with missed diagnosis/delayed treatment. Therefore, in infants with prolonged fever and few or no clinical features, consider echocardiography and inflammatory labs.

**HISTORY**

- Fever is the first sign during the acute phase.
- Symptoms may not occur all at once but usually occur in close proximity.

**PHYSICAL EXAM**

- High-spiking and remittent fever for ≥5 days
  - Fever is high (102–105°F [39.4–40.5°C]) and unresponsive to antibiotics.
  - May be prolonged up to 3 to 4 weeks
  - Extreme irritability is a very common feature.
- Bilateral, painless, nonpurulent, conjunctival injection without corneal ulceration or edema. Limbic sparing is usually seen.
- Changes in lips and oral cavity
  - Redness and swelling of lips in the acute stage; cracking, fissuring, bleeding in subacute phase
– Strawberry/erythematous tongue

● Extensive erythematous polymorphous rash: within 5 days of fever
  – Morbilliform is most common. May be maculopapular, scarlatiniform; can resemble erythema multiforme, erythroderma, urticarial exanthem; rarely micropustular
  – Perineal desquamation, especially in skin folds

● Extremity changes
  – Reddened palms and soles on days 3 to 5
  – Edema of hands and feet on days 4 to 7; painful induration
  – Desquamation of fingers and toes that begins in periungual area at 2 to 3 weeks

● Acute, unilateral cervical lymphadenopathy (least common symptom)
  – ≥1 lymph nodes >1.5 cm, firm, nonfluctuant, and usually with no to slight tenderness

● Cardiac exam: tachycardia, gallop rhythms, hyperdynamic precordium, innocent flow murmurs, depressed contractility

● Other organ system involvement
  – Cardiovascular: myocarditis; pericarditis (often subclinical), CAAs, and other medium-sized arterial aneurysms
  – Gastrointestinal: anorexia, abdominal pain, vomiting/diarrhea, acute gallbladder hydrops, hepatic enlargement, jaundice
  – Renal: proteinuria, sterile pyuria
  – Joints: polyarthritis of small joints in acute phase; weight-bearing joints affected after 10th day from onset of fever
  – Neurologic: irritability, aseptic meningitis, peripheral neuropathy (unilateral facial palsy), transient high-frequency hearing loss

DIFFERENTIAL DIAGNOSIS

● Bacterial: staphylococcal scalded-skin syndrome, toxic shock syndrome, scarlet fever, bacterial cervical lymphadenitis, *Mycoplasma* infection, leptospirosis, Lyme disease, Rocky Mountain spotted fever

● Viral: measles, adenovirus, Epstein-Barr virus

● Toxoplasmosis

● Reiter syndrome

● Hypersensitivity drug reactions (erythema multiforme minor, Stevens-Johnson syndrome)

● Juvenile rheumatoid arthritis

● Acrodynia (mercury poisoning)
DIAGNOSTIC TESTS & INTERPRETATION
- Initial workup: CBC with differential, urinalysis (UA)/culture, blood culture; lumbar puncture if signs of meningitis or if <90 days old
  - Leukocytosis (12,000 to 40,000 cells/mm$^3$) with immature and mature granulocytes
  - Anemia: normochromic, normocytic
  - Thrombocytosis (500,000 to >1,000,000/mm$^3$) in 2nd and 3rd week. Thrombocytopenia during acute phase is associated with CAA and MI.
- Elevated C-reactive protein (CRP) (>35 mg/L in 80% cases), erythrocyte sedimentation rate (ESR) (>60 mm/hr in 60% cases), and $\alpha_1$-antitrypsin
- Normal ESR, CRP, and PLTs after day 7 suggest diagnosis other than KS.

**ALERT**
ESR can be artificially high after intravenous immunoglobulin (IVIG) therapy.

- Hyponatremia
- Moderately elevated AST, ALT, GGT, and bilirubin
- Decreased albumin and protein
- CSF pleocytosis may be seen (lymphocytic with normal protein and glucose).
- N-terminal brain natriuretic peptide might be elevated in acute phase, but definitive cut-off values have not been established.
- Sterile pyuria but not seen in suprapubic collection
- Nasal swab to rule out adenovirus

**Initial Tests (lab, imaging)**
- If KS is suspected, obtain ECG and echocardiogram.
  - ECG may show arrhythmias, prolonged PR interval, and ST/T wave changes.
  - Echocardiography has a high sensitivity and specificity for detection of abnormalities of proximal left main coronary artery, and right coronary artery may show perivascular brightening, ectasia, decreased left ventricular contractility, pericardial effusion, or aneurysms.
  - Repeat echocardiography frequency determined by degree of abnormal; more significant findings should be followed twice weekly until aneurismal progression halts.
  - Cardiac stress test if CAA seen on echocardiogram
- Baseline chest x-ray (CXR): may show pleural effusion, atelectasis, and congestive heart failure (CHF)
Hydrops of the gallbladder may be associated with abdominal pain or may be asymptomatic.

**Diagnostic Procedures/Other**
- No laboratory study is diagnostic; diagnosis rests on constellation of clinical features and exclusion of other illnesses.
- Magnetic resonance coronary angiography is noninvasive modality to visualize coronary arteries for stenosis, thrombi, and intimal thickening (1).
- Patients with complex coronary artery lesions may benefit from coronary angiography after the acute inflammatory process has resolved; generally recommended in 6 to 12 months

---

**TREATMENT**

**GENERAL MEASURES**
Use antibiotics until bacterial etiologies are excluded (e.g., sepsis or meningitis).

**MEDICATION**
- Optimal therapy is IVIG 2 g/kg IV over 10 to 12 hours with high-dose aspirin preferably within 7 to 10 days of fever, followed by low-dose aspirin until follow-up echocardiograms indicate a lack of coronary abnormalities.
  - IVIG lowers the risk of CAA and may shorten fever duration.
  - The extreme irritability often resolves very quickly after IVIG is given.
- Retreatment with IVIG if clinical response is incomplete or fever persists/returns >36 hours after start of IVIG treatment
  - ≥10% of patients do not respond to initial IVIG treatment. 2/3 of nonresponders respond to the 2nd dose of IVIG.
  - Nonresponders tend to have ↑ bands, ↓ albumin, and an abnormal echo.
- Aspirin, 80 to 100 mg/kg/day in 4 doses beginning with IVIG administration. Switch to low-dose aspirin (3 to 5 mg/kg/day) when afebrile for 48 to 72 hours, or continue until day 14 of illness. Maintain low dose for 6 to 8 weeks until follow-up echocardiogram is normal and CRP and/or ESR are normal. Continue salicylate regimen in children with coronary abnormalities, long term or until documented regression of aneurysm (2)[C].
- Aspirin does not appear to reduce CAA (3)[B].
- Corticosteroids have conflicting evidence for use and:
  - Should not be used as first-line agent in all KS patients (1)[B]
– Should be used in conjunction with IVIG and ASA as initial treatment to decrease risk of CAAs in those at highest risk of IVIG failure (4)[A]

- **Contraindications**
  - IVIG: documented hypersensitivity, IgA deficiency, anti-IgE/IgG antibodies, severe thrombocytopenia, coagulation disorders
  - Aspirin: vitamin K deficiency, bleeding disorders, liver damage, documented hypersensitivity, hypoprothrombinemia

- **Precautions**
  - No statistically significant difference is noted between different preparations of IVIG.
  - High-dose aspirin therapy can result in tinnitus, decrease of renal function, and increased transaminases.
  - Do not use ibuprofen in children with CAAs who are taking aspirin for antiplatelet effects.
  - Significant possible interactions: Aspirin therapy has been associated with Reye syndrome in children who develop viral infections, especially influenza B and varicella. Yearly influenza vaccination thus is recommended for children requiring long-term treatment with aspirin. Delay any live vaccines for 11 months after IVIG treatment.

**Second Line**

- In patients refractory to IVIG and steroids, consider infliximab or cyclosporine (5)[B].
- Plasma exchange may decrease likelihood of CAA in IVIG nonresponders (6) [B].

**ISSUES FOR REFERRAL**

Pediatric cardiologist if abnormalities on echo or if extensive stenosis

**ADDITIONAL THERAPIES**

- Treatment and prevention of thrombosis are crucial.
- Antiplatelet agents (clopidogrel, dipyridamole), heparin, low-molecular-weight heparin, or warfarin are sometimes added to the low-dose aspirin regimen, depending on severity of CAAs.
- Clarithromycin given with IVIG may reduce relapse rates and length of hospital stay.

**SURGERY/OTHER PROCEDURES**
Rarely needed; coronary artery bypass grafting for severe obstruction/recurrent MI. Younger patients have a higher mortality rate.

Coronary revascularization via percutaneous coronary intervention for patients with evidence of ischemia on stress testing.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Normal saline (NS) for rehydration and 1/2 NS for maintenance
- Discharge if afebrile after IVIG treatment for 24 hours.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

With aneurysms, contact and high-risk sports should be avoided.

**Patient Monitoring**

- Repeat ECG and echocardiogram at 6 to 8 weeks. If abnormal, repeat at 6 to 12 months.
- Patients with complex coronary artery lesions may benefit from coronary angiography at 6 to 12 months.

**PROGNOSIS**

- Usually self-limited
- Moderate-sized aneurysms usually regress in 1 to 2 years, resolving in 50–66% of cases.
- Recurrence (3% in Japan, <1% in the United States)
- Sudden death in early adulthood (rare)

**COMPLICATIONS**

- 15–25% of untreated patients develop CAAs in convalescent phase.
- 2–7% of treated patients develop aneurysms. 1% develop giant aneurysms.
- Risk factors for aneurysm
  - Male, <1 year of age, ↑ ESR >4 weeks, fever >2 weeks, fever >48 hours after IVIG treatment
- Mortality of 0.08–0.17% is due to cardiac disease.
REFERENCES

ADDITIONAL READING

CODES

ICD10
M30.3 Mucocutaneous lymph node syndrome [Kawasaki]

CLINICAL PEARLS

- The diagnosis of KS rests on a constellation of clinical features.
- Once KS is suspected, all patients need an inpatient cardiac evaluation, including ECG and echocardiogram.
- Expert recommendation for optimal therapy is IVIG 2 g/kg IV over 10 hours, with high-dose aspirin 80 to 100 mg/kg/day in 4 doses.
KERATOACANTHOMA

Patrick M. Zito, DO, PharmD, RPh, FASCP, FRSPH • Kenneth Beer, MD

BASICS

DESCRIPTION

- Most common is a solitary, rapidly proliferating, dome-shaped, erythematous or flesh-colored papule or nodule with a central keratinous plug, typically reaching 1 to 2 cm in diameter.
- Clinically and microscopically resemble squamous cell carcinoma (SCC)
- Other presentations include grouped, multiple, keratoacanthoma (KA) centrifugum marginatum, intraoral, subungual, regressing, nonregressing, generally eruptive (1).
- Majority are benign and resolve spontaneously, but lesions do have the potential for invasion and metastasis, therefore require treatment.
- Three clinical stages of KAs (1):
  - Proliferative: rapid growth of the lesion over weeks to several months
  - Maturation/stabilization: Lesion stabilizes and growth subsides.
  - Involution: spontaneous resolution of the lesion, leaving a hypopigmented, depressed scar; most but not all lesions will enter this stage.
- System(s) affected: integumentary

EPIDEMIOLOGY

- Greatest incidence age >50 years but may occur at any age
- Presentation increased during summer and early fall seasons
- Most frequently on sun-exposed, hair-bearing skin but may occur anywhere
- Predominant sex: male > female (2:1)
- Most commonly in fair-skinned individuals; highest rates in Fitzpatrick I to III
- 104 cases per 100,000 individuals

ETIOLOGY AND PATHOPHYSIOLOGY

- Derived from an abnormality causing hyperkeratosis within the follicular infundibulum
- Squamous epithelial cells proliferate to extend upward around the keratin plug and proceed downward into the dermis; followed by invasion of elastic and
collagen fibers
- Cellular mechanism responsible for the hyperkeratosis is currently unknown; role of human papillomavirus (HPV) has been discussed but has no established causality (2).
- Regression may be due to immune cytotoxicity or terminal differentiation of keratinocytes.
- Multiple etiologies have been suggested:
  - UV radiation
  - May be provoked by surgery, cryotherapy, chemical peels, or laser therapy
  - Viral infections: HPV or Merkel cell polyomavirus
  - Genetic predisposition: Muir-Torre syndrome, xeroderma pigmentosum, Ferguson-Smith syndrome
  - Immunosuppression
  - BRAF inhibitors (1)
  - Chemical carcinogen exposure

**Genetics**
- Mutation of p53 or H-ras
- Ferguson-Smith (AD)
- Witten-Zak (AD)
- Muir-Torre (AD)
- Xeroderma pigmentosum (AR)
- Gzybowski (sporadic)
- Incontinentia pigmenti (XLD)

**RISK FACTORS**
- UV exposure/damage: outdoor and/or indoor tanning
- Fitzpatrick skin type I to III
- Trauma (typically appears within 1 month of injury): laser resurfacing, surgery, cryotherapy, tattoos
- Chemical carcinogens: tar, pitch, and smoking
- Immunocompromised state
- Discoid lupus erythematosus
- HPV infection

**GENERAL PREVENTION**
Sun protection
COMMONLY ASSOCIATED CONDITIONS

- Frequently, the patient has concurrent sun-damaged skin: solar elastosis, solar lentigines, actinic keratosis, nonmelanoma skin cancers (basal cell carcinoma, SCC).
- In Muir-Torre syndrome, KAs are found with coexisting sebaceous neoplasms and malignancy of the GI and GU tracts; may have sebaceous differentiation known as a seboacanthoma

DIAGNOSIS

HISTORY

- Lesion begins as a small, solitary, pink macule that undergoes a rapid growth phase; classically reaching a diameter of 1 to 2 cm; size may vary.
- Once the proliferative stage has subsided, lesion size remains stable.
- May decrease in size, indicating regression
- Asymptomatic, occasionally tender
- If multiple lesions present, important to elicit a family history and recent therapies or treatments
- If sebaceous neoplasms present, must review history for signs/symptoms of GI or GU malignancies

PHYSICAL EXAM

- Firm, solitary, erythematous or flesh-colored, dome-shaped papule or nodule with a central keratin plug, giving a crateriform appearance
- Surrounding skin and borders of lesion may show telangiectasia, atrophy, or dyspigmentation.
- Usually solitary; multiple lesions can occur.
- Most commonly seen on sun-exposed areas: face, neck, scalp, dorsum of upper extremities, and posterior legs
- May also be seen on areas without sun exposure: buttocks, anus, subungual, mucosal surfaces
- Subungual KAs are very painful and seen on the first 3 digits of the hands.
- Examine for regional lymphadenopathy due to chance of lesion invasion and metastasis.
- Dermoscopy (3)
  - Central keratin highest sensitivity to distinguish from SCC (4)
  - White circles, blood spots; white circles highest specificity (4)
– Cannot reliably distinguish between KA and SCC

**DIFFERENTIAL DIAGNOSIS**

- SCC
- Nodular or ulcerative basal cell carcinoma
- Cutaneous horn
- Hypertrophic actinic keratosis
- Amelanotic melanoma
- Merkel cell carcinoma
- Metastasis to the skin
- Molluscum contagiosum
- Prurigo nodularis
- Verruca vulgaris
- Verrucous carcinoma
- Sebaceous adenoma
- Hypertrophic lichen planus
- Hypertrophic lupus erythematosus
- Deep fungal infection
- Atypical mycobacterial infection
- Nodular Kaposi sarcoma

**DIAGNOSTIC TESTS & INTERPRETATION**

- Excisional biopsy, including the center of the lesion as well as the margin, is the best diagnostic test (2)[C].
- A shave biopsy may be insufficiently deep to distinguish KA from an SCC.
- If unable to perform an excisional biopsy, a deep shave (saucerization) of the entire lesion, extending into the subcutaneous fat, can be done.
- Punch biopsies should be avoided because they give an insufficient amount of tissue to represent the entire lesion.

**Initial Tests (lab, imaging)**

- Subungual KA: radiograph of the digit to monitor for osteolysis (cup-shaped radiolucent defect)
- Aggressive tumors may need CT with contrast for evaluation of lymph nodes and MRI if there is concern of perineural invasion.
- Most lesions do not need any form of imaging.

**Test Interpretation**
Pathology of biopsy: a well-demarcated central core of keratin surrounded by well-differentiated, mildly pleomorphic, atypical squamous epithelial cells with a characteristic glassy eosinophilic cytoplasm

Histopathology: keratin-filled crater encompassed with epithelial lips
May see elastic and collagen fibers invading into the squamous epithelium

Histologic differentiation of a KA from an SCC may be difficult and unreliable, although immunochemical staining for cellular protein Ki-67 may help do this (4).

KAs have a greater tendency than SCC to display fibrosis and intraepidermal abscesses of neutrophils and eosinophils.

Regressing KA shows flattening and fibrosis at base of lesion.

TREATMENT

Treatment of choice is an excisional procedure plus electrodessication and curettage (ED&C); however, there are many treatment options available (2) [C].
Aggressive tumors (>2 cm) or lesions in cosmetically sensitive areas (face, digits, genitalia) that require tissue sparing, consider Mohs micrographic surgery
– Mohs is the treatment of choice in cases with perineural or perivascular invasion.

Small lesions (<2 cm) of the extremities may undergo ED&C.

Immunocompromised patients should receive immediate surgical treatment.

MEDICATION

Nonsurgical management is a viable and relatively cost-effective option in these select cases not amenable to surgery due to lesion number, size, or location; also for patients with multiple comorbidities who are unwilling or unable to withstand surgery

Evidence for the following treatments based on case reports and retrospective reviews:
– Intralesional methotrexate 12.5 to 25.0 mg in 0.5 mL normal saline every 2 to 3 weeks for 1 to 4 treatment sessions (5) [B]
  o Monitor for pancytopenia with complete blood count (5) [C].
– 5% imiquimod cream 3 times per week for 11 to 13 weeks (5) [B]
– Topical 5% 5-fluorouracil cream daily, 61–92% cure rate (5) [B]
– Intralesional 5-fluorouracil of 50 mg/mL on a weekly basis for 3 to 8
treatment sessions—98% cure rate (5)[B]
- Intralesional IFN α-2a or α-2b (83%, 100% cure rate, respectively) (5)[B]
- Intralesional bleomycin—100% cure rate (5)[B]
- Isotretinoin oral 0.5 to 1.0 mg/kg/day

ISSUES FOR REFERRAL
Dermatology referral if lesions are >2 cm, numerous, mucosal, or subungual

ADDITIONAL THERAPIES
- Photodynamic therapy with methyl aminolevulinic acid and red light, successful case reports (1)[B] but also reported aggravation following treatment
- Cryotherapy (1)
- Argon or YAG lasers
- Radiotherapy, primary or adjuvant: KAs may regress with low doses of radiation but may require doses up to 25 to 50 Gy in low-dose (5 to 10 Gy) fractions for possible SCC (1)[B].
- Erlotinib (EGFR inhibitor) 150 mg daily for 21 days, single case report (1)[B]

SURGERY/OTHER PROCEDURES
Excisional and office-based procedures as discussed above

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
After the surgical site has healed or lesion has resolved, patient should be seen every 6 months due to increased risk of developing new lesions or skin cancers, annually at minimum (3)[C].

Patient Monitoring
- Skin self-exams should be routinely performed with detailed instructions (see “Additional Reading”).
- If multiple KAs are present in patient or family members, evaluate for Muir-Torre syndrome and obtain a colonoscopy beginning at age 25 years, as well as testing for genitourinary cancer (3)[C].

PATIENT EDUCATION
• Sun protection measures: sun block with SPF >30, wide-brimmed hats, long sleeves, dark clothing, avoiding indoor tanning
• Arc welding may produce harmful UV radiation and skin should not be exposed.
• Tar, pitch, and smoking should be avoided.

PROGNOSIS
• Atrophic scarring and hypopigmentation can occur with self-resolution but may be significantly reduced by intervention.
• 52 of 445 cases (12%) spontaneously regressed without treatment and none of these recurred (2).
• 393 (88%) regressed following medical or excisional treatment (2).
• 445 cases reported with no metastases or deaths attributable to the KA (2)
• 4–8% recurrence
• Mucosal and subungual lesions do not regress; must undergo treatment

SEE ALSO
Squamous Cell Carcinoma, Cutaneous

CODES
ICD10
- D23.9 Other benign neoplasm of skin, unspecified
- D48.5 Neoplasm of uncertain behavior of skin
- L85.8 Other specified epidermal thickening

CLINICAL PEARLS
- Suspect KA with a solitary, dome-shaped, erythematous or flesh-colored papule or nodule with a central keratinous plug.
- If KA is in the differential diagnosis, elicit time frame of onset during patient encounter; rapid onset supports diagnosis.
- Due to the broad differential diagnosis of a suspected KA and unreliable clinical differentiation between these, strongly consider surgical excision as first-line diagnostic test and therapy.
- Medical and radiation therapies are reasonable and effective options available for patients who are not surgical candidates or for lesions that are not amenable for surgery.
KERATOSIS, ACTINIC

Zoltan Trizna, MD, PhD

**BASICS**

**DESCRIPTION**

- Common, usually multiple, premalignant lesions of sun-exposed areas of the skin. Many resolve spontaneously, and a small proportion progresses to squamous cell carcinoma (SCC).
- Common consequence of excessive cumulative ultraviolet (UV) light exposure
- Synonym(s): solar keratosis

**Geriatric Considerations**

Frequent problem

**Pediatric Considerations**

Rare (if child, look for freckling and other stigmata of xeroderma pigmentosum)

**EPIDEMIOLOGY**

**Incidence**

- Rates vary with age group and exposure to sun.
- Predominant age: ≥40 years; progressively increases with age
- Predominant sex: male > female
- Common in those with blonde and red hair; rare in darker skin types

**Prevalence**

- Age-adjusted prevalence rate for actinic keratoses (AKs) in U.S. Caucasians is 6.5%.
- For 65- to 74-year-old males with high sun exposure: ~55%; low sun exposure: ~18%

**ETIOLOGY AND PATHOPHYSIOLOGY**

- The epidermal lesions are characterized by atypical keratinocytes at the basal layer with occasional extension upward. Mitoses are present. The histopathologic features resemble those of SCC in situ or SCC, and the
distinction depends on the extent of epidermal involvement.

- Cumulative UV exposure

**Genetics**
The p53 chromosomal mutation has been shown consistently in both AKs and SCCs. Many new genes have been shown recently to have similar expression profiles in AKs and SCCs.

**RISK FACTORS**
- Exposure to UV light (especially long-term and/or repeated exposure due to outdoor occupation or recreational activities, indoor or outdoor tanning)
- Skin type: burns easily, does not tan
- Immunosuppression, especially organ transplantation

**GENERAL PREVENTION**
Sun avoidance and protective techniques are helpful.

**COMMONLY ASSOCIATED CONDITIONS**
- SCC
- Other features of chronic solar damage: lentigines, elastosis, and telangiectasias

**DIAGNOSIS**

**HISTORY**
- The lesions are frequently asymptomatic; symptoms may include pruritus, burning, and mild hyperesthesia.
- Lesions may enlarge, thicken, or become more scaly. They also may regress or remain unchanged.
- Most lesions occur on the sun-exposed areas (head and neck, hands, forearms).

**PHYSICAL EXAM**
- Usually small (<1 cm), often multiple red, pink, or brown macules, papules, or plaques that are rough to palpation
- Yellow or brown adherent scale is often present on top of the lesion.
- Several clinical variants exist.
- Atrophic: dry, scaly macules with indistinct borders and an erythematous base
- Hypertrophic: Overlying hyperkeratosis (in an extreme form, cutaneous horn) may be impossible to differentiate from SCC clinically.
- Pigmented: smooth tan/brown plaque, spreading centrifugally
- Bowenoid: red scaly plaques with distinct borders
- Actinic cheilitis: inflammatory lesion involving usually the lower lip

**DIFFERENTIAL DIAGNOSIS**

- SCC (hypertrophic type)
- Keratoacanthoma
- Bowen disease
- Basal cell carcinoma
- Verruca vulgaris
- Less likely: verrucous nevi, warty dyskeratoma, lichenoid keratoses, seborrheic keratoses, porokeratosis, seborrheic dermatitis or psoriasis (near hairline), lentigo maligna, solar lentigo, discoid lupus erythematosus

**DIAGNOSTIC TESTS & INTERPRETATION**

**Diagnostic Procedures/Other**

- The diagnosis is usually made clinically, except where there is a suspicion of carcinoma.
- Skin biopsy is especially recommended if large, ulcerated, indurated, or bleeding; or if the lesions are nonresponsive to treatment.

**Test Interpretation**

- Dysplastic keratinocytes in lower levels of epidermis with a dermal lymphocytic infiltrate
- Neoplastic cells, mostly found in the lower epidermal layers, are cytologically identical to those of SCCs.
- If neoplastic cells extend throughout entire epidermis or into the dermis, the lesions will qualify as an SCC in situ or invasive SCC, respectively.
- Malignant cells are sparse except of the Bowenoid variety.
- Hypertrophic, atrophic, Bowenoid, acantholytic, and pigmented varieties show the corresponding epidermal findings.
TREATMENT

First-line treatment is cryotherapy (technically, this is considered surgery, especially by insurance companies) (1,2)[A]. Medical therapy is usually reserved for extensive AKs (“field therapy”).

GENERAL MEASURES

- Sun-protective techniques
- Sunscreens and physical sun protection recommended

MEDICATION

First Line

- Topical treatments target both visible and subclinical lesions.
- With the exception of generic 5-fluorouracil, medication cost is high ($600 to $1,200 per course).
- Topical fluorouracil (Efudex, Carac, Fluoroplex cream, Fluoroplex solution)
  - Every day—BID for 3 to 6 weeks, depending on the brand, concentration, and formulation
  - Can be very irritating
  - May be most effective of the topical treatments listed in this section (3)[A]
- Topical imiquimod (Aldara) 5% cream
  - Apply 2 days per week at HS for up to 16 weeks to an area not larger than the forehead or one cheek.
  - Can be irritating
- Topical imiquimod (Zyclara) 3.75% cream
  - Apply once a day for 2 weeks, followed by no treatment for the next 2 weeks; then apply once a day for another 2 weeks.
  - Can be irritating
- Topical ingenol mebutate (Picato) 0.015% and 0.05% gel
  - Apply to the face and scalp once a day for 3 consecutive days.
  - Apply to the trunk and extremities once a day for 2 consecutive days.
    - It should only be used on one contiguous skin area of not >25 cm².
    - Cases of severe allergic reactions (including anaphylaxis) and herpes zoster reactivation unrelated to application errors have been reported.
- Diclofenac (Solaraze) 3% gel
  - Apply BID for 60 to 90 days.
Second Line
- Topical tretinoin (Retin-A) or tazarotene (Tazorac): may be used to enhance the efficacy of topical fluorouracil
- Systemic retinoids: used infrequently

ADDITIONAL THERAPIES
Close monitoring with no treatment is an appropriate option for mild lesions.

SURGERY/OTHER PROCEDURES
- Cryosurgery ("freezing," liquid nitrogen)
  - Most common method for treating AK
  - Cure rate: 75–98.8%
  - May cause atrophy and hypopigmentation
  - May be superior to photodynamic therapy for thicker lesions
- Photodynamic therapy with a photosensitizer (e.g., aminolevulinic acid) and "blue light"
  - May clear >90% of AKs
  - Less scarring than cryotherapy
  - May be superior to cryotherapy, especially in the case of more extensive skin involvement
- Curettage and electrocautery (electrodesiccation and curettage [ED&C]; "scraping and burning")
- Medium-depth peels, especially for the treatment of extensive areas
- CO2 laser therapy
- Dermabrasion
- Surgical excision (excisional biopsy)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Depends on associated malignancy and frequency with which new AKs appear

PATIENT EDUCATION
- Teach sun-protective techniques.
  - Limit outdoor activities between 10 AM and 4 PM.
– Wear protective clothing and wide-brimmed hat.
– Proper use (including reapplication) of sunscreens with SPF >30, preferably a preparation with broad-spectrum (UV-A and UV-B) protection
• Teach self-examination of skin (melanoma, squamous cell, basal cell).
• Patient education materials
  – www.skincarephysicians.com/actinickeratosesnet/index.html
  – www.skincancer.org/Actinic-Keratosis-and-Other-Precancers.htm

PROGNOSIS
Very good. A significant proportion of the lesions may resolve spontaneously (4), with regression rates of 20–30% per lesion per year.

COMPLICATIONS
• AKs are premalignant lesions that may progress to SCCs. The rate of malignant transformation is unclear; the reported percentages vary (4) but range from 0.1% to a few percent per year per lesion.
• Patients with AKs are at increased risk for other cutaneous malignancies.
• Approximately 60% of SCCs arise from an AK precursor.

REFERENCES

ADDITIONAL READING
• Kanellou P, Zaravinos A, Zioga M, et al. Genomic instability, mutations and

**CODES**

**ICD10**

L57.0 Actinic keratosis

**CLINICAL PEARLS**

- AKs are premalignant lesions.
- Often more easily felt than seen
- Therapy-resistant lesions should be biopsied, especially on the face.
KERATOSIS, SEBORRHEIC

Christopher J. Weber, MD • Cesar R. Mojica Vazquez, MD

BASICS

DESCRIPTION

- Common benign tumor of the epidermis
- Formed from keratinocytes
- Frequently appears in multiples on the head, neck, and trunk of older individuals but may occur on any hair-bearing area of the body. Lesions spare the palms and soles.
- Typically can present as multiple, well circumscribed, yellow to brown raised lesions that feel greasy, velvety, or warty usually described as having “stuck-on” appearance
- Clinical variants include the following:
  - Common seborrheic keratosis
  - Dermatosis papulosa nigra
  - Stucco keratosis
  - Flat seborrheic keratosis
  - Pedunculated seborrheic keratosis
- System(s) affected: integumentary
- Synonym(s): SK, verruca seborrhoica; seborrheic wart; senile wart; basal cell papilloma; verruca senilis; basal cell acanthoma; benign acanthokeratoma; barnacles of aging

EPIDEMIOLOGY

Incidence

- Predominant age
  - Rarely seen before 30 years
- Predominant sex: slightly more common and more extensive involvement in males
- Most common among Caucasians, except for the dermatosis papulosa nigra variant, which usually presents in darker skinned individuals
Prevalence
- 69–100% in patients >50 years of age (1)
- The prevalence rate increases with advancing age.

ETIOLOGY AND PATHOPHYSIOLOGY
- Seborrheic keratoses are monoclonal tumors.
- Etiology still is largely unclear.
- Ultraviolet (UV) light and genetics are thought to be involved.
- The role of human papillomavirus is uncertain.

Genetics
An autosomal dominant inheritance pattern is suggested.

RISK FACTORS
- Advanced age
- Exposure to UV light and genetic predisposition are possible factors (1).

GENERAL PREVENTION
Sun protection methods may help prevent seborrheic keratoses from developing.

COMMONLY ASSOCIATED CONDITIONS
- Sign of Leser-Trélat: A paraneoplastic syndrome characterized by a sudden outbreak of multiple seborrheic keratoses in association with an internal malignancy, most commonly adenocarcinoma of the stomach (2). Seborrheic keratosis may resolve with treatment of the malignancy and reappear with neoplasm recurrence (1).
- Documentation of other cutaneous lesions, such as basal cell carcinoma, malignant melanoma, Bowen disease, or squamous cell carcinoma, growing adjacent to or within a seborrheic keratosis, has been reported. The exact relationship between lesions is unclear.

DIAGNOSIS

HISTORY
- Usually asymptomatic
- Trauma or irritation of the lesion may result in pruritus, erythema, bleeding, pain, and/or crusting.
PHYSICAL EXAM

- Typically begin as oval- or round-shaped, flat, dull, sharply demarcated patches
- As they mature, may develop into thicker, elevated, uneven, verrucous-like papules, plaques, or peduncles with a waxy or velvety surface, and appear “stuck on” to the skin (1)
- Commonly appear on sun-exposed areas of the body, predominately the head, neck, or trunk but may appear on any hair-bearing skin
- Vary in color from black, brown, tan, gray to white, or skin-colored; and range in size from several millimeters to several centimeters, but the average diameter is 0.5 to 1.0 cm (1)
- Usually occur as multiples; patients having >100 is not uncommon.
- If irritated, may be bleeding, inflamed, painful, pruritic, or crusted
- Common clinical variants include the following (3):
  - Common seborrheic keratoses: on hair-bearing skin, usually on the face, neck, and trunk; verrucous-like, waxy, or velvety lesions that appear “stuck on” to the skin
  - Dermatosis papulosa nigra: Small black papules that usually appear on the face, neck, chest, and upper back; most common in darker skinned individuals, more common in females; most have a positive family history.
  - Stucco keratoses: small gray-white, rough, verrucous papules; usually occur in large numbers on the lower extremities or forearms; more common in men
  - Flat seborrheic keratoses: oval-shaped, brown patches or macules on face, chest, and upper extremities; increases with age
  - Pedunculated seborrheic keratoses: Hyperpigmented peduncles appear on areas of friction (neck, axilla).

DIFFERENTIAL DIAGNOSIS

Consider the following diagnoses if the seborrheic keratosis is:

- Pigmented
  - Malignant melanoma
  - Melanocytic nevus
  - Angiokeratoma
  - Pigmented basal cell carcinoma
- Lightly pigmented
  - Basal cell carcinoma
  - Bowen disease
– Condyloma acuminatum
– Fibroma
– Verruca vulgaris
– Eccrine poroma
– Invasive squamous cell carcinoma
– Acrochordon
– Acrokeratosis verruciformis of Hopf
– Follicular infundibulum tumor

- Flat
  – Solar lentigo
  – Verrucae planae juveniles
- Hyperkeratotic
  – Actinic keratosis

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
Not needed unless internal malignancy is suspected

**Diagnostic Procedures/Other**

- Diagnosis is made clinically.
- Dermoscopy
  – If uncertain, can aid in diagnosis
  – Common findings are comedo-like openings, fissures, ridges, sharply demarcated borders, milia-like cysts, pseudofollicular openings, hairpin vessels, and horn pseudocysts (4,5).
- Biopsy and histologic exam should be performed if the seborrheic keratosis
  – Is atypical
  – Has inflammation
  – Recently changed in appearance
  – Diagnosis remains unclear.

**Test Interpretation**

- Histologic findings include the following:
  – Acanthosis and papillomatosis due to basaloid cell proliferation
  – “Squamous eddies” or squamous epithelial cell clusters
  – Hyperpigmentation
  – Hyperkeratosis
  – Horn cysts
– Pseudocysts
- Several histologic variants exist.

**TREATMENT**
- Treatment is not usually necessary due to the benign nature of the lesions.
- Removal of seborrheic keratoses may be indicated if
  - Symptomatic (e.g., easily irritated, gets caught on clothing or jewelry)
  - Aesthetically displeasing or undesirable (common)
  - There is a question of malignancy.

**MEDICATION**
Current topical treatments of seborrheic keratoses are less effective than a surgical approach.

**ISSUES FOR REFERRAL**
- New seborrheic keratoses appear abruptly.
- A seborrheic keratosis becomes inflamed or changes in appearance.

**SURGERY/OTHER PROCEDURES**
- A surgical approach to treatment is preferred.
- Choice depends on physician preference and availability of the treatment.
- The following procedures are used:
  - Cryotherapy (liquid nitrogen)
    - Spray flat lesions for 5 to 10 seconds; may require more time or additional treatments if the seborrheic keratosis is thicker
    - Possible complications include scarring, hypopigmentation, recurrence.
  - Curettage
    - Requires local anesthesia
    - Metal hand tool with small scoop at the tip (curette) used to scrape off the lesion
  - Electrodesiccation
    - Requires local anesthesia
    - Requires tool with needle-like metal tip that uses electric current to destroy affected tissue
  - Shave excision
    - Requires local anesthesia
    - Requires scalp to remove lesion
– Laser
  o Requires local anesthesia
  o Uses intense beam of light that burns and vaporizes the lesion
– Chemical peel
  o Involves application of chemical solution (e.g., Trichloroacetic acid) to remove top layer of skin

No statistically significant differences were found in patient’s ratings of cosmetic appearance between cryotherapy and curettage. The majority of patients preferred cryotherapy over curettage due to decreased postoperative wound care, despite the increased discomfort experienced and increased frequency of seborrheic keratosis remaining after cryotherapy when compared to curettage (6).

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
After initial diagnosis, follow-up is not usually required unless
• Inflammation or irritation develops.
• There is a change in appearance.
• New seborrheic keratoses suddenly appear.

PATIENT EDUCATION
• Sun-protective methods may help reduce seborrheic keratosis development.
• Patient education materials
  – www.cdc.gov/cancer/skin/basic_info/prevention.htm

PROGNOSIS
• Seborrheic keratoses generally do not become malignant.
• Sign of Leser-Trélat usually represents a poor prognosis.

COMPLICATIONS
• Irritation and inflammation due to mechanical irritation (i.e., from clothing, jewelry)
• Possible complications of surgical treatment include hypopigmentation, hyperpigmentation, scarring, incomplete removal, and recurrence.

• Misdiagnosis (rare)

REFERENCES

ADDITIONAL READING

• Krupashankar DS; and IADVL Dermatosurgery Task Force. Standard

**CODES**

**ICD10**

- L82.1 Other seborrheic keratosis
- L82.0 Inflamed seborrheic keratosis

**CLINICAL PEARLS**

- Seborrheic keratoses are one of the most common benign tumors of the epidermis.
- Prevalence increases with age.
- Underlying internal malignancy should be considered if large numbers of seborrheic keratoses appear suddenly.
KNEE PAIN
Cory N. Mitchell, MD • J. Herbert Stevenson, MD

BASICS
DESCRIPTION
A common outpatient complaint with a broad differential

- Knee pain may be acute, chronic, or an acute exacerbation of a chronic condition.
- Trauma, overuse, and degenerative change are frequent causes.
- A detailed history, including patient age, pain onset and location, mechanism of injury, and associated symptoms can help narrow the differential diagnosis.
- A thorough and focused examination of the knee (as well as the back, hips, and ankles) helps to establish the correct diagnosis and appropriate treatment.

