  - Hop test for tibial stress fracture: With a stress fracture, the patient cannot hop on one leg 10 times; if able to perform test, consider shin splints (medial tibial stress syndrome).
  - Fulcrum test for femoral stress fracture: With patient seated, provoke pain by applying downward force on the distal femur while other hand uses the midthigh as fulcrum on femoral shaft (if clinical suspicion is high, defer or use only with extreme caution to avoid completing a femoral neck stress...
fracture).
- Single-leg hyperextension (Stork) test for pars interarticularis fracture of lumbar spine: Stand on one leg and extend lumbar spine; positive if painful on symptomatic side
- Anatomic malalignment may be present (leg length discrepancy, pes planus/cavus).

DIFFERENTIAL DIAGNOSIS

- Shin splints (medial tibial stress syndrome—pain resolves with rest; stress fracture pain does not)
- Infection (osteomyelitis)
- Soft tissue injury (sprain, tendonitis, and periostitis)
- Compartment syndrome
- Bony fracture
- Neoplasm (osteoid osteoma)
- Nerve entrapment syndromes
- Intermittent claudication

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Laboratory tests are not required unless clinically indicated for suspected disease (e.g., female athlete triad, hyperparathyroidism, and vitamin D deficiency).
- Plain films:
  - First line in suspected stress fracture
  - Findings typically seen 2 to 8 weeks after pain onset
  - Sensitivity during early stages (1 to 2 weeks) may be as low as 10%.
  - May see periosteal callus, “gray cortex sign” (region of decreased cortical intensity), osteopenia, endosteal reaction, or ill-defined cortical margin
  - Severe cases may show discrete fracture.

Follow-Up Tests & Special Considerations

- MRI:
  - Gold standard for imaging stress fractures
  - Highly sensitive; more complete evaluation of exact anatomic location and extent of injury
- Bone scan:
  - Sensitive but nonspecific for stress fracture
– Useful for suspected rib or spine stress fractures
– Should not be used to assess healing

CT scan:
– Less sensitive than MRI or bone scan for early stress fractures but has an important role in evaluating occult fractures of foot, tibia, carpal scaphoid, and pars interarticularis
– Can distinguish conditions (osteoid osteoma, malignancy, and osteomyelitis) that mimic stress fracture on bone scan
– Bony detail provided by CT scan allows differentiation of complete versus incomplete fracture, especially if MRI is equivocal.

US: not routinely used but may help to distinguish metatarsal stress fracture from other causes of metatarsalgia (e.g., Morton neuroma)

Classification by radiographic findings (CT, MRI, bone scan or radiograph) (3)[C]

Grade I: asymptomatic stress reaction; no pain, imaging evidence of stress fracture, no fracture line
Grade II: symptomatic stress reaction; pain on exam, imaging evidence of stress fracture, no fracture line seen on imaging
Grade III: non-displaced fracture; pain on exam, nondisplaced fracture line seen on imaging
Grade IV: displaced fracture; pain on exam, displaced fracture >2 mm seen on imaging
Grade V: nonunion; pain on exam, nonunion characteristics on imaging, longstanding symptoms

## TREATMENT

Grade I to Grade II, and low-risk stress fractures are generally treated nonoperatively, including non-weight bearing and immobilization (4).
Grade III to Grade V, and high-risk stress fractures are treated either operatively or nonoperatively based on the imaging characteristics and fracture site (4).

Protection, rest, ice, compression, and elevation (PRICE) for acute pain and edema
Decrease activity to the level of pain-free functioning.
Consider temporarily immobilizing patients who have pain at rest or with gentle range of motion (ROM).
If patients have pain with ambulation, use crutches with periodic walking trial
to monitor readiness for nonaided (pain-free) ambulation.

- Pneumatic leg brace is effective in decreasing the return-to-play time for tibial shaft stress fracture.
- For low-risk stress fracture, slowly increase impact loading once ambulation and daily activities are pain free. Progression of activity depends on the individual and should be modified according to symptoms (4,5).
- High-risk fractures typically require immediate immobilization and a period of non-weight bearing. Many patients require early surgical intervention to avoid nonunion and facilitate earlier return to sport (4).
- In bisphosphonate-associated femoral stress fracture, prophylactic nail fixation may avoid fracture completion, shorten hospital stay, and decrease subsequent morbidity.