EPIDEMIOLOGY
Incidence
- Knee complaints account for 12.5 million primary care visits annually.
- The incidence of knee osteoarthritis (OA) is 240 cases/100,000 person-years.

Prevalence
- The knee is a common site of lower extremity injury.
  - Patellar tendinopathy and patellofemoral syndrome are the most common causes of knee pain in runners (1).
- OA of the hip/knee is 11th cause of global disability and 38th most common cause of disability-adjusted life years (DALYS).

ETIOLOGY AND PATHOPHYSIOLOGY
- Trauma (ligament or meniscal injury, fracture, dislocation)
- Overuse (tendinopathy, patellofemoral syndrome, bursitis, apophysitis)
- Age (arthritis, degenerative conditions in older patients; apophysitis in younger patients)
- Rheumatologic (rheumatoid arthritis [RA], gout, pseudogout)
- Infectious (bacterial, postviral, Lyme disease)
- Referred pain (hip, back)
- Vascular: popliteal artery aneurysm, deep vein thrombosis
- Others: tumor, cyst, plica

**RISK FACTORS**
- Obesity
- Malalignment
- Poor flexibility, muscle imbalance, or weakness
- Rapid increases in training frequency and intensity
- Improper footwear, training surfaces, technique
- Activities that involve cutting, jumping, pivoting, deceleration, kneeling
- Previous injuries

**GENERAL PREVENTION**
- Maintain normal body mass index.
- Proper exercise technique, volume, and equipment; avoid overtraining.
- Correct postural strength and flexibility imbalances.

**COMMONLY ASSOCIATED CONDITIONS**
- Fracture, contusion
- Effusion, hemarthrosis
- Patellar dislocation/subluxation
- Meniscal or ligamentous injury
- Tendinopathy, bursitis
- Osteochondral injury
- OA, septic arthritis
- Muscle strain

**DIAGNOSIS**

**HISTORY**
- Pain location, quality and mechanism of injury guide diagnostic reasoning (also see “Differential Diagnosis”):
  - Diffuse pain: OA, patellofemoral pain syndrome, chondromalacia
  - Pain ascending/descending stairs: meniscal injury, patellofemoral pain syndrome
  - Pain with prolonged sitting, standing from sitting: patellofemoral pain syndrome
Mechanical symptoms (locking): meniscal injury

Mechanism of injury:
- Hyperextension, deceleration, cutting: anterior cruciate ligament (ACL) injury
- Hyperflexion, fall on flexed knee, “dashboard injury”: posterior cruciate ligament (PCL) injury
- Lateral force (valgus load): medial collateral injury
- Twisting on planted foot: meniscal injury

Effusion:
- Rapid onset (2 hours): ACL tear, patellar subluxation, tibial plateau fracture. Hemarthrosis is common.
- Slower onset (24 to 36 hours), smaller: meniscal injury, ligament sprain
- Swelling behind the knee: popliteal (Baker) cyst; prepatellar: bursitis

PHYSICAL EXAM
- Observe gait (antalgia), patellar tracking.
- Inspect for malalignment, atrophy, swelling, ecchymosis, or erythema.
- Palpate for effusion, warmth, and tenderness.
- Evaluate active and passive range of motion (ROM) and flexibility of quadriceps and hamstrings.
- Evaluate strength and muscle tone.
- Note joint instability, locking, and catching.
- Evaluate hip ROM, strength, and stability.
- Special tests:
  - Patellar apprehension test: patellar instability; patellar grind test: patellofemoral pain or OA (1)
  - Lachman test (more sensitive and specific), pivot shift, anterior drawer: ACL integrity
  - Posterior drawer, posterior sag sign: PCL integrity
  - Valgus/varus stress test: medial/lateral collateral ligament (MCL/LCL) integrity
  - McMurray test, Apley grind, Thessaly test: meniscal injury
  - Ober test: iliobibial band (ITB) tightness
  - Dial test: positive with posterolateral corner laxity
  - Patellar tilt test and squatting may help suggest patellofemoral pain syndrome, but there is not yet one definitive test.
  - Patella facet tenderness suggests OA or patellofemoral pain syndrome (1) [A].

mebooksfree.com
DIFFERENTIAL DIAGNOSIS

- Acute onset: fracture, contusion, cruciate or collateral ligament tear, meniscal tear, patellar dislocation/subluxation; if systemic symptoms: septic arthritis, gout, pseudogout, Lyme disease, osteomyelitis
- Insidious onset: patellofemoral pain syndrome/chondromalacia, ITB syndrome, OA, RA, bursitis, tumor, tendinopathy, loose body, bipartite patella, degenerative meniscal tear
- Anterior pain: patellofemoral pain syndrome, patellar injury, patellar tendinopathy, pre- or suprapatellar bursitis, tibial apophysitis, fat pad impingement, quadriceps tendinopathy, OA
- Posterior pain: PCL injury, posterior horn meniscal injury, popliteal cyst or aneurysm, hamstring or gastrocnemius injury, deep venous thrombosis (DVT)
- Medial pain: MCL injury, medial meniscal injury, pes anserine bursitis, medial plica syndrome, OA
- Lateral pain: LCL injury, lateral meniscal injury, ITB syndrome, OA

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Suspected septic joint, gout, pseudogout:
  - Arthrocentesis with cell count, Gram stain, culture, protein/glucose, synovial fluid analysis
- Suspected RA:
  - CBC, erythrocyte sedimentation rate (ESR), rheumatoid factor
- Consider Lyme titer.
- Radiographs to rule out fracture in patients with acute knee trauma (Ottawa rules):
  - Age >55 years or
  - Tenderness at the patella or fibular head or
  - Inability to bear weight 4 steps or
  - Inability to flex knee to 90 degrees
- Radiographs help diagnose OA, osteochondral lesions, patellofemoral pain syndrome:
  - Weight bearing, upright anteroposterior, lateral, merchant/sunrise, notch/tunnel views

Follow-Up Tests & Special Considerations

- MRI is a “gold standard” for soft tissue imaging.
- Ultrasound may help diagnose tendinopathy (2)[B].
CT can further elucidate fracture.

**Diagnostic Procedures/Other**
Arthroscopy may be beneficial in the diagnosis of certain conditions, including meniscus and ligament injuries.

**Geriatric Considerations**
OA, degenerative meniscal tears, and gout are more common in middle-aged and elderly populations.

**Pediatric Considerations**
- 3 million pediatric sports injuries occur annually.
- Look for physeal/apophyseal and joint surface injuries in skeletally immature:
  - Acute: patellar subluxation, avulsion fractures, ACL tear
  - Overuse: patellofemoral pain syndrome, apophysitis, osteochondritis dissecans, patellar tendonitis, stress fracture
  - Others: neoplasm, juvenile RA, infection, referred pain from slipped capital femoral epiphysis

**TREATMENT**

**GENERAL MEASURES**
Acute injury: PRICEMM therapy (protection, relative rest, ice, compression, elevation, medications, modalities)

**MEDICATION**

**First Line**
- Oral medications:
  - Acetaminophen: up to 3 g/day; safe and effective in OA
  - Nonsteroidal anti-inflammatory drugs (NSAIDs):
    - Ibuprofen: 200 to 800 mg TID
    - Naproxen: 250 to 500 mg BID:
      - Useful for acute sprains, strains
      - Useful for short-term pain reduction in OA. Long-term use is not recommended due to side effects.
      - Not recommended for fracture, stress fracture, chronic muscle injury; may be associated with delayed healing; low dose and brief course
only if necessary
- Tramadol/opioids: not recommended as first-line treatment; can be used with acute injuries for severe pain
  - Celecoxib: 200 mg QD may be effective in OA with less GI side effects than NSAIDs (3)[A].

Topical medications:
- Topical NSAIDs may provide pain relief in OA and are more tolerable than oral medications.
- Topical capsaicin may be an adjuvant for pain management in OA.

Injections:
- Intra-articular corticosteroid injection may provide short-term benefit in knee OA stage 2 or 3 (2)[A].
- Viscosupplementation may reduce pain and improve function in patients with OA (2)[A]. Peak effectiveness is 5 to 13 weeks.
- Equivocal evidence for platelet-rich plasma (PRP) compared to viscosupplementation
- Stem cell therapy with insufficient data

**ISSUES FOR REFERRAL**
- Acute trauma, young athletic patient
- Joint instability
- Lack of improvement with conservative measures
- Salter-Harris physeal fractures (pediatrics)

**ADDITIONAL THERAPIES**
- Physical therapy is recommended as initial treatment for patellofemoral pain (4) and tendinopathies (2)[A].
- Muscle strengthening improves outcome in OA.
- Foot orthoses, taping, acupuncture
- May need bracing for stability (4)[B]
- Botulinum toxin A for patellofemoral pain syndrome (5)[B]

**SURGERY/OTHER PROCEDURES**
- Surgery may be indicated for certain injuries (e.g., ACL tear in competitive athletes or Grade IV OA).
- Chronic conditions refractory to conservative therapy may require surgical intervention.
COMPLEMENTARY & ALTERNATIVE MEDICINE

May reduce pain and improve function in early OA:
- Glucosamine sulfate (500 mg TID)
- Chondroitin (400 mg TID)
- Turmeric or curcumin 1,000 mg/day (6)
- Collagen hydrolysates 10 g daily
- S-adenosylmethionine (SAMe), ginger extract, methylsulfonylmethane: less reliable improvement with inconsistent supporting evidence
- Acupuncture: need to do 4 weeks or 10 sessions

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Activity modification in overuse conditions
- Rehabilitative exercise in OA:
  - Low-impact exercise: walking, swimming, cycling
  - Strength, ROM, and proprioception training

Patient Monitoring

- Rehabilitation after initial treatment of acute injury
- In chronic and overuse conditions, assess functional status, rehabilitation adherence, and pain control at follow-up visit.

DIET

Weight reduction by 10% improved function by 28%.

PATIENT EDUCATION

- Review activity modifications.
- Encourage active role in the rehabilitation process.
- Review medication risks and benefits.

PROGNOSIS

Varies with diagnosis, injury severity, chronicity of condition, patient motivation to participate in rehabilitation, and whether surgery is required
COMPLICATIONS

- Disability
- Arthritis
- Chronic joint instability
- Deconditioning

ADDITIONAL READING

- Patel S, Dhillon MS, Aggarwal S, et al. Treatment with platelet-rich plasma is more effective than placebo for knee osteoarthritis: a prospective, double-

**SEE ALSO**

Algorithms: [Knee Pain](#); [Popliteal Mass](#)

**CODES**

**ICD10**

- M25.569 Pain in unspecified knee
- M17.9 Osteoarthritis of knee, unspecified
- M76.50 Patellar tendinitis, unspecified knee

**CLINICAL PEARLS**

- A careful history (location/quality of pain and mechanism of injury) targets diagnosis for most causes of knee pain.
- Consider ligamentous injury, meniscal tear, and fracture for patients presenting with acute knee pain.
- Consider OA, patellofemoral pain syndrome, tendinopathy, bursitis, and stress fracture in patients presenting with more chronic symptoms.
- Consider physeal, apophyseal, or articular cartilage injury in young patients presenting with knee pain.
- The presence of an effusion in a patient <30 years of age indicates a significant injury.
- Referred pain from the hip (slipped capital femoral epiphysis, Legg-Calvé-Perthes disease) can present as knee pain.
LABYRINTHITIS
Mary S. Lindholm, MD

BASICS
DESCRIPTION

- The sudden and persistent onset of vertigo, often accompanied by hearing loss, caused by acute inflammation or infection of the labyrinth
- Labyrinthitis is a clinical diagnosis in absence of neurologic deficits.
- Typically presents with false sense of motion or room-spinning vertigo lasting for hours or days and often sudden unilateral hearing loss
- Often associated with vestibular hypofunction of the involved ear. Peripheral vertigo improves over time with central compensation.
- System(s) affected: nervous, special sensory (auditory and vestibular)
- Synonym(s): acute peripheral vestibulopathy; vestibular neuronitis (vertigo/dizziness only); vestibular neuritis (vertigo/dizziness only)

ALERT

- “Vertigo” and “dizziness” are commonly used terms. Clarify symptoms by giving options of alternative descriptions such as light-headedness, disequilibrium, room-spinning vertigo, or imbalance.
- Hearing loss and duration of symptoms can help narrow the differential diagnosis in patients with vertigo.
- Benign paroxysmal positional vertigo (BPPV) is the most common cause of vertigo. Unlike labyrinthitis, BPPV is episodic, with severe symptoms lasting <1 minute. BPPV is diagnosed using the Dix-Hallpike maneuver. Unlike labyrinthitis, it is not associated with hearing loss.
- Ménière disease presents with the classic triad of episodic vertigo, tinnitus, and sensorineural hearing loss that is often fluctuant (1)[C].

Geriatric Considerations

- Elderly are less likely to compensate fully and may report symptoms of disequilibrium lasting weeks to months after resolution of the acute vertigo.
- Avoid excessive use of scopolamine, meclizine, and other vestibular suppressants following the initial event, as this will delay central compensation.
Benzodiazepines are preferred vestibular suppressant treatment but do increase the risk of falls in older persons.

**Pediatric Considerations**
Less common in children; incidence of vestibular vertigo in 10-year-olds estimated to be 5.7% (2)[C]

**EPIDEMIOLOGY**
- 10% of all patients seen for dizziness
- Most common in 30 to 50 years of age (3)
- Predominant sex: female = male

**Incidence**
- Viral labyrinthitis is the most common etiology.
- Suppurative or serous labyrinthitis secondary to otitis media is increasingly rare.

**Prevalence**
In the United States, second most common cause of dizziness due to persistent peripheral vestibular hypofunction (9%); benign positional vertigo (40%) is most common. More than 1/3 of adults see a health care provider for vertigo in their lifetimes (4).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Acute inflammation or damage to the inner ear, involving both branches of the vestibulocochlear nerve
- Viruses pass via hematogenous spread into the labyrinth or directly from the middle ear to labyrinth via the round/oval window.
- Bacterial toxins and host inflammatory mediators from a middle ear infection may reach the inner ear.
- Ischemia: Ischemic or thromboembolic events involving the labyrinthine artery can cause symptoms that mimic acute labyrinthitis; often presents with associated neurologic symptoms
- Autoimmune: Local or systemic inflammatory processes may affect the inner ear via autoantibodies vasculitis of the labyrinthine artery.
  - Wegener granulomatosis, Cogan syndrome, systemic lupus erythematosus, polyarteritis nodosa, Behçet disease
- Infections
– Common viral: cytomegalovirus, mumps, varicella zoster, rubeola, influenza, parainfluenza, herpes simplex, adenovirus, coxsackievirus, respiratory syncytial virus, HIV
– Common bacterial: *Streptococcus pneumoniae, Haemophilus influenzae, Moraxella catarrhalis, Neisseria meningitidis, Streptococcus* spp., *Staphylococcus* spp., *Borrelia burgdorferi*
– Treponemal: *Treponema pallidum*
  • Ototoxic drugs (e.g., aspirin, aminoglycosides, loop diuretics, cisplatin)

**Genetics**
No known genetic link

**RISK FACTORS**
• Viral upper respiratory infection
• Otitis media
• Vestibulotoxic/ototoxic medications
• Head trauma
• History of allergies
• Meningitis
• Cerebrovascular disease
• Other risk factors include autoimmune disease, herpes zoster infection, excessive alcohol consumption, and smoking.

**GENERAL PREVENTION**
• Scheduled immunizations (to prevent common viral pathogens)
• Prevent maternal transmission of pathogens, including syphilis and HIV.

**COMMONLY ASSOCIATED CONDITIONS**
• Viral upper respiratory infection
• Allergies
• Otitis media
• Cholesteatoma
• Head injury

**DIAGNOSIS**

**HISTORY**
Vertigo AND (often) hearing loss in one ear
Vertigo is acute in onset and lasts days to weeks.
Nausea and vomiting are common.
Fullness of affected ear
Tinnitus of affected ear (roaring, ringing)
Upper respiratory tract infection symptoms
Otorrhea or otalgia (not common with viral causes)
Severe headache, fever, and nuchal rigidity in the setting of meningitis
Recurrent symptoms should raise suspicion for autoimmune causes.
Profound imbalance or associated focal neurologic signs are not typical and should prompt imaging.

PHYSICAL EXAM
Nystagmus
- Fast-beating nystagmus toward affected ear (acutely)
- Fast-beating nystagmus away from affected ear (chronically)
Symptoms abate in supine position and with eyes closed or with visual fixation.
Otologic exam may be unremarkable in the setting of viral labyrinthitis.
Serous/purulent effusion may be present in the middle ear.
Retraction of the tympanic membrane and keratinaceous debris may be present with cholesteatoma.

DIFFERENTIAL DIAGNOSIS
Vestibular neuritis/neuronitis (vertigo without hearing loss)
BPPV: episodic, vertigo lasting seconds/minutes, worse when lying down or looking up
Ménière disease: episodic vertigo lasting minutes to hours, associated with the triad of episodic vertigo, tinnitus, and hearing loss
Vestibular migraine
Autoimmune inner ear disease
Postconcussive syndrome
Acute otitis media
Ototoxicity
Cardiovascular accident (CVA)/brainstem infarct
Cerebellopontine-angle tumors (e.g., vestibular schwannoma)
Less common etiologies: parainfectious encephalomyelitis or cranial polyneuritis, Ramsay Hunt syndrome, HIV infection, syphilis, temporal lobe epilepsy, perilymphatic fistula, superior canal dehiscence, idiopathic sudden
single-sided deafness, multiple sclerosis, vasculitis (cerebral or systemic)

**DIAGNOSTIC TESTS & INTERPRETATION**

- Routine lab studies are not helpful in making the diagnosis unless an autoimmune cause is highly suspected.
- Consider culture of otorrhea or middle ear fluid to direct antibiotic choice.
- Consider lumbar puncture only if meningitis is suspected.
- Consider screening for syphilis or HIV when clinically indicated by risk factors or clinical history.
- Imaging is not required for the diagnosis of acute labyrinthitis.
- If associated neurologic symptoms or sensorineural hearing loss are present, an MRI and MR angiography of brain and brainstem are recommended.
- Vertigo usually spontaneously resolves, and there is a low risk of developing Ménière disease or migraines.

**Follow-Up Tests & Special Considerations**

Labyrinthitis ossificans is fibrosis of the internal auditory canal following bacterial meningitis and is thought to occur due to a suppurative labyrinthitis. This can occur rapidly, especially after *S. pneumoniae* meningitis.

**Diagnostic Procedures/Other**

- Audiogram should be obtained.
- Vestibular tests are not typically indicated in the acute setting. If vertigo and dizziness persist after expected resolution of symptoms, electronystagmography should be used.

**Test Interpretation**

- Audiogram may show varying degrees of both hearing loss and discrimination.
- Caloric testing may show relative weakness of the horizontal semicircular canal of the affected side. Sensitivity and specificity of this test are variable within literature.

**TREATMENT**

- Symptom management and reassurance
- Vestibular rehabilitation is the mainstay of treatment and has been shown to be safe and effective management for unilateral peripheral vestibular
dysfunction (5)[A].
- Patients should begin exercises as soon as the acute phase resolves and movement is tolerable, generally within 2 to 3 days of onset.
- Vestibular suppressants as needed (see “Medication”) for severe acute attacks of vertigo only. Patients should be advised NOT to use these medications as scheduled medications or for prophylaxis without symptoms.
- Sudden single-sided hearing loss (onset within 2 weeks) should be managed with high-dose oral steroids as soon as possible.
- Auricular acupuncture and Ginkgo biloba may be emerging adjunctive therapies to reduce vertiginous symptoms, although research is limited.
- For suppurative labyrinthitis, appropriate antibiotics to eradicate infection

GENERAL MEASURES
Vestibular exercises for prolonged symptoms and unilateral vestibular loss have been shown to alleviate postural control.

MEDICATION
Use of the following drugs should be on a PRN basis. Benzodiazepines can also assist with the anxiety associated with vertigo. No patient should take vestibular suppressants as a chronic medication, as they can block central compensation.

- Vestibular suppressants
  - Lorazepam (Ativan): 0.5 to 2.0 mg SL/PO BID PRN or diazepam (Valium) 2 to 5 mg QID PO PRN
  - Meclizine (Antivert, Bonine, Zentrip [dissolvable]) 12.5 to 25.0 mg PO BID–TID PRN
  - Dimenhydrinate (Dramamine) 25 to 50 mg PO q4–6h PRN
- Antiemetics
  - Ondansetron (Zofran) 4 to 8 mg PO TID PRN or granisetron (Kytril) 1 mg PO TID PRN
  - Meclizine (Antivert, Bonine) 12.5 to 25.0 mg PO q4h PRN
  - Promethazine (Phenergan) 12.5 to 25.0 mg PO/PR QID PRN or prochlorperazine (Compazine) 25 mg PR BID PRN
  - Metoclopramide (Reglan) 10 mg PO TID PRN
- Antivirals
  - Acyclovir 800 mg PO 5 times per day for 7 days can be used in cases associated with herpes.
- Steroids
  - Adults: methylprednisolone initially 100 mg PO daily and then tapered to
10 mg PO daily over 3 weeks
- Pediatrics: prednisone 1 mg/kg PO daily 3 times per week and then taper over 3 weeks
- Given early in the setting of bacterial meningitis, may decrease the otologic sequelae, specifically labyrinthitis ossificans
- Used in treatment of labyrinthitis for associated sudden sensorineural hearing loss

**Pregnancy Considerations**
Dimenhydrinate, diphenhydramine, ondansetron, granisetron, and metoclopramide are pregnancy Category B.

**First Line**
- Benzodiazepines, which are better vestibular suppressants, are preferred over antihistamine/anticholinergics such as meclizine. Sublingual benzodiazepines are very effective for vertigo and should be considered first-line therapy.
- Urgent steroid treatment in acute setting

**ISSUES FOR REFERRAL**
- Consider neuro-otology referral for other peripheral causes of vertigo or unremitting vertigo.
- Consider neurology referral for suspected central causes of vertigo or dizziness.
- Consider otolaryngology referral for progressive bilateral hearing loss and vertigo after preliminary laboratory workup excluding rheumatologic causes.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Patients with systemic infection, young age, or intractable vertigo with nausea and vomiting may need to be hospitalized for intravenous fluids and medications.
- Usually outpatient management

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
**Patient Monitoring**

Follow hearing loss weekly with audiograms until hearing stabilizes. Acute vertiginous symptoms may last up to 6 weeks. Residual symptoms have been documented to last months or years.

**Diet**

Avoid alcohol, as this may exacerbate symptoms.

**Patient Education**

Lie still with eyes closed in a darkened room during acute attacks. Otherwise, encourage activity as tolerated. Minimize rapid head movement until symptoms resolve.

**Prognosis**

Prognosis depends on cause of labyrinthitis.

**Complications**

Permanent hearing loss, more common with bacterial causes, and chronic impairment of balance.

**References**

**Additional Reading**

**SEE ALSO**

Ménière Disease; Postconcussion Syndrome (Mild Traumatic Brain Injury); Tinnitus

**CODES**

**ICD10**

- H83.09 Labyrinthitis, unspecified ear
- H83.01 Labyrinthitis, right ear
- H83.02 Labyrinthitis, left ear

**CLINICAL PEARLS**

- Ask patients to describe symptoms in their own words; alternative symptoms include light-headedness, vertigo, disequilibrium, or imbalance.
- Benzodiazepines are better vestibular suppressants and are preferred over antihistamine/anticholinergics such as meclizine.
- Episodic vertigo tends to be caused by BPPV or Ménière disease, whereas persistent vertigo is more consistent with labyrinthitis.
LACTOSE INTOLERANCE

Nihal K. Patel, MD

BASICS

DESCRIPTION

- Inability to digest lactose into constituent components (glucose and galactose) due to low levels of lactase in the brush border of the small intestinal mucosa
- Causes bloating, borborygmi (audible stomach “rumblings”), abdominal pain, and diarrhea
  - Congenital lactose intolerance: very rare
  - Primary lactose intolerance: common in adults who develop low lactase levels after childhood
  - Secondary lactose intolerance: inability to digest lactose caused by any condition injuring the intestinal mucosa (e.g., infectious enteritis, celiac disease, eosinophilic gastroenteritis, or inflammatory bowel disease) or a reduction of available mucosal surface (e.g., resection)
- Lactase activity peaks at birth then decreases after the first few months of life, declining continuously throughout life. 75% of adults’ worldwide exhibit decline in lactase activity. Only 50% of lactase activity is needed to digest lactose without causing symptoms of lactose intolerance.
- Lactose malabsorption also results from reduction of lactase activity; asymptomatic and equally common in healthy patients and those with functional bowel disorders
- System(s) affected: endocrine/metabolic, gastrointestinal

Pediatric Considerations

- Primary lactose intolerance begins in late childhood.
- No consensus on whether young children (<5 years of age) should avoid lactose following diarrheal illness
- Lactose-free formulas are available.
- Exclude milk protein allergy.

EPIDEMIOLOGY

Incidence

- ≥50% of infants with acute or chronic diarrheal disease have lactose
intolerance; particularly common with rotavirus infection

- Lactose intolerance is common with giardiasis, ascariasis, irritable bowel syndrome (IBS), tropical and nontropical sprue, and AIDS malabsorptive syndrome.

**Prevalence**

- In South America, Africa, and Asia, rates of lactose intolerance are >50%.
- In the United States, the prevalence is 15% among whites, 53% among Hispanic Americans, and 80% among African Americans.
- In Europe, lactose intolerance varies from 15% in Scandinavian countries to 70% in Italy.
- Predominant age:
  - Primary: teenage and adult
  - Secondary: depends on underlying condition
- Predominant sex: male = female

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Primary lactose intolerance: Normal decline in the lactase activity in the intestinal mucosa is genetically controlled and permanent after weaning from breast milk.
- Secondary lactose intolerance: associated with gastroenteritis in children and with nontropical and tropical sprue, regional enteritis, abetalipoproteinemia, cystic fibrosis, inflammatory bowel disease, celiac disease, and immunoglobulin deficiencies in both adults and children

**Genetics**

- In Caucasians, lactase deficiency has been associated with a single nucleotide polymorphism (SNP) consisting of a nucleotide switch of T for C 13910bp on chromosome 2. This results in variants of CC-13910 (lactase nonpersistence) OR CT-13910/TT-13910 (lactase persistence) (1).
- SNP (C/T-13910) is associated with lactase persistence in northern Europeans.
- Other SNPs (G/C-14010, T/G-13915, and C/G-13907) have been linked to lactase persistence in Africans.

**RISK FACTORS**

- Adult-onset lactase deficiency has wide geographic variation.
- Age:
– Signs and symptoms usually do not become apparent until after age 6 to 7 years.
– Symptoms may not be apparent until adulthood, depending on dietary lactose intake and rate of decline of intestinal lactase activity.
– Lactase activity correlates with age, regardless of symptoms.

GENERAL PREVENTION
Lactose avoidance relieves symptoms. Patients can learn what level of lactose is tolerable in their diet.

COMMONLY ASSOCIATED CONDITIONS
• Tropical or nontropical sprue
• Giardiasis
• Inflammatory bowel disease
• Immunoglobulin deficiencies
• Celiac disease
• Cystic fibrosis

DIAGNOSIS
• Lactose intolerance is defined by a positive lactose hydrogen breath test and clinical symptoms.
• Lactose intolerance can mimic symptoms of functional gastrointestinal disorders. Lactose intolerance can also be a coexisting condition.

HISTORY
• Assess daily lactose consumption. A single dose of lactose (12 g, equivalent to 1 cup of milk) consumed alone produces no or minor symptoms in persons with lactose intolerance or maldigestion.
• Lactose doses of 15 to 18 g are well tolerated with other nutrients. Doses >18 g cause progressively more symptoms, and quantities >50 g elicit symptoms in most individuals.
• Symptoms may arise 30 minutes to 2 hours after consumption of lactose-containing products.
• Symptoms include bloating, cramping, abdominal discomfort, vomiting, diarrhea or loose stools, and flatulence.
• Symptoms appear 30 minutes to 2 hours after eating.
• Abdominal pain may be crampy in nature and often is localized to the
periumbilical area or lower quadrant.

- Stools usually are bulky, frothy, and watery.
- Only 1/3 to 1/5 of individuals with lactose malabsorption develop symptoms.

**PHYSICAL EXAM**
Borborygmi may be audible on physical examination and bothersome to the patient. The exam is otherwise typically normal or nonspecific.

**DIFFERENTIAL DIAGNOSIS**

- Sucrase deficiency
- Cow’s milk protein allergy
- IBS
- Bacterial overgrowth
- Celiac disease
- Inflammatory bowel disease

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- The lactose breath hydrogen test (LBT) is the preferred diagnostic test for lactose intolerance. It is noninvasive, easy to perform, and cost effective. It is limited only by suboptimal sensitivity \((2)[B]\). Intestinal bacteria digest carbohydrates and produce hydrogen and methane that are measurable in expired air:
  - Oral lactose is administered when fasting (2 g/kg; max dose 25 g). Breath hydrogen is sampled at baseline and at 30-minute intervals for 3 hours. The postlactose and baseline values are compared. A breath hydrogen value of 10 ppm is normal. Values between 10 and 20 ppm may be indeterminate unless accompanied by symptoms; values >20 ppm are diagnostic for lactose malabsorption.
  - The biochemical assay of lactase activity on duodenal sampling is as sensitive as LBT in detecting lactase deficiency. It is more accurate than LBT in predicting the clinical response to a lactose-free diet. Cost and invasiveness limit clinical utility.
  - For patients with symptoms of lactose intolerance who are undergoing endoscopy for other reasons, a biochemical assay on duodenal biopsies can rule out lactose malabsorption.
  - A positive LBT confirms lactose malabsorption but does not define the etiology.
**Diagnostic Procedures/Other**

Lactose absorption test is an alternative to LBT in adults (more invasive and equivalent in sensitivity and specificity to breath test). Following oral administration of a 50-g test dose in adults (2 g/kg in children), blood glucose levels are monitored at 0, 60, and 120 minutes. An increase in blood glucose of <20 mg/dL (1.1 mmol/L) with the concurrent development of symptoms is diagnostic. False-negative results may occur in patients with diabetes or bacterial overgrowth.

**Test Interpretation**

Lactase deficiency in intestinal mucosa may be patchy or focal.

---

**TREATMENT**

There is insufficient evidence to recommend any treatment (including probiotics, colonic adaptation, and other supplements) as definitive first line.

- Treatment of lactose malabsorption in the absence of a correctable underlying disease includes four general principles (3)[B].
  - Avoid milk and dairy products in order to improve symptoms.
  - Up to 12 to 15 g of lactose can be tolerated in patients with lactose intolerance without significant symptoms (1 cup of milk).
  - Lactose should be gradually reintroduced along with other nutrients until the patient’s threshold for symptoms is reached. Spreading lactose servings throughout the day improves tolerance.
  - If symptoms persist, substitute fermented and matured milk products for lactose.
- Certain strains, concentrations, and preparations of probiotics may alleviate symptoms.
- Incrementally increasing doses of lactose to induce colonic adaptation have limited success.
- Insufficient scientific evidence exists to strongly recommend lactose-reduced or hydrolyzed milk, lactase supplements taken with milk, probiotics, or colonic adaptation to treat lactose intolerance. Use of supplements should be considered case by case.
- Maintain calcium and vitamin D intake.

---

**MEDICATION**
**First Line**

Lactase (Lactaid, Lactrase):
- Commercially available “lactase” preparations are bacterial or yeast β-galactosidases.
- Take 1 to 2 capsules or tablets prior to ingesting dairy products.
- Effectiveness at preventing symptoms varies.
- Can add tablets or contents of capsules to milk (1 to 2 caps-tabs per quart of milk) before drinking; also commercially available in milk in some areas
- Not effective for all people with lactose intolerance
- High-quality, large, randomized controlled trials showing efficacy and safety are lacking.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Certain probiotic formulations taken with meals may alleviate some symptoms of lactose intolerance (4)[B].

**ONGOING CARE**

**DIET**
- Reduce or restrict dietary lactose to control symptoms—patient-specific “trial and error.”
- Yogurt and fermented products such as hard cheese are often better tolerated than milk.
- Supplement calcium (e.g., calcium carbonate)
- Prehydrolyzed milk (Lactaid) is available.

**PATIENT EDUCATION**
- Read labels on commercial products—milk sugar is used in many products and may cause symptoms.
- Patients may tolerate whole milk or chocolate milk better than skim milk due to slower rate of gastric emptying.
- Lactose consumed with other food products is better tolerated than when consumed with milk alone.
- Primary lactase deficiency is permanent; secondary lactose intolerance usually is temporary, although it may persist for months after the inciting event.
• 20% of prescription drugs and 6% of over-the-counter (OTC) medicines contain lactose as a base.
• Most patients with lactose intolerance or malabsorption can tolerate up to 12 to 15 g of lactose.

PROGNOSIS
• Normal life expectancy
• Symptoms can be controlled through diet alone if lactase tablets are ineffective.

COMPLICATIONS
Calcium deficiency: Avoidance of milk and other dairy products can lead to reduced calcium intake, which may increase the risk for osteoporosis and fracture.

REFERENCES

ADDITIONAL READING
• Furnari M, Bonfanti D, Parodi A, et al. A comparison between lactose breath test and quick test on duodenal biopsies for diagnosing lactase deficiency in

**CODES**

**ICD10**

- E73.9 Lactose intolerance, unspecified
- E73.8 Other lactose intolerance
- E73.1 Secondary lactase deficiency

**CLINICAL PEARLS**

- The diagnosis of lactose intolerance is based on clinical history and can be confirmed by hydrogen breath testing.
- Most lactose intolerant patients can tolerate up to 12 to 15 g of lactose per day.
- Lactose-intolerant patients may tolerate yogurt and fermented products better than milk and cheese.
- A diary helps identify problematic foods.
- Patients should read ingredient labels to look for milk, lactose, whey, and curd.
- Lactose-intolerant patients may tolerate whole milk or chocolate milk better than skim milk due to a slower rate of gastric emptying.
- Many patients with lactose intolerance unnecessarily avoid all dairy products, potentially causing an inadequate intake of calcium and vitamin D, which could predispose to osteoporosis.
LARYNGITIS
Sheila O. Stille, DMD • Hugh Silk, MD, MPH, FAAFP

BASICS

DESCRIPTION
- Laryngitis is inflammation, erythema, and edema of the mucosa of the larynx and/or vocal cords characterized by hoarseness, loss of voice, throat pain, coughing, and often a negative impact on a person’s quality of life and daily activities.
- There is a range of severity, but most cases are acute and are associated with viral upper respiratory infection, irritation, or acute vocal strain.
- System(s) affected: pulmonary; ears, nose, throat (ENT)
- Synonym(s): acute laryngitis; chronic laryngitis; croup or laryngotracheitis (in children)

EPIDEMIOLOGY
- Predominant age: affects all ages
- Children more susceptible than adults due to increased risk of symptomatic inflammation from smaller airways
- Predominant sex: male = female

Incidence
Common

Prevalence
Common; approximately 1.7% of population have dysphonia with 50% of this being caused by acute laryngitis. Prevalence rates are increasing but difficult to calculate as many patients do not seek medical attention.

ETIOLOGY AND PATHOPHYSIOLOGY
- Misuse or abuse of voice
- Infectious
  - Viral: influenza A, B; parainfluenza; adenovirus; coronavirus; rhinovirus; human papillomavirus; cytomegalovirus; varicella-zoster virus; herpes simplex virus; respiratory syncytial virus; coxsackievirus
– Fungal: uncommon but thought to be underdiagnosed, potentially accounting for up to 10% of presentations in both immunocompromised and immunocompetent patients; risk factors include recent antibiotic or inhaled corticosteroid use (1): histoplasmosis, blastomycosis, *Coccidioides*, *Cryptococcus*, and *Candida*.
– Secondary syphilis if left untreated
– Leprosy (in 30–55% of those with leprosy, larynx is affected; in tropical and warm countries)

- Irritants
  – Inhalation of irritating substances (e.g., air pollution, cigarette smoke)
  – Aspiration of caustic chemicals
  – Gastroesophageal reflux disease (GERD)/laryngopharyngeal reflux disease (LPRD)
  – Excessively dry environment
  – Allergy exposures (including pollens)

- Anatomic
  – Aging changes: muscle atrophy, loss of moisture in larynx, and bowing of vocal cords
  – Vocal cord nodules/polyps (“singer’s nodes”)
  – Local cancer

- Iatrogenic: inhaled steroids such as those used to treat asthma, surgical injury, endotracheal intubation injury

- Idiopathic

- Neuromuscular disorder (e.g., myasthenia gravis); stroke

- Rheumatoid arthritis

- Trauma (e.g., blunt or penetrating trauma to neck)

**RISK FACTORS**

- Acute:
  – Infection or trauma
  – Upper respiratory tract viral infection (e.g., influenza, rhinovirus, adenovirus, parainfluenza)
  – Voice overuse—excess talking, singing, or shouting
  – Pneumonia—viral or bacterial
  – Coughing
- Lack of immunization for pertussis or diphtheria
- Immunocompromised
- Recent endotracheal intubation or local surgery

**Chronic (persists beyond 3 weeks):**
- Allergic laryngitis *(2)*
- Chronic rhinitis/sinusitis
- Voice abuse
- GERD/LPRD *(1)*
- Smoking: primary or secondhand
- Excessive alcohol use
- Autoimmune disorders (e.g., rheumatoid arthritis) *(1,3)*
- Granulomatous diseases (e.g., sarcoidosis) *(1)*
- Stroke
- Environmental pollution; constant exposure to dust or other irritants such as chemicals at workplace
- Medications: inhaled steroids, anticholinergics, antihistamines, anabolic steroids

**Geriatric Considerations**
May be more ill, slower to heal; need to consider neoplasm

**Pediatric Considerations**
- Common in this age group
- Consider congenital/anatomic causes.

**GENERAL PREVENTION**
- Avoid overuse of voice (speech therapy/voice training is helpful for vocal musicians/public speakers).
- Influenza virus vaccine is recommended.
- Quit smoking, and avoid secondhand smoke.
- Limit or avoid alcohol/caffeine/acidic foods.
- Control GERD/LPRD.
- Maintain proper hydration status.
- Avoid allergens.
- Wear mask around chemical/environmental irritants.
- Good hand washing (infection prevention)

**COMMONLY ASSOCIATED CONDITIONS**
- Viral pharyngitis
- Diphtheria (rare): Membrane can descend into the larynx.
- Pertussis: larynx involved as part of the respiratory system
- Bronchitis
- Pneumonitis
- Croup, epiglottitis, in children

**DIAGNOSIS**

**HISTORY**
- Hoarseness, throat “tickle,” dry cough, and rawness (4)
- Dysphonia (abnormal-sounding voice)
- Constant urge to clear the throat
- Possible fever
- Malaise
- Dysphagia/odynophagia
- Regional cervical lymphadenopathy
- Stridor or possible airway obstruction in children (1)
- Cough may be worse at night in children.
- Hemoptysis
- Laryngospasm or sense of choking
- Allergic rhinitis/rhinorrhea/postnasal drip (PND) (4)
- Occupation or other reasons for voice overuse
- Smoking history
- Blunt or penetrating trauma to neck
- GERD/LPRD

**PHYSICAL EXAM**
- Head and neck exam, including airway patency, cervical nodes; cranial nerve exam
- Visualization of the larynx: preferably with a flexible or rigid endoscope or with an indirect mirror examination as a screening technique to dictate further appropriate testing (4)
- Note quality of voice (i.e., hoarse, breathy, wet, “hot potato like,” asthenic [weak], strained) (2).

**DIFFERENTIAL DIAGNOSIS**
- Diphtheria
- Vocal nodules or polyps
- Laryngeal malignancy
- Thyroid malignancy
- Upper airway malignancy (2,4)[A]
- Epiglottitis
- Pertussis
- Laryngeal nerve trauma/injury
- Foreign body (in children)
- Autoimmune (rheumatoid arthritis) (3)[A]

**DIAGNOSTIC TESTS & INTERPRETATION**

- Rarely needed
- WBCs elevated in bacterial laryngitis
- Viral culture (seldom necessary)

**Follow-Up Tests & Special Considerations**

- Barium swallow, only if needed for differential diagnosis
- CT scan if foreign body suspected

**Diagnostic Procedures/Other**

- Fiber-optic or indirect laryngoscopy: looking for red, inflamed, and occasionally hemorrhagic vocal cords; rounded edges and exudate (Reinke edema)
- Consider otolaryngologic evaluation and biopsy: laryngitis lasting >2 weeks in adults with history of smoking or alcohol abuse, to rule out malignancy.
- pH probe (24-hour): no difference in incidence of pharyngeal reflux as measured by pH probe between patients with chronic reflux laryngitis and healthy adults (2)[A]
- Strobovideo laryngoscopy for diagnosis of subtle lesions (e.g., vocal cord nodules or polyps) (4)[A]

**TREATMENT**

- Limited but good evidence that treatment beyond supportive care is ineffective (4)[A]
- Supportive care consists of hydration, voice rest, humidification, and
limitation of caffeine (1)[A].

- Antibiotics appear to have no benefit, as etiologies are predominantly viral (1,5)[A].
- Corticosteroids in severe cases of laryngitis to reduce inflammation such as croup
- May need voice training, if voice overuse
- Nebulized epinephrine reduces croup symptoms 30 minutes posttreatment; evidence does not favor racemic epinephrine or L-epinephrine or IPPB over simple nebulization. Racemic epinephrine reduces croup symptoms at 30 minutes, but effect lasts only 2 hours (5)[A].

GENERAL MEASURES

- Acute:
  - Usually a self-limited illness lasting <3 weeks and not severe
  - Antibiotics of no value (5)[A]
  - Avoid excessive voice use, including whispering.
  - Steam inhalations or cool-mist humidifier
  - Increase fluid intake, especially in cases associated with excessive dryness.
  - Avoid smoking (or secondhand exposure).
  - Warm saltwater gargles
- Chronic:
  - Symptomatic treatment as above
  - Voice therapy (for patients with intermittent dysphagia and vocal abuse)
  - Smoking cessation
  - Reduction or cessation of alcohol intake
  - Occupational change or modification, if exposure driven
  - Allergen avoidance
  - Consider discontinuing offending medication (e.g., inhaled steroids) (5)[A].
- Reflux laryngitis: Elevate head of bed, diet changes, other antireflux lifestyle change management; proton pump inhibitors (1)[A]

MEDICATION

Usually none

First Line

- Analgesics
- Antipyretics (rare)
- Cough suppressants
- Throat lozenges
- Plenty of fluids

**Second Line**
- Inhaled corticosteroids (consider only if allergy induced) (2)
- Oral corticosteroids: only if urgent need in adults (presenter, singer, actor)
  - Oral corticosteroids: Evidence of benefit has been studied with single-dose dexamethasone in children ages 6 months to 5 years for moderate-severity croup; reduces symptoms within 6 hours; reduces hospitalizations, hospital length of stay, and revisits to office (5)[A]
- Standard of care is to prescribe proton pump inhibitors for chronic laryngitis if GERD or LPRD is suspected; however, evidence suggests only a modest benefit, if any (1)[A].
- Treat nonviral infectious underlying causes.
- Candidal laryngitis:
  - Mild cases: oral antifungal (fluconazole)
  - Amphotericin B or echinocandin can be given in life-threatening cases (1) [A].

**ISSUES FOR REFERRAL**
- Immediate emergency ENT referral for patients with stridor or respiratory distress (1)[A]
- ENT referral for persistent symptoms (>2 to 3 weeks) or concern for foreign body
- Consider otolaryngologic evaluation and biopsy for laryngitis lasting >3 weeks in adults, especially in those with history of smoking or alcohol abuse to rule out malignancy.
- Consider GI consult to rule out GERD/LPRD.

**SURGERY/OTHER PROCEDURES**
- Vocal cord biopsy of hyperplastic mucosa and areas of leukoplakia if cancer or TB is suspected
- Removal of nodules or polyps if voice therapy fails

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Some experts, although not well studied, have recommended the following:
- Barberry, black currant, *Echinacea*, *Eucalyptus*, German chamomile,
goldenrod, goldenseal, warmed lemon and honey, licorice, marshmallow, peppermint, saw palmetto, slippery elm, vitamin C, zinc

ONGOING CARE

PATIENT EDUCATION

- Educate on the importance of voice rest, including whispering.
- Provide assistance with smoking cessation.
- Help the patient with modification of other predisposing habits or occupational hazards.

PROGNOSIS

Complete clearing of the inflammation without sequelae

COMPLICATIONS

Chronic hoarseness

REFERENCES

ADDITIONAL READING

ICD10

- J04.0 Acute laryngitis
- J37.0 Chronic laryngitis
- J04.2 Acute laryngotracheitis

CLINICAL PEARLS

- Laryngitis is usually self-limited and needs only comfort care. Standard treatment is voice rest, hydration, humidification, and limit caffeine intake.
- Refer to ENT for direct visualization of vocal cords for prolonged laryngitis.
- Corticosteroids have some benefits for children with moderately severe croup.
- Voice training useful for chronic laryngitis
LEAD POISONING

Jason Chao, MD, MS

BASICS

DESCRIPTION
- Consequence of a high body burden of lead (Pb), an element with no known physiologic value
- Synonym(s): lead poisoning, inorganic

EPIDEMIOLOGY
- Predominant age: 1 to 5 years, adult workers
- Predominant sex: male > female (1:1 in childhood)

Prevalence
- Centers for Disease Control and Prevention (CDC) estimates half a million U.S. children aged 1 to 5 years have blood Pb levels >5 μg/dL. Levels vary among communities and populations.
- 2013 case prevalence rate blood Pb level ≥10 μg/dL is 20 per 100,000 employed adults, a slight decline over the prior 3 years

ETIOLOGY AND PATHOPHYSIOLOGY
- Inhalation of Pb dust or fumes, or ingestion of Pb
- Pb replaces calcium in bones. Pb interferes with heme synthesis, causes interstitial nephritis, and interferes with neurotransmitters, especially glutamine; high levels affect blood–brain barrier and lead to encephalopathy, seizures, and coma.
- Early life Pb exposure causes methylation changes leading to epigenetic alterations that may lead to brain dysfunction.

RISK FACTORS
- Children with pica or with iron-deficiency anemia
- Residence in or frequent visitor to deteriorating pre-1960 housing with Pb-painted surfaces or recent renovation
- Soil/dust exposure near older homes, Pb industries, or urban roads
- Sibling or playmate with current or past Pb poisoning
Dust from clothing of Pb worker or hobbyist

Pb dissolved in water from Pb or Pb-soldered plumbing (Example: Flint, Michigan 2014 to 2015)

Pb-glazed ceramics leach (especially with acidic food or drink)

Folk remedies and cosmetics
  – Mexico: Azarcon, Greta
  – Dominican Republic: Litargirio, a topical agent
  – Asia and Middle East: Chuifong tokuwan, pay-loo-ah, ghasard, bali goli, kandu, ayurvedic herbal medicine from South Asia, kohl (alkohl, ceruse), surma, saoott, cebagin

Hobbies: target shooting, glazed pottery making, Pb soldering, preparing Pb shot or fishing sinkers, stained-glass making, car or boat repair, home remodeling

Occupational exposure: plumbers, pipe fitters, Pb miners, auto repairers, glass manufacturers, shipbuilders, printer operators, plastic manufacturers, Pb smelters and refiners, steel welders or cutters, construction workers, rubber product manufacturers, battery manufacturers, bridge reconstruction workers, firing range workers, military and law enforcement

Dietary: zinc or calcium deficiency

Imported toys with Pb

Retained bullet fragments

**Pediatric Considerations**

Children are at increased risk because of incomplete development of the blood–brain barrier at <3 years of age, allowing more Pb into the CNS; ingested Pb has 40% bioavailability in children (10% in adults).

Common childhood behaviors such as frequent hand-to-mouth activity and pica (repeated ingestion of nonfood products) increase the risk of Pb ingestion.

**GENERAL PREVENTION**

Counsel families on sources of Pb and methods to decrease Pb exposure. Screen children at high risk (1)[C].

Warn parents about the dangers posed by unsafe home renovations.

Wet mopping and dusting with a high-phosphate solution (e.g., powdered automatic dishwasher detergent with 1/4 cup/gallon of water) helps control Pb-bearing dust. High-phosphate detergent is no longer available in some states.

If tap water is potentially Pb contaminated, preferentially use cold water
instead of hot water and run for 30 to 60 seconds to flush pipes. Preferentially use Pb-free water source if available (bottled or distilled water).

- Screen at-risk pregnant women (2)[C].

COMMONLY ASSOCIATED CONDITIONS
Iron-deficiency anemia

DIAGNOSIS

HISTORY
- Often asymptomatic
- Mild-to-moderate toxicity
  - Myalgias, paresthesias, fatigue, irritability, lethargy
  - Abdominal discomfort, arthralgia, difficulty concentrating, headache, tremor, vomiting, weight loss, muscular exhaustibility
- Severe toxicity: three major clinical syndromes:
  - Alimentary type: anorexia, metallic taste, constipation, severe abdominal cramps due to intestinal spasm and sometimes associated with abdominal wall rigidity
  - Neuromuscular type (characteristic of adult plumbism): peripheral neuritis, usually painless and limited to extensor muscles
  - Cerebral type or Pb encephalopathy (more common in children): seizure, coma, and long-term sequelae, including neurologic defects, delayed mental development, and chronic hyperactivity
- Chronic exposure may cause renal failure.

PHYSICAL EXAM
Often normal, but abdominal tenderness may be severe. Neurologic exam may reveal neuropathy or encephalopathy. Historical feature is “crackpot skull”—resonant cranium secondary to hydrocephalus.

DIFFERENTIAL DIAGNOSIS
- Alimentary type may present as acute abdomen.
- Neuromuscular type presents similar to other polyneuropathies.
- Cerebral type may be confused with ADD, mental retardation, autism, dementia, and other causes of seizures.
- Elevated erythrocyte protoporphyrin may be caused by iron-deficiency anemia.
or, less commonly, hemolytic anemia.

- Erythropoietic protoporphyria produces a very high erythrocyte protoporphyrin level.

**DIAGNOSTIC TESTS & INTERPRETATION**

- Venous blood Pb >5 μg/dL (0.24 μmol/L)
- Confirm screening capillary Pb levels >5 μg/dL (0.24 μmol/L) with a venous sample.
- Hemoglobin and hematocrit slightly low; eosinophilia or basophilic stippling on peripheral smear may be seen but is not diagnostic of Pb toxicity.
- Renal function is decreased in late stages.
- Abdominal radiograph for Pb particles in gut if recent ingestion is suspected
- Radiograph of long bones may show lines of increased density in the metaphyseal plate resulting from growth arrest. This does not usually alter management and films are not routinely recommended.

**TREATMENT**

<table>

</tr>
</tbody>
</table>

**ALERT**

- For blood Pb levels persistently >15 μg/dL, contact local public health department for home inspection.
- For Pb levels between 5 and 45 μg/dL, higher levels require urgent need for confirmation.
- For any elevated level, educate on sources of Pb.
- Pb level > ref level to <45: Complete history and physical exam, follow up Pb monitoring; complete inspection of home or workplace to determine source of Pb and Pb-hazard reduction; neurodevelopmental monitoring: iron status, Hgb, or Hct (3)[C]
- Pb level 45 to 69: Treatment to lower level plus free erythrocyte protoporphyrin, oral chelation therapy, or hospitalization if Pb-safe environment cannot be ensured (3)[C]
Pb >70: Hospitalize for chelation therapy (4)[C].

MEDICATION
- Consider oral chelation for asymptomatic and Pb >45 and <70; chelation (preferably parenteral) for Pb >70 or symptomatic Pb <70 (4)[C]
- Do not begin chelation until Pb particles present in gut are cleared (5)[C].

First Line
- Oral chelation: Succimer (Chemet), dimercaptosuccinic acid (DMSA) 350 mg/m² or 10 mg/kg q8h for 5 days; then q12h for 2 weeks. This may be repeated after 2 weeks off if Pb levels are not stabilized at <15 μg/dL (<0.72 μmol/L) (4)[C].
- Parenteral chelation (begin after establishment of adequate urine output):
  - Dimercaprol (British anti-Lewisite [BAL]) 75 mg/m² given deep IM; then BAL 450 mg/m²/day divided q4h for 5 days plus Ca edetate calcium disodium (EDTA) 1,500 mg/m²/day continuous IV infusion for 5 days. If rebound Pb level ≥45 μg/dL (≥2.17 μmol/L), chelation may be repeated after 2-day interval if symptomatic or after 5-day interval if asymptomatic.
  - Ca EDTA 1,000 mg/m²/day for 5 days; may be repeated after 5 to 7 days
- Diazepam for initial control of seizures; further control maintained with paraldehyde
- Contraindications: Do not give BAL to patients with a peanut allergy (the drug solution contains peanut oil).
- Precautions
  - Succimer: GI upset, rash, nasal congestion, muscle pains, elevated liver function tests
  - BAL: nausea, vomiting, fever, headache, transient hypertension, hepatocellular damage
  - Ca EDTA: renal failure, increased excretion of zinc, copper, and iron
- Significant possible interactions
  - Do not give vitamins with oral chelation.
  - BAL may precipitate hemolytic crisis in a patient with glucose-6-phosphate dehydrogenase deficiency.

Second Line
Oral chelation with penicillamine (D-penicillamine, Depen, Cuprimine) (5)[C]
- Penicillin-allergic patient should not receive penicillamine (cross-sensitivity is common).
10 to 15 mg/kg/day given BID mixed in apple juice/sauce on empty stomach (not FDA approved)

Penicillamine may cause GI upset, renal failure, granulocytopenia, liver dysfunction, iron deficiency, and drug-induced lupus-like syndrome.

ISSUES FOR REFERRAL
Consider consultation if parenteral chelation is required.

ADDITIONAL THERAPIES
Remove patient from potential source of Pb if Pb level >45 until complete home inspection is performed.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Garlic has been used to treat mild to moderate Pb poisoning in adults.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Blood Pb level >70 μg/dL
- If symptomatic, blood Pb level >35 μg/dL
- Outpatient care unless parenteral chelation or immediate removal from contaminated environment is required.
- If Pb source is in the home, the patient must reside elsewhere until the abatement process is completed.
- Avoid visit to any site of potential contamination.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Check for rebound Pb level 7 to 10 days after chelation therapy. Monitor biweekly or monthly thereafter.
- Correct iron or other detected nutritional deficiencies.
- Once Pb <35 μg/dL, repeat testing every 1 to 3 months until level <25 μg/dL is achieved. Then, monitor every 3 to 6 months until level <10 μg/dL. Once <9 μg/dL, test every 6 to 9 months (3)[C].
DIET
- If symptomatic, avoid excessive fluids.
- Avoid pica.
- Adequate calcium, iron, zinc, and vitamin C to reduce absorption and retention of Pb (5) [B]

PATIENT EDUCATION
- National Lead Information Center, 422 South Clinton Avenue, Rochester, NY 14620; 800-424-5323; www.epa.gov/lead/
- National Safety Council, 1121 Spring Lake Drive, Itasca, IL 60143-3201; 800-621-7615; http://www.nsc.org/learn/safety-knowledge/Pages/Lead-Poisoning-Prevention.aspx

PROGNOSIS
- Symptomatic Pb poisoning without encephalopathy generally improves with chelation, but subtle CNS toxicity may be long lasting or permanent.
- Children with high lead Pb levels at age 11 years have lower IQ score and socioeconomic status in adulthood.
- With Pb encephalopathy, permanent sequelae (e.g., mental retardation, seizure disorder, blindness, and hemiparesis) occurs in 25–50%.

COMPLICATIONS
- CNS toxicity may be long lasting or permanent.
- Long-term Pb exposure may cause chronic renal failure (Fanconi-like syndrome), gout, or Pb line (blue–black) on gingival tissue.
- Pb exposure in pregnancy is associated with reduced birth weight and premature birth.
- Pb is an animal teratogen.

Centers for Disease Control and Prevention; 2012.

**ADDitional Reading**

**SEE ALSO**

Anemia, Iron Deficiency

**CODES**

**ICD10**

- T56.0X4A Toxic effect of lead and its compounds, undetermined, init
- T56.0X1A Toxic effect of lead and its compounds, accidental, init

**Clinical Pearls**

- Screen the following children:
  - 6 to 11 months of age with ≥1 risk factors:
    - Living in or visit a house built before 1960 with peeling paint or recent renovation
    - Sibling/playmate with elevated Pb
    - Living with adult with job or hobby involving Pb
    - Living near industry likely to release Pb
– Children living in high-risk communities (>12% elevated Pb) should be tested annually from 1 to 5 years of age.
– Newly arrived refugees
  • There is no clear safe Pb level. Many experts consider Pb levels >4 μg/dL as elevated.
  • There are no studies that show benefit of chelation for asymptomatic children with Pb <45. Removal of sources of Pb within the environment is critical.
LEGIONNAIRES’ DISEASE
Andrew G. Alexander, MD • Kenneth A. Ballou, MD • Maegen Dupper, MD

BASICS

DESCRIPTION

- *Legionnaires’ disease* was named for an epidemic of lower respiratory tract disease at an American Legion convention in Philadelphia in 1976. The causative bacterium was previously unrecognized. It was isolated, identified, and named *Legionella pneumophila*. The organism primarily causes pneumonia and flulike illness. *Legionella* preferentially colonizes commercial water systems (e.g., hotels, hospitals, air conditioning cooling towers).
  - Among the three most common clinical pneumonias
  - Most common atypical pneumonia
- System(s) affected: pulmonary, gastrointestinal
- Synonym(s): Legionella pneumonia; legionellosis

EPIDEMIOLOGY

- Predominant age: 15 months to 84 years; 74–91% of patients are >50 years old.
- Predominant gender: male > female

Incidence

- U.S. cases of Legionnaires’ disease have increased 4-fold since 2000; >6,000 cases were reported in 2015 (1).
- Outbreaks are most common in late summer and early fall.
- Represents 2–9% of all cases of pneumonia in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

- *L. pneumophila* is a weak gram-negative aerobic saprophytic freshwater bacterium. It is widely distributed in soil and water. Bipolar flagella provide motility; grows optimally at 40–45°C
- Exists in nature as protozoan parasite and within fresh water biofilms
- Serogroups 1 to 6 account for clinical disease.
- Serogroup 1 represents 70–92% of all clinical cases of *Legionella* in the
United States.
- In the lung, *Legionella* infects alveolar macrophages.
- The organism is transmitted by breathing in contaminated water droplets or by aspiration of contaminated water (e.g., contaminated shower water responsible for the inaugural Philadelphia outbreak).
- Recently, community outbreaks associated with whirlpools, spas, fountains, and aboard cruise ships

**RISK FACTORS**
- Impaired cellular immunity (*Legionella* are intracellular pathogens.)
- Male gender
- Smoking; alcohol abuse
- Immunosuppression; HIV; diabetes; organ transplant recipients; corticosteroid use
- Chronic cardiopulmonary disease
- Advanced age
- Use of antimicrobials within the past 3 months

**GENERAL PREVENTION**
- *Not transmitted person to person* (respiratory isolation is unnecessary)
- Superheat and flush water systems: Heat water to 70°C and flush outlets with hot water for 30 minutes (2)[°C].
- Ultraviolet light or copper–silver ionization are bactericidal.
- Monochloramine disinfection of municipal water supplies decreases risk for *Legionella* infection.
- 0.2 micron water filters—change regularly.
- Keep water heaters >60°C, cold water <20°C.

**COMMONLY ASSOCIATED CONDITIONS**
Pontiac fever: self-limited flulike illness without pneumonia caused by *Legionella* species

**DIAGNOSIS**
- Illness ranges from asymptomatic seroconversion and mild febrile illness to severe pneumonia.
- Wound infections with *Legionella* also reported
- Incubation period is 2 to 14 days.
HISTORY
- Signs and symptoms (with associated percentage):
  - Dry cough: 92% (occasionally productive)
  - Fever/chills: 90%
  - Dyspnea: 62%
  - Pleuritic chest pain: 35%
  - Headache: 48%
  - Myalgia/arthritis: 40%
  - Watery diarrhea: 50%
  - Nausea and vomiting: 49%
  - Neuropsychiatric symptoms include encephalopathy, confusion, disorientation, obtundation, depression, hallucinations, insomnia, seizure: 53%.
- History of immunosuppression increases risk.

PHYSICAL EXAM
- Fever
- Relative bradycardia (key sign)
  - Defined as a temperature ≥102°F with an inappropriately low pulse pressure <100 beats/min (normal compensatory reaction to fever is tachycardia >110 beats/min)
- Rales and signs of consolidation (egophony; tactile fremitus)

DIFFERENTIAL DIAGNOSIS
- Other bacterial pneumonias, especially atypical pneumonias: Mycoplasma pneumoniae, Q fever (Coxiella burnetii), Chlamydia pneumoniae, Chlamydia psittaci, Francisella tularensis
- Viral pneumonias, such as adenovirus, influenza (human, avian, swine), cytomegalovirus (CMV)

DIAGNOSTIC TESTS & INTERPRETATION
Indications for Legionella testing:
- Failed outpatient antibiotic treatment for community-acquired pneumonia
- Severe pneumonia, in particular those requiring intensive care
- Immunocompromised patients with pneumonia
- Patients with a travel history (patients who have traveled away from their home within 10 days of illness onset)
- Pneumonia in the setting of a known Legionnaires’ disease outbreak
Patients at risk for Legionnaires’ disease with health care–associated pneumonia (pneumonia with onset ≥48 hours after admission)

**Initial Tests (lab, imaging)**

- **Diagnosis:**
  - *Legionella* culture (gold standard) requires a good sputum sample and special media (BCYE agar). Culture has variable sensitivity (10–80%) and time delays of up to 7 days for results.
  - Urinary antigen test (UAT) detects serogroup 1 (which causes 80% of disease). UATs are highly specific (95–100%) but variably sensitive.
  - *Legionella* PCR detects ~100% of all *Legionella* species from respiratory secretions (3)[C].
  - PCR can provide rapid diagnosis and is used to test environmental sources.
  - Direct fluorescent antibody staining for *Legionella* requires expertise and can be used as a confirmatory test (4)[A].

- Other lab abnormalities (seen less commonly with other forms of pneumonia):
  - Hyponatremia
  - Hypophosphatemia (transient)
  - Lymphopenia
  - Mildly elevated serum transaminases; elevated LDH; elevated creatinine kinase
  - Microscopic hematuria
  - Highly elevated C-reactive protein (CRP) (>30)
  - Highly elevated ferritin (≥2 times normal)

- **Chest radiograph**
  - Not specific for *Legionella*
  - Commonly shows unilateral lower lobe patchy alveolar infiltrate with consolidation
  - Cavitation and abscess formation is more common in immunocompromised patients.
  - Pleural effusion occurs in up to 50%.
  - May take 1 to 4 months for radiographic findings to resolve. Progression of infiltrate on x-ray can be seen despite antibiotic therapy.

**Diagnostic Procedures/Other**

Transtracheal aspiration/bronchoscopy occasionally necessary to obtain sputum/lung samples
Test Interpretation

- Multifocal pneumonia with alveolitis and bronchiolitis and fibrinous pleuritis; may have serous or serosanguineous pleural effusion
- Abscess formation occurs in up to 20% of patients.
- Progression of infiltrates on x-ray (despite appropriate therapy) suggests Legionnaires’. Radiographic improvement may not correlate with clinical findings (longer lag times).

TREATMENT

GENERAL MEASURES

- Severity of illness and available resources dictate the appropriate site for care.
- Supportive care:
  - Oxygenation, hydration, and electrolyte balance with antibiotic therapy
- Extrapulmonary complications and higher mortality in patients with AIDS
- In severe pneumonia, guidelines recommend obtaining a UAT and starting empiric antibiotics to include coverage for Legionella (5)[C].

MEDICATION

First Line

- Antibiotics that achieve high intracellular concentrations (e.g., macrolides, tetracyclines, fluoroquinolones) are most effective; first-line treatment is levofloxacin; No prospective randomized controlled trials have compared fluoroquinolones to macrolides for the treatment of Legionella; levofloxacin associated with more rapid defervescence, fewer complications, decreased hospital stay by 3 days, and decreased mortality (4% vs. 10.9%) compared with macrolide antibiotics (5)[A]
- Start antibiotics parenterally if sufficiently ill due to the GI symptoms associated with Legionella:
  - Levofloxacin is the preferred agent:
    o Levofloxacin 750 mg/day IV (switch to PO when patient is afebrile/tolerating PO) for 5 days or 750 mg/day for 7 to 10 days
  - Azithromycin may also be used first line. It requires a shorter duration of treatment than levofloxacin due to a longer half-life:
    o Azithromycin 500 mg/day IV (switch to PO when afebrile/tolerating PO) for 7 to 10 days
**Contraindications:** hypersensitivity reactions

**Precautions:** liver disease

**Significant drug interactions:**
- Can increase theophylline, carbamazepine, and digoxin levels; can increase activity of oral anticoagulants
- May decrease the effectiveness of digoxin, quinidine, oral contraceptives, and hypoglycemic agents

**Longer courses of treatment** (up to 21 days) may be needed in immunocompromised patients or if treating valvular heart disease.

**Second Line**
- Doxycycline 100 mg IV/PO q12h for 14 days; for severe infections, initial dose is 200 mg IV/PO q12h.
- Doxycycline cannot be used in pregnant patients and is not approved for children <8 years of age.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Inability to tolerate oral antibiotics
- Hypoxemia

**Criteria for direct admission to the ICU:**
- Any major criteria for severe CAP:
  - Septic shock requiring vasopressor support
  - Acute respiratory failure requiring intubation and/or mechanical ventilation
- Three or more minor criteria for severe CAP:
  - RR ≥30 breaths/min; PaO₂:FiO₂ ratio ≤250; multilobular infiltrates; confusion/disorientation; uremia (BUN ≥20 mg/dL); leukopenia (WBC <4,000 cells/mm³); thrombocytopenia (PLT <100,000 cells/mm³); hypothermia (temperature <36°C); hypotension requiring aggressive fluid resuscitation

**Discharge criteria**
- Afebrile
- Able to tolerate oral antibiotics
- Normal room air oxygen saturation
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Monitor respiratory status, hydration, and electrolyte status closely.
- Chest radiography lags behind the clinical status and may not help with monitoring clinical response.

PATIENT EDUCATION
- Disease prevention: Eliminate pathogens from water supplies, low-emission cleaning of cooling towers with control measurements of water and air samples.
- *Legionella* is not spread person to person.

PROGNOSIS
- Improved prognosis when appropriate antibiotics are started early in the disease course
- Recovery is variable:
  - Patients may clinically worsen despite appropriate initial treatment (first 1 to 2 days of therapy).
  - Improvement with defervescence in 3 to 5 days and complete recovery in 6 to 10 days is typical. Some have a more protracted course.
- Mortality in nosocomial infections ranges from 15% to 34%.

COMPLICATIONS
- Dehydration
- Hyponatremia
- Respiratory insufficiency requiring ventilator support
- Bacteremia/lung abscess formation in up to 20%
- Extrapulmonary diseases:
  - Endocarditis (most common extrapulmonary site)
  - Cellulitis
  - Sinusitis
  - Pancreatitis
  - Pyelonephritis
  - Encephalitis
  - Pericarditis
- Perirectal abscess
- Renal failure
- Disseminated intravascular coagulation
- Multiple organ dysfunction syndrome (MODS)
- Coma
- Death occurs in 8–12% of treated immunocompetent patients and in up to 80% of untreated immunocompromised patients.

Pneumonia, Bacterial

CODES
ICD10
- A48.1 Legionnaires’ disease
- A48.2 Nonpneumonic Legionnaires’ disease [Pontiac fever]

CLINICAL PEARLS
- *Legionella* is an intracellular organism that can only be grown on buffered charcoal yeast extract agar.
- Serology is not useful in early stages of the disease (an increase in *Legionella* antibody titers cannot be detected >3 to 4 weeks).
- UAT and *Legionella* sputum PCR are the most sensitive and practical initial tests. Sputum culture is definitive but can take up to 7 days.
- Consider Legionnaires’ disease in cases of nosocomial pneumonia.
- Consider Legionnaires’ disease in patients with pneumonia who have extrapulmonary findings (atypical CAP) and a relative bradycardia. Relative lymphopenia, mildly elevated serum transaminases (aspartate aminotransferase/alanine aminotransferase), highly increased ferritin levels, or hypophosphatemia are other laboratory clues to *Legionella* infection.
LESBIAN HEALTH

Tina D’Amato, DO

BASICS

DESCRIPTION

- A lesbian is a woman who has her primary emotional and sexual relationships with women.
- Other sexual minorities include bisexual, transgender, and transsexual women.
- Sexual behaviors
  - May be celibate, sexually active only with women or with both men and women
  - ~75% of self-reported lesbians have reported prior or ongoing sexual contact with men.
- Sexual orientation and gender nonconformity are complex concepts, and defining them can be challenging.

EPIDEMIOLOGY

Prevalence

- Estimated to be between 1% and 5%
- Approximately 1.4 million women living in the United States identify as lesbians. Another 2.6 million women identify as bisexual.
- 2011 American Community Survey from United States Census Bureau reports a total of 321,177 households headed by female same-sex couples.

RISK FACTORS

Higher incidence for the following risk factors compared to heterosexual women:

- Elevated BMI
  - Lesbian women have a higher prevalence of overweight/obesity than all other female sexual orientation groups.
- Alcohol use
  - More common use than reported in heterosexual women
  - Age 20 to 34 years is at highest risk for daily use and heavy use of alcohol. Those numbers decline in older age groups.
• Tobacco use
  – 2 times more likely to smoke than heterosexual women
• Sexual minority stress (1)
  – Increased risk for health issues secondary to greater exposure to social stresses related to prejudice and stigma
• The above factors can increase risks for
  – Cardiovascular disease (CVD)
  – Type 2 diabetes
  – Hepatic disease
  – Cancers

COMMONLY ASSOCIATED CONDITIONS

• Cervical cancer
  – Lesbians are equally at risk for developing cervical cancer compared to heterosexual women.
  – HPV can be transmitted genitally skin to skin, oral to genitals, and digital to genitals.
  – Risk of cervical cancer is highest in lesbians:
    o With prior HPV infection/abnormal Pap smear
    o Who have had a history of heterosexual intercourse
  – Lesbian and bisexual women are 10 times less likely to have adequate cervical cancer screening compared to heterosexual women.
  – Tobacco use influences cervical cell atypia.
• Breast cancer
  – Risk factors same as heterosexual women
    o Moderate or heavy alcohol consumption
    o Obesity
    o Nulliparity or first child born after age 30 years
  – Mammogram screening rates lower among lesbians
  – New data suggests lesbians have increased mortality rate compared to heterosexual women (2).
• Ovarian cancer
  – Elevated BMI and tobacco use increases risks.
  – Lesbians less likely to have been on hormonal contraception for 5 years or longer
  – Lesbians less likely to have been pregnant or breastfed an infant before age 30 years
  – Lesbians at increased risk for ovarian cancer may want to explore potential benefits of long-term progestin-containing contraception to reduce risk.
• CVD
  – Lesbians have higher rates of obesity, smoking, and stress which increase risks for CVD.
• Mental health diagnoses
  – 2 times more likely to see general physician for mental/emotional complaint
    o Depression
      ■ Double the rate compared to heterosexual women
      ■ Discrimination stress proposed factor
    o Anxiety disorders
      ■ 2- to 4-fold higher rate of generalized anxiety disorder
      ■ Higher rates of PTSD, panic, phobia
      ■ Multiple diagnoses
      ■ 3 times risk
    o Alcohol abuse
      ■ Greatest in lesbians ages 20 to 34 years
      ■ Bar culture
      ■ May not feel comfortable in traditional Alcoholics Anonymous environment
      ■ Alcohol dependency 3 times more common compared to heterosexual women (3)
• Sexually transmitted infections (STI)
  – Many lesbians underestimate their STI risks.
  – >10% of women with exclusively female partners have a history of at least one STI (4).
  – Lesbian sexual practices include the following:
    o High risk: oral–vaginal contact, genital–genital contact, oral–anal contact, digital stimulation/penetration, and sharing of sex toys
    o Lower risk: kissing, rubbing genitals against partner’s body
• Bacterial vaginosis
  – Higher rate than heterosexual women
  – Increased incidence with smoking and multiple sexual partners
  – Often found in monogamous lesbian couples suggesting it can be sexually transmitted
• Chlamydia
  – Can be transmitted woman to woman (WTW)
• Gonorrhea
  – Can be transmitted WTW
• Hepatitis B
  – Can be transmitted WTW
- Herpes
  - Can be transmitted WTW
- HPV
  - Can be transmitted WTW
- HIV
  - Transmission between women rare but possible
  - Women having sex with women (WSW) more likely to have sexual contact with men having sex with men (MSM) than heterosexual women
- Syphilis
  - Can be transmitted WTW
- Trichomonas
  - Can be transmitted WTW
- STI screening and prevention
  - Screen based on woman’s history.
  - Encourage safer sex practices:
    - Avoid menstrual blood/open sores.
    - Dental dams for oral sex
    - Condoms on sex toys and cleaning immediately after use
    - Vinyl/latex gloves for manual sex
- Psychosocial considerations
  - Sexual abuse
    - 3 times more likely than heterosexual women to report having been sexually assaulted
    - 43% of lesbians reported at least one sexual assault in their lifetime.
    - History of childhood sexual abuse can be associated with more complicated and difficult “coming out.”
  - Intimate partner violence
    - 17–45% of lesbians report at least one act of physical violence at the hands of a lesbian partner.
  - Parenthood
    - A reported 41% of lesbians desire to have a child.
      - Perinatal depression is common and may be more common than in heterosexual women.
    - >30% have biologic children.
      - Often from previous heterosexual relationship
      - Adoption
      - Assisted reproductive technology/donor insemination
      - Some will engage in high-risk sexual behaviors (MSM, “one-night stand”) in an attempt to get pregnant.
Providers should discuss parenting with their lesbian patients.
Encourage both partners or nonbiologic parent to adopt child to ensure permanent legal relationship to child.
Discuss durable power of attorney for health care and finances in the event of death or separation.
Adolescents who have been reared in lesbian mother families since birth demonstrate healthy psychological adjustment.

- Adolescent lesbians
  - Increased risk for eating disorders
  - Higher rates of substance use particularly polysubstance abuse
  - If also having sexual contact with males, higher rates of pregnancy compared to heterosexual counterparts due to (5)
  - High rates of early sexual initiation
  - Greater number of partners
  - Less contraceptive use
  - Higher rates of physical and/or sexual abuse
  - Childhood sexual abuse does not cause children to become LGBTQ.

- Aging lesbians
  - Elders aging “back into the closet”
    - Discrimination by religious and other groups that own nursing homes
    - Fear of discrimination by caregivers/health care workers
    - Few elder care programs specifically directed at LGBT persons

TREATMENT

GENERAL MEASURES

- Create a safe practice environment for lesbian patients.
  - Have nondiscrimination policy posted where it is visible to patients.
  - Educate staff to be comfortable dealing with the needs of lesbian patients and their families.
  - Intake forms should include options for patient to indicate sexual preference and current partnership status.
  - Use “gender-neutral” language.
    - “Do you have a significant other?”
  - Avoid heterosexist assumptions (“What do you use for birth control?” asking instead “Do you plan to become pregnant or have a child? Do you need birth control?”).
● Ask about sexual orientation.
  – Many physicians do not ask.
  – Intake/annual physical forms should include questions about orientation/activity.
● Take a detailed sexual history.
  – Sexual identity and sexual behaviors not always strongly correlated
  – Ask about behaviors (“Do you have sex with women, men or both?”); do not just assume current/past sexual activity with women.
  – STI screening based on reported history/activity
  – Address contraception when appropriate.
● Respect the partners.
  – Treat her as you would any other spouse/partner.
  – Assure access if partner hospitalized.
  – Recommend durable power of attorney.
● Follow same preventive screening guidelines and lifestyle recommendations as for heterosexual women (Pap smear, mammography, colonoscopy screening, safer sex, exercise, diet, alcohol moderation, and tobacco avoidance).
● Legal/U.S. government
  – Healthy People 2010 identified lesbian/gay Americans as 1 of 6 population groups affected by health care disparities.
  – Healthy People 2020 goals to increase routine data collection efforts on LGBT populations via health care surveys
  – Access to health insurance was increased with Supreme Court decisions on *United States v. Windsor* in 2013 and *Obergefell v. Hodges* in 2015.
    – Some states still recognize same-sex civil union, but access to health insurance varies by state.
  – Affordable Care Act (ACA)
    – Prohibits discrimination based on sexual orientation in any program receiving federal funds (Medicare/Medicaid)
    – Increased emphasis on research and data collections in LGBT population
    – 2013 National Health Interview Survey (NHIS)
      – First time nationally representative data on sexual orientation and health are available.