MEDICATION

*First Line*

- Calcium and vitamin D supplementation should be initiated when dietary intake is inadequate or deficiencies are found.
- Acetaminophen is useful for pain.
- NSAIDs are beneficial for pain and inflammation but may adversely affect fracture healing and should, therefore, be used only sparingly.

ISSUES FOR REFERRAL

Orthopedic consultation for high-risk fractures, failure to improve with standard treatment, evidence of nonunion within 3 to 4 weeks, or inability to tolerate rehabilitation

ADDITIONAL THERAPIES

- Electrical stimulation may be an adjunct for delayed union and nonunion.
- Extracorporeal shock wave therapy (ESWT) and pulsed US may have potential benefit but require additional study.
- Physical therapy:
  - Correct training errors and inappropriate mechanics predisposing to stress fracture.
  - Strengthen surrounding musculature.
  - Encourage cross-training to maintain fitness.
  - Correct anatomic variations.
  - Antigravity treadmills
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Once the patient is pain free, low-impact training can start and be advanced gently as tolerated.
- Once running has resumed, increase mileage slowly; no more than 10% per week.

Patient Monitoring

- Imaging every 4 to 6 weeks to assess healing.
- An MRI is generally the preferred imaging technique for follow-up of early stage stress fractures.
- Radiographs are less expensive and can be used for follow-up of higher grade stress fractures.

PATIENT EDUCATION

- Gradually increase activity as long as pain free.
- Rest and reevaluate if there is a recurrence of pain.
- Correct mechanical and training errors.
- Strengthen core muscles.

PROGNOSIS

- Young patients have a good prognosis.
- Older patients or those with metabolic bone disease often develop insufficiency fractures in other bones.
- Time to return to full activity (4)[C]:
  - Grade I: 3+ weeks
  - Grade II: 5+ weeks
  - Grade III: 11+ weeks
  - Grade IV and V: 14+ weeks

COMPLICATIONS

- Completion of fracture
- Delayed union
- Nonunion
- May require surgery with internal fixation
REFERENCES

ADDITIONAL READING

SEE ALSO

Algorithm: Foot Pain

CODES

ICD10

- M84.38XA Stress fracture, other site, initial encounter for fracture
- M84.369A Stress fracture, unsp tibia and fibula, init for fx
- M84.376A Stress fracture, unspecified foot, init enctr for fracture

CLINICAL PEARLS

- The diagnosis of stress fractures requires a high index of suspicion. X-rays are often negative initially.
- Identify and treat female athletic triad to prevent stress fractures.
- To help prevent stress fractures, gradually increase training volume and avoid sudden increases in high-impact activity or running mileage.
- High-risk fractures require immediate immobilization and non-weight bearing. Patients may also require early surgery.
STROKE, ACUTE (CEREBROVASCULAR ACCIDENT [CVA])
Scott A. Drummond Jr., DO, DABR

BASICS
DESCRIPTION
Stroke is the sudden onset of a focal neurologic deficit(s) resulting from either infarction or hemorrhage within the brain.

- Two broad categories: ischemic (thrombotic or embolic; 87%) and hemorrhagic (13%)
- Hemorrhage can be intracerebral or subarachnoid.
- System(s) affected: neurologic; vascular
- Synonym(s): CVA; cerebral infarct; brain attack
- Related terms: transient ischemic attack (TIA), a transient episode of neurologic dysfunction due to focal ischemia without permanent infarction on imaging (see topic “Transient Ischemic Attack [TIA]”)

Pediatric Considerations
- Cardiac abnormalities (congenital heart disease, paradoxical embolism, rheumatic fever, bacterial endocarditis)
- Metabolic: homocystinuria, Fabry disease

EPIDEMIOLOGY
Incidence
Annual incidence in the United States is ~795,000.