REFERENCES

**ADDITIONAL READING**

- E66.3 Overweight
- Z72.0 Tobacco use
- F10.10 Alcohol abuse, uncomplicated

**CLINICAL PEARLS**

- Create a safe health care environment for all patients.
- Use gender-neutral language.
- Do not assume heterosexuality.
- Be aware that some patients may openly identify as lesbian, but others may only identify when asked directly. Some may be engaging in a same-sex relationship and not identify as a lesbian.
- Follow same preventive screening guidelines and lifestyle recommendations as for heterosexual women.
- Discuss durable power of attorney for health care needs to ensure partner’s involvement in care.
LEUKEMIA, ACUTE LYMPHOBLASTIC (ALL) IN ADULTS

Katyayini Aribindi, MD • Adrian DaSilva-DeAbreu, MD • Mark A. Farnie, MD

BASICS

DESCRIPTION

- Acute lymphoblastic leukemia (ALL) in adults is the result of a clonal proliferation, survival, and impaired differentiation of immature lymphocytes. The World Health Organization (WHO) defines ALL as the presence of ≥25% lymphoblasts in the bone marrow (1). Nevertheless, the National Comprehensive Cancer Network uses a ≥20% as cutoff (2).
- ALL and lymphoblastic lymphoma (LBL) can arise from the same precursor cell line, and therefore can be considered diseases along the same spectrum:
  - LBL presents as a mass, possibly but not limited to the mediastinum, with <25% blasts in the bone marrow.
  - ALL may present with a mass lesion but contains ≥25% bone marrow involvement.
- Any organ can be affected

Pregnancy Considerations

Many chemotherapy (CTX) drugs are teratogenic.

Pediatric Considerations

ALL is the most common malignancy in children—it accounts for 30% of all pediatric malignancies, and 80% of pediatric leukemias (see “Acute Lymphoblastic Leukemia, Pediatric”).

Geriatric Considerations

Patients >60 years with ALL have a 42% mortality during induction CTX. The cause of death is usually CTX-related complications or relapse. Survival is often reduced due to poor tolerance of CTX, thus leading to dose reductions and ineffective medication delivery.
EPIDEMIOLOGY
- Incidence of ALL is 1.7/100,000 per year.
- Higher incidence in males, whites, those with history of radiation, CTX, or certain genetic disorders
- Bimodal distribution: early peak at 4 to 5 years of age, second peak at ~50 years
- 80% of cases occur in children, 20% in adults.

ETIOLOGY AND PATHOPHYSIOLOGY
Unknown in most patients

Genetics
- Higher rates in monozygotic and dizygotic twins
- Increased risk of ALL with diseases related to chromosomal instability: Bloom syndrome, Fanconi anemia, ataxia-telangiectasia, neurofibromatosis
- Increased risk with inherited chromosomal abnormalities: Down syndrome, Klinefelter syndrome, etc.
- See “Follow-Up Tests & Special Considerations.”

RISK FACTORS
- Age >70 years, radiation exposure, and infection with HIV are risk factors for developing ALL.
- Human T-cell lymphotropic virus type 1 is associated with adult T-cell ALL.
- Epstein-Barr virus is associated with mature B cell ALL.

DIAGNOSIS

HISTORY
- Symptoms arise from sequelae of bone marrow suppression and/or from leukemic cell organ infiltration.
- B symptoms: fever, weight loss, night sweats
- Anemia: fatigue, shortness of breath, light-headedness, angina, headache
- Thrombocytopenia: easy bruising
- Neutropenia: fever, infection
- Lymphocytosis: bone pain
- CNS: confusion
- Organ infiltration: organ-specific symptoms and signs
PHYSICAL EXAM
- Thrombocytopenia: petechiae, ecchymoses, epistaxis, retinal hemorrhages
- Anemia: pallor
- Neutropenia: fever, infection sites
- Lymphocytosis: lymphadenopathy, splenomegaly; less often, hepatomegaly
- CNS: cranial nerve palsies, meningeal signs
- Testicular invasion: abnormal testicular exam

DIFFERENTIAL DIAGNOSIS
- Malignant disorders: other leukemias, especially AML, chronic myeloid leukemia in lymphoid blast phase, prolymphocytic leukemia, malignant lymphomas; multiple myeloma, bone marrow metastases from solid tumors (breast, prostate, lung, renal), and myelodysplastic syndromes
- Nonmalignant disorders: aplastic anemia, myelofibrosis, autoimmune diseases (Felty syndrome, lupus), infectious mononucleosis, pertussis, autoimmune thrombocytopenic purpura, leukemoid reaction to infection

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- CBC with differential:
  - Anemia: normocytic, normochromic
  - Thrombocytopenia
  - Peripheral blood lymphoblasts (B cell or T-cell)
- Elevated lactate dehydrogenase and uric acid
- CT of the neck, chest, abdomen, and pelvis with contrast and PET/CT if suspicion of lymphomatous involvement
- CT/MRI of head with contrast if neurologic symptoms are present.
- Scrotal US if abnormal testicular exam

Follow-Up Tests & Special Considerations
- Immunophenotyping of marrow/blood lymphoblasts: B lineage (CD19, CD20, CD22, CD24), T lineage (CD2, CD3, CD5, CD7), common ALL antigen (CD10); human leukocyte antigen (HLA)-DR, terminal deoxynucleotidyl transferase (TdT), aberrant myeloid antigens (CD13, CD33), and stem cell antigen (CD34).
- Cytochemical stains: myeloperoxidase negative; Sudan black B usually negative; TdT positive; periodic acid–Schiff ± is variable, depending on
subtype.
- Cytogenetics: Specific recurring chromosomal abnormalities have independent diagnostic and prognostic significance (hyperdiploidy >50 chromosomes or t[14q11q13] are favorable; the Philadelphia [Ph] chromosome, t[9;22], t[4;11], −7, and +8 are unfavorable). A translocation t(8;14) or t(2;8) or t(8;22) identifies Burkitt-type mature B cell leukemia that requires specific therapy.
- Reverse transcription polymerase chain reaction for rapid diagnosis of BCR/ABL1+ ALL
- Genomic analysis by next-generation sequencing: detection of mutations associated with Ph-like ALL
- HLA typing of patient and siblings for hematopoietic stem cell transplantation

**Diagnostic Procedures/Other**
- Bone marrow aspiration/biopsy with immunohistochemistry, immunophenotyping, cytogenetics, and molecular diagnostics
- Lymph node biopsy if available
- Lumbar puncture is mandatory and typically done both for diagnosis of CNS involvement and for intrathecal (IT) chemotherapy. It should be done at diagnosis and immediately if neurologic symptoms or signs are present. Repeat lumbar puncture after bone marrow remission is achieved to evaluate occult CNS involvement and continue prophylactic CNS treatment.

**Test Interpretation**
Diagnosis of ALL is generally based on the presence of ≥20% (NCCN definition) (2) or ≥25% (WHO definition) (1) lymphoblasts in the bone marrow. In some cases, the diagnosis of ALL can be made based on the presence of certain mutations (1), even if the percentage of blasts is lower than these numbers. The bone marrow biopsy typically shows diffuse replacement of marrow and lymph node architecture by sheets of malignant lymphoblasts, T-cell or B cell lineage determined by CD expression.

**TREATMENT**

**GENERAL MEASURES**
- Three phases to treatment:
  - Induction + CNS prophylaxis
– Consolidation
– Prolonged maintenance

- Multi-drug approach to eradicate disease, restore normal hematopoiesis, and prevent relapse due to resistant cells
- Adequate calcium and vitamin D supplementation may reduce bone injury from corticosteroids and avascular necrosis (AVN) of large joints.

MEDICATION

- Induction
  - The mainstay of treatment is a regimen called Hyper-CVAD (3)[A]: hyperfractionated cyclophosphamide, vincristine, anthracyclines, and dexamethasone. Hyper-CVAD is the most widely used regimen for ALL in adolescents and young adults, but for patients ≥60 years, HCVD is preferred.
  - Hyper-CVAD consists of eight alternating treatment cycles of parts A and B:
    o Part A: Hyper-CVAD
    o Part B: high-dose methotrexate (MTX) and cytarabine
    o Granulocyte colony-stimulating factors are given after each cycle to prevent delay in treatment and hasten bone marrow recovery (4)[A].
    o CNS prophylaxis: IT CTX consistent of IT-MTX, twice for each part A cycle (2)[A]
    o Those with CNS leukemia at diagnosis will need twice a week IT therapy, until CSF is cleared on three subsequent lumbar punctures (2)[A].
  - <40 years of age, and achieve complete remission after the first induction, the next step is either consolidation CTX or allogeneic stem cell transplant based on risk and ability to obtain donor.
  - Minimal residual disease (MRD), measured by flow cytometry in the US signifies CTX refractory disease, usually in 8 months from start of treatment with continued CTX. These patients should be evaluated for an allogeneic bone marrow transplant (2)[A].

- Consolidation
  - Purpose is to eliminate residual leukemic cells after induction therapy.
  - Induction phase drugs are used.
  - Although peg-asparaginase is widely used in pediatric ALL, it has been identified by the UKALL14 trail as too toxic with poorer outcomes in adult ALL (5)[A].

- Prolonged maintenance
- Purpose is to prevent relapse and prolong remission.
- Consist of POMP: daily 6-MP, weekly MTX, monthly vincristine, with pulses of prednisone for 2 to 3 years. Little benefit has been shown for >3 years of prolonged maintenance (3,6)[A].
- Dexamethasone can be substituted for prednisone, a.k.a DOMP.

Special considerations
- Besides Hyper-CVAD, some pediatric ALL regimens have shown superior complete remission outcomes for adults from 15 to 39 years. These usually contain vincristine and peg-asparaginase, nonmyelosuppressive agents.
- Allogeneic stem cell transplantation is also recommended with relapsed ALL during the first remission or if there are high-risk genetic features.
- Burkitt leukemia requires only 18 weeks of treatment and has better outcomes with MTX and alkylating agents in the initial therapy. Rituximab (anti-CD20 monoclonal antibody) also improves outcomes.
- Rituximab improves outcomes if CD20 expression is >20% of blast cells in ALL.
- Immunotherapy:
  - Bispecific anti-CD19/anti-CD3 antibody blinatumomab is approved for relapsed/refractory ALL.
  - Ofatumumab is a 2nd-generation anti-CD20 monoclonal antibody undergoing trials with concomitant Hyper-CVAD in pre-B cell ALL with CD20 expression >1%.
  - Ph-positive ALL have improved prognosis with tyrosine kinase inhibitors (TKI) targeting BCR-ABL1 translocation. Consolidation/maintenance with a TKI may be used instead of allogeneic stem cell transplant in these patients.
  - Adult T-cell ALL is much less common than B cell ALL and unfortunately has a relapse rate up to 50% with traditional Hyper-CVAD therapy. Nelarabine is a T-cell–specific purine nucleoside and currently is approved for relapsed T-cell ALL, with additional clinical trials studying a combination of Hyper-CVAD and nelarabine as part of induction therapy.
  - Patients with unfavorable cytogenetic subtypes should undergo allogeneic stem cell transplantation in first remission if an HLA-identical donor is available.
- A novel agent, inotuzumab-ozogamicin combination, has shown higher rates of complete remission and longer progression free and overall survival in patients with relapsed or refractory ALL when compared to standard therapy (7)[A].
ISSUES FOR REFERRAL
ALL can quickly become a fatal disorder, and thus, when the diagnosis is suspected, patients should be referred to and treated by an oncologist immediately, preferably at a comprehensive cancer center where medication regimen can be tailored as appropriate with a combination of multiple modalities.

SURGERY/OTHER PROCEDURES
In some centers, patients may undergo surgical placement of a port for chemotherapy. Nevertheless, PICC lines are preferred as they can be easily removed after chemotherapy cycles to decrease the risk of infections. This is very important, as these patients can get neutropenic.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Unproven; may result in adverse drug interactions with chemotherapy

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Ambulatory as tolerated

Patient Monitoring
- Requires inpatient admission during induction CTX for continuous infusion and monitoring of metabolic and infectious complications
- Weekly clinic visits with remission consolidation CTX
- Monthly clinic visits during maintenance therapy
- Outpatient follow-up every 3 months thereafter

DIET
- Nutritional support; enteral nutrition is preferred over IV hyperalimentation.
- Avoid alcohol.
- Calcium and vitamin D for steroid-induced osteoporosis

PATIENT EDUCATION
- High risk of infection, must take neutropenic precautions with avoidance of
fresh fruit and vegetables
- Early physical rehabilitation is always recommended due to high risk of deconditioning.
- All patients should be counseled to stop smoking, regardless of ALL diagnosis.

PROGNOSIS
~80–90% of adults <60 years will achieve a complete remission; however, only 40–50% will remain cured due to relapses. Only 30–40% of adults have a 5-year overall survival as opposed to 90% in children.

COMPLICATIONS
- Tumor lysis syndrome (elevated uric acid, potassium, and phosphate with decreased calcium, leading to renal failure, disseminated intravascular coagulation, and cardiac arrhythmias) may be prevented by administering allopurinol prior to CTX. Allopurinol doses should be reduced if used with mercaptopurine or azathioprine. Increased fluids should be given; IV urate oxidase (rasburicase) can be used to treat hyperuricemia rapidly (if not G6PD deficient).
- Neutropenia requiring precautions
- High-dose cyclophosphamide causes severe nausea and vomiting. Use appropriate antiemetic regimen.
- Vincristine can cause neurotoxicity and ileus.
- AVN or osteonecrosis may occur with alkylating agents and corticosteroids.
- Steroid-induced hyperglycemia may require starting patients on insulin/oral anti-hyperglycemics.
- Anthracyclines can cause cardiotoxicity and require assessment of left ventricular ejection fraction by transthoracic echocardiography before Hyper-CVAD initiation begins and monitoring during treatment.
- Asparaginase therapy increases the risks for deep vein thromboses and veno-occlusive disease.
- Infections (*Pneumocystis carinii* pneumonia, bacterial pneumonia or sepsis, fungal pneumonia)
- Adverse reactions from blood product transfusions for pancytopenia
- CTX can cause sterility.
- Arachnoiditis and CNS effects from IT CTX, high-dose MTX and irradiation
- Pancreatitis and liver dysfunction from CTX
- Relapse of ALL in marrow or extramedullary sites (CNS, testis)
REFERENCES

CODES

**ICD10**

- C91.00 Acute lymphoblastic leukemia not having achieved remission
- C91.01 Acute lymphoblastic leukemia, in remission
- C91.02 Acute lymphoblastic leukemia, in relapse

CLINICAL PEARLS

- The diagnosis of ALL is based on the presence of ≥20% (NCCN) or 25% (WHO) lymphoblasts, or characteristic mutations in the bone marrow.
• Adult patients with ALL suffer higher mortality rates than pediatric ones.
• Hyper-CVAD is still the main therapy; however, newer immunotherapeutic agents targeting specific mutations in ALL are currently being investigated.
• Treatment at an appropriate cancer center allows for tailored therapy based on mutations in ALL cells.
• Patients need to be monitored closely for CTX toxicities and progression of disease.
LEUKEMIA, ACUTE MYELOID

Jan Cerny, MD, PhD

BASICS

DESCRIPTION

- Acute myeloid leukemia (AML) is characterized by proliferation and accumulation of abnormal immature myeloid progenitors (blasts) with reduced capacity to differentiate into more mature cellular elements. This leads to bone marrow failure and results in a variety of systemic symptoms.
- Previously, the French–American–British (FAB) classification system divided AML based on the cell morphology with the addition of cytogenetics (subtypes M0–M7).
- The World Health Organization (WHO) classification attempts to provide more meaningful prognostic information.
  - AML with characteristic genetic abnormalities: translocation t(8;21), t(15;17), and inversion in chromosome 16 inv(16)
  - AML with multilineage dysplasia: presence of a prior myelodysplastic syndrome (MDS) or myeloproliferative neoplasm (MPN) that transformed into AML
  - AML and MDS, therapy related
  - AML not otherwise categorized
  - Acute leukemias of ambiguous lineage (biphenotypic acute leukemia)

EPIDEMIOLOGY

- ~19,950 cases estimated in 2016 making it the most common type of leukemia in adults
- Predominant sex: male ≥ female

Incidence
The incidence of AML increases with age, and median age is 67 years.

ETIOLOGY AND PATHOPHYSIOLOGY

Precise causes unknown, but some risk factors have been identified (see “Risk Factors”).
Genetics
- Unknown; some are familial.
- Cytogenetics and genetics play an important role in diagnosis and prognosis of AML and have implications for therapy.
- Three risk groups
  - Good risk: inv(16), t(8;21), t(15;17)
  - Standard risk: normal karyotype
  - Poor risk: monosomy 5 and 7 (typically secondary AML), deletion 5q, abnormalities of 11q23 or complex karyotype
- FLT3 gene mutations, especially internal tandem duplications (FLT3-ITD), have been associated with poor survival in AML. These and growing list of (onco)gene (e.g., NPM1, DNMT3A, and P53) mutations have been studied to further risk-stratify patients (1,2)[A].

RISK FACTORS
- Genetic predisposition (e.g., Down syndrome); other familial disorders are Bloom syndrome (~25% develop AML), Fanconi anemia (52%), neurofibromatosis, Li-Fraumeni syndrome, Wiskott-Aldrich syndrome, Kostmann syndrome, and Diamond-Blackfan anemia.
- Radiation exposure
- Immunodeficiency states
- Chemical and drug exposure (nitrogen mustard and alkylating agents; benzene)
- MDS
- Cigarette smoking

GENERAL PREVENTION
None currently identified, but treatment of high-risk MDS with demethylating agents (Vidaza, 5-azacitidine) has been shown to prolong time to transformation from MDS into AML (3)[A].

COMMONLY ASSOCIATED CONDITIONS
The following are oncologic emergencies:
- Disseminated intravascular coagulopathy (DIC) especially in acute promyelocytic leukemia (APL) but may be seen in any AML
- Leukostasis (high blast number and increased adhesive ability of blasts)
- Tumor lysis syndrome (TLS): spontaneous or in response to chemotherapy
DIAGNOSIS

HISTORY
Fatigue (anemia or tumor burden); bleeding (low platelets or DIC); difficulty clearing infections (neutropenia or immune dysregulation)

PHYSICAL EXAM
- Mostly nonspecific and related to marrow or tissue infiltration
  - Fever
  - Bleeding
  - Pallor
  - Splenomegaly
  - Hepatosplenomegaly
  - Lymphadenopathy (usually reactive)
- If CNS is involved, symptoms of increased intracranial pressure can be present.
- Occasionally, patients will present with prominent extramedullary sites of leukemia (e.g., skin infiltration or ultimately as a myeloid sarcoma).

DIFFERENTIAL DIAGNOSIS
- Virus-induced cytopenia, lymphadenopathy, and organomegaly
- Immune cytopenias (including systemic lupus erythematosus [SLE])
- Drug-induced cytopenias
- Other marrow failure and infiltrative diseases (e.g., aplastic anemia, paroxysmal nocturnal hemoglobinuria, MDSs, Gaucher disease)

DIAGNOSTIC TESTS & INTERPRETATION
- CBC shows subnormal RBCs, neutrophils, and platelets.
- Bone marrow for histology, flow cytometry, and cytogenetics to establish diagnosis and prognosis
- ESR
- Lactate dehydrogenase (LDH) and uric acid can be elevated (e.g., TLS).
- Coagulation profile can be normal or prolonged (e.g., DIC).
- Drugs that may alter lab results: chemotherapy agents, corticosteroids
- Other special tests: Spinal tap may reveal fluid with leukemic cells.
- Ultrasonography or CT scan of the abdomen may discover organomegaly.

Diagnostic Procedures/Other
Bone marrow studies are usually necessary to make the diagnosis.

- Aspirates: for cell morphology, cytochemistries, immunophenotyping (can confirm differentiation stage of AML); cytogenetics: chromosomal aberration (prognostic value; see “Genetics”)
- Biopsies provide valuable information for cellularity, architecture, and so forth.

**Test Interpretation**
- Marrow is usually hypercellular and the normal architecture effaced; leukemic blast count is 20% or more.
- Liver and spleen may be infiltrated with leukemic cells.

**TREATMENT**
- Chemotherapy is the backbone of AML therapy; it consists of induction and consolidation phase ± maintenance (APL).
- Bone marrow transplantation (BMT) for high-risk AML
- Only modest improvements have been made in AML induction chemotherapy. Supportive care had improved significantly.

**GENERAL MEASURES**
- Ongoing assessment of bone marrow, liver, heart, and kidney functions during therapy
- Close monitoring of coagulation parameters (risk for DIC)
- Supportive therapy with
  - Good hydration
  - Transfusions of packed RBCs and platelets based on patient’s needs (threshold as for platelets as low as 5,000); use leukoreduced, irradiated blood products, as all patients can be considered for BMT.
  - Avoid antiplatelet agents (e.g., aspirin products).
  - Follow febrile neutropenic guidelines in neutropenic patient who becomes febrile (even low-grade fever).

**Geriatric Considerations**
- Older patients (>60 to 65 years of age) remain a therapeutic challenge. These patients are offered so-called reduced-intensity or nonmyeloablative BMT.
- Adding growth factors (granulocyte colony-stimulating factor [G-CSF]) may
reduce toxicity in older patients (but is not broadly accepted).

- Hypomethylating agent, such as 5-azacitidine, significantly prolongs survival in older adults with low marrow blast count (<30%).

**Pediatric Considerations**
Tolerate intense treatments better

**Pregnancy Considerations**
Chemotherapy is a viable option in the 2nd and 3rd trimesters.

**MEDICATION**

**First Line**

- APL (APL, AML with t[15;17])
  - All-trans retinoic acid (ATRA) and arsenic trioxide both promote maturation to granulocytes.
  - Idarubicin is often added to induction therapy.

- Treatment of AML in younger adults: AML (other than APL)
  - Induction (daunorubicin or idarubicin [anthracycline and cytarabine]): The generally accepted combination is 3 + 7 (anthracycline is given for 3 days and cytarabine for 7 days) or more intensive regimens with high-dose cytarabine (HiDAC) or high dose of anthracycline.

- Remission is typically consolidated in younger patients by the following:
  - In good-risk AML, 3 to 4 cycles of HiDAC and BMT is reserved for time of recurrence.
  - In poor-risk patients, 1 to 2 cycles of HiDAC (until donor is identified) are followed by allogeneic BMT.
  - Intermediate-risk AML should be treated based on individual patient’s features, donor availability, and access to clinical trials. A meta-analysis showed that even intermediate-risk patients benefit from allogeneic BMT (4)[A].

- Treatment of AML in older adults (>65 years of age) remains a challenge. These patients have poor performance status, more likely secondary AML, higher incidence of unfavorable cytogenetics, comorbidities, shorter remissions, and shorter overall survival.
  - Intensive chemotherapy may be feasible for patients with good performance status; alternative regimens with mitoxantrone, fludarabine, and clofarabine. New drugs (hypomethylating agents as above, FLT3 inhibitors, monoclonal antibodies, etc.) are being studied in clinical trials (5)[A].
• Contraindications: comorbidities; therapy has to be individualized.
• Precautions
  – If organ failure, some drugs may be avoided or dose reduced (e.g., no anthracyclines in patients with preexisting cardiac problems).
  – Patients will be immunosuppressed during treatment. Avoid live vaccines. Administer varicella-zoster or measles immunoglobulin as soon as exposure of patient occurs.
• Significant possible interactions: Allopurinol accentuates the toxicity of 6-mercaptopurine.
• Novel targeted therapies: Midostaurin for AML with FLT3 mutations (both ITD and TKD). Enasidenib (IDH2 inhibitor) for relapsed/refractory AML with IDH2 mutation; gemtuzumab ozogamicin (anti-CD33 monoclonal antibody) for relapsed/refractory AML with CD33 expression

**Second Line**
Healthy, younger patients usually are offered reinduction chemotherapy and allogeneic BMT.

**ISSUES FOR REFERRAL**
• AML should be managed by specialized team led by a hematologist/oncologist.
• Refer patient to a transplant center early because a search for a donor may be necessary.

**SURGERY/OTHER PROCEDURES**
• BMT: Decision between myeloablative and nonmyeloablative approach should be based on patient’s performance status, comorbidities, and AML risk factors.
  – Allogeneic BMT is usually indicated in first remission in intermediate- or high-risk AML or in second remission in all other AML patients. Matched related donor used to be preferred over matched unrelated donor (lower risk of graft-versus-host disease); recent data suggest equal outcomes, as allogeneic transplant regimens and posttransplant care have improved significantly.
• Haploidentical transplants and cord blood have emerged as alternative sources of hematopoietic stem cells for adults that show comparable outcomes as well.
• Autologous BMT may be acceptable in specific situations (e.g., no donor is available).
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Induction treatment for AML requires inpatient care, usually on a specialized ward. Episodes of febrile neutropenia typically require admission and IV antibiotics.
- Appropriate hydration to prevent TLS
- IV may lead to chemical burns in the event of extravasation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Ambulatory, as tolerated; no intense or contact sports; no aspirin due to risk of bleeding

Patient Monitoring

- Repeat bone marrow studies to document remission and also if a relapse is suspected.
- Follow CBC with differential, coagulation studies, uric acid level, and other chemistries related to TLS (creatinine, potassium, phosphate, calcium); monitor urinary function at least daily during induction phase and less frequently later.
- Physical evaluation, including weight and BP, should be done frequently during treatment.

DIET

Ensure adequately balanced calorie/vitamin intake; total parenteral nutrition (TPN) in case of severe mucositis

PATIENT EDUCATION

- Leukemia Society of America, 600 Third Avenue, New York, NY 10016, 212-573-8484
- National Cancer Institute, Bethesda, MD, has pamphlets and telephone education.
PROGNOSIS
AML remission rate is 60–80%, with only 20–40% long-term survival. The wide variable prognosis is due to prognostic group (age, cytogenetics, and genetics).

COMPLICATIONS
- Acute side effects of chemotherapy, including febrile neutropenia
- TLS
- DIC
- Late-onset cardiomyopathy in patients treated with anthracyclines
- Chronic side effects of chemotherapy (secondary malignancies)
- Graft-versus-host disease in patients who have received allogeneic BMT

REFERENCES

ADDITIONAL READING
SEE ALSO
Disseminated Intravascular Coagulation; Leukemia, Acute Lymphoblastic (ALL) in Adults; Leukemia, Chronic Myelogenous; Myelodysplastic Syndromes (MDS); Myeloproliferative Neoplasms

CODES

ICD10
- C92.00 Acute myeloblastic leukemia, not having achieved remission
- C92.01 Acute myeloblastic leukemia, in remission
- C92.02 Acute myeloblastic leukemia, in relapse

CLINICAL PEARLS
- Prognosis of leukemia depends on the cytogenetic and molecular profile of the disease.
- Allogeneic transplant remains the only therapy with curative potential for patients with intermediate- and high-risk AML.
LEUKEMIA, CHRONIC LYMPHOCYTIC

Jan Cerny, MD, PhD • Amy E. Pratt, DO

BASICS

DESCRIPTION

• Chronic lymphocytic leukemia (CLL) is a monoclonal disorder characterized by a progressive accumulation of mature but functionally incompetent lymphocytes.
• CLL should be distinguished from prolymphocytic leukemia (PLL); based on percentage of prolymphocytes, the disease may be regarded as CLL (<10% prolymphocytes), PLL (>55% prolymphocytes), or CLL/PLL (>10% and <55% prolymphocytes).
• Small lymphocytic lymphoma is a lymphoma variant of CLL.
• System(s) affected: hematologic, lymphatic, immunologic

EPIDEMIOLOGY

Incidence

• CLL represents the most common form of leukemia in adults in the United States with an estimated 18,960 new cases diagnosed in 2016 (1)[A].
• In 2016, an estimated 4,660 adults in the United States died from CLL, which makes it the second leading cause of death among adults with leukemia in the United States after acute myeloid leukemia (1)[A].
• Predominant age: CLL primarily affects elderly individuals, median age of diagnosis being 70 years. Incidence continues to rise in those age >55 years.
• Predominant sex: male > female (1.7:1)
• The incidence is higher among Caucasians than among African Americans.

ETIOLOGY AND PATHOPHYSIOLOGY

• The cell of origin in CLL is a clonal B cell arrested in the B-cell differentiation pathway, intermediate between pre–B cells and mature B cells. In the peripheral blood, these cells resemble mature lymphocytes and typically show B-cell surface antigens: CD19, CD20, CD21, and CD23. In addition, they express CD5 (usually found on T cells).
• The bcl2 proto-oncogene is overexpressed in B-CLL. Bcl2 is a known suppressor of apoptosis (programmed cell death), resulting in extremely long
life of the affected lymphocytes.
- Genetic mutations leading to disrupted function and prolonged survival of affected lymphocytes are suspected but unknown.

**Genetics**
CLL is an acquired disorder, and reports of truly familial cases are exceedingly rare. CLL has been shown, however, to occur at higher frequency among first-degree relatives of patients with the disease, and several somatic gene mutations have been identified at significantly higher rates among CLL patients.

**RISK FACTORS**
- As in the case of most malignancies, the exact cause of CLL is uncertain.
- Possible chronic immune stimulation is suspected but is still being evaluated.
- Monoclonal B-cell lymphocytosis: 1% risk progression to CLL

**GENERAL PREVENTION**
Unknown

**COMMONLY ASSOCIATED CONDITIONS**
- Immune system dysregulation is common.
- Conditions that may accompany CLL:
  - Autoimmune hemolytic anemia (AIHA)
  - Immune thrombocytopenia purpura (ITP)
  - Pure red cell aplasia (PRCA)

**DIAGNOSIS**

**HISTORY**
- Insidious onset. It is not unusual for CLL to be discovered incidentally (up to 40% of patients are asymptomatic at the time of diagnosis).
- Others may have the following symptoms:
  - B symptoms: fevers, night sweats, >10% weight loss
  - Fatigue and/or other symptoms of anemia
  - Enlarged lymph nodes (lymphadenopathy = LAD)
  - Mucocutaneous bleeding and/or petechiae
  - Early satiety and/or abdominal discomfort related to an enlarged spleen
  - Recurrent infection(s)
PHYSICAL EXAM
- Lymphadenopathy (localized or generalized)
- Organomegaly (splenomegaly, hepatomegaly)
- Mucocutaneous bleeding (thrombocytopenia)
- Skin: petechiae (thrombocytopenia), pallor (anemia), rash (leukemia cutis)

DIFFERENTIAL DIAGNOSIS
- Infectious:
  - Bacterial (tuberculosis, pertussis)
  - Viral (mononucleosis)
- Neoplastic:
  - Leukemic phase of non-Hodgkin lymphomas
  - Hairy cell leukemia
  - PLL
  - Large granular lymphocytic leukemia
  - Waldenstrom macroglobulinemia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- CBC with differential: B cell absolute lymphocytosis with >5,000 B lymphocytes/μL; often also shows anemia and/or thrombocytopenia
- Blood smear: ruptured lymphocytes (“smudge” cells) and morphologically small mature-appearing lymphocytes
- Confirm diagnosis with immunophenotyping: CLL cells are positive for CD19, CD20, CD23, and CD5; low levels of surface membrane immunoglobulin (Ig)—either IgM or IgM&D; only a single Ig light chain is expressed (κ or λ) confirming monoclonality.
- Additional labs:
  - Hemolysis labs (in cases associated with high disease activity or AIHA):
    high LDH and indirect bilirubin, low haptoglobin, +/- elevated reticulocyte count (bone marrow infiltration)
  - High plasma β₂-microglobulin (poor prognosis)
  - Hypogammaglobulinemia
- Liver/spleen ultrasound: may demonstrate organomegaly and enlarged abdominal lymph nodes
- CT scan of chest/abdomen/pelvis: not necessary for staging but may identify compression of organs or internal structures from enlarged lymph nodes
- Positron emission tomography (PET) scan: not recommended unless Richter transformation suspected and biopsy necessary (see “Prognosis”)

**Follow-Up Tests & Special Considerations**
Frequency and type of follow-up depend on severity of symptoms as well as risk factors (see “Prognosis”).

**Diagnostic Procedures/Other**
- Bone marrow biopsy: has prognostic value (diffuse infiltration is a risk factor) but not performed routinely
- Lymph node biopsy: Consider if lymph node(s) begins to rapidly enlarge in a patient with known CLL to assess the possibility of transformation to a high-grade lymphoma (Richter syndrome), especially when accompanied by fever, weight loss, and painful lymphadenopathy.

**Test Interpretation**
- Bone marrow biopsy aspirate usually shows >30% lymphocytes.
- Cytogenetics (fluorescence in situ hybridization) may show chromosomal changes, which are prognostic:
  - Unfavorable: del(17p), del(11q)
  - Neutral: normal, trisomy 12
  - Favorable: del(13q), del(6q)

**TREATMENT**

**GENERAL MEASURES**
Patients with CLL with frequent infections associated with hypogammaglobulinemia are likely to benefit from infusions of intravenous immunoglobulin (IVIG).

**MEDICATION**

**First Line**
- Standard of care for new diagnosis with no symptoms or early stage disease: observation
- Standard of care for new diagnosis with symptoms (B symptoms, symptomatic anemia and/or thrombocytopenia, AIHA and/or thrombocytopenia poorly responsive to corticosteroids, progressive
organomegaly) or progressive lymphocytosis (increase >50% in 2 months or a
doubling time of <6 months): Initiate treatment.

- Low-risk disease, Rai stage 0, and Binet stage A: observation with periodic
follow-up
- Intermediate-risk group, Rai stages I and II, and Binet stage B: Observe until
evidence of disease progression or development of symptoms.
- High-risk patients, Rai stage III and IV, and Binet stage C: Initiate treatment.
- Selection of first-line therapy depends on patient factors: age, performance
status, and medical comorbidities.
- Three main groups of chemotherapeutic drugs:
  - Alkylators: cyclophosphamide (C), chlorambucil, and bendamustine
  - Purine analogs: fludarabine (F) and pentostatin
  - Monoclonal antibodies: rituximab (R) (chimeric anti-CD20) and
    alemtuzumab (anti-CD52)
- Commonly used single-agent regimens: bendamustine, cyclophosphamide
  (historically, the standard of care in older patients with comorbidities), and
  fludarabine
- Commonly used fludarabine- and rituximab-based combination regimens: FC,
  FR (lower toxicity), FCR (preferred first-line regimen if tolerable to patient),
  and PCR
- Steroids, high dose: useful in autoimmune manifestations of CLL (AIHA,
  ITP)

**Second Line**

- Second-line therapy consists of combinations of chemotherapeutic agents that
  patient did not fail yet or, occasionally, retreatment with a drug used
  previously.
- Novel agents (listed below) have also shown promising activity in CLL:
  - Ibrutinib (Bruton tyrosine kinase inhibitor): showed favorable findings in
    older patients with comorbidities and previously untreated CLL (2)[A]
  - Idelalisib (PI3Kδ kinase inhibitor): Combination of this drug with
    rituximab compared to placebo with rituximab significantly improved the
    rate of progression-free survival in patients with comorbidities and relapsed
    CLL unable to undergo standard chemotherapy (3)[A].
  - Venetoclax (βCL-2 inhibitor): ongoing studies for use in relapsed/refractory
    CLL and in patients with 17p deletion
  - Obinutuzumab (humanized anti-CD20 monoclonal antibody): Combination
    of this drug with chlorambucil improved response rates and prolonged
    progression-free survival in patients with comorbidities and previously
untreated CLL (\(4\))[A].

- Ofatumumab (anti-CD20 monoclonal antibody distinct from rituximab)
- Lenalidomide, a thalidomide derivative, is sometimes first line for elderly patients or second line when combined with rituximab for relapsed/refractory disease.
- Alemtuzumab (anti-CD52) is second line when used for relapsed/refractory disease.
- Allogenic (nonmyeloablative conditioning) and autologous hematopoietic stem cell transplant (hSCT) may be considered in high-risk and younger patients, particularly those with refractory (limited data available as still considered experimental therapy).

**ISSUES FOR REFERRAL**

- Surgical consultation for splenectomy in patients with progressive splenomegaly +/- refractory cytopenias
- Radiation oncology consultation for large or bulky lymphadenopathy, particularly those causing compressive symptoms

**ADDITIONAL THERAPIES**

- Patients requiring therapy who are high risk for tumor lysis syndrome should be given allopurinol to prevent uric acid nephropathy.
- Vaccinations (avoid live vaccines):
  - Annual influenza vaccine
  - Pneumococcal vaccine every 5 years

**SURGERY/OTHER PROCEDURES**

See “Issues for Referral” above.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

No specific criteria but may require inpatient admission for complications of disease (AIHA) or of therapy (febrile neutropenia, tumor lysis syndrome)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
**Patient Monitoring**
Patients with low-risk CLL and/or patients in remission:
- CBC with differential (lymphocytosis), LDH, and $\beta_2$-microglobulin every 3 to 6 months
- Physical exam (lymphadenopathy, organomegaly)

**DIET**
- Ensure adequately balanced calorie/vitamin intake.
- Follow weights.

**PATIENT EDUCATION**
Leukemia and Lymphoma Society has educational pamphlets:

**PROGNOSIS**
- Two staging systems are used, but neither is completely satisfactory: Rai system in the United States and Binet system in Europe
- Rai staging system:
  - Stage 0: lymphocytosis only; low risk status
  - Stage I: lymphocytosis and adenopathy; intermediate risk status
  - Stage II: lymphocytosis +/- adenopathy and splenomegaly and/or hepatomegaly; intermediate risk status
  - Stage III: lymphocytosis and anemia (hemoglobin <11 g/dL); high risk status
  - Stage IV: lymphocytosis and thrombocytopenia (platelets <100 × 10^9/L); high risk status
- Binet staging system:
  - Stage A: hemoglobin ≥10 g/dL, platelets ≥100 × 10^9, and <3 lymph node areas involved (Rai stages 0, I, and II); survival >120 months
  - Stage B: hemoglobin and platelet levels as in stage A and ≥3 lymph node areas involved (Rai stages I and II); survival 61 months
  - Stage C: hemoglobin <10 g/dL, platelets <100 × 10^9, and any number of lymph nodes involved (Rai stages III and IV); survival 32 months
- Adverse risk factors:
  - Advanced Rai or Binet stage
  - Peripheral lymphocyte doubling time <12 months
- Diffuse marrow infiltration
- Increased number of prolymphocytes or cleaved cells
- Poor response to chemotherapy
- High $\beta_2$-microglobulin and thymidine kinase levels and low micro RNAs (miRNAs)
- Abnormal karyotyping: del(17p) and del(11q)
- Mutated immunoglobulin heavy chain variable (IgHV) genes (expression of ZAP-70 >20% or CD38 >30% evaluated by immunophenotyping are surrogate markers)
- NOTCH1 mutation (associated with unmutated IgVH)

COMPLICATIONS
- Acute or long-term effects of chemotherapy
- Richter syndrome
- AIHA (some cases may be related to the use of fludarabine)
- Slightly increased risk of solid tumors (especially Kaposi sarcoma, malignant melanoma, laryngeal cancer, lung cancer, colon cancer)
- Infection
- Membranoproliferative glomerulonephritis (MPGN) or other glomerular pathology

CODES

ICD10
- C91.10 Chronic lymphocytic leukemia of B-cell type not achieve remission
- C91.11 Chronic lymphocytic leukemia of B-cell type in remission
- C91.12 Chronic lymphocytic leukemia of B-cell type in relapse

CLINICAL PEARLS
- CLL is the most common form of leukemia in adults in the United States.
- CLL primarily affects elderly individuals, median age of diagnosis being 70 years. Incidence continues to rise in those age >55 years.
- Clinical monitoring of asymptomatic and low-risk patients is a reasonable approach (“watch and wait”).
- High-risk patients, patients with bulky disease, and patients who fail fludarabine- and rituximab-based therapies typically have poor prognoses and may require intensive therapies, including allogeneic hematopoietic stem cell transplantation.
- Several novel agents are being developed to improve therapeutic approaches to CLL.
LEUKEMIA, CHRONIC MYELOGENOUS
Jan Cerny, MD, PhD

BASICS

DESCRIPTION

- Chronic myelogenous leukemia (CML) is a myeloproliferative neoplasm characterized by clonal proliferation of myeloid precursors in the bone marrow with continuing differentiation into mature granulocytes.
- Hallmark of CML is Philadelphia chromosome (translocation t[9;22]).
- Natural history of the disease evolves in three clinical phases: a chronic phase, an accelerated phase, and a blast phase or crisis (transformation to acute leukemia).

EPIDEMIOLOGY

Incidence

- Per year, 1.6 cases/100,000 persons
- Predominant age: 50 to 60 years
- Predominant sex: male > female (1.3:1)

Prevalence

Accounts for 15–20% of adult leukemias

ETIOLOGY AND PATHOPHYSIOLOGY

Philadelphia chromosome is a balanced translocation between BCR (on chromosome 22) and ABL (on chromosome 9) genes t(9;22)(q34;q11). This fusion gene, BCR-ABL, codes for an abnormal constitutively active tyrosine kinase that affects numerous signal transduction pathways, resulting in uncontrolled cell proliferation and reduced apoptosis.

Genetics

Acquired genomic changes

RISK FACTORS

Ionizing radiation exposure (uncommon)
GENERAL PREVENTION
None currently identified

DIAGNOSIS
85–90% of patients present in the chronic phase, and the disease can be found accidentally during routine screening.

HISTORY
- Chronic phase: fatigue, weight loss, night sweats, abdominal fullness owing to enlarged spleen, early satiety, dyspnea, bleeding. Rare: bruising, left upper quadrant abdominal pain, sternal pain (owing to expanding bone marrow), and gouty arthritis; up to 30% of patients are asymptomatic.
- Accelerated phase progressive splenomegaly and left upper quadrant abdominal pain occasionally referred to the left shoulder (owing to splenic infarction or rupture), progressive weight loss and sweats, unexplained fever or bone pain, chloromas (extramedullary tumors)
- Blast phase: bleeding, bruising, infections, prominent constitutional symptoms

PHYSICAL EXAM
- Splenomegaly (50–90%), hepatomegaly (up to 50%)
- Less common: splenic friction rub, lymphadenopathy

DIFFERENTIAL DIAGNOSIS
- Chronic myelomonocytic leukemia, chronic neutrophilic leukemia, chronic eosinophilic leukemia, juvenile myelomonocytic leukemia, infectious mononucleosis, leukemoid reaction, polycythemia vera, and treatment with granulocyte-stimulating factors
- Acute myelogenous leukemia resembles blast crisis with myeloid blasts, and acute lymphoblastic leukemia resembles blast crisis with lymphoid blasts.
- Atypical CML is a chronic myeloproliferative disorder with a clinical hematologic picture similar to CML, but it lacks Philadelphia chromosome and BCR-ABL rearrangement.

DIAGNOSTIC TESTS & INTERPRETATION
- CBC
  - Hematocrit: may be normal, slightly increased, or decreased
- WBC count: markedly increased (50,000 to 100,000/μL), with granulocytes in all stages of development, including occasional blasts <10% in chronic phase, basophilia, eosinophilia
- Platelets: normal, elevated (34%), or occasionally low
- In accelerated phase: anemia, 10–19% blood or marrow blasts, basophils plus eosinophils >20%, thrombocytopenia
- Blast phase: blood or marrow blasts >20%

• Genetics
  - Demonstration of the Philadelphia chromosome, t(9;22), by cytogenetic techniques, fluorescence in situ hybridization (FISH), or reverse transcription-polymerase chain reaction (RT-PCR)
  - Additional cytogenetic abnormalities occur in the accelerated and blast phases (monosomy 7, t[3,21], trisomies 8 and 19, Philadelphia chromosome duplication, abnormalities of chromosome 17 such as monosomy, trisomy, and isochromosome mutations). These may contribute to resistance to tyrosine kinase inhibitors (TKIs; e.g., imatinib). Further molecular testing (mutations within BCR-ABL) is suggested in case of loss of response to therapy.
  
• Others:
  - Low or absent leukocyte alkaline phosphatase in neutrophils
  - High lactate dehydrogenase (LDH)
  - Elevated uric acid

**Initial Tests (lab, imaging)**

• CBC, LDH, uric acid, bone marrow biopsy and aspiration, cytogenetics on bone marrow, and FISH for BCR-ABL, RT-PCR, LFTs
• Abdominal ultrasound or CT scan shows splenomegaly; not mandatory

**Follow-Up Tests & Special Considerations**

• Mutation analysis of tyrosine kinase domain of ABL kinase, as they may cause resistance to therapy with TKIs
• HLA-A*02 positive is associated with CML, and a protective effect is seen with the HLA-B*35 allele (pooled odds ratio 0.64, 95% CI 0.48–0.86).

**Diagnostic Procedures/Other**

Bone marrow aspiration and biopsy

**Test Interpretation**
Myeloid hyperplasia with elevated myeloid: erythroid ratio, normal maturation, marrow basophilia, and increased reticulin fibrosis

**TREATMENT**

**MEDICATION**

- TKIs (e.g., imatinib) provide durable, long-term control of disease.
- The response to TKIs is assessed at specific time points from the beginning of treatment and is categorized as follows:
  - Complete hematologic response (CHR): normalization of peripheral counts, no disease symptoms, no immature cells
  - Minor/partial/complete cytogenetic response (CCR): 1–34%, 35–90%, no Philadelphia-positive metaphases
  - Major molecular response (MMR): decreased level of BCR-ABL transcript by PCR 3-log
  - Complete molecular response (CMR): BCR-ABL transcript is undetectable by PCR.

**First Line**

- Imatinib mesylate (Gleevec), an oral TKI, 400 mg/day
- Side effects: thrombocytopenia, anemia, elevated liver enzymes, edema, GI disturbances, rash

  - **International Randomized Study of Interferon versus STI571 (IRIS)** established imatinib as first-line therapy (1)[A].
  - Imatinib dose can be increased to 600 and 800 mg/day if only suboptimal response is achieved with standard dose.

  - 2nd-generation TKIs have shown higher efficacy and fewer side effects and are approved for first-line therapy of chronic phase CML: nilotinib (Tasigna) and dasatinib (Sprycel) (2,3)[A].

**Second Line**

- Dasatinib, 2nd-generation TKI; active against most of BCR-ABL mutants; not active in T315I mutation
  - 100 mg/day in patients resistant or intolerant to imatinib and 70 mg BID or 140 mg/day for patients in accelerated or blastic phase
  - Side effects: pleural effusions, cytopenias
- Nilotinib, also 2nd-generation TKI; highly selective and more potent BCR-
ABL TKI; active against most BCR-ABL mutants; not active in *T315I* mutation
- 400 mg PO BID in patients resistant or intolerant to imatinib in chronic or accelerated phase
- Side effects: cytopenias, QTc prolongation, pancreatitis
- Bosutinib and omacetaxine are now approved for patient who failed or did not tolerate two TKIs previously. Bosutinib is being tested in trials for front-line setting. Ponatinib has now more restricted approval, but together with omacetaxine, in addition they are the only effective agents in patients with *T315I* mutation. Agents targeting leukemic stem cells are being developed for clinical use.

**ISSUES FOR REFERRAL**
All patients with CML should be referred to a hematologist. Patients with inadequate response to TKIs or with *T315I* mutation should consult with a bone marrow transplant (BMT) physician.

**SURGERY/OTHER PROCEDURES**
Allogeneic BMT
- It is the only known cure; however, 71% of patients who achieve CCR with imatinib maintain that response beyond 7 years, and no patient progressed on the trial between years 5 and 6 of treatment.
- Most effective in patients <50 years of age who are in the chronic phase
- Initial mortality is higher (related to the use of myeloablative regimens) than medical management but provided higher rates of survival in pre-TKI era.
- Significant improvement in transplant techniques leading to better outcomes, such as alternative sources of stem cells; nonmyeloablative regimens have shown improvements in transplant-related mortality.
- Transplant option should be thoroughly discussed with young patients in chronic phase and considered an alternative to TKIs especially if the patient does not tolerate TKIs or disease is not responding.
- Can be considered in patients who fail to achieve CHR by 3 months, have no cytogenetic response or cytogenetic relapse, or have *T315I* mutation

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Acute abdominal symptoms (infarcted or ruptured spleen); tumor lysis syndrome owing to initial therapy; complications of BMT
– Hydroxyurea might be given, with the goal of reduction of the WBC count, but it has minimal impact on patient response to TKIs.
– Induction chemotherapy (for acute leukemia) in setting of blastic phase
– Allopurinol to prevent tumor lysis syndrome in patients with very high counts; however, probably not necessary when TKIs are used

• Discharge criteria: abatement of acute symptoms

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

• Frequency depends on stage at presentation and response to first-line therapy.
• Although splenomegaly persists, avoid contact sports or trauma to abdomen.

**Patient Monitoring**

• CBC with differential: weekly until blood counts stable and then every 2 to 4 weeks during CHR; once in CCR and stable, patient can be followed less frequently (3-month intervals).
• Bone marrow cytogenetics (evaluation for clonal evolution) every 6 months while in CHR, every 12 to 18 months while in CCR, MMR, CMR
• Quantitative RT-PCR every 3 months (peripheral blood)
• ECGs (concern for QT prolongation), LFTs while on TKIs. Nilotinib, bosutinib, and ponatinib can cause pancreatitis.
• Blood pressure monitoring as several TKIs have been associated with elevated blood pressure and related cardiovascular complications

**PROGNOSIS**

• With treatment and good response, the survival is similar to the normal population.
• Without treatment: CML invariably will progress to accelerated phase within 2 to 5 years and blast phase within several months of the accelerated phase.
• Poor prognosis: patients presenting in accelerated or blastic phase or presenting with very large spleen size, platelets >700,000/μL, and patients resistant to TKIs (T315I mutation)

**COMPLICATIONS**

• Splenic infarct or rupture
• Progression to accelerated or blastic phase
Thrombotic events owing to elevated platelets
Bleeding owing to low or dysfunctional platelets
Sequela of anemia

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- C92.10 Chronic myeloid leukemia, BCR/ABL-positive, not having achieved remission
- C92.11 Chronic myeloid leukemia, BCR/ABL-positive, in remission
- C92.12 Chronic myeloid leukemia, BCR/ABL-positive, in relapse
CLINICAL PEARLS

- CML belongs to the myeloproliferative disorders group.
- The gold standard for diagnosis of CML is detection of the Philadelphia chromosome or its products, \textit{BCR-ABL} mRNA, and fusion protein.
- TKIs provide durable, long-term control of the disease and have dramatically altered treatment.
- Atypical CML is a form of clinically typical CML but without the presence of the typical \textit{BCR-ABL} translocation.
- Blast crisis is a form of acute leukemia that is a possible complication of CML.
LEUKOPLAKIA, ORAL
Kathya M. Chartre, MD • Robert C.M. Ander, MD

BASICS

DESCRIPTION
- Oral leukoplakia is a white plaque or patches on the oral mucosa, generally precancerous.
- System(s) affected: gastrointestinal
- Hyperplasia of squamous epithelium

EPIDEMIOLOGY
- Develops in middle age, increases with age
- Most common in India, where more people smoke and chew tobacco and areca nuts

Prevalence
- 0.1–0.5% of the adult population is affected.
- Usual age of onset is >40 years old with peak in the 60s.
- Males twice as often as females

Geriatric Considerations
Malignant transformation to carcinoma is more common in older patients.

ETIOLOGY AND PATHOPHYSIOLOGY
Hyperkeratosis or dyskeratosis of the oral squamous epithelium
- Tobacco use in any form
- Alcohol consumption/alcoholism
- Periodontitis
- *Candida albicans* infection may induce dysplasia and increase malignant transformation.
- Human papillomavirus, types 16 and 18
- Sunlight
- Vitamin deficiency
- Syphilis
- Dental restorations/prosthetic appliances
- Estrogen therapy
- Chronic trauma or irritation
- Epstein-Barr virus (oral hairy leukoplakia)
- Areca nut/betel (Asian populations)
- Mouthwash preparations and toothpaste containing the herbal root extract sanguinaria

**Genetics**
- Dyskeratosis congenital and epidermolysis bullosa increase the likelihood of oral malignancy.
- P53 overexpression, PTEN allelic loss correlates with leukoplakia and particularly squamous cell carcinoma.

**RISK FACTORS**
- 70–90% of oral leukoplakia is related to tobacco, particularly smokeless tobacco or areca/betel nut use.
- Similar to risk factors for squamous cell carcinoma
- Alcohol increases risk 1.5-fold.
- Repeated or chronic mechanical trauma from dental appliances or cheek biting
- Chemical irritation to oral regions
- Diabetes
- Age
- Socioeconomic status
- Risk factors for malignant transformation of leukoplakia
  - Female
  - Long duration of leukoplakia
  - Nonsmoker (idiopathic leukoplakia)
  - Located on tongue or floor of mouth
  - Size >200 mm²
  - Nonhomogenous type
  - Presence of epithelial dysplasia

**GENERAL PREVENTION**
- Avoid tobacco of any kind, alcohol, habitual cheek biting, tongue chewing.
- Use well-fitting dental prosthesis.
- Regular dental check-ups to avoid bad restorations
- Diet rich in fresh fruits and vegetables may help to prevent cancer.
- HPV vaccination may be preventive.
COMMONLY ASSOCIATED CONDITIONS
- HIV infection is closely associated with hairy leukoplakia.
- Erythroplakia in association with leukoplakia, “speckled leukoplakia,” or erythroleukoplakia is a marker for underlying dysplasia.
- 1–20% of lesions will progress to carcinoma within 10 years.

DIAGNOSIS
Leukoplakia is an asymptomatic white patch on the oral mucosa.

HISTORY
- Usually asymptomatic
- History of tobacco or alcohol use or oral exposure to irritants

PHYSICAL EXAM
- Location
  - 50% on tongue, mandibular alveolar ridge, and buccal mucosa
  - Also seen on maxillary alveolar ridge, palate, and lower lip
  - Infrequently seen on floor of the mouth and retromolar areas
  - Floor of mouth, ventrolateral tongue, and soft palate complex are more likely to have dysplastic lesions.
- Appearance
  - Varies from homogeneous, nonpalpable, faintly translucent white areas to thick, fissured, papillomatous, indurated plaques
  - May feel rough or leathery
  - Lesions can become exophytic or verruciform.
  - Color may be white, gray, yellowish white, or brownish gray.
  - Cannot be wiped or scraped off
- World Health Organization classification
  - Homogeneous refers to color.
    - Flat, corrugated, wrinkled, or pumice
  - Nonhomogeneous refers to color and texture (more likely to be dysplastic or malignant).
    - Erythroleukoplakia (mixture of red and white)
    - Proliferative verrucous leukoplakia (PVL) (multifocal, mostly women)

DIFFERENTIAL DIAGNOSIS
White oral lesions that can be rubbed off: acute pseudomembranous candidiasis

White oral lesions that cannot be rubbed off (1):

- Developmental/genetic (rare):
  - Cannon white sponge nevus (diffuse bilateral white plaques of buccal mucosa, tongue)
  - Hereditary benign intraepithelial dyskeratosis
  - Pachyonychia congenita

- Reactive/frictional:
  - Leukoedema (delicate gray-white lines, disappear with stretching)
  - Contact desquamation
  - Morisatio mucosae oris (cheek/gum biting)
  - Benign alveolar ridge keratosis (ill-fitting dentures)
  - Hairy tongue (elongated filiform papillae, may become pigmented from food/bacteria)
  - Nicotinic stomatitis & smokeless tobacco keratosis (South Asian “paan” or “gutka”; American/Swedish snuff; Ethiopian “toombak”)

- Infectious:
  - Candidiasis
  - Hairy leukoplakia (associated with EBV & HIV-infected individuals)

- Immune-mediated:
  - Lichen planus (typically symmetric, bilateral, reticular white lesions)
  - Lichenoid lesions
  - Benign migratory glossitis

- Autoimmune:
  - SLE
  - Chronic graft-versus-host disease

**DIAGNOSTIC TESTS & INTERPRETATION**

Biopsy is the gold standard.

**Initial Tests (lab, imaging)**

- Laboratory tests generally are not indicated.
  - Consider saliva culture if *C. albicans* infection is suspected.
- No imaging is indicated.

**Follow-Up Tests & Special Considerations**

- Biopsy is necessary to rule out carcinoma if lesion is persistent, changing, or
unexplained.

- Consider CBC, rapid plasma reagin (RPR).

**Diagnostic Procedures/Other**

- Oral cytology is superior to conventional oral examination (2)[A].
- Computer-assisted cytology or liquid-based cytology is not superior to oral cytology (2)[A].
- Noninvasive brush biopsy and analysis of cells with DNA–image cytometry constitute a sensitive and specific screening method.
- Patients with dysplastic or malignant cells on brush biopsy should undergo more formal excisional biopsy.
- Excisional biopsy is definitive procedure.

**Test Interpretation**

- Biopsy specimens range from hyperkeratosis to keratosis of unknown significance (KUS) to dysplasia to invasive carcinoma.
- At initial biopsy, 6% are invasive carcinoma.
- 0.13–6% subsequently undergo malignant transformation.
- Location is important: 60% on floor of mouth or lateral border of tongue are cancerous; buccal mucosal lesions are generally not malignant but require biopsy if not resolving.

**TREATMENT**

- All oral leukoplakias should be treated.
- Treatment may include the following:
  - For 2 to 3 circumscribed lesions, surgical excision
  - For multiple or large lesions where surgery would cause unacceptable deformity, consider cryosurgery or laser surgery (3)[C].
  - Abstinence from predisposing habits (alcohol and tobacco)
- Complete excision is standard treatment for dysplasia or malignancy.
- After treatment, up to 30% of leukoplakia recurs, and some leukoplakia still transforms to squamous cell carcinoma (3)[B].
- Oral hairy leukoplakia may be treated with podophyllin with acyclovir cream.

**GENERAL MEASURES**

- Eliminate habitual lip biting.
Correct ill-fitting dental appliances, bad restorations, or sharp teeth.
Stop smoking and using alcohol.
Some small lesions may respond to cryosurgery.
β-Carotene, lycopene, retinoids, and cyclooxygenase 2 (COX-2) inhibitors may cause partial regression.
For hairy tongue: tongue brushing

**MEDICATION**
Carotenoids; vitamins A, C, and K; bleomycin, and photodynamic therapy ineffective to prevent malignant transformation and recurrence

**ISSUES FOR REFERRAL**
Consider otolaryngologist or oral surgery referral for extensive disease.

**SURGERY/OTHER PROCEDURES**
- Scalpel excision, laser ablation, electrocautery, or cryoablation
- Cryotherapy slightly less effective than photodynamic therapy response (73% vs. 90%) and recurrence (27% vs. 24%) [4][A]
- CO₂ laser had 20% recurrence and 10% malignant transformation within 5 years [5][B].
- Biopsy/excision algorithm [1][C]:
  - KUS that is poorly demarcated and likely frictional: Rebiopsy and follow up.
  - KUS that is well demarcated and >3 cm: Follow up every 3 months; rebiopsy every 12 months.
  - KUS that is <3 cm: excise/ablate with narrow margins; follow up every 3 months; if recurs, excise with wider margins.
  - PVL: Follow up every 3 months; excise verrucous or nodular areas.
  - Dysplastic/SCC: Excise.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Eliminate etiologic factors.
- Reevaluate in 7 to 14 days.
- Biopsy if lesion is persistent.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Regular, close follow-up, even after successful treatment
- Biopsy as needed

DIET
Regular

PATIENT EDUCATION
- If biopsy is negative, stress importance of periodic and careful follow-up.
- Initiate a dental referral to eliminate dental factors.
- Stress importance of stopping tobacco and alcohol use.
- Encourage participation in smoking cessation program.

PROGNOSIS
- Most leukoplakia is benign.
- Leukoplakia may regress, remain stable, or progress.
- 0.13–6% of initially benign lesions subsequently develop into cancer.
- Size >4 cm increases risk of malignant transformation.
- 5-year survival rate of oral cancer is 50%.

COMPLICATIONS
- New lesions may develop after treatment.
- Risk of malignant transformation to squamous cell carcinoma is approximately 5–17%.
- Larger lesions and nonhomogeneous leukoplakia are associated with higher rates of malignant transformation.

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

HIV/AIDS; Infectious Mononucleosis, Epstein-Barr Virus Infections

**CODES**

**ICD10**

- K13.21 Leukoplakia of oral mucosa, including tongue
- K13.3 Hairy leukoplakia

**CLINICAL PEARLS**

- Excisional biopsy is indicated for any undiagnosed leukoplakia.
- After treatment, up to 30% of leukoplakia recurs, and some leukoplakia still transforms to squamous cell carcinoma; thus, long-term surveillance is essential.
- To lessen risk of malignant transformation, encourage tobacco and alcohol cessation and consider *C. albicans* eradication.
LICHEN PLANUS

Mercedes E. Gonzalez, MD • Herbert P. Goodheart, MD

BASICS

Lichen planus (LP) is an idiopathic eruption with characteristic shiny, flat-topped (Latin: planus, “flat”) purple (violaceous) papules and plaques on the skin, often accompanied by characteristic mucous membrane lesions. Itching may be severe.

DESCRIPTION

- Classic (typical) LP is a relatively uncommon inflammatory disorder of the skin and mucous membranes; hair and nails may also be affected.
  - Skin lesions are small, flat, angular, red-to-violaceous, shiny, pruritic papules and/or plaques with overlying fine, white lines (called Wickham striae), or gray-white puncta; most commonly seen on the flexor surfaces of the upper extremities, extensor surfaces of the lower extremities, the genitalia, and on the mucous membranes
  - On the oral mucosa, lesions typically appear as raised white lines in a lacelike pattern seen most often on the buccal mucosa.
  - Onset is abrupt or gradual. Course is unpredictable; may resolve spontaneously, recur intermittently, or persist for many years
- Drug-induced LP
  - Clinical and histopathologic findings may mimic those of classic LP. Lesions usually lack Wickham striae (see in the following text) and oral involvement is rare.
  - There is generally a latent period of months from drug introduction until lesions appear.
  - Lesions resolve when the inciting agent is discontinued, often after a prolonged period.
- LP variants
  - Follicular: also called lichen planopilaris; typically seen on the scalp, can lead to scarring alopecia
  - Annular: Papules spread centrifugally as central area resolves; occur on glans penis, axillae, and oral mucosa
  - Linear: may be an isolated finding
  - Hypertrophic: itchy, hyperkeratotic, thick plaques on dorsal legs and feet
– Atrophic: rare, most often the result of resolved lesions
– Bullous LP: Intense inflammation in the dermis leads to blistering of epidermis.
– LP pemphigoides: a combination of LP and bullous pemphigoid (IgG autoantibodies to collagen 17)
– Nail LP: affects the nail matrix, lateral thinning, longitudinal ridging, and fissuring

- System(s) affected: skin/exocrine
- Synonym(s): lichenoid eruptions

**EPIDEMIOLOGY**

- Predominant age: 30 to 60 years old; rare in children and the geriatric population
- Predominant sex: female > male

**Prevalence**

In the United States, 450/100,000

**ETIOLOGY AND PATHOPHYSIOLOGY**

LP is considered to be a T cell–mediated autoimmune response to self-antigens on damaged keratinocytes.

**RISK FACTORS**

Exposure to certain drugs or chemicals

- Thiazides, furosemide, β-blockers, sulfonylureas, antimalarials, penicillamine, gold salts, and angiotensin-converting enzyme inhibitors
- Rarely: photo-developing chemicals, dental materials, tattoo pigments

**COMMONLY ASSOCIATED CONDITIONS**

- An association has been noted between LP and hepatitis C virus infection, particularly in certain geographic regions (Asia, South America, the Middle East, Europe) (1). Hepatitis should be considered in patients with widespread presentations of LP and those with primarily oral disease.
- In addition, chronic active hepatitis, lichen nitidus, and primary biliary cirrhosis have been noted to coexist with LP.
- Association with dyslipidemia has been reported (2)[B].
- LP has also been reported in association with other diseases of altered immunity, more often than would be expected by chance.
– Bullous pemphigoid
– Alopecia areata
– Myasthenia gravis
– Vitiligo
– Ulcerative colitis
– Graft-versus-host reaction
– Lupus erythematosus (lupus erythematosus–LP overlap syndrome)
– Morphea and lichen sclerosis et atrophicus

**DIAGNOSIS**

LP is most commonly diagnosed by its appearance despite its range of clinical presentations. A skin biopsy should be performed if the diagnosis is in doubt.

**HISTORY**

A minority of patients have a family history of LP. Affected families have an increased frequency of human leukocyte antigen B7 (HLA-B7). A thorough drug history should be performed.

**PHYSICAL EXAM**

- Skin (often severe pruritus)
  - Papules: 1 to 10 mm, shiny, flat-topped (planar) lesions that occur in crops; lesions may have a fine scale.
  - Evidence of scratching (i.e., crusts and excoriations) is usually absent.
  - Color: violaceous, with white lacelike pattern (Wickham striae) on surface of papules. Wickham striae are best seen after topical application of mineral oil and, if present, are virtually pathognomonic for LP.
  - Shape: polygonal or oval. Annular lesions may appear on trunk and mucous membranes. Various shapes and sizes may be noted (polymorphic).
  - Arrangement: may be grouped, linear, or scattered individual lesions
  - Koebner phenomenon (isomorphic response): New lesions may be noted at sites of minor injuries, such as scratches or burns.
  - Distribution: ventral surface of wrists and forearms, dorsa hands, glans penis, dorsa feet, groin, sacrum, shins, and scalp. Hypertrophic (verrucous) lesions may occur on lower legs and may be generalized.
  - Postinflammatory hyperpigmentation: Lesions typically heal, leaving darkly pigmented macules in their wake.
- Mucous membranes (40–60% of patients with skin lesions; 20% have mucous
membrane lesions without skin involvement.)
- Most commonly asymptomatic, nonerosive, milky-white lines with an elegant, lacy, netlike streaked pattern
- Usually seen on buccal mucosa but may appear on tongue, gingiva, palate, or lips
- Less commonly, LP may be erosive; rarely bullous
- Painful, especially if ulcers present
- Lesions may develop into squamous cell carcinoma (1–3%).
- Glans penis, labia minora, vaginal vault, and perianal areas may be involved.
- **Hair/scalp**
  - LP of the hair follicle (lichen planopilaris) presents with keratotic plugs at the follicle orifice with a violaceous rim; may result in atrophy and permanent destruction of hair follicles (scarring alopecia)
- **Nails (10%)**
  - Involvement of nail matrix may cause proximal-to-distal linear grooves and partial or complete destruction of nail bed with pterygium formation.

**DIFFERENTIAL DIAGNOSIS**

- **Skin**
  - Lichen simplex chronicus
  - Eczematous dermatitis
  - Psoriasis
  - Discoid lupus erythematosus
  - Other lichenoid eruptions (those that resemble LP)
  - Pityriasis rosea
  - Lichen nitidus
- **Oral mucous membranes**
  - Leukoplakia
  - Oral hairy leukoplakia
  - Candidiasis
  - Squamous cell carcinoma (particularly in ulcerative lesions)
  - Aphthous ulcers
  - Herpetic stomatitis
  - Secondary syphilis
- **Genital mucous membranes**
  - Psoriasis (penis and labia)
  - Nonspecific balanitis, Zoon balanitis
  - Fixed drug eruption (penis)
– Candidiasis (penis and labia)
– Pemphigus vulgaris, bullous pemphigoid, and Behçet disease (all rare)

Hair and scalp
– Scarring alopecia (central centrifugal cicatricial alopecia)

**DIAGNOSTIC TESTS & INTERPRETATION**

If suggested by history

- Serology for hepatitis
- Liver function tests

**Diagnostic Procedures/Other**

- Skin biopsy
- Direct immunofluorescence helps to distinguish LP from discoid lupus erythematosus.

**Test Interpretation**

- Dense, bandlike (lichenoid) lymphocytic infiltrate of the upper dermis
- Vacuolar degeneration of the basal layer
- Hyperkeratosis and irregular acanthosis, increased granular layer
- Basement membrane thinning with “saw-toothing”
- Degenerative keratinocytes, known as colloid or Civatte bodies, are found in the lower epidermis.
- Melanin pigment in macrophages

**TREATMENT**

Although LP can resolve spontaneously, treatment is usually requested by patients who may be severely symptomatic or troubled by its cosmetic appearance.

**GENERAL MEASURES**

- Goal is to relieve itching and resolve lesions.
- Asymptomatic oral lesions require no treatment.

**MEDICATION**

*First Line*

- Skin
- Superpotent topical steroids (e.g., 0.05% clobetasol propionate) twice daily
  - Potent topical steroids such as triamcinolone acetonide 0.1% or fluocinonide 0.05% under occlusion
  - Intralcaleral corticosteroids (e.g., triamcinolone [Kenalog] 5 to 10 mg/mL) for recalcitrant and hypertrophic lesions
  - Antihistamines (e.g., hydroxyzine 25 mg PO q6h) have limited benefit for itching but may be helpful for sedation at bedtime.
  - “Soak and smear” technique: can lead to a rapid improvement of symptoms in even 1 to 2 days and may obviate the need for systemic steroids. Soaking allows water to hydrate the stratum corneum and allows the anti-inflammatory steroid in the ointment to penetrate more deeply into the skin. Smearing of the ointment traps the water in the skin because water cannot move out through greasy materials.
    - Soaking is done in a bathtub using lukewarm plain water for 20 minutes and then, without drying the skin, the affected area is immediately smeared with a thin film of the steroid ointment containing clobetasol or another superpotent topical steroid.
    - Soak and smear may be done for 4 to 5 days or longer, if necessary. The treatments are best done at night because the greasy ointment applied to the skin gets on pajamas (instead of on daytime clothes) and the ointment is on the skin during sleep. A topical steroid cream is applied thereafter during the daytime hours, if necessary.

- Mucous membranes
  - For oral, erosive, painful LP, a Cochrane review found at best weak evidence for the effectiveness of any intervention (3)[A].
    - Topical corticosteroids (0.1% triamcinolone [Kenalog] in Orabase) or 0.05% clobetasol propionate ointment BID
    - Intralcaleral corticosteroids
      - Topical 0.1% tacrolimus (Protopic ointment) BID or 1% pimecrolimus (Elidel) cream BID. A Cochrane review found no evidence that calcineurin inhibitors are better than placebo (4)[A].
      - Topical retinoids (e.g., 0.05% tretinoin [retinoic acid] in Orabase)

**Pediatric Considerations**
Children may absorb a proportionally larger amount of topical steroid because of larger skin surface-to-weight ratio.

**Second Line**
Skin and mucous membranes

- Intralesional corticosteroids
- Topical 0.1% tacrolimus (Protopic ointment) BID or topical 1% pimecrolimus (Elidel) cream BID
- Oral prednisone: used only for a short course (e.g., 30 to 60 mg/day for 2 to 4 weeks) or IM triamcinolone (Kenalog) 40 to 80 mg every 6 to 8 weeks
  - Precautions with systemic steroids
    - Systemic absorption of steroids may result in hypothalamic-pituitary-adrenal axis suppression, Cushing syndrome, hyperglycemia, or glucosuria.
    - Increased risk with high-potency topical steroids (i.e., use over large surface area, prolonged use, occlusive dressings)
    - In pregnancy: usually safe, but benefits must outweigh the risks
- Oral retinoids: Isotretinoin in doses of 10 mg PO daily for 2 months, acitretin 30 mg, or altretinoin 30 mg PO daily have resulted in improvement in some refractory cases. Observe carefully for resultant dyslipidemia.
- Oral metronidazole 500 mg BID for 20 to 60 days can be given as a safer alternative to systemic corticosteroids.
- Cyclosporine may be used in severe cases, but cost and potential toxicity limit its use; topical use for severe oral involvement refractory to other treatments
- Thalidomide
  - Psoralen ultraviolet-A (PUVA), broad- or narrow-band ultraviolet B (UVB) (5)[A]
  - Low-level laser therapy and photodynamic therapy
  - Griseofulvin (5)[A]
  - Azathioprine
  - Mycophenolate mofetil
  - Metronidazole

**ALERT**
Avoid oral and topical retinoids during pregnancy.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Outpatient care
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

**Patient Monitoring**
Serial oral examinations for erosive/ulcerative lesions

**PATIENT EDUCATION**

- Oral, erosive, or ulcerative LP: annual follow-up to screen for malignancy (6)
- Avoid spicy foods, cigarettes, and excessive alcohol.
- Avoid dry, crispy foods such as corn chips, pretzels, and toast.

**PROGNOSIS**

- Spontaneous resolution in weeks is possible, but disease may persist for years, especially oral lesions and hypertrophic lesions on the shins.
- There is a tendency toward relapse.
- Recurrence in 12–20%, especially in those with generalized involvement

**COMPLICATIONS**

- Alopecia
- Nail destruction
- Squamous cell carcinoma of the mouth or genitals

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- L43.9 Lichen planus, unspecified
- L43.0 Hypertrophic lichen planus
- L43.1 Bullous lichen planus

**CLINICAL PEARLS**

- Remember the 7 P’s of LP: purple, planar, polygonal, polymorphic, pruritic (not always), papules that heal with postinflammatory hyperpigmentation.
- Serial oral or genital exams are indicated for erosive/ulcerative LP lesions to monitor for the development of squamous cell carcinoma.
- An association has been noted between LP and hepatitis C virus infection, chronic active hepatitis, and primary biliary cirrhosis.
- The “soak and smear” technique can lead to a rapid improvement of symptoms in 1 to 2 days and may obviate the need for systemic steroids.
LICHEN SIMPLEX CHRONICUS
Jeremy Golding, MD, FAAFP

BASICS
DESCRIPTION
- Lichen simplex chronicus (LSC) is a chronic dermatitis resulting from chronic, repeated rubbing or scratching of the skin. Skin becomes thickened with accentuated lines (“lichenification”).
- System(s) affected: skin
- Synonym(s): LSC; lichen simplex; localized neurodermatitis; neurodermatitis circumscripta

EPIDEMIOLOGY
Geriatric Considerations
Most common in middle aged and elderly

Pediatric Considerations
Rare in preadolescents

Incidence
- Common
- Peak incidence 35 to 50 years
- Predominant sex: females > males (2:1)

Prevalence
Common

ETIOLOGY AND PATHOPHYSIOLOGY
- Itch–scratch cycle leads to a chronic dermatosis. Repeated scratching or rubbing causes inflammation and pruritus, which leads to continued scratching.
- Primary LSC: scratching secondary to nonorganic pruritus, habit or a conditioned response to stress/anxiety
- Common triggers are excess dryness of skin, heat, sweat, and psychological stress.
Secondary LSC: begins as a pruritic skin disease that evolves into neurodermatitis, which persists after resolution of the primary condition. Precursor dermatoses include atopic dermatitis, contact dermatitis, lichen planus, stasis dermatitis, psoriasis, tinea, and insect bites.

There is a possible relation between disease development and underlying neuropathy, particularly radiculopathy or nerve root compression.

Pruritus-specific C neurons are temperature sensitive, which may explain itching that occurs in warm environments.

**RISK FACTORS**
- Anxiety disorders
- Dry skin
- Insect bites
- Pruritic dermatosis

**GENERAL PREVENTION**
Avoid common triggers such as psychological distress, environmental factors such as heat and excessive dryness, skin irritation, and the development of pruritic dermatoses.

**COMMONLY ASSOCIATED CONDITIONS**
- Prurigo nodularis is a nodular variety of the same disease process.
- Atopic dermatitis
- Anxiety, depression, and obsessive-compulsive disorders

**DIAGNOSIS**

**HISTORY**
- Gradual onset
- Begins as a localized area of pruritus
- Most patients acknowledge that they respond with vigorous rubbing, itching, or scratching, which brings temporary satisfaction.
- Pruritus is typically paroxysmal, worse at night, and may lead to scratching during sleep.
- Can be asymptomatic with patient scratching at night while asleep

**PHYSICAL EXAM**
- Well-circumscribed lichenified plaques with varying amounts of overlying excoriation or scaling
- Lichenification: accentuation of normal skin lines
- Hyperpigmentation or hypopigmentation can be seen.
- Scarring is uncommon with typical LSC; can be seen following ulcer formation or secondary infection
- Most commonly involves easily accessible areas
  - Lateral portions of lower legs/ankles
  - Nape of neck (lichen simplex nuchae)
  - Vulva/scrotum/anus
  - Extensor surfaces of forearms
  - Palmar wrist
  - Scalp

**DIFFERENTIAL DIAGNOSIS**
- Lichen sclerosis
- Psoriasis
- Atopic dermatitis
- Contact, irritant, or stasis dermatitis
- Extramammary Paget disease
- Lichen planus
- Mycosis fungoides
- Lichen amyloidosis
- Tinea
- Nummular eczema

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- No specific diagnostic test
- Microscopy (i.e., KOH prep) and culture preparation may be helpful in identifying possible bacterial or fungal infection.

**Diagnostic Procedures/Other**
- Skin biopsy if diagnosis is in question.
- Patch testing may be used to rule out a contact dermatitis.

**Test Interpretation**
- Hyperkeratosis
- Acanthosis
- Lengthening of rete ridges
- Hyperplasia of all components of epidermis
- Mild to moderate lymphohistiocytic inflammatory infiltrate with prominent lichenification

**TREATMENT**

**GENERAL MEASURES**
- Patient education is critical.
- Low likelihood of resolution if patient unable to avoid scratching
- Treatment aimed at reducing inflammation and pruritus

**MEDICATION**

**First Line**
- Reducing inflammation
  - Topical steroids are first-line agents (1)[C].
  - High-potency steroids alone, such as 0.05% betamethasone dipropionate cream or 0.05% clobetasol propionate cream, can be used initially but should be avoided on the face, anogenital region, or intertriginous areas. They should be used on small areas only, for no longer than 2 weeks except under the close supervision of a physician.
  - Switch to intermediate- or low-potency steroids as response allows.
  - An intermediate-potency steroid, such as 0.1% triamcinolone cream, may be used for initial, brief treatment of the face and intertriginous areas, and for maintenance treatment of other areas.
  - A low-potency steroid, such as 1% hydrocortisone cream, should be used for maintenance treatment of the face and intertriginous areas.
  - Steroid tape, flurandrenolide, has optimized penetration and provides a barrier to continued scratching. Change tape once daily.
  - Intrallesional steroids, such as triamcinolone acetate, are also safe and effective for severe cases.
- Preventing scratching
  - Topical antipruritic agents
  - 1st-generation oral antihistamines such as diphenhydramine and hydroxyzine for antipruritic and sedative effects
  - Sedating tricyclics, such as doxepin and amitriptyline, for nighttime itching
Itching may occur at night while the patient is asleep; occlusive dressings may be helpful in these cases.

**ALERT**
High-dose and prolonged treatment with topical steroids can cause dermal/epidermal atrophy as well as pigmentary changes and should not be used on the face, intertriginous areas, or anogenital region. Duration of treatment on other parts of the body should not exceed 3 weeks without close physician supervision.

**Second Line**
All recommendations
- Topical aspirin has been shown to be helpful in treating neurodermatitis (2)[C].
- Topical 5% doxepin cream has significant antipruritic activity (2)[C].
- Topical capsaicin cream can be helpful for treatment of early disease manifestations (2)[C].
- 0.1% tacrolimus applied twice daily over 6 weeks as an effective alternative treatment (3)[C].
- Gabapentin was found to decrease symptoms in patients who are nonresponsive to steroids.
- Topical lidocaine can be effective in decreasing neuropathic pruritus (2)[C].
- Intradermal botulinum toxin injections have been reported to improve symptoms in patients with recalcitrant pruritus.
- Transcutaneous electrical nerve stimulation may relieve pruritus in patients for whom topical steroids were not effective (4)[C].
- A case report showed NB-UVB as a possible off-label treatment of refractory LSC (5)[C].
- SSRIs may be effective in controlling compulsive scratching secondary to psychiatric diagnosis.

**ISSUES FOR REFERRAL**
- No response to treatment
- Presence of signs and symptoms suggestive of a systemic cause of pruritus
- Consultation with a psychiatrist for patients with severe stress, anxiety, or compulsive scratching
- Consultation with an allergist for patients with multisystem atopic symptoms
ADDITIONAL THERAPIES

- Cooling of the skin with ice or cold compresses
- Soaks and lubricants to improve barrier layer function
- Occlusion of lesion with bandages or Unna boots
- Nail trimming
- Silk underwear to decrease friction in genital LSC

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture has been shown as an effective treatment for pruritus (6)[C].
- Cognitive-behavioral therapy may improve awareness and help to identify coping strategies.
- Hypnosis may be beneficial in decreasing pruritus and preventing scratching.
- Homeopathic remedies (i.e., thuja and graphite) have been used.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Patients should be followed for response to therapy, complications from therapy (especially topical steroids), and secondary infections.

DIET
Regular balanced diet

PATIENT EDUCATION

- Patients should understand the cause of this disease and the critical role they play in its resolution:
  - Emphasize that scratching and rubbing must stop for lesions to heal; medications ineffective if scratching continues
- Stress reduction techniques can be useful for patients for whom stress plays a role.
- Avoid exposure to known triggers.

PROGNOSIS

- Often chronic and recurrent
• Good prognosis if the itch–scratch cycle can be broken
• After healing, the skin should return to normal appearance but may also retain accentuated skin markings or post inflammatory pigmentary changes that may be slow to resolve.

**COMPLICATIONS**
• Secondary infection
• Scarring is rare without ulceration or secondary infection.
• Complications related to therapy, as mentioned in medication precautions
• Squamous cell carcinoma within affected regions is rare.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

L28.0 Lichen simplex chronicus

**CLINICAL PEARLS**

- LSC is a chronic inflammatory condition that results from repeated scratching
and rubbing.
- Primary LSC originates de novo, whereas secondary LSC occurs in the setting of a preexisting pruritic dermatologic condition.
- LSC is a clinical diagnosis based on history and skin examination with biopsy only indicated in difficult or unclear cases.
- Stopping the itch–scratch cycle through patient education, skin lubrication, and topical medications is key.
- Treatment aimed at decreasing both inflammation and pruritus utilizing topical steroids and antipruritics
LONG QT INTERVAL

Henry DeYoung, MD • Yousef Ahmed, MD • Derek Lodico, DO

BASICS

DESCRIPTION

- QT interval: the measurement interval from the beginning of the QRS complex to the end of the T wave on the surface electrocardiogram (ECG). This represents the period from the onset of depolarization to completion of repolarization of the ventricular myocardium.

- Corrected QT interval (QTc): The QT interval has an inverse relationship with heart rate. The QTc is the QT interval corrected for heart rate. See formulas.

- Prolonged QTc is generally defined as >450 ms for adult males and >470 ms for adult females (1):
  - 430 to 450 ms considered borderline in men
  - 450 to 470 ms considered borderline in women (1–3)
  - 440 to 460 ms considered borderline in children aged 1 to 15 years old (4)

- Most cases of prolonged QT are acquired, but several genetic mutations cause inherited long QT syndrome (LQTS) (3).

- Prolonged QTc from any cause can precipitate polymorphic ventricular tachycardia (VT) called torsade de pointes (TdP), leading to dizziness, syncope, and sudden cardiac death from ventricular fibrillation (VF).

EPIDEMIOLOGY

Incidence

Incidence of medication-induced QTc prolongation and TdP varies with medication and a host of other factors. Exact incidences are difficult to estimate but may be 1:2,000 to 1:2,500 (2).

Prevalence

- Hereditary LQTS is estimated to occur in 1/2,500 to 1/7,000 births.
- Five thousand people across the United States may die yearly due to LQTS-related cardiac arrhythmia.
ETIOLOGY AND PATHOPHYSIOLOGY

- **Acquired**
  - Demographics: increasing age, female sex
  - Electrolyte abnormalities: hypokalemia, hypocalcemia, and hypomagnesemia
  - Noncardiac disease: hypothyroidism renal impairment, and hepatic impairment
  - Cardiac disease: heart failure, LVH, and myocardial ischemia (2)
  - Scenarios: rapid increase in the QT interval >60 ms, conversion from atrial fibrillation/bradycardia (5)
  - Medications (3)
    - Antiarrhythmic medications (quinidine, procainamide, dronedarone, dofetilide, sotalol, disopyramide, and amiodarone)
    - Antipsychotic medications: especially if given IV (haloperidol*, chlorpromazine*, thioridazine*, pimozide*)
    - Antidepressants: most commonly used drugs responsible (SSRIs, SNRIs, trazodone, TCAs)
    - Antibiotics/antivirals/antifungals/antiprotozoals/antimalarialis: macrolides (clarithromycin*, erythromycin* also CYP3A4 inhibitors), fluoroquinolones, quinine, and chloroquine
    - Antiemetics: metoclopramide, ondansetron, promethazine
    - Opioids: methadone*, buprenorphine
    - Antihistamines: cetirizine, hydroxyzine, diphenhydramine
    - Decongestants: pseudoephedrine, phenylephrine
    - Stimulants: albuterol, phentermine
    - Misc: chloroquine*, pentamidine*, various antimuscarinics, and anticonvulsants
    - *Denote “high-risk” medication for TdP (2,5).

- **Congenital**
  - Loss of function mutations in several potassium ion membrane channels or gain of function mutations in the sodium or calcium ion membrane channels in cardiac myocytes (6)

- **Pathophysiology**
  - Depolarization (phase 0) of the myocardium results from the rapid influx of sodium through sodium channels (I_{Na}) causing myocyte contraction during systole; seen on ECG as the QRS complex
  - Repolarization occurs through the efflux of potassium from the cell (phases 2 and 3) by rapid (I_{Kr}) and slow (I_{Ks}) components of the delayed rectifier;
represented by the T wave on an ECG.

- Drug-induced QT prolongation most often due to blockade of the \( I_{Kr} \) channel leading to delay in phase 3 rapid repolarization (2).
- In both cases, deviation from normal ion channel function leads to transmural dispersion of repolarization currents across the myocardium, triggering early after depolarizations which may devolve into TdP (3,6).
- Prolonged QT interval alone does not denote imminent risk for TdP; TdP is often self-limited, but TdP can cause syncope or degrade to VF (2).

**Genetics**

- 13+ distinct genotypes are linked to LQTS (1,6).
- Penetrance is highly variable making both diagnosis and management challenging (3).
- LQT1 (40–55%) is the most common cause of LQTS. Loss of function in the KCNQ1 gene coding for the \( I_{Ks} \) transport protein; arrhythmias triggered by sympathetic activation (stress/exercise—especially swimming), leading to shorter ventricular repolarization
- LQT2 (30–45%) results from a mutation in the KCNH2 gene causing a defect in the \( I_{Kr} \) transport protein; at risk for cardiac events due to abrupt catecholamine surges like auditory stimuli/emotional arousal (postpartum)
- LQT3 (5–10%) is caused by a mutation in the SCN5A gene leading to a gain of function in the alpha subunit of the \( I_{Na} \) transport protein. Excessive sodium accumulates in the cell, increasing repolarization time. Prominent during sleep due to amplified inward flow of sodium at low heart rates (1,3,6).
- LQT4 to LQT13—<1% of the total frequency.
- Jervell and Lange-Nielsen syndrome (JLNS): autosomal recessive inheritance through homozygous or compound heterozygous mutations of the KCNQ1 or KCNE1 genes. Reduced function in the \( I_{Ks} \) transport protein; associated with sensorineural hearing loss
- Romano-Ward syndrome (RWS): most common. Results from any of the 13 identified gene mutations; autosomal dominant with variable penetrance and normal hearing
- Others: Andersen-Tawil syndrome (LQT7), Timothy syndrome (LQT8). Both are very rare (3,6).

**RISK FACTORS**

For the feared complication, TdP, risk factors include the following (2,5):
Female (~2 times increased risk)
QTc >500 ms (2 to 3 times increased risk)
QTc >60 ms over previous baseline
For every 10 ms increase in the QTc, there is a 5–7% increased risk for developing TdP
History of syncope or presyncope
History of TdP
Bradycardia
Liver or kidney disease (by increasing blood levels of QT-prolonging medications)
Medications that cause QTc prolongation
  – High doses
  – Fast infusions
  – Combination of medications
Medications that inhibit CYP3A4
Electrolyte abnormalities
  – Hypokalemia
  – Hypomagnesemia
  – Hypocalcemia
For hereditary LQTS
  – Catecholamine surges from exercise, emotional stress, loud noises, postpartum

**GENERAL PREVENTION**

- Avoid (or use with caution) causative medications, including combinations with potentially additive effects (1,2,5)[C].
- Replete electrolytes (goal Mg >2, K 4.5 to 5.0) (2)[C].
- Treat underlying diseases.
- Avoid strenuous sports in LQTS.
- Avoid sudden loud noises in LQTS (alarm clocks, doorbells, telephones).
- 36th Bethesda Conference recommends restriction of athletes from participation to class 1A activities (e.g., bowling, golf, riflery) although evidence of safe participation is emerging (3)[C].

![DIAGNOSIS](checkmark)

**HISTORY**
Incidental finding on ECG in asymptomatic patients
Evaluate for syncope, presyncopal episodes, palpitations, and associated precipitating events (emotional triggers, swimming, diving).
Family history of syncope or sudden cardiac death
History of seizures in patient or family members (tonic–clonic movement may due to cerebral hypoperfusion during episodes of ventricular arrhythmia or syncope)
Detailed medication history
Congenital deafness

PHYSICAL EXAM
The physical exam is typically unremarkable.
Signs of underlying cardiac disease
Signs of hypothyroidism, liver, or renal impairment
Congenital deafness present in many forms of LQTS

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- ECG
- Metabolic panel: especially calcium, magnesium, and potassium
- TSH

Follow-Up Tests & Special Considerations
- Echocardiogram to evaluate for cardiomyopathy
- Outpatient cardiac rhythm monitoring
- Consider provocative testing (epinephrine infusion, exercise stress testing) to evaluate for QTc interval changes and/or for coronary artery disease (2)[C].
- Genetic testing for LQTS mutations

Test Interpretation
- The QT interval is best measured from the onset of the QRS to the completion of the T wave; most commonly measured in lead II or V2
- QTc calculation can be performed in several ways using RR interval immediately preceding the QT interval for calculation. The Bazett formula is most commonly used method (1,2).
  - Framingham formula: QT + 0.154 (1 - RR)
  - Bazett formula: QTc = QT / √(RR) (all measurements in seconds, and RR obtained by direct measurement or 60/heart rate)
Fridericia formula is similar to Bazett but uses the cube root RR interval.

\[ QTc = \frac{QT}{(RR)^{1/3}} \]

**TREATMENT**

**GENERAL MEASURES**
- Treat VT, TdP, and VF emergently per ACLS guidelines.
- Withdraw offending agents and correct electrolytes.\(^2\)[C].
- Transvenous cardiac pacing or isoproterenol may be used for drug-induced TdP to prevent bradycardia. Maintain heart rate 90 to 110 beats/min.

**MEDICATION**

**First Line**
- For TdP: magnesium sulfate 2 g infused over 2 to 5 minutes, followed by continuous infusion of 2 to 4 mg/min if needed. Flushing is a normal side effect of bolus injections. Monitor for magnesium toxicity in those with renal insufficiency \(^1,2\)[C].
  - For hereditary LQTS, to prevent life-threatening arrhythmias: propranolol or nadolol generally regarded as the best \(\beta\)-blockers for management of LQTS, although rigorous studies are lacking \(^7\)[B]
  - \(\beta\)-Blockers are effective in decreasing but not eliminating the risk of fatal arrhythmias.
  - For high-risk patients who remain symptomatic on a \(\beta\)-blocker, implantable cardiac defibrillators (ICDs) with or without pacemaker may be indicated \(^2,6\)[B].

**Second Line**
- Atenolol or metoprolol may be used, although switching \(\beta\)-blockers may precipitate lethal or near-lethal events \(^7\)[B].

**ISSUES FOR REFERRAL**
- Refer to cardiologist to establish diagnosis, especially for hereditary LQTS.
- Symptomatic prolonged QT

**SURGERY/OTHER PROCEDURES**
- ICD for those with a history of major cardiac events
• Left cervical-thoracic sympathetic denervation was used for symptomatic LQTS prior to the advent of β-blockers. It is still an option for those patients with LQTS who are refractory to β-blocker therapy (3)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Treat TdP, VT, and VF promptly as per ACLS guidelines. Correct electrolytes on an emergent basis. Evaluate for acquired QT prolongation. If no cause is found, consider hereditary LQTS.
• Patients with prolonged QTc and syncope/near syncope should be monitored on telemetry.
• Obtain a baseline ECG if initiating or combining medications with QT-prolonging medications, then when the drug reaches steady state, at 30 days, and annually thereafter.
• Avoid QT-prolonging medications in patients with congenital LQTS.
• Patients at risk of LQTS should be educated on symptoms arrhythmia.
• Monitor electrolytes, urgently treat hypomagnesemia and hypokalemia, and discontinue/change offending medications (1,2)[C]
• Avoid sudden loud noises or emotional stress for those who have LQTS.
• Review adherence to β-blocker therapy.
• Clinical decision support systems may be useful to assess the risk of drug induced risk of QT prolongation while considering clinical scenario (5).
• Notify others if telemetry monitoring reveals prolonged QT interval.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
On routine visits, ask about syncope, presyncope, and palpitations in those who have QTc prolongation.
• Consider ECG and/or outpatient cardiac rhythm monitoring with medication additions or dosage changes.
• Prompt evaluation is warranted for symptomatic QTc prolongation of any cause.
• Check and correct for electrolyte imbalances.

PATIENT EDUCATION
- Educate patients with QTc prolongation about medications side effects and medication interactions.
- Patients with congenital forms of LQTS should be aware of, and avoid triggers (depending on their specific gene mutation)
- Consider the emotional and psychological impacts. Additional reading by Fortescue shares personal impact of LQTS.
- Information and support from groups listed may be helpful (see “Additional Reading”).

**PROGNOSIS**

Acquired LQTS will resolve after withdrawal of offending agents and normalization of metabolic abnormalities. Patients with underlying cardiovascular disease may be at increased risk of mortality and require further intervention. Prognosis for congenital LQTS if untreated is quite poor. Perhaps 20% of untreated patients presenting with syncope die within 1 year, 50% within 10 years (4,6).

### CODES

ICD10
I45.81 Long QT syndrome

CLINICAL PEARLS

- Evaluate for acquired causes before making a diagnosis of hereditary LQTS.
- For accurate diagnosis, calculate QTc manually.
- The ideal management of TdP is prevention; avoid multiple “stacking” risk factors and seek alternates to high-risk medications, correct electrolytes, and monitor treatment with serial ECGs if no alternatives exist.
- Magnesium sulfate is the treatment of choice during ACLS for TdP.
- β-Blockers are initial treatment of choice for hereditary LQTS.
LUNG, PRIMARY MALIGNANCIES

Brian P. Bateson, DO • Nathaniel Walsh, MD • Carsten Schroeder, MD, PhD

BASICS

DESCRIPTION

- Lung cancers (primary) are the leading cause of cancer-related death in the United States (estimated 159,260 deaths in 2015, 27% of all cancer-related deaths).
- Divided into two broad categories
  - Non–small cell lung cancer (NSCLC) (>85% of all lung cancers); normally originate in periphery
    - Adenocarcinoma (~40% of NSCLC): Most common type in the United States, most common type in nonsmokers, metastasizes earlier than squamous cell, poor prognosis; lepidic growth, a subtype of adenocarcinoma has better prognosis.
    - Squamous cell carcinoma (~25% of NSCLC): dose-related effect with smoking; slower growing than adenocarcinoma
    - Large cell (~10% of NSCLC): prognosis similar to adenocarcinoma
  - Small cell lung cancer (SCLC) (16% of all lung cancers): centrally located, early metastases, aggressive
- Other: mesothelioma and carcinoid tumor
- Staging
  - Both NSCLC and SCLC: staged from I to IV based on: primary tumor (T), lymph node status (N), and presence of metastasis (M)
  - SCLC further staged by:
    - Limited disease: confined to ipsilateral hemithorax, which may include malignant pleural or pericardial effusion or hematogenous metastases (stage IV)
    - Extensive disease: beyond ipsilateral hemithorax (stages IIIB and IV)
    - Tumor locations: upper: 60%; lower: 30%; middle: 5%; overlapping and main stem: 5%
    - May spread by local extension to involve chest wall, diaphragm, pulmonary vessels, vena cava, phrenic nerve, esophagus, or pericardium
    - Most commonly metastasize to lymph nodes (pulmonary, mediastinal),
then liver, adrenal, bone, brain

**EPIDEMIOLOGY**

**Incidence**
- Estimated 224,210 new cases in the United States in 2015
- Predominant age: >40 years; peak at 70 years
- Predominant sex: male > female

**Prevalence**
- Most common cancer worldwide
- Lifetime probability: men: 1 in 13; women: 1 in 16

**ETIOLOGY AND PATHOPHYSIOLOGY**
Multifactorial; see “Risk Factors.”

**Genetics**
NSCLC
- Oncogenes: Ras family (H-ras, K-ras, N-ras)
- Tumor suppressor genes: retinoblastoma, p53

**RISK FACTORS**
- Smoking
- Secondhand smoke exposure
- Radon
- Environmental and occupational exposures
  - Asbestos exposure (synergistic increase in risk for smokers)
  - Air pollution
  - Ionizing radiation
  - Mutagenic gases (halogen ethers, mustard gas, aromatic hydrocarbons)
  - Metals (inorganic arsenic, chromium, nickel)
- Lung scarring from tuberculosis
- Radiation therapy to the breast or chest

**GENERAL PREVENTION**
- Smoking cessation and prevention programs
- Screening recommended by NCCN and shown to reduce mortality in National Lung Screening Trial (NLST) (1)[A].
- Annual screening recommended with low-dose computed tomography in
adults ages 55 to 74 years who have a 30 pack-year smoking history and currently smoke or have quit within the past 15 years

- Screening should be discontinued once a person has not smoked for 15 years or develops a health problem that substantially limits life expectancy or the ability or willingness to have curative lung surgery.
- Prevention via aggressive smoking cessation counseling and therapy; a 20–30% risk reduction occurs within 5 years of cessation.
- Avoid hormone replacement therapy in postmenopausal smokers or former smokers (increased risk of death from NSCLC).

COMMONLY ASSOCIATED CONDITIONS
- Paraneoplastic syndromes: hypertrophic pulmonary osteoarthropathy, Lambert-Eaton syndrome, Cushing syndrome, hypercalcemia from ectopic parathyroid-releasing hormone, syndrome of inappropriate antidiuretic hormone (SIADH)
- Hypercoagulable state
- Pancoast syndrome
- Superior vena cava syndrome
- Pleural effusion
- Chronic obstructive pulmonary disease (COPD), other sequelae of cigarette smoking

DIAGNOSIS

HISTORY
- May be asymptomatic for most of course
- Respiratory
  - Cough (new or change in chronic cough)
  - Wheezing and stridor
  - Dyspnea
  - Hemoptysis
  - Pneumonitis (fever and productive cough)
- Constitutional
  - Malaise
  - Bone pain (metastatic disease)
  - Fatigue
  - Weight loss, anorexia
– Fever
– Anemia
– Clubbing of digits
• Other presentations:
  – Chest pain (dull, pleuritic)
  – Shoulder/arm pain (Pancoast tumors)
  – Dysphagia
  – Plethora (redness of face or neck)
  – Hoarseness (involvement of recurrent laryngeal nerve)
  – Horner syndrome
  – Neurologic abnormalities (e.g., headaches, syncope, weakness, cognitive impairment)
  – Pericardial tamponade (pericardial invasion)

PHYSICAL EXAM
• General: fever, chills, night sweats, weight loss
• Head, eye, ear, nose, throat (HEENT): Horner syndrome, dysphonia, stridor, scleral icterus, dysphagia
• Neck: supraclavicular/cervical lymph nodes, mass
• Lungs: effusion, wheezing, airway obstruction, dyspnea
• Abdomen/groin: hepatomegaly or lymphadenopathy
• Extremities: signs of hypertrophic pulmonary osteoarthropathy, deep venous thrombosis (DVT)
• Neurologic: headache, syncope, weakness, cognitive impairment

DIFFERENTIAL DIAGNOSIS
• COPD (may coexist)
• Granulomatous (tuberculosis, sarcoidosis)
• Cardiomyopathy
• Congestive heart failure (CHF)

DIAGNOSTIC TESTS & INTERPRETATION

*Initial Tests (lab, imaging)*
• Serum
  – CBC
  – Comprehensive metabolic panel (CMP)
  – Hypercalcemia (paraneoplastic syndrome)
  – Hyponatremia (SIADH)
- Lactate dehydrogenase (LDH)
- Sputum cytology
- Chest x-ray (CXR) (compare with prior XRs)
  - Nodule or mass, especially if calcified
  - Persistent infiltrate
  - Atelectasis
  - Mediastinal widening
  - Hilar enlargement
  - Pleural effusion
- CT scan of chest (with IV contrast)
  - Nodule or mass (central or peripheral)
  - Lymphadenopathy
- Evaluation for metastatic disease
  - Positron emission tomography (PET) scan to evaluate metastasis
    mediastinal lymphadenopathy (replacing CT abdomen/pelvis and bone scan)
  - Brain MRI: Lesions may be necrotic, bleeding.

**Follow-Up Tests & Special Considerations**
CBC, BUN, serum creatinine, LFTs prior to each cycle of chemotherapy

**Diagnostic Procedures/Other**
- Pulmonary function tests
  - Bronchoscopy
  - Transbronchial biopsy (Wang needle)
  - Enlarged mediastinal lymph nodes necessitate staging by mediastinoscopy,
    video-assisted thoracoscopy, endobronchial ultrasound or fine needle aspiration.
- Biopsy with pathology review
- In patients with advanced NSCLC, determination of epidermal growth factor receptor (EGFR)-activating mutations, KRAS/NRAS mutations, and ALK gene rearrangements in patients with nonsquamous or mixed squamous histology
- Cervical mediastinoscopy (biopsy of upper and lower paratracheal and subcarinal lymph nodes)
- Video-assisted thoracoscopy (associated pleural disease and suspected mediastinal nodal spread)
- Bone marrow aspirate (small cell)
**Test Interpretation**
Pathologic changes from smoking are progressive: basal cell proliferation, development of atypical nuclei, stratification, metaplasia of squamous cells, carcinoma in situ, and then invasive disease.

---

**TREATMENT**

**GENERAL MEASURES**

- **NSCLC**
  - Stage I, stage II, and selected stage III tumors are surgically resectable. Neoadjuvant or adjuvant therapy is recommended for many patients with high risk IB, II, and IIIA NSCLC. Patients with resectable disease who are not surgical candidates may receive radiation therapy.
  - Patients with unresectable or N2, N3 disease are treated with concurrent chemoradiation. Selected patients with T3 or N2 disease can be treated effectively with surgical resection and either pre- or postoperative chemotherapy or chemoradiation therapy.
  - Patients with distant metastases (M1B) can be treated with radiation therapy or chemotherapy for palliation or best supportive care alone.

- **SCLC**
  - Limited stage: concurrent chemoradiation
  - Extensive stage: combination chemotherapy
  - Consider prophylactic cranial irradiation (PCI) in patients achieving a complete or partial response (2)[A].

- Quality-of-life assessments: Karnofsky performance scale (KPS) ([http://www.hospicepatients.org/karnofsky.html](http://www.hospicepatients.org/karnofsky.html)); Eastern Cooperative Oncology Group (ECOG)
- Discussions with patient and family about end-of-life care

**MEDICATION**

- Chemotherapy is the mainstay of treatment.
- Adjuvant chemotherapy following surgery improves survival in patients with fully resected stage II to III NSCLC.
- Palliative measures: analgesics
- Dyspnea: oxygen, morphine

**First Line**
• NSCLC
  – Stages II to III: neoadjuvant or adjuvant chemotherapy
    o Cisplatin-based doublets (combination with paclitaxel, etoposide, vinorelbine, docetaxel, gemcitabine)
    o Carboplatin alternative for patients unlikely to tolerate cisplatin
    o Cisplatin plus pemetrexed (nonsquamous cell)
  – Unresectable stage IIA, IIB
    o Concurrent chemoradiation
      ■ Cisplatin plus etoposide, vinblastine, or pemetrexed (nonsquamous cell) plus concurrent radiation
      ■ Carboplatin plus pemetrexed (nonsquamous cell) plus concurrent radiation
  – Stage IV
    – No chemotherapy regimen can be recommended for routine use.
    – Cisplatin- or carboplatin-based doublets
    – +/- bevacizumab (nonsquamous cell)
    – Erlotinib or afatinib for patients with EGFR mutations
    – Crizotinib for patients with EML4-ALK translocations
      o Ceritinib for patients that fail or are intolerant to crizotinib
    – Maintenance therapy after 4 to 6 cycles in patients achieving a response or stable disease
      o Continuation of bevacizumab, pemetrexed (nonsquamous cell), gemcitabine, erlotinib, or crizotinib or switch to pemetrexed (nonsquamous cell), erlotinib (EGFR mutations), docetaxel or observation
  • SCLC
    – Cisplatin or carboplatin plus etoposide

**Second Line**
• NSCLC
  – Cisplatin-based doublets +/- bevacizumab (nonsquamous cell) if not previously used
  – Docetaxel, pemetrexed (nonsquamous cell), erlotinib, gemcitabine, ramucirumab plus docetaxel, or nivolumab (squamous cell)
• SCLC
  – Topotecan or CAV (cyclophosphamide, doxorubicin, vincristine), gemcitabine, docetaxel, paclitaxel

**ADDITIONAL THERAPIES**
• Immunotherapy
  – Anti PD-L1 (programmed cell death ligand) antibody therapy
• Smoking cessation counseling
• Consider IV bisphosphonates or denosumab in patients with bone metastases to reduce skeletal-related events.

SURGERY/OTHER PROCEDURES
• Resection for NSCLC, for stages I, II, and IIIA, if medically fit to undergo surgery
• Resection of isolated, distant metastases has been achieved and may improve survival.
• Resection involves lobectomy in 71%, wedge in 16%, and complete pneumonectomy in 18%.
• Resection should be accompanied by lymph node dissection for pathologic staging.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
• Depends on clinical history; in general, postoperative visits every 3 to 6 months in the first 2 years after surgery with physical exam and CT scan
• Follow-up usually lifelong with CT scans, following NCCN criteria

PATIENT EDUCATION
• National Cancer Institute: http://www.cancer.gov/
• Smokefree.gov: http://smokefree.gov/

PROGNOSIS
• For combined, all types and stages, 5-year survival rate is 16% (NSCLC: 17%; SCLC: 6%).
• NSCLC
  – Localized disease (stages I and II): 49%
  – Regional disease: 16%
  – Distant metastatic disease: 2%
• SCLC
– Without treatment: median survival from diagnosis of only 2 to 4 months
– 5-year survival rate: ranges from 2% (stage IV) to 31% (stage I)
– Extensive-stage disease: median survival of 6 to 12 months; long-term disease-free survival is rare.

COMPLICATIONS

- Development of metastatic disease, especially to brain, bones, adrenals, and liver
- Local recurrence of disease
- Postoperative complications
- Side effects of chemotherapy or radiation

REFERENCES

ADDITIONAL READING

CODES

ICD10

- C34.90 Malignant neoplasm of unsp part of unsp bronchus or lung
- C34.10 Malignant neoplasm of upper lobe, unsp bronchus or lung
- C34.30 Malignant neoplasm of lower lobe, unsp bronchus or lung

CLINICAL PEARLS

- Two types: NSCLC and SCLC
NSCLC (>85% of all lung cancers); normally originate in periphery
  - Adenocarcinoma (~40% of NSCLC)
  - Squamous cell carcinoma (~25% of NSCLC)
  - Large cell (~10% of NSCLC)
SCLC centrally located, early metastases, aggressive
- Prognosis and treatment of lung cancer differs greatly between small cell- and non–small cell histologies.
- Adjuvant cisplatin-based chemotherapy improves survival in patients with completely resected stage II to III NSCLC.
- Chemotherapy, with or without radiation, can be offered to patients with advanced NSCLC or SCLC.
- There is little role for surgery in the treatment of SCLC.
LUPUS ERYTHEMATOSUS, SYSTEMIC (SLE)

Katherine M. Tromp, PharmD • Hershey S. Bell, MD, MS, FAAFP

BASICS

DESCRIPTION

- Systemic lupus erythematosus (SLE) is a multisystem autoimmune inflammatory disease characterized by a chronic relapsing/remitting course; can be mild to severe and may be life-threatening (CNS and renal forms)
- System(s) affected: mucocutaneous; musculoskeletal; renal; nervous; pulmonary; cardiac; hematologic; vascular; gastrointestinal (GI)
- Synonym(s): SLE; lupus

ALERT

Women with SLE have a 7- to 50-fold increased risk of coronary artery disease and may present with atypical/nonspecific symptoms.

EPIDEMIOLOGY

Predominant age: 15 to 45 years

Incidence

- Per year, 1.6 to 7.6/100,000 and increasing due to better diagnosis
- Most common: African American women (8.1 to 11.4/100,000/year)
- Least common: Caucasian men (0.3 to 0.9/100,000/year)

Prevalence

Occurs in 30 to 50/100,000 and increasing due to increased survival

ETIOLOGY AND PATHOPHYSIOLOGY

- Skin: photosensitivity; scaly erythematous, plaques with follicular plugging, dermal atrophy, and scarring; nonscarring erythematous psoriasiform/annular rash; alopecia; mucosal ulcers
- Musculoskeletal: nonerosive arthritis; ligament and tendon laxity, ulnar
deviation, and swan neck deformities; avascular necrosis
- Renal: glomerulonephritis
- Pulmonary: pleuritis, pleural effusion, alveolar hemorrhage, pneumonitis, interstitial fibrosis, pulmonary hypertension, pulmonary embolism (PE)
- Cardiac: nonbacterial verrucous endocarditis, pericarditis, myocarditis, atherosclerosis
- CNS: thrombosis of small intracranial vessels ± perivascular inflammation resulting in micro- or macroinfarcts ± hemorrhage
- Periarticular: mononeuritis multiplex, peripheral neuropathy
- GI: pancreatitis, peritonitis, colitis
- Hematologic: hemolytic anemia, thrombocytopenia, leukopenia, lymphopenia
- Vascular: vasculitis, thromboembolism
- Most cases are idiopathic with possible environmental factors.
- Drug-induced lupus: hydralazine, D penicillamine, quinidine, procainamide, minocycline, isoniazid, etc.

**Genetics**
- Identical twins: 24–58% concordance
- Fraternal twins and siblings: 2–5% concordance
- 8-fold risk if first-degree relative with SLE
- Major histocompatibility complex associations: HLA-DR2, HLA-DR3
- Deficiency of early complement components, especially C1q, C1r/s, C2, and C4
- Immunoglobulin receptor polymorphisms: FCγR2A, FCγR3A, and others
- Polymorphism in genes associated with regulation of programmed cell death, protein tyrosine kinases, and interferon production

**RISK FACTORS**
- Race: African Americans, Hispanics, Asians, and Native Americans
- Predominant sex: females > males (10:1)
- Environmental: UV light, infectious agents, stress, diet, drugs, hormones, vitamin D deficiency, and tobacco

**COMMONLY ASSOCIATED CONDITIONS**
- Overlap syndromes: rheumatoid arthritis (RA), Sjögren syndrome, scleroderma
- Antiphospholipid syndrome; coronary artery disease; nephritis; depression
DIAGNOSIS

Consider SLE in multisystem disease including fever, fatigue, and signs of inflammation.

HISTORY
- Fever, fatigue, malaise, weight loss, headache
- Rash (discoid [LR+] = 18, malar [LR+] = 14), photosensitivity [LR+] = 11, alopecia
- Oral/nasal ulcers (usually painless)
- Arthritis, arthralgia, myalgia, weakness
- Pleuritic chest pain, cough, dyspnea, hemoptysis
- Early stroke (age <50 years), unexplained seizure/psychosis [LR+] = 13, cognitive deficits
- Proteinuria, cellular casts
- Hemolytic anemia, leukopenia, lymphopenia, thrombocytopenia
- Abdominal pain, anorexia, nausea, vomiting
- Raynaud phenomenon

PHYSICAL EXAM
- Vital signs: fever, hypertension
- Malar, discoid, psoriasiform, or annular rash, alopecia
- Oral/nasal ulcers (often minimally symptomatic)
- Lymphadenopathy, splenomegaly
- Acrocyanosis
- Inflammatory arthritis, tenosynovitis
- Pleural/pericardial rub, heart murmur
- Bibasilar rales
- Cranial/peripheral neuropathies

DIFFERENTIAL DIAGNOSIS
Undifferentiated connective tissue disease, Sjögren syndrome, fibromyalgia, RA, vasculitis, idiopathic thrombocytopenia purpura, antiphospholipid antibody syndrome, drug-induced lupus

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
American College of Rheumatology (ACR) and Systemic Lupus International Collaborating Clinics (SLICC) criteria

- ACR and the SLICC have established diagnostic criteria for SLE.
- ACR requires at least 4 of 11 criteria be met (95% specificity; 85% sensitivity).
- SLICC requires at least 4 of 13 criteria including at least one abnormal clinical criterion and one abnormal immunologic criterion or patient must have biopsy—confirmed lupus nephritis and elevated ANA or anti-dsDNA levels (97% specificity; 84% sensitivity)
- ACR remains the gold standard; SLICC not yet endorsed by ACR
  - Cardiac/pulmonary: ACR: pleuritic or pericarditis; SLICC: serositis
  - Hematologic: ACR: hemolytic anemia or leukopenia or lymphopenia or thrombocytopenia; SLICC: hemolytic anemia, leukopenia or lymphopenia more than once, thrombocytopenia
  - Immunologic: ACR: positive antinuclear antibody (ANA), elevated anti double-stranded DNA (anti-dsDNA), anti-Smith (anti-Sm) or antiphospholipid antibodies; SLICC: positive ANA, elevated anti-dsDNA, anti-Sm, or phospholipid antibodies, low complement (C3, C4, CH50) or direct Coombs test (in absence of hemolytic anemia), chronic cutaneous lupus, nonscarring alopecia, oral ulcers or nasal ulcers
  - Musculoskeletal: ACR: nonerosive arthritis involving 2 or more joints; SLICC: synovitis involving 2 or more joints, or tenderness at 2 or more joints and at least 30 minutes of morning stiffness
  - Neuropsychiatric: ACR: seizure or psychosis; SLICC: seizures, psychosis, mononeuritis complex, myelitis, or peripheral or cranial neuropathy
  - Renal: ACR: persistent proteinuria >0.5 g per day or >3+ on urine dipstick, or cellular casts; SLICC: urinary creatinine (or 24-hour urinary protein) >500 mg, or red blood cell casts
  - Skin/mucosal: ACR: malar rash; SLICC: acute or subacute cutaneous lupus

Initial imaging is dependent on presenting symptoms.
- Radiograph of involved joints
- Chest x-ray: infiltrates, pleural effusion, low lung volumes
- Chest CT scan, ventilation/perfusion (V/Q) scan, duplex ultrasound for PE or deep vein thrombosis
- Head CT scan: ischemia, infarct, hemorrhage
- Brain MRI: focal areas of increased signal intensity
- Echocardiogram: pericardial effusion, valvular vegetations, pulmonary hypertension
Contrast angiography for medium-size artery vasculitis: mesenteric/limb ischemia, CNS symptom

**Follow-Up Tests & Special Considerations**
- Hemolytic anemia: elevated reticulocyte count and indirect bilirubin, low haptoglobin, positive direct Coombs test
- Confirm positive phospholipid antibodies results in 12 weeks.
- If phospholipid antibodies are initially negative, but symptoms arise, repeat, as they may become positive over time.
- 24-hour urine collection/spot protein/creatinine to quantify proteinuria
- Histone antibodies present in >95% of drug-induced lupus (vs. 80% of idiopathic SLE)
- Fasting lipid panel and glucose
- Follow vitamin D(25(OH)) levels and replenish PRN.

**Diagnostic Procedures/Other**
- Renal biopsy to diagnose lupus nephritis (if UA abnormal)
- Skin biopsy with immunofluorescence on involved and uninvolved non–sun-exposed skin *(lupus band test)* may help differentiate SLE rash from others.
- Lumbar puncture in patients with fever and CNS/meningeal symptoms
- EEG for seizures/global CNS dysfunction
- Neuropsychiatric testing for cognitive impairment
- EMG/nerve conduction study (NCS) for peripheral neuropathy and myositis
- Nerve and/or muscle biopsy
- ECG, cardiac enzymes, stress tests

**Test Interpretation**
- Skin: vascular/perivascular inflammation, immune-complex deposition at dermal–epidermal junction, mucinosis, basal layer vacuolar changes
  - Similar findings seen in other connective tissue disorders such as dermatomyositis
- Renal: mesangial hypercellularity/matrix expansion, subendothelial/subepithelial immune deposits, glomerular sclerosis, fibrous crescents
  - Vary depending on degree of involvement
- Vascular: immune-complex deposition in vessel walls with fibrinoid necrosis and perivascular mononuclear cell infiltrates, intraluminal fibrin thrombi
TREATMENT

GENERAL MEASURES

- Education, counseling, and support
- Influenza/pneumococcal vaccines are safe; weigh risk versus benefit for live vaccines in immunocompromised patients
- Low-estrogen oral contraceptives safe in mild SLE

MEDICATION

First Line

- Antimalarial agents and NSAIDs are first-line therapy for patients with mild SLE (1)[A].
  - Hydroxychloroquine for constitutional and musculoskeletal symptoms, rash, mild serositis; may reduce flares and increase long-term survival (1)[A],(2)[C]; recommended maximum dose is 5 mg/kg based on actual body weight (3)[C].
  - NSAIDs for musculoskeletal manifestations, mild serositis, headache, and fever (1)[A]

- Systemic glucocorticoids (prednisone or equivalent)
  - Low dose (<0.5 mg/kg) for minor disease activity not responsive to NSAIDs or when NSAIDs are contraindicated (1)[A]
  - High dose (1 to 2 mg/kg/day) (1)[A] or IV pulse methylprednisolone for organ-threatening disease, particularly CNS and renal; often combined with immunosuppressive agent (1)[A]

- Topical corticosteroids for skin manifestations

Second Line

- Methotrexate (4)[C], azathioprine (4)[C], mycophenolate mofetil (4)[C], or leflunomide as steroid-sparing agent for persistent active disease or to maintain remission
  - Requires laboratory monitoring for toxicity

- Belimumab as adjunct for preventing flares in patients with active lupus despite first-line therapy (5)[B]
  - 10 mg/kg IV q2wk × 3 doses and then monthly

- Treatments under investigation: rituximab, epratuzumab, abatacept, interferon-α inhibitors
- Immunosuppressive agents for severe disease
– Cyclophosphamide (1)[A]: adequate hydration to reduce risk of hemorrhagic cystitis
– Mycophenolate mofetil (1)[A]: more efficacious for lupus nephritis (4)[A]

SURGERY/OTHER PROCEDURES
Renal transplant for end-stage renal disease

COMPLEMENTARY & ALTERNATIVE MEDICINE
Biofeedback, visual imagery, cognitive therapy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

• Difficult to differentiate SLE flare from infection; may need to treat both pending full evaluation
• IV pulse Solu-Medrol 1 g/day for 3 to 5 days for life- or organ-threatening disease (1)[A]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

• Clinical evaluation for signs and symptoms
  – Weekly to monthly for active disease
  – Every 3 to 6 months for mild/inactive disease
• Measures of disease activity and damage: Systemic Lupus Erythematosus Disease Activity Index, British Isles Lupus Assessment Group Index, European Consensus Lupus Activity Measure
• Laboratory studies
  – CBC with differential
  – Serum creatinine, UA
  – Vitamin D
  – Declining C3/C4 and rising DS-DNA and ESR may correlate with disease activity
• Monitor for adverse effects of treatment.
  – NSAIDs: GI bleeding and/or ulceration
– Glucocorticoids: glucose, lipids, bone density
– Hydroxychloroquine: ophthalmologic exam every 6 to 12 months
– Methotrexate: CBC, creatinine, albumin, aspartate aminotransferase (AST), alanine aminotransferase (ALT) every 2 months
– Azathioprine and mycophenolate mofetil: CBC every 1 to 3 months
– Cyclophosphamide
  o CBC, creatinine, UA every 2 weeks, and liver function tests monthly during treatment
  o UA every 6 to 12 months for life

**DIET**

- No special diet unless for complications such as renal failure, diabetes, hyperlipidemia (1)[A]
- Adequate calcium/vitamin D intake in patients on corticosteroids (1)[A]
- Low glycemic index or calorie-restricted diet in patients on corticosteroids

**PATIENT EDUCATION**

- Avoid UV light exposure: sunscreens (SPF ≥30), protective clothing (1)[A].
- Weight control, smoking cessation, exercise (1)[A]
- Stress avoidance/management

**PROGNOSIS**

- Permanent treatment-free remission is uncommon
- 5-year survival after diagnosis is 95%.
- Poor prognostic factor: major organ involvement
- Drug-induced lupus resolves within weeks to months after discontinuation of the offending drug.

**COMPLICATIONS**

Infections, neoplasms, cardiac disease, nephritis, neuropsychiatric lupus; depression

**Pregnancy Considerations**

- Exacerbations during pregnancy are less common when in remission for 6 months prior to conception.
- Fetal loss is increased, especially in those with active lupus/antiphospholipid antibodies.
- A 2% risk of congenital heart block if anti-SS-A (Ro) or anti-SS-B (La)
antibodies are present.

- See “Antiphospholipid Antibody Syndrome” for recommendations regarding use of aspirin and heparin to prevent pregnancy complications.

SEE ALSO

Antiphospholipid Antibody Syndrome
CODES

ICD10
- M32.9 Systemic lupus erythematosus, unspecified
- M32.10 Systemic lupus erythematosus, organ or system involv unsp
- M32.14 Glomerular disease in systemic lupus erythematosus

CLINICAL PEARLS
- Aggressiveness of therapy should reflect intensity of disease.
- Most important diagnostic test is the UA: if abnormal, order kidney biopsy; serum and urine lab values often do not reveal extent of kidney disease.
- Atherosclerotic and atheroembolic complications are the major cause of death; address modifiable cardiovascular risk factors.
LUPUS NEPHRITIS

Neena R. Gupta, MD

BASICS

DESCRIPTION

- The renal manifestation of systemic lupus erythematosus (SLE)
- American College of Rheumatology (ACR) criteria: persistent proteinuria >500 mg/day or ≥3 on dipstick and/or presence of cellular casts; alternatively, spot urine protein-to-creatinine ratio >0.5 and “active urinary sediment” (>5 RBC/hpf, >5 WBC/hpf in absence of infection, or cellular casts—RBC or WBC casts) (1)
- Clinical manifestations primarily due to immune complex–mediated glomerular disease. Tubulointerstitial and vascular involvement often coexist. Diagnosis is based on clinical findings, urine abnormalities, autoantibodies, and renal biopsy.
- Treatment and prognosis depend on International Society of Nephrology/Renal Pathology Society (ISN/RPS) histologic class—risk of end-stage renal disease (ESRD) highest in class IV.
- Delay in diagnosis/treatment increases risk of ESRD.

EPIDEMIOLOGY

- Peak incidence of SLE is 15 to 45 years of age.
- Predominant sex: female > male (10:1)
- Once SLE develops, lupus nephritis (LN) affects both genders equally; it is more severe in children and men and less severe in older adults.

Incidence

- SLE: 1.4 to 22/100,000
- Up to 60% of SLE patients develop LN over time; 25–50% of SLE patients have nephritis as the initial presentation.

Pediatric Considerations

LN is more common and more severe in children: 60–80% of children have LN at or soon after SLE onset.
**Prevalence**
SLE: 7.4 to 159.4/100,000

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Immune complex–mediated inflammation injures glomeruli, tubules, interstitium, and vasculature.
- Glomeruli: Varying degrees of mesangial proliferation, crescent formation, and fibrinoid necrosis cause reduced glomerular filtration rate (GFR).
- Persistent inflammation (chronicity) leads to sclerosis and glomerular loss.
- Tubulointerstitial injury (edema, inflammatory cell infiltrate acutely; tubular atrophy in chronic phase) with or without tubular basement membrane immune complex deposition leads to reduced renal function.
- Vascular lesions: immune complex deposition and noninflammatory necrosis in arterioles
- SLE is a multifactorial disease, with multigenic inheritance; exact etiology remains unclear.
- Defective T-cell autoregulation and polyclonal B-cell hyperactivity contribute to dysregulated apoptosis. Impaired clearance of apoptotic cells inhibits self-tolerance to nuclear antigen.
- Anti-DNA, anti-C1q, anti-α-actin, and other nuclear component autoantibodies develop.
- Deposition of circulating immune complexes or autoantibodies attaching to local nuclear antigens leads to complement activation, inflammation, and tissue injury.
- Interaction of genetic, hormonal, and environmental factors leads to great variability in LN severity.

**Genetics**
Multigenic inheritance; clustering in families, ~25% concordance in identical twins

**RISK FACTORS**
Younger age, African American or Hispanic race, more ACR criteria for SLE, longer disease duration, hypertension, lower socioeconomic status, family history of SLE, anti-dsDNA antibodies

**COMMONLY ASSOCIATED CONDITIONS**
Skin, hematologic, cerebral, pulmonary, GI, and cardiopulmonary systems are
often involved in SLE.

**DIAGNOSIS**

**HISTORY**
Assess for risk factors and other signs/symptoms of SLE: rash, photosensitivity, arthritis, neurologic complaints, fever, weight loss, alopecia.

**PHYSICAL EXAM**
- Hypertension, fever
- Pleural/pericardial rub
- Skin rash
- Edema
- Arthritis
- Alopecia
- Oral ulcers

**DIFFERENTIAL DIAGNOSIS**
- Primary glomerular disease
- Secondary renal involvement in other systemic disorders such as antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis, Henoch-Schönlein purpura (HSP), antiglomerular basement membrane disease, and viral infections
- Mixed connective tissue disorder may have glomerulonephritis indistinguishable from LN.

**DIAGNOSTIC TESTS & INTERPRETATION**
- Renal biopsy is the gold standard for diagnosing and classifying LN.
- Combine clinical data with serologic and renal biopsy patterns to differentiate LN from other conditions.
- Active urine sediment suggests nephritis.
- Autoantibodies, low C3, C4, and CH50 complement levels support LN diagnosis.

**Initial Tests (lab, imaging)**
- Urinalysis may show hematuria, proteinuria, and active urine sediment (2)[C].
- Serum electrolytes, BUN, creatinine, albumin, routine serologic markers of
SLE such as antinuclear antibody (ANA), anti-dsDNA, anti-Ro, anti-La, anti-RNP, anti-Sm, antiphospholipid antibody, C3, C4, CH50, CBC with differential, and C-reactive protein (CRP) (2)[C]

- CBC may show anemia, thrombocytopenia, and leukopenia.
- Renal ultrasound (2)[C]

**Follow-Up Tests & Special Considerations**
- Monitor disease activity q3mo (2)[C]: urinalysis for hematuria and proteinuria; blood for C3, C4, anti-dsDNA, serum albumin, and creatinine.
- Patients with estimated glomerular filtration rate (eGFR) of <60 mL should be managed according to the National Kidney Foundation guidelines for chronic kidney disease (CKD).
  

**Pregnancy Considerations**
- Pregnancy leads to worsening of renal function in LN. Risk factors include renal impairment at baseline, active disease, hypertension, and proteinuria.
- Risk factors for fetal loss include elevated serum creatinine, heavy proteinuria, hypertension, and anticardiolipin antibodies.
- Mycophenolate mofetil (MMF) is contraindicated in pregnancy; azathioprine can be safely used.

**Test Interpretation**
- Adequate renal biopsy (at least 10 glomeruli for light microscopy or total 20 to 25 glomeruli) is essential. Light, immunofluorescence, and electron microscopy are needed for accurate classification.
- On immunofluorescence microscopy: Immune complex deposits consisting of IgG, IgA, IgM, C1q, and C3 (“full house”) are highly suggestive of LN.
- Revised ISN/RPS histologic classification guides therapeutic decisions. http://jasn.asnjournals.org/content/15/2/241.full.pdf
- LN is classified as purely mesangial (classes I and II), focal proliferative: <50% glomeruli (class III), diffuse proliferative: ≥50% (class IV), membranous (class V), and advanced sclerosis (class VI); subdivisions for activity (A) and chronicity (C) in class III/IV and for segmental (S) or global (G) glomerular involvement in class IV (class III A, C, A/C and class IV S[A], G[A], S[A/C], S[C], G[C])
- LN may change to another class over time or with therapy.
- Focal and diffuse proliferative LN (classes III and IV) are common and most
likely to progress to ESRD.

TREATMENT

GENERAL MEASURES
- Monitor bone density; optimize vitamin D and calcium intake in patients on glucocorticoid therapy.
- Low-salt diet for hypertension and edema. For eGFR <60 mL: Follow National Kidney Foundation guidelines for CKD.
- Avoid sun or ultraviolet light exposure.

MEDICATION
Note: Other than methylprednisolone and prednisone, no other medications listed below are FDA-approved for LN.

First Line
- **Class I + II LN:** No specific therapy is needed, as long-term renal prognosis is good; renin-angiotensin system blockade (ACE inhibitors or angiotensin receptor blockers) to manage BP and proteinuria (e.g., lisinopril 5 to 40 mg/day PO, losartan 25 to 100 mg/day PO)
- **Proliferative LN (class III, IV, V + III/IV):** Induce remission by steroids + IV cyclophosphamide or MMF and maintenance of remission by low-dose steroids and azathioprine or MMF (1).

Principles of treatment:
- Avoid delay; induce remission quickly (3 to 6 months).
- Maintain response and avoid iatrogenic morbidity.

**INDUCTION:** steroids + immunosuppressive agent (for mild class III, high-dose steroids may be sufficient):
- Glucocorticoids: methylprednisolone pulse 0.5 to 1.0 g/day for 3 days followed by oral prednisone 0.5 to 1.0 mg/kg/day PO (max 60 mg/day, taper after 4 to 8 weeks) (3)[A] AND
- Cyclophosphamide: IV cyclophosphamide (high dose = 0.5 to 1.0 g/m² monthly for 6 doses—NIH regimen; low dose = 0.5 g q2wk for 6 doses—Euro-Lupus regimen) OR
- MMF: 1 to 3 g/day PO divided BID (target 3 g/day as tolerated) for 6 months. MMF is as effective as cyclophosphamide in achieving remission with fewer side effects (3)[A].
MAINTENANCE:
- Glucocorticoids: oral prednisone tapered to low doses (generally <10 mg/day by 6 months) AND
- MMF 1 to 2 g/day divided BID PO OR azathioprine: 1.0 to 2.5 mg/kg/day PO (3)[A]
- In the ALMS (Aspreva Lupus Management Study), MMF shown to be superior to azathioprine for maintenance therapy in a varied population (4)[A].
- In the MAINTAIN nephritis trial, MMF shown to be equal to azathioprine for maintenance therapy in mostly Caucasian population (5)[A].
- Cyclophosphamide IV quarterly for 1 to 2 years after renal remission; not used now due to availability of less toxic regimen
- Optimum duration of maintenance therapy is unclear but periods ranging from 3 to 10 years have been studied in clinical trials (4,5).

Class V LN: good prognosis, no standardized treatment
- For subnephrotic patients, no specific treatment except renin-angiotensin system blockade
- Options for nephrotic patients include steroids with either calcineurin inhibitors, IV cyclophosphamide, azathioprine, or MMF (3)[B].
- Class V LN with presence of class III or class IV biopsy findings needs aggressive combination regimen as for class III/IV.

Second Line
Other treatments in selected patients: rituximab, plasma exchange, IVIG, calcineurin inhibitors. Belimumab was approved by FDA in 2011, but trials excluded patients with severe active LN (3)[C].

ISSUES FOR REFERRAL
Nephrology consults for initial management and relapses

ADDITIONAL THERAPIES
- KDIGO guidelines for LN state that all patients with LN of any class be treated with hydroxychloroquine (maximum daily dose of 6.0 to 6.5 mg/kg ideal body weight), unless they have a specific contraindication.
- BP control; treat dyslipidemia and other modifiable cardiovascular risk factors.
- Anticoagulation for symptomatic antiphospholipid antibody syndrome
SURGERY/OTHER PROCEDURES
- Renal transplant for ESRD when indicated
- Patient and graft survival rates similar to non-SLE patients
- Risk of recurrent LN in renal transplant recipients ranges between 0% and 30%; graft loss due to recurrence is rare.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization
  - Uncontrolled hypertension, acute kidney injury
  - Severe extrarenal manifestation
  - Control hypertension and proteinuria, if present.
  - Labs to help confirm SLE/LN, renal ultrasound
  - Nephrology for manage input and renal biopsy
- Patients who have nephrotic syndrome or acute kidney injury should be fluid restricted.
- Once the patient is stabilized and renal biopsy is performed, manage safely as an outpatient.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Monitor urine protein-to-creatinine ratio, urine microscopy, serum albumin and creatinine, antibody titers (especially anti-dsDNA), C3, C4, BP at least every 3 months for first 2 to 3 years [2][C].
- Once stable on maintenance therapy with no active disease, follow-up every 6 to 12 months [2][C].
- Cyclophosphamide: CBC; ensure adequate hydration.
- MMF: CBC, LFT, SrCr
- Azathioprine: CBC

DIET
Low-salt diet. For eGFR <60 mL: Follow National Kidney Foundation guidelines for CKD.
PATIENT EDUCATION
Medication adherence and self-monitoring for relapse

PROGNOSIS
- 10-year survival of 88% and 94% in SLE patients with and without renal involvement (1)
- Relapse rate is ~35%. 10–20% of patients progress to ESRD within 10 years.
- 5-year renal survival of class IV LN <30% before 1970 has improved to >80% in last 2 decades.
- Early and complete remission of proteinuria with treatment is the best prognostic factor. Other predictors of remission include low baseline proteinuria, normal creatinine, Caucasian race, and treatment initiated within 3 months of diagnosis.
- Indicators of poor prognosis: diffuse proliferative LN (especially crescentic), higher activity/chronicity index, African American race, lower socioeconomic status, poor response to treatment, high creatinine at baseline, uncontrolled hypertension, and relapse

COMPLICATIONS
- Risks of immunosuppressive therapy: infections, malignancy
- Treatment side effects: Cyclophosphamide causes primary amenorrhea.
- MMF may cause GI upset and nausea and is a teratogen (azathioprine recommended for women who desire pregnancy).
- Risk of vascular thromboses (hypercoagulable state from antiphospholipid antibodies)
- About 10–20% of patients develop ESRD from progressive disease refractory to treatment requiring dialysis/kidney transplantation.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

M32.14 Glomerular disease in systemic lupus erythematosus

**CLINICAL PEARLS**

- Early diagnosis, correct classification (requires renal biopsy), and rapid treatment improve renal survival in patients with LN.
- Treat proliferative/progressive LN with a short induction course followed by maintenance therapy using glucocorticoids and immunosuppressants.
- Survival rates for patients with LN have improved dramatically over the past several decades.
LYME DISEASE

Felix B. Chang, MD, DABMA, FAAMA • Vinay Bhamidipati, MD, MPH

BASICS

DESCRIPTION

- A multisystem infection caused by *Borrelia* spirochetes, transmitted primarily by ixodid ticks
  - *Ixodes scapularis* (deer ticks) in the New England and Great Lakes areas
  - *Ixodes pacificus* in the West (blacklegged ticks and Western blacklegged ticks)
  - *Ixodes ricinus* in Europe
  - *Ixodes persulcatus* in Asia and Russia
- Early localized Lyme disease includes a characteristic expanding skin rash (erythema migrans [EM]) (80%) and constitutional flulike symptoms (1).
- Early neurologic manifestations 15%: cranial nerve palsy, meningitis, acute radiculopathy, or mononeuropathy
- Disseminated Lyme disease presents with involvement of ≥1 organ systems; most commonly neurologic, cardiac, and pauciarticular arthritis
- Lyme carditis: AV block, myopericarditis 1%
- Post-Lyme disease syndrome includes arthritis (50%) and chronic neurologic syndromes.
- System(s) affected: hemic/lymphatic/immunologic; musculoskeletal; skin/exocrine; cardiac; neurologic
- Synonym(s): Lyme arthritis; Lyme borreliosis

EPIDEMIOLOGY

Incidence

- 96% of U.S. cases (2014) reported from Connecticut, Massachusetts, New York, New Jersey, Delaware, Pennsylvania, Virginia, Maryland, Maine, Minnesota, Wisconsin, New Hampshire, Vermont, and Rhode Island (1)
- In endemic states, the incidence is 0.5 per 1,000 but can be substantially higher in local areas.
- Cases have been reported from all 50 states.
Estimated 329,000 cases/year reported in the United States
Fifth most common reportable disease in the United States

**Prevalence**
- The most reported vector-borne illness in the United States
- Estimated 106 cases per 100,000 persons
- Predominant age: most common in children ages 5 to 14 years and in adults aged 55 to 70 years of age
- Predominant sex: male > female in the United States

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Infection with spirochete *Borrelia burgdorferi* in the United States, or *Borrelia afzelii* or *Borrelia garinii* in Europe, transmitted by the bite of ixodid ticks
- Approximately 90% of cases are transmitted during the nymph stage of the tick life cycle.
- Average incubation period 7 to 10 days
- Most transmissions occur in late May to September when nymphal tick activity is highest.
- If a tick is infected, the chance of transmission increases with time attached: 12% at 48 hours, 79% at 72 hours, and 94% at 96 hours of attachment.
- Primary animal reservoir is the white-footed mouse.
- Spirochetes multiply and spread within dermis. Host response results in characteristic (EM) rash. Hematogenous dissemination results in disease within CNS, cardiovascular, or other organ systems.
- Star ticks (*Amblyomma americanum*), the American dog tick (*Dermacentor variabilis*), the Rocky Mountain wood tick (*Dermacentor andersoni*), and the brown dog tick (*Rhipicephalus sanguineus*) are not known to transmit Lyme disease.

**Genetics**
Human leukocyte antigen: Patients with haplotype DR4 or DR2 may be more susceptible to prolonged arthritis.

**RISK FACTORS**
- Exposure in tick-infested area, particularly from April to November
- Those who reside or are employed in endemic areas where ixodid ticks are found are at increased risk.
Ixodid ticks are commonly found on deer. Hunters may be at an increased risk.

GENERAL PREVENTION
- “Tick checks”: Examine skin after outdoor activities.
- Remove ticks within 36 hours to limit transmission.
- Wear clothing covering the ankles in endemic areas.
- Use insect repellents containing N,N-diethyl-meta-toluamide (DEET).
- Apply permethrin to clothes, shoes, and tents.
- Antibiotic prophylaxis is recommended for the prevention of Lyme disease in endemic areas following an *Ixodes* tick bite.

Prophylactic treatment with 1 dose of 200 mg of doxycycline within 72 hours of a tick bite in highly endemic areas is 87% effective. Contraindicated in pregnancy and in children; no prophylactic agent is approved for these groups (1)[A].

COMMONLY ASSOCIATED CONDITIONS
- Coinfection with babesiosis has been reported; suggested by high fever
- Southern tick–associated rash illness may be mistaken for Lyme disease. It is seen in the Southeastern and South Central United States and is associated with the bite of the lone star tick, *A. americanum*.
- Comorbid human granulocytic anaplasmosis and/or babesiosis in patients living in endemic regions

DIAGNOSIS

HISTORY
- History of a tick bite followed by EM and/or illness. About 1/3 of patients recall tick bite.
- Round, flat or raised, erythematous lesion that expands in diameter over days to weeks, may have area of central clearing, typically arises about 7 to 14 days after tick detaches.
- Common EM sites: axilla, back, abdomen, groin, or popliteal fossa
- 75–80% presenting with EM having a single lesion
- Early Lyme disease: incubation period 3 to 30 days
  - Some patients may be asymptomatic (2).
  - Fever; headache; myalgias; arthralgias, regional lymphadenopathy
• Disseminated Lyme disease
  – Carditis (pleuritic chest pain; palpitations)
  – Facial palsies or other cranial neuropathies
  – Joint pain (polyarthritis/algias; late disease: monoarthritis-like knee)
  – Iritis, conjunctivitis
  – Migratory musculoskeletal pain
• Late Lyme disease arises months after exposure.
  – Recurrent synovitis
  – Recurrent tendonitis and bursitis
  – Encephalopathic symptoms
    o Headaches
    o *Cognitive slowing*
    o Confusion
    o Profound fatigue
  – Symptoms mimicking other CNS diseases
    o Multiple sclerosis–like symptoms
    o Stroke-like symptoms
    o Transverse myelitis
  – Peripheral neuropathic symptoms: motor, sensory, or autonomic neuropathies
  – Meningitis
  – Acrodermatitis chronic atrophicans: fibrosing skin process often involving extremities

**PHYSICAL EXAM**
• Early Lyme disease
  – EM
• Disseminated Lyme disease
  – Multiple EM
  – Facial palsies or other cranial neuropathies
  – Heart block—irregular pulse
  – Pericarditis—friction rub
  – Arthritis
  – Other focal neurologic findings

**DIFFERENTIAL DIAGNOSIS**
• Other rickettsial disease (Rocky Mountain spotted fever [RMSF])
• Juvenile rheumatoid arthritis (RA); systemic lupus erythematosus (SLE); RA
• Viral syndromes
• Coinfection: ehrlichiosis; babesiosis
• Contact dermatitis; cellulitis; granuloma annulare (mimic EM)
• Syphilis
• AV block
• Malignant neoplastic diseases

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Testing and treatment not indicated if tick attached for <48 hours
- Diagnosis is based mainly on clinical findings in endemic areas (2).
- Serology: enzyme-linked immunosorbent assay (ELISA) for IgM and IgG *B. burgdorferi* antibodies, followed by a Western blot test if positive or equivocal, or an indirect immunofluorescence assay
- Culture of CSF for *B. burgdorferi*
- Plasma polymerase chain reaction (PCR) testing is of little value (only exception is synovial fluid analysis).
- No imaging routinely indicated
- For non-EM presentations: Two-tier serologic testing is recommended, synovial fluid when arthritis is suspected, and CSF analysis when neurologic involvement suspected.
- Tests yet to be validated:
  - Urine antigen capture assays
  - Culture, immunofluorescence staining, or cell sorting of cell wall-deficient or cystic forms of *B. burgdorferi*
  - Lymphocyte transformation tests
  - Quantitative CD57 lymphocyte assays
  - “Reverse Western blots”
  - In-house criteria for interpretation of immunoblots
  - Measurements of antibodies in joint fluid (synovial fluid)
  - IgM or IgG tests without a previous ELISA/EIA/IFA

**Follow-Up Tests & Special Considerations**

Disorders that may alter lab results: false-positive response with RMSF, syphilis, SLE, and RA

- Arthritis: Serology + PCR of synovial fluid is both sensitive and specific.
- Neuroborreliosis: serology + CSF pleocytosis (PCR of CSF has a very low sensitivity)
- Late-stage disease with negative serology may be seen in patients receiving
early antibiotic treatment.

- After an infection, antibodies may persist for months to years. *Serologic tests do not distinguish active from past infection* (3).
- Antibodies are not protective.

**Diagnostic Procedures/Other**

Lumbar puncture when neurologic findings are present, with ELISA or CSF for *B. burgdorferi* antibodies (2)

**Test Interpretation**

Culture of *B. burgdorferi* from blood or skin has low yield.

**TREATMENT**

**GENERAL MEASURES**

Early and disseminated Lyme disease can usually be treated as an outpatient except when complicated by carditis or meningitis (requires parenteral antibiotics).

**MEDICATION**

**First Line**

- EM (4,5)[A]
  - Doxycycline (Vibramycin) 100 mg PO BID for 10 to 21 days (do not use in children <8 years old or in pregnant women) (3)[A]; or
  - Amoxicillin 500 mg PO TID for 14 to 21 days (pediatric dose 50 mg/kg/day); or
  - Cefuroxime axetil 500 mg PO BID for 14 to 21 days
    - Doxycycline has the advantage of covering other tick-borne infections such as ehrlichiosis, anaplasmosis, and RMSF.
    - Alternative: azithromycin 500 mg QD for 7 to 10 days or clarithromycin 500 mg BID for 14 to 21 days

- Neurologic disease
  - Normal CSF, treat for 14 to 21 days.
  - Doxycycline 100 mg PO BID or amoxicillin 500 mg PO TID
  - Abnormal CSF, treat for 4 weeks: ceftriaxone 2 g QD IV, cefotaxime 2 g q8h, or penicillin G 5 mIU q6h
  - Cardiac disease
- Mild (first-degree AV block, PR <300 ms): doxycycline 100 mg PO BID or amoxicillin 500 mg PO TID for 14 to 21 days
- More serious: ceftriaxone 2 g QD IV for 30 days

- Arthritis without neurologic disease
  - Oral treatment for 28 days with doxycycline 100 mg BID or amoxicillin 500 mg TID
  - If oral treatment fails, repeat oral regimen for 28 days or begin IV treatment with ceftriaxone 2 g QD for 2 to 4 weeks.

- Contraindications
  - Allergy to specific medication
  - Doxycycline is contraindicated in children and in women who are pregnant or breastfeeding.

- Precautions
  - In ~15% of patients treated with IV therapy, a Jarisch-Herxheimer–type reaction develops within 24 hours of initiation of therapy.

- Significant possible interactions:
  - Oral anticoagulants may require dose adjustments.
  - Oral contraceptives may be less effective.

**Pediatric Considerations**
- Amoxicillin is the drug of choice in children.
- Tetracyclines are contraindicated.

**Pregnancy Considerations**
- Because *B. burgdorferi* can cross the placenta, pregnant patients with active disease should be treated with parenteral antibiotics.
- Doxycycline should not be used in pregnancy.

**Second Line**
- Azithromycin, 500 mg PO daily for 7 days, can be used for those allergic to β-lactams and unable to take tetracyclines but is less effective (4,5)[A].
- There is no evidence for meaningful clinical benefit from prolonged treatment or retreatment of patients with persistent unexplained symptoms despite previous antibiotic treatment of Lyme disease.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission is recommended for patients with Lyme carditis and symptoms of
chest pain, syncope, or dyspnea and for those with second- or third-degree heart block or first-degree heart block of ≥300 ms.
- Admission is also recommended for patients with symptoms of meningitis.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Based on the severity of symptoms, patients with Lyme carditis, neurologic syndromes, or arthritis may require prolonged follow-up.

**DIET**
No restrictions

**PATIENT EDUCATION**
- In endemic areas, patients should be advised to protect themselves against tick exposure.
- Dispose of a live tick by submerging in alcohol, placing in a sealed bag/container, wrapping tightly in tape, or flushing down the toilet. Never crush a tick with fingers.
- Avoid “painting” the tick with nail polish or petroleum jelly, or using heat to make the tick detach from the skin. Remove the tick as quickly as possible.
- Prevention
  - Use repellents that contain 20–30% DEET on exposed skin and clothing for protection lasting several hours.
  - Use 0.5% permethrin on clothing.
  - Bathe or shower as soon as possible after coming indoors (preferably within 2 hours) and perform regular tick checks after outdoor activities.
  - [https://www.cdc.gov/lyme/](https://www.cdc.gov/lyme/)

**PROGNOSIS**
- Early treatment with antibiotics can shorten the duration of symptoms and prevent later disease.
- Response of late-stage disease to treatment is variable. Symptoms may take weeks to resolve after beginning treatment.
- Untreated rash usually resolves in 3 to 4 weeks.
• Excellent long-term prognosis with early antibiotic treatment
• Neurologic symptoms arise in about 15% of untreated Lyme disease patients.

COMPLICATIONS
• Recurrent synovitis, tendonitis, bursitis
• Chronic neurologic symptoms
• Peripheral neuropathies
• Posttreatment Lyme disease syndrome: 10–20% lingering symptoms of fatigue, pain, or joint and muscle aches; can last for 6 months
• Lyme carditis >40% syncopal presentation

REFERENCES

ADDITIONAL READING
CODES

ICD10
- A69.20 Lyme disease, unspecified
- A69.23 Arthritis due to Lyme disease

CLINICAL PEARLS

- The presence of EM following a tick bite in an endemic area is an indication for empiric antibiotic treatment for presumptive Lyme disease.
- Repeat episodes of EM in appropriately treated patients are due to reinfection.
- Lyme disease during pregnancy may lead to infection of the placenta and possible stillbirth.
- Ticks must be attached for at least 24 hours or more to transmit Lyme disease.
- The human Lyme disease vaccine is no longer available.
LYMPHANGITIS
Amar Kapur, DO

BASICS
DESCRIPTION
Acute or chronic inflammation of lymphatic channels due to a skin breach or local trauma; presents as red, tender streaks along lymphatic channels extending to regional lymph nodes
- May result from compromised lymphatic drainage following surgical procedures
- May be infectious or noninfectious

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute infection
  - Usually caused by group A β-hemolytic Streptococcus
  - Less commonly caused by:
    o Staphylococcus aureus
    o Pasteurella multocida
    o Erysipelothrix
    o Spirillum minus (rat bite disease)
    o Pseudomonas
    o Other Streptococcus sp.
    o Immunocompromised patients can be infected with gram-negative rods, gram-negative bacilli, or fungi.
    o In fresh water exposures, Aeromonas hydrophila
- Nodular lymphangitis
  - Also known as sporotrichoid lymphangitis
  - Painful or painless nodular subcutaneous swellings along lymphatic vessels
  - Lesions may ulcerate with accompanying regional lymphadenopathy.
  - Typical of infections from: Sporothrix schenckii, Nocardia brasiliensis, Mycobacterium marinum, leishmaniasis, tularemia, and systemic mycoses
  - Pathology may show granulomas.
- Noninfectious granulomatous lymphangitis
  - Rare-acquired lymphedema of the genitalia in children
  - May be due to atypical Crohn disease or sarcoidosis (1)[C]
Filarial lymphangitis
- Mosquito bites transmit parasites causing lymphatic inflammation and dilatation; can predispose to secondary bacterial infection
- Usually caused by nematodes *Wuchereria bancrofti*. Other causes include *Brugia malayi* and *Brugia timori*.

Lymphangitis can occur after surgical procedures and lymph node dissection.

Cutaneous lymphangitis carcinomatosa is rare. Represents ~5% of all skin metastases; caused by neoplastic occlusion of dermal lymphatic vessels (2)

Sclerosing lymphangitis of the penis
- Swelling around coronal sulcus of penis as a result of vigorous sexual activity or masturbation

**RISK FACTORS**
- Impaired lymphatic drainage due to surgery, nodal dissection, or irradiation
- Diabetes mellitus
- Chronic steroid use
- Peripheral venous catheter
- Varicella infection
- Immunocompromising condition
- Human, animal, or insect bites; skin trauma
- Fungal, bacterial, or mycobacterial skin infections
- IV drug abuse
- Residence in endemic areas of filariasis

**GENERAL PREVENTION**
- Reduce chronic lymphedema with compression devices or by treating underlying process.
- Insect repellent; arthropod bite precautions
- Proper wound and skin care

**COMMONLY ASSOCIATED CONDITIONS**
- Lymphedema
- Prior lymph node dissection
- Tinea pedis (athlete’s foot)
- Sporotrichosis
- Cellulitis, erysipelas
- Filarial infection (*W. bancrofti*)
DIAGNOSIS

HISTORY
- Trauma to skin, cut, abrasion, or fungal infection
- Systemic symptoms:
  - Malaise
  - Fever and chills
  - Loss of appetite
  - Headache
  - Muscle aches
- Travel to a tropical zone or region with filariasis

PHYSICAL EXAM
Local signs:
- Erythematous, macular linear streaks from site of infection toward regional lymph nodes
- Tenderness and warmth over affected skin or lymph nodes
- Blistering of affected skin
- Fluctuance, swelling, or purulent drainage
- Nodular lymphangitis can present with subcutaneous swellings along the lymphatic channels.
- Sporotrichosis may present with papulonodular lesions that may ulcerate.
- Sites may be painless.

DIFFERENTIAL DIAGNOSIS
- Superficial thrombophlebitis
  - Thrombus or infection within the thrombosis (septic thrombophlebitis)
- Contact dermatitis
- Allergic reaction: less likely to be allergic if >24 hours after exposure (e.g., insect bite)
- Lymphangitis carcinomatosa
- Malignancy-related inflammation

DIAGNOSTIC TESTS & INTERPRETATION
- CBC may show leukocytosis; blood smear may show filarial infection.
- Blood or wound cultures
- Biopsy cultures
- FNAC for filariasis of testiculoscrotal swelling but not for other superficial locations (3)

**Initial Tests (lab, imaging)**
Plain films are unnecessary; consider lymphangiography for lymphedema (4) [C].

**Diagnostic Procedures/Other**
- Swab, aspirate, and/or biopsy primary site, purulent discharge, nodule or distal ulcer for culture, acid fast staining, histology, and microscopy
- Blood cultures if systemically ill
- Serology (e.g., *Francisella tularensis*, histoplasma)
- Blood film/smear (e.g., filaria)
- Lymphangiography to determine lymphedema or lymphatic obstruction

**TREATMENT**

**GENERAL MEASURES**
- Hot, moist compresses to affected area
- Compression garments and weight loss may help lymphedema.
- Abstinence from sexual activity (for sclerosing lymphangitis)

**MEDICATION**
- Treat common organisms empirically. Use culture and susceptibility to guide antibiotic treatment.
- If mild disease, outpatient oral antibiotics
- If no improvement after 48 hours of oral antibiotics, reassess and consider IV antibiotics and/or hospitalization.
- IV antibiotics if systemically ill
- If necrotizing fasciitis is suspected, treat aggressively with antibiotics and surgical intervention.

**First Line**
- Antibiotics for group A streptococcal infection
  - Amoxicillin (if known group A *Streptococcus*)
    - Dosing
      - Adults
Mild to moderate: 500 mg PO q12h
Severe: 875 mg PO q12h or 500 mg PO q8h

- Children <3 months: 30 mg/kg/day PO divided q12h
- Children ≥3 months, ≤40 kg
  - Mild to moderate: 25 mg/kg/day PO divided q12h or 20 mg/kg/day divided q8h
  - Severe: 45 mg/kg/day PO divided q12h or 40 mg/kg/day divided q8h
- Children ≥40 kg same as adult dosing

- Common adverse effects
  - Diarrhea
- Serious adverse effects
  - Anaphylaxis, Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN)
  - Drug interactions
    - Methotrexate, venlafaxine, warfarin, hormonal contraceptives
- Contraindications
  - Hypersensitivity to penicillin

Ampicillin/sulbactam
- Dosing
  - Adults and children ≥40 kg: 1.5 to 3.0 g IV/IM q6h
  - Children <40 kg: 200 mg/kg/day IV infusion, in divided doses q6h; maximum 8 g ampicillin/day
- Common adverse effects
  - Diarrhea, injection site reactions
- Serious adverse effects
  - *Clostridium difficile* diarrhea, pseudomembranous enterocolitis
- Drug interactions
  - Hormonal contraceptives
- Contraindications
  - Hypersensitivity reactions

Ceftriaxone
- Dosing
  - Adults: 1 to 2 g IV/IM q24h
  - Children: 50 to 75 mg/kg/day IV/IM once daily or in divided doses q12h; maximum 2 g/day
- Common adverse effects
  - Injection site reactions, diarrhea
- Serious adverse effects: same as amoxicillin or ampicillin
- Drug interactions
  - Do not administer calcium-containing solutions in the same IV line.
- Contraindications
  - Hypersensitivity to cephalosporins
  - Concurrent calcium-containing IV fluids
  - Increased risk of kernicterus, salt precipitation in lungs and kidneys in neonates <28 days (use cefotaxime instead)

Cephalexin
- Dosing
  - Adults: 500 mg PO q12h
  - Children: 25 to 50 mg/kg/day divided q12h
- Common adverse effects
  - Diarrhea
- Serious adverse effects
  - SJS, TEN, interstitial nephritis, renal failure, pseudomembranous enterocolitis, anaphylaxis
- Contraindications
  - Hypersensitivity to cephalosporins

Azithromycin (if penicillin or cephalosporin allergy)
- Dosing
  - Adults: 500 mg PO on day 1 followed by 250 mg/day PO on days 2 to 5
  - Children ≥2 years: 12 mg/kg/day PO (maximum dose: 500 mg/day) once daily for 5 days (FDA off-label use for skin infections in children)
- Common adverse effects
  - Abdominal pain, nausea, vomiting, diarrhea, headache
- Serious adverse effects
  - Prolonged QT interval, torsades de pointes, liver failure, Lambert-Eaton syndrome, myasthenia gravis, corneal erosion, anaphylaxis
- Drug interactions
  - Nelfinavir, warfarin, other medications with potential to prolong QT interval
- Contraindications
  - Hepatic dysfunction or cholestatic jaundice with prior treatment
  - Hypersensitivity to macrolide (azithromycin, erythromycin, clarithromycin)

Diethylcarbamazine, ivermectin, albendazole, and doxycycline are used to treat filarial infection.

Acetaminophen or ibuprofen (NSAIDs) for pain and fever
SURGERY/OTHER PROCEDURES
 ● Incision and drainage of abscess if present
 ● Necrotizing fasciitis requires surgical evaluation and likely débridement.
 ● Nodular lymphangitis may benefit from I&D.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
 ● Admit for signs of serious illness: fluids if in hypotensive shock.
 ● Fever, chills, systemic toxicity
 ● IV antibiotics, ICU or surgery as indicated
 ● Discharge on oral antibiotics after systemic symptoms resolve. Home IV antibiotics are an option depending on clinical setting.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
 ● Elevate affected area.
 ● 48-hour follow-up to ensure improvement
 ● Work up recurrent lymphangitis to ascertain underlying cause (other infectious organism, anatomic abnormality, etc.).

Patient Monitoring
Close follow-up to ensure decreasing inflammation

PATIENT EDUCATION
Instruct patients on proper wound and skin care.

PROGNOSIS
 ● Good prognosis for uncomplicated cases
 ● Antimicrobial therapy is effective in 90% of patients.
 ● Untreated, can spread rapidly, especially group A Streptococcus

COMPLICATIONS
Sepsis, cellulitis, necrotizing fasciitis, myositis

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- I89.1 Lymphangitis
- L03.91 Acute lymphangitis, unspecified
- N48.29 Other inflammatory disorders of penis

**CLINICAL PEARLS**

- Lymphangitis classically presents with erythematous linear streaks of the skin from site of entry (e.g., bite, cut, abrasion) to regional lymph nodes.
- Patients with prior surgical lymph node dissection are predisposed to lymphangitis.
- Patients with severe systemic symptoms should be admitted for treatment with IV antibiotics.
- Parasitic or fungal infections can cause acute or chronic lymphangitis.
- Treatment of underlying skin infection (such as tinea pedis) may prevent recurrence.
LYMPHEDEMA
Jon S. Parham, DO, MPH

BASICS
DESCRIPTION
- Accumulation of lymphatic fluid in the interstitial tissue causing swelling
- Lymphedema can develop when lymphatic vessels are missing or impaired (primary) or when lymph vessels are damaged or lymph nodes are removed (secondary).
- Most common in the lower limb(s) (80%) but also can occur in the arm(s), face, trunk, and external genitalia

EPIDEMIOLOGY

Incidence
- Predominant sex: female > male
- Predominant age: any age
- 13% of patients with breast cancer treated with surgery; 42% of those treated with surgery and radiation therapy; 25% after GYN cancer surgery
- Milroy disease presents at birth; estimated to be between 1/6,000 and 1/300 live births
- Meige disease develops during puberty.

Prevalence
- 120 million people worldwide are affected with lymphatic filariasis in 73 countries but no primary infections in United States.
- 10 million people are affected by nonfilarial secondary lymphedema in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY
Secondary lymphedema:
- Postoperative: gradual failure of distal lymphatics, which have to “pump” lymph at a greater pressure through damaged proximal ducts
- Risk is higher with postoperative radiation because radiation reduces regrowth of ducts due to fibrous scarring.
Trauma; recurrent infection; malignancy, including metastatic disease, and marked obesity
Lymphangiogenesis inhibition and tissue fibrosis promotion by T cells appear to promote lymphedema
Developing countries: Most common cause is filariasis (*Wuchereria bancrofti*).

**Genetics**
- Milroy disease: autosomal dominant; diagnosed either at birth or the 1st year of life
- Lymphedema praecox has onset between the ages of 1 and 35 years.
- Lymphedema tarda occurs in those >35 years of age.
- Genetics referral: Primary and lymphedema tarda

**RISK FACTORS**
- Filariasis: most common cause worldwide
- Mastectomy, melanoma surgery
- Prior trauma, serious burns, infection of affected limb
- Lymphadenectomy or radiation therapy for malignancy
- Obesity (>50 body mass index)
- Inflammatory disorders: arthritis, sarcoidosis, dermatitis

**GENERAL PREVENTION**
Healthy body weight maintenance; treatment of congestive heart failure (CHF), early recognition of infection and cancer, and venous insufficiency

**COMMONLY ASSOCIATED CONDITIONS**
Venous disease, morbid obesity, regional cancer, filarial disease (Africa and Asia)

**DIAGNOSIS**

**HISTORY**
Recent surgery: Vein stripping can significantly exacerbate mild lymphedema:
- First symptom: painless swelling
- Feeling of heaviness in the limb, especially at the end of the day and in hot weather
ALERT
After 1st year, edema becomes nonpitting.

PHYSICAL EXAM
- Initial: pitting edema, can spread proximally or distally
- Later: nonpitting; after 1st year, does not spread proximally/distally, but spreads radially
- Hyperkeratosis (thicker skin)
- Papillomatosis (rough skin)
- Increase in skin turgor
- Positive Stemmer sign (inability to pinch the skin of the dorsum of the second toe between the thumb and forefinger), false positives are rare.

DIFFERENTIAL DIAGNOSIS
- CHF, renal failure, lipedema
- Hypoalbuminemia, protein-losing nephropathy
- DVT, chronic venous disease
- Postoperative complications following ipsilateral surgery
- Cellulitis, Baker cyst, idiopathic edema

DIAGNOSTIC TESTS & INTERPRETATION
- Lack of response to elevation or diuretic therapy may indicate a lymphatic insufficiency.
- Diuretics increase excretion of salt and water, thereby decreasing plasma volume, venous capillary pressure, and filtration. Diuretics improve filtration edema but do not improve lymph drainage over the long term.
- Some relevant protein biomarkers for lymphedema have been identified and show promise for early- and latent-stage diagnosis.

Initial Tests (lab, imaging)
- Comprehensive chemistry panel: hepatic or renal impairment
- TSH: hypothyroidism
- Urinalysis: protein-losing nephropathy
- Ultrasound: evaluates for acute/chronic DVT; gives information about soft tissue changes but does not inform about truncal anatomy of the lymphatics
- Duplex ultrasound: Lymphedema causes gradual impedance of venous return that aggravates the edema; 82% of patients with unexplained limb edema were diagnosed using a combination of duplex ultrasound and lymphoscintigram.
Follow-Up Tests & Special Considerations

- Lymphangiogram: direct cannulation of lymphatics through the skin; risk for infection, local inflammation; rarely used now
- Fluorescence microlymphography may be highly sensitive (91.4%) and specific (85.7%), atraumatic and is without radiation in diagnosis of leg lymphedema.
- Lymphoscintigram: radiolabeled protein technetium-99m–labeled colloid
  - Measures lymphatic function, lymph movement, lymph drainage, and response to treatment
  - Sensitivity, 73–97%; specificity, 100%
  - Best to use 1 hour and delayed images together
- Indocyanine green lymphography: reported
  - Superior to lymphoscintigraphy in early diagnosis of arm
  - Accurately screens postsurgically for subclinical lymphedema (1)[B]
- CT scan: calf skin thickening, thickening of the SC compartment, increased fat density, thickened perimuscular aponeurosis; typical honeycomb appearance
- MRI: circumferential edema, increased volume of SC tissue, honeycomb pattern above the fascia between the muscle and subcutis; cannot differentiate primary from secondary lymphedema

TREATMENT

GENERAL MEASURES

- Seek optimal weight, early treatment of cellulitis, avoid trauma to affected area (direct injury, venipunctures, inept nail care, extreme heat/cold).
- Achieve mechanical reduction and maintenance of limb size: compression garments via professionals.
- Elevate affected limb/area, but avoid stasis.
- Avoid BP cuffs and other focal constriction in affected limbs.
- Prevent skin infection with daily cleansing, inspection, and skin care (with emollients).
- Nonsurgical treatment of varicose veins in some
- Doubtful that air travel is associated with increased limb volumes

MEDICATION
ALERT
No medications, including diuretics, are useful.

ISSUES FOR REFERRAL
- Refer to physical therapist with lymphedema training for manual decongestive therapy.
  - In patients with recurrent or metastatic disease, discuss with oncologist prior to initiation of complete decongestive therapy in order not to promote the spread of cancer.
- Provide education for patient/family for self-administration of therapy in future.
- Education for family about bandaging
- Fitting for compression garments (2)[A]

ADDITIONAL THERAPIES
- Exercise: Lymph flow occurs as a result of inspiratory reduction in the intrathoracic pressure associated with inspiration. Best results are achieved with combination of flexibility, strength, and aerobic training.
- Compression with custom-made elastic stocking (minimum pressure is 40 mm Hg)
  - Protection against external incidental trauma
  - Decreases the intrinsic trauma on the skin due to chronically increased interstitial pressures, which cause stretch of the skin and SC tissues
  - No data on preference of custom-made versus prefabricated
  - Replace every 3 to 6 months or when starting to lose elasticity.
- Multilayer bandaging: inner layer of tubular stockinette followed by foam and padding to protect the joint flexures and to even out the contours of the limb so that pressure is distributed evenly; outer layer of at least two short-stretch extensible bandages; more effective than hosiery alone
- Pneumatic pumps develop high pressures like systolic BP and can reduce limb girth significantly; wear a compression sock afterward (2)[A].
- Advanced pneumatic compression devices (APCDs) are programmable, offer a more individualized fit, reduced rates of cellulitis by at least 75%, and reduce early treatment costs by 37–54% depending on health care setting (3)[B].

SURGERY/OTHER PROCEDURES
- Bypass procedures: creation of lymphatic–venous anastomosis or lymph node
transplantation (most effective) via microsurgery showed a reduction in use of conservative compression therapy (4)[C]: reserved for refractory cases only.

- Low-level laser therapy in smaller studies was shown to be noninferior to manual lymphatic drainage or in combination in arm volume reduction among breast cancer patients in half the treatment time (4)[C].

- Axillary reverse mapping during axillary node dissection in selected preclinical breast cancer can significantly reduce lymphedema incidence (5)[A].

- Thoracic sympathetic ganglion block for breast cancer–related lymphedema, a new treatment showed better life quality and arm size reduction >50%, especially in patients with high-grade lymphedema.

- Debulking procedures (Charles procedure): radical excision of SC tissue with primary or staged skin grafting
  - Men had less improvement than women.
  - Main risk is infection and necrosis of the skin graft.
  - Liposuction is cosmetically preferred to debulking (4)[C].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Heat therapy: Microwave and electromagnetic irradiation may be helpful.

- Selenium ingestion has been reported to reduce lymphedema volume (not approved indication in United States).

- Benzopyrene oral medicine (flavonoids and coumarin; neither are approved in the United States)
  - Flavonoids: Micronized purified flavonoid fraction (Daflon 500 mg) reported to decrease venous stasis and idiopathic cyclic edema, chronic venous insufficiency, and postmastectomy lymphedema.
  - Coumarin reduces edema fluid by increasing the number of macrophages and enhancing proteolysis, resulting in the removal of protein, some reports of bleeding, and hepatotoxicity (4)[C].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Systemic signs of infection
  - May admit to specialized rehabilitation unit for combination treatment in patients with heart failure or severe pulmonary disease
  - IV antibiotics for infection; cellulitis is most common.

- Affected extremity positioning with some distal elevation
Encourage patient mobilization/exercise.

Patient education for bandaging/wound care

Discharge criteria
- Improved signs/symptoms of infection (e.g., elevated WBC count, fever, abnormal vital signs)
- Clinical improvement in wound appearance

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Lymphedema will return in several days if patient stops wearing compression garments during the day and bandaging at night.

Patient Monitoring
- Daily visit to therapist for acute treatment
- Monthly visits for maintenance care

DIET

Lower sodium, healthy protein, and weight loss-oriented (if needed)

PATIENT EDUCATION
- Use compression garments, especially when exercising.
- Avoid affected limb(s) being dependent for long period of time: Patient should perform daily skin examination.

PROGNOSIS

No cure, but treatment can produce good results with daily care.

COMPLICATIONS
- Infection (local vs. systemic): common
- Risk of wound formation (punctures/abrasions) that are difficult to heal: common
- Lymphangiosarcoma: Found in lymphedematous arms of patients following radical mastectomy; also in patients with Milroy disease. Treatment is radiotherapy with surgery, reserved for patients with discrete nonmetastastic disease.
REFERENCES

ADDITIONAL READING

CODES

ICD10

- I89.0 Lymphedema, not elsewhere classified
- Q82.0 Hereditary lymphedema
- I97.89 Oth postproc comp and disorders of the circ sys, NEC

CLINICAL PEARLS

- Refer primary lymphedema and lymphedema tarda to genetics.
- Affected skin with heavy feeling, painless swelling initially, later nonpitting swelling
- Rule out DVT if unilateral limb or CHF if bilateral
- Early referral to lymphedema therapist for manual therapy, compression devices/wrappings
- Aggressive weight loss and health promotion as needed
- High risk for cutaneous-sourced infections, so promote therapeutic skin care.
- Lymphoscintigram is standard diagnostic if clinically diagnosis is uncertain.
MACULAR DEGENERATION, AGE-RELATED

Richard W. Allinson, MD

BASICS

DESCRIPTION
- Age-related macular degeneration (ARMD) is the leading cause of irreversible, severe visual loss in persons age >65 years.
- ARMD results in pigmentary changes in the macula or typical drusen associated with visual loss to the 20/30 level or worse, not caused by cataract or other eye disease, in individuals >50 years of age, although some definitions exclude age or visual acuity criteria.
- Stages
  - Atrophic/nonexudative
  - Neovascular/exudative
- System(s) affected: nervous
- Synonym(s): senile macular degeneration; subretinal neovascularization (SRN)

EPIDEMIOLOGY
- Neovascular/exudative form is rare in blacks and more common in whites.
- Predominant sex: female

Incidence
- In the Framingham Eye Study (FES), drusen were noted in 25% of all participants who were ≥52 years of age. ARMD-associated visual loss was noted in 5.7%.
- Atrophic/nonexudative stage accounts for 20% of cases of severe visual loss.
- Neovascular/exudative stage accounts for 80% of cases of severe visual loss.

Prevalence
Per FES study:
- People 65 to 74 years old: 11%
- People ≥75 years old: 27.9%
ETIOLOGY AND PATHOPHYSIOLOGY

- Breaks in the Bruch membrane allow choroidal neovascular membranes (CNVMs) to invade the retinal pigment epithelium (RPE) and grow into the subretinal space.
- Atrophic/nonexudative: drusen and/or pigmentary changes in the macula
- Neovascular/exudative: growth of blood vessels underneath the retina
- Visible light can result in the formation and accumulation of metabolic by-products in the RPE, a pigment layer underneath the retina that normally helps remove metabolic by-products from the retina. Excess accumulation of these metabolic by-products interferes with the normal metabolic activity of the RPE and can lead to the formation of drusen.
- Neovascular stage generally arises from the atrophic stage.
- Most do not progress beyond the atrophic/nonexudative stage; however, those who do are at a greater risk of severe visual loss.

**Genetics**

- Genetic susceptibility may be a factor in ARMD: ~25% genetically determined
- Complement factor H is an important susceptibility gene for ARMD.
- Although the development of ARMD may be predicted by specific alleles, the clinical response to antivascular endothelial growth factor (VEGF) is not.

**RISK FACTORS**

- Obesity
- Ethnicity: non-Hispanic whites
- Cigarette smoking
- *Chlamydia pneumoniae* infection
- Family history
- Excess sunlight exposure
- Blue or light iris color
- Hyperopia
- History of cardiovascular disease
- Short stature
- Aspirin use
- Female sex

**GENERAL PREVENTION**

- Ultraviolet (UV) protection for eyes
Routine ophthalmologic visits
- Every 2 to 4 years for patients age 40 to 64 years
- Every 1 to 2 years after age 65 years

Patients who take statins, which modify lipid profiles, may have a reduced risk.

COMMONLY ASSOCIATED CONDITIONS
- Presumed ocular histoplasmosis syndrome
- Exudative retinal detachment
- Vitreous hemorrhage
- Other causes of CNVMs

DIAGNOSIS

HISTORY
- Patients frequently notice distortion of central vision.
- Patients may notice straight lines appear crooked (e.g., telephone poles).

PHYSICAL EXAM
- Atrophic/nonexudative stage retinal exam
  - Drusen (small yellowish white lesions)
    - Subtypes: hard drusen and soft drusen
  - Atrophy of the RPE
    - When the area of absent or attenuated RPE is contiguous, the condition is termed geographic atrophy (GA) of the RPE.
- Neovascular/exudative stage retinal exam
  - Blood vessels growing underneath the retina from the choroid are called CNVMs or SRN. The choroid is the vascular layer underneath the RPE.
  - Subretinal fluid or hemorrhage
  - Exudates
  - On Amsler grid testing, the horizontal or vertical lines may become broken, distorted, or missing.
- Disciform scar: an advanced stage resulting in a fibrovascular scar

DIFFERENTIAL DIAGNOSIS
- Idiopathic SRN
- Presumed ocular histoplasmosis syndrome
• Diabetic retinopathy
• Hypertensive retinopathy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Diagnostic Procedures/Other**

• Amsler grid testing
• Fluorescein angiography
  – Detection of CNVMs
  – Differentiates between atrophic and neovascular ARMD
• Indocyanine green video angiography: may identify occult or hidden CNVMs
• Optical coherence tomography (OCT) is useful in determining the presence of subretinal fluid, the degree of retinal thickening, and the presence of a pigment epithelial detachment (PED).
  – Fluorescein angiography is better than time-domain OCT in detecting new-onset CNVMs.
  – Newer generation OCT modalities, including Spectral Domain OCT (SD-OCT) are preferred for evaluating ARMD.

**Test Interpretation**

Drusen: deposits of hyaline material between the RPE and Bruch membrane (the limiting membrane between the RPE and the choroid)

**TREATMENT**

**MEDICATION**

**First Line**

• Ranibizumab (Lucentis)
  – Antibody fragment that inhibits all active forms of VEGF
  – Approved for neovascular (wet) ARMD
  – Injected intravitreally, at a dose of 0.5 mg, every 4 weeks
  – 1 year after treatment, up to 40% of patients treated with ranibizumab gained at least three lines of vision, and ~95% maintained vision.
  – Ranibizumab is superior to verteporfin in the treatment of predominately classic CNVMs.
  – The PrONTO study demonstrated OCT-guided, variable-dosing regimen with ranibizumab resulted in similar results to the MARINA (minimally
classic/occult CNVM trial) and ANCHOR (predominantly classic CNVM trial) studies with monthly injections of ranibizumab.

- When comparing ranibizumab and bevacizumab in a multicenter study, both treatments were effective in stabilizing visual loss, and no difference was found in the visual outcome between the two treatment groups. A slightly higher rate of serious systemic adverse events was noted in the bevacizumab group.
  - In this study, treatment as needed resulted in less gain in visual acuity, whether instituted at enrollment or after 1 year of monthly treatment.
  - Visual gains during the first 2 years were not maintained at 5 years. At the 5-year visit, 50% of eyes had vision of 20/40 or better and 20% had vision of 20/200 or worse (1)[A].
  - Cystoid macular edema is a marker for poorer visual outcomes in patients with CNVMs.

- Eyes with \( \geq 50\% \) of the lesion composed of blood had a similar visual prognosis compared to other treated eyes in the Comparison of Age-related Macular Degeneration Treatments Trials (CATT). Neovascular ARMD lesions composed of \( >50\% \) blood can be managed similarly to those with less or no blood (2)[A].

- The treat and extend regimen (TER) is commonly used to decrease the treatment burden. Once no signs of CNVM activity are detected, patient follow-ups and treatments are then extended by intervals of 2 weeks as long as no signs of CNVM activity are present, up to a maximum interval of 12 weeks. If examination shows any sign of recurrence, the interval is shortened by 2 weeks at a time, until the disease is considered to be inactive. Interval extension is then restarted, with the maximum final interval being 2 weeks less than the period when the previous recurrence was observed.

- Ranibizumab and bevacizumab had equivalent effects on visual acuity at 1 year using the TER. The visual acuity results at 1 year were comparable to those of other clinical trials with monthly treatment (3)[A].

- **VEGF Trap-Eye/aflibercept (Eylea)**
  - A decoy VEGF receptor that inhibits all isoforms of VEGF-A and placental growth factor (PGF), the members of the VEGF family in mammals primarily involved in ocular neovascularization
  - Approved for neovascular (wet) ARMD
  - Injected intravitreally, at a dose of 2 mg, every 4 weeks for 12 weeks and then every 8 weeks
  - Dosed as needed after the 12-week fixed dosing schedule resulted in a 5.3-
letter gain in best corrected visual acuity at 52 weeks.
– Routine use of prophylactic antibiotics after intravitreal injections may be unnecessary.
– May be beneficial in patients who are not responding to ranibizumab or bevacizumab
– Anti-VEGF treatment with either ranibizumab or aflibercept showed limited efficacy for the complete resolution of PED.
  o Patients with a PED tend to have worse outcomes when switched from a fixed regimen to a PRN strategy (4)[A].
  o Patients with PEDs and intraretinal cysts have a worse visual prognosis.
  o PEDs treated with aflibercept showed a better anatomical response than eyes treated with ranibizumab, but the visual outcomes were the same.

Second Line
● Bevacizumab (Avastin) is a full-length antibody to VEGF, administered intravitreally at a dose of 1.25 mg; widely used off-label because of its lower cost
● Fovista, a platelet-derived growth factor (PDGF) antagonist, when administered in combination with ranibizumab demonstrated more favorable outcomes compared with ranibizumab monotherapy (5)[A].
● Intravitreal lampalizumab, which selectively inhibits activation of the alternative complement pathway, may help reduce the rate of progression of GA.
● No Food and Drug Administration-approved stem cell therapies for retinal disease exist.

GENERAL MEASURES
Low-vision aids may be helpful.

SURGERY/OTHER PROCEDURES
● Laser treatment for CNVMs located ≥200 microns from the center of the macula has been evaluated in the Macular Photocoagulation Study (MPS).
  – Anti-VEGF treatment is first-line therapy for subfoveal CNVMs.
● Vitrectomy has been used to remove CNVMs, but this is generally not recommended.
● CNVMs can bleed spontaneously, leaving blood underneath the retina. Vitrectomy to remove subretinal blood may be of benefit and should be performed within 7 days of the bleed. Tissue plasminogen activator (tPA)
instilled into the eye may help remove a subretinal hemorrhage. In some cases, intravitreal gas with or without tPA may displace submacular blood:  
- Intravitreal anti-VEGF monotherapy may be helpful in the treatment of neovascular ARMD associated with a submacular hemorrhage.

- Photodynamic therapy (PDT) with verteporfin reduces vision loss in patients with >50% “classic” subfoveal CNVMs. Verteporfin is administered IV, and a diode laser at 689 nm is applied to the CNVM.
  - Patients should be informed of a <4% risk of acute, severe vision loss after PDT.
  - Ranibizumab has greater clinical efficacy than PDT.
  - Combination treatment with intravitreal ranibizumab and PDT appears to offer similar gain in visual acuity when compared with ranibizumab monotherapy.
  - Combination treatment with ranibizumab and PDT may reduce the number of ranibizumab retreatments.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Free radical formation in the retina, induced by visible light, may play a role in cellular damage that results in atrophic/nonexudative macular degeneration. The Age-Related Eye Disease Study (AREDS) found that a high-dose regimen of antioxidant vitamins and mineral supplements reduced progression of ARMD in some cases.

- Recommended daily doses: vitamin C 500 mg, vitamin E 400 IU, β-carotene 15 mg, zinc oxide 80 mg, and cupric oxide 2 mg
  - Exercise caution with β-carotene use in smokers due to potential link to lung cancer.
- The AREDS2 found the addition of lutein with zeaxanthin alone or in combination with omega-3 fatty acids had no overall effect in further reducing the risk of progression to advanced ARMD.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Amsler grid can aid in discovering visual disturbances.
Patients with soft drusen or pigmentary changes in the macula are at an increased risk of visual loss. They should monitor their vision, such as by daily Amsler grid testing, and subjective measures of visual acuity, such as reading ability; if no new symptoms, follow-up examination in 6 to 12 months.

**DIET**
- Eating dark green, leafy vegetables (spinach/collard greens), which are rich in carotenoids, may decrease the risk of developing the neovascular/exudative stage.
- Fish consumption with omega-3 fatty acid intake reduces the risk of ARMD.
- A Western-type diet characterized by higher intake of red meat, processed meat, high-fat dairy products, French fries, refined grains, and eggs increases the risk of ARMD as compared to an Oriental-type diet characterized by higher intake of vegetables, legumes, fruit, whole grains, tomatoes, and seafood which decreases the risk of ARMD.
  - A Mediterranean diet may reduce the risk of developing ARMD.

**PATIENT EDUCATION**
Instruct visually impaired patients to check with the local low-vision center for aids.

**PROGNOSIS**
- Patients with bilateral soft drusen and pigmentary changes in the macula, but no evidence of exudation, have an increased likelihood of developing CNVMs and subsequent visual loss.
- Patients with bilateral drusen carry a cumulative risk of 14.7% over 5 years of suffering significant visual loss in one eye from the neovascular stage of ARMD.
- Patients with neovascular stage in one eye and drusen in the opposite eye are at an annual risk of 5–14% of developing the neovascular stage in the opposite eye with drusen.
- Macular atrophy progression and severity were the primary anatomic determinants of visual outcomes 7 years after treatment with ranibizumab.
- High incidence of recurrence after thermal laser treatment for CNVMs.

**COMPLICATIONS**
- Blindness
- The intraocular pressure should be monitored in eyes receiving intravitreal
anti-VEGF injections.

- 7 or more intravitreal injection of bevacizumab annually is associated with a higher risk of glaucoma surgery compared to less frequent administration (6)[A].

REFERENCES

CODES

ICD10

- H35.30 Unspecified macular degeneration
- H35.32 Exudative age-related macular degeneration
- H35.31 Nonexudative age-related macular degeneration
CLINICAL PEARLS

- Patients frequently notice distortion of central vision.
- Patients may notice straight lines appear crooked (e.g., telephone poles).
- Hyperopia is a risk factor for ARMD.
- The AREDS study found that a high-dose regimen of antioxidant vitamins and mineral supplements reduces progression of ARMD in some cases.
- Tobacco cessation should be strongly encouraged.
MALARIA
Paul M. Arguin, MD

BASICS

DESCRIPTION
- Acute or chronic infection transmitted to humans by Anopheles spp. mosquitoes
- Most morbidity and mortality is caused by Plasmodium falciparum. An estimated 212 million cases occur annually, including 429,000 deaths, most of which occur in children <5 years of age in sub-Saharan Africa (1).
- Nonimmune individuals are most susceptible to rapid progression to severe disease.
- System(s) affected: cardiovascular, hematologic, renal, respiratory, cerebral, lymphatic, immunologic

EPIDEMIOLOGY
- Cases imported to the United States: 66% P. falciparum; 13% Plasmodium vivax; 3% Plasmodium malariae; 5% Plasmodium ovale; 1% mixed; 12% unknown
- Occurs worldwide in tropical latitudes: P. falciparum, P. malariae, P. vivax, and P. ovale; Plasmodium knowlesi in parts of Southeast Asia

Incidence
- Most U.S. cases (>99%) are imported.
- ~1,700 cases and 5 deaths per year in the United States (2)

Prevalence
- Predominant age: all ages
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY
- Malarial parasites digest red blood cell (RBC) proteins and alter the RBC membrane, causing hemolysis, increased splenic clearance, and anemia.
- RBC lysis stimulates release of cytokines and tumor necrosis factor (TNF-α) causing fever and systemic symptoms.
- *P. falciparum* alters RBC viscosity, causing obstruction and end-organ ischemia.

**Genetics**
Unknown genetic predilection, but inherited conditions may affect disease severity and susceptibility (glucose-6-phosphate dehydrogenase deficiency, sickle cell disease or trait, and hereditary elliptocytosis).

**RISK FACTORS**
- Travel to or migration from endemic areas (primarily sub-Saharan Africa)
- Rarely, blood transfusion, mother-to-fetus transmission, and local autochthonous transmission

**GENERAL PREVENTION**
- Mosquito avoidance: Use insect repellent, wear clothing to cover exposed skin, use mosquito nets treated with permethrin, and avoid outdoor activity from dusk to dawn.
- *Malarial chemoprophylaxis when in endemic area*
  - Mefloquine: Begin at least 2 weeks before arrival and continue for 4 weeks after leaving area. Adults, 250 mg (1 tablet) weekly; children <9 kg, 5 mg/kg; children >9 to 19 kg, 1/4 tablet weekly; children >19 to 30 kg, 1/2 tablet weekly; children >30 to 45 kg, 3/4 tablet weekly; children >45 kg as adult
    - Caution: mefloquine-resistant areas
  - Atovaquone/proguanil: Begin 1 to 2 days before arrival and continue for 1 week after leaving area. Adults, 1 adult tablet daily; children 5 to 8 kg, 1/2 pediatric tablet daily; children 9 to 10 kg, 3/4 pediatric tablet daily; children 11 to 20 kg, 1 pediatric tablet daily; children 21 to 30 kg, 2 pediatric tablets daily; children 31 to 40 kg, 3 pediatric tablets daily; children >40 kg, 1 adult tablet daily
  - Doxycycline: Begin 1 to 2 days before arrival and continue for 4 weeks after leaving area. Adults, 100 mg daily; children, 2 mg/kg up to 100 mg daily (not for children <8 years old)
  - Chloroquine: Begin 1 to 2 weeks before arrival and continue for 4 weeks after leaving area. Adults, 500 mg (300-mg base) weekly; children, 8.3 mg/kg (5-mg base/kg) weekly up to 300 mg
    - Caution: chloroquine-resistant areas
  - Primaquine: Begin 1 to 2 days before arrival and continue for 1 week after
leaving area; adults, 30 mg/day; children, 0.5 mg/kg/day up to adult dose
  o For use only in areas predominantly endemic for P. vivax
  o Caution: Glucose-6-phosphate dehydrogenase deficiency must be excluded prior to first use.

COMMONLY ASSOCIATED CONDITIONS
Bacterial coinfections sometimes occur.

DIAGNOSIS

HISTORY

- Initial symptoms of malaria are nonspecific. Suspect malaria in ill patients returning from endemic area with
  - Fever, malaise, myalgias, chills, headache, nausea, splenomegaly (with chronic infection), hypotension, anemia (with chronic or severe disease), thrombocytopenia, jaundice, vomiting, and/or diarrhea (resembling gastroenteritis)
- P. falciparum
  - Incubation usually 12 to 14 days, symptoms within 1 month of infection in most individuals (partially immune individuals such as immigrants may become ill up to 1 year after last exposure)
  - Severe disease and complications: vascular collapse, CNS impairment, renal failure, and acute respiratory distress syndrome
- P. vivax and P. ovale
  - Incubation period 12 to 18 days for primary infection and up to 12 months (and longer) for relapses; generally presents with fevers
  - Dormant parasites may remain in liver and reactivate years after initial infection.
  - Can be severe
- P. malariae
  - Incubation period ~35 days
  - May become chronic; untreated can persist asymptptomatically in human host for years.
- P. knowlesi
  - Incubation period ~12 days
  - Possibly severe
PHYSICAL EXAM

- Often not specific
- General: elevated temperature, fatigue, tachycardia, tachypnea, jaundice
- Neurologic: mental status and motor–sensory exam (cerebral malaria)
- Cardiopulmonary exam: hemodynamic stability and signs of vascular leak (effusion)
- Skin exam: pallor, rash
- Abdominal exam: organomegaly

DIFFERENTIAL DIAGNOSIS

- Infections (disseminated or localized): abscess, viral, gastroenteritis, typhoid/paratyphoid, other bacteremias, rickettsial disease, mycobacteria
- Collagen vascular disease (systemic lupus erythematosus [SLE], vasculitides)
- Neoplasms (lymphoma, leukemia, other blood dyscrasias, other tropical causes of splenomegaly)
- Severe malaria infection may mimic hepatitis, pneumonia, stroke, or sepsis.

DIAGNOSTIC TESTS & INTERPRETATION

- Malarial smear thick and thin preparations (3)[A]
  - Microscopy to evaluate for presence of parasite forms, determine species, and quantify the percentage of RBCs that are infected; relatively easy to perform with proper training
  - Test should be performed on site, immediately, with results quickly available.
- Rapid antigen testing: can detect the presence of malaria parasites within minutes. Cannot determine species or quantify parasitemia. Positive and negative results must always be confirmed by microscopy.
- Other tests: species-specific PCR; species confirmation by PCR is encouraged.
- General laboratory findings (nonspecific)
  - In uncomplicated infection
    - Elevated liver function tests and lactate dehydrogenase
    - Thrombocytopenia, anemia, and leukopenia
- Note: A low to low-normal platelet count or a slightly high bilirubin should alert the clinician to the diagnosis after exposure in an endemic setting.
- Note: Incomplete antimalarial prophylaxis may reduce parasitemia.

*Initial Tests (lab, imaging)*
- CBC with differential and platelets
- Basic chemistry panel including bilirubin
- Malaria thick and thin blood films (if negative, repeat q12–24h for at least three sets)
- Imaging necessary only for respiratory disease (chest x-ray) or cerebral malaria (CT scan prior to lumbar puncture)