Prevalence
- Prevalence in the United States: 550/100,000
- Predominant age: Risk increases >45 years of age and is highest during the 7th and 8th decades.
- Predominant sex: male > female at younger age but higher incidence in women with age ≥75 years

ETIOLOGY AND PATHOPHYSIOLOGY
87% of stroke is ischemic, three main subtypes: thrombosis, embolism, and systemic hypoperfusion. Large vessel atherothrombotic strokes often involve the origin of the internal carotid artery. Small vessel lacunar strokes are commonly due to lipohyalinotic occlusion. Embolic strokes are largely from a cardiac source (due to left atrial thrombus, atrial fibrillation, recent MI, valve disease, or mechanical valves) or ascending aortic atheromatous disease (>4 mm).

13% of stroke is hemorrhagic; most commonly due to HTN. Other causes include intracranial vascular malformations (cavernous angiomas, AVMs), cerebral amyloid angiopathy (lobar hemorrhages in elderly), and anticoagulation.

Other causes include fibromuscular dysplasia (rare), vasculitis, or drug use (cocaine, amphetamines).

**Genetics**

Stroke is a polygenic multifactorial disease.

**RISK FACTORS**

- Uncontrollable: age, gender, race, family history/genetics, prior stroke or TIA
- Controllable/modifiable/treatable
  - Metabolic: diabetes, dyslipidemia
  - Lifestyle: smoking, cocaine and amphetamine use
  - Cardiovascular: hypertension, atrial fibrillation, valvular heart disease, endocarditis, recent MI, severe carotid artery stenosis, hypercoagulable states, and patent foramen ovale

**GENERAL PREVENTION**

Smoking cessation, regular exercise, weight control to maintain nonobese BMI and prevent type 2 diabetes, moderate alcohol use; control BP; manage hyperlipidemia; use antiplatelet agent (e.g., aspirin) in high-risk persons; treat nonvalvular atrial fibrillation with dose-adjusted warfarin or dabigatran, apixaban, and rivaroxaban.

**COMMONLY ASSOCIATED CONDITIONS**

Coronary artery disease is the major cause of death during the first 5 years after a stroke.
**DIAGNOSIS**

**HISTORY**
- Acute onset of focal arm/leg weakness, facial weakness, difficulty with speech or swallowing, vertigo, visual disturbances, diminished consciousness
- Vomiting and severe headache favor hemorrhagic stroke.

**PHYSICAL EXAM**
- Assess airway, breathing, and circulation (ABC).
- Anterior (carotid) circulation: hemiparesis/hemiplegia, neglect, aphasia, visual field defects
- Posterior (vertebrobasilar) circulation: diplopia, vertigo, gait and limb ataxia, facial paresis, Horner syndrome, dysphagia, dysarthria, alternating sensory loss

**DIFFERENTIAL DIAGNOSIS**
- Migraine (complicated)
- Postictal state (Todd paralysis)
- Systemic infection, including meningitis or encephalitis (infection also may uncover or enhance previous deficits)
- Toxic or metabolic disturbance (hypoglycemia, acute renal failure, liver failure, drug intoxication)
- Brain tumor, primary or metastases
- Head trauma, encephalopathy
- Other types of intracranial hemorrhage (epidural, subdural, subarachnoid)
- Trauma, septic emboli

**DIAGNOSTIC TESTS & INTERPRETATION**
Used to narrow differential and identify etiology of stroke

**Initial Tests (lab, imaging)**
- Serum glucose (REQUIRED to exclude hypo- and hyperglycemia) (1)
- ECG
- CBC; electrolyte panel
- Coagulation studies: PT, PTT, INR
- Markers of cardiac ischemia
- Emergent brain imaging with noncontrast CT (or brain MRI with diffusion weighted [DW-MRI]) to exclude hemorrhage (can be lifesaving) (1)
Subsequent multimodal CT (perfusion CT, CTA, unenhanced CT) or MRI improves diagnosis of acute ischemic stroke.

Follow-Up Tests & Special Considerations
Consider LFT, tox screen, blood alcohol, ABG, lumbar puncture if suspected subarachnoid hemorrhage (SAH); EEG if suspect seizures, blood type and cross

- DW-MRI is more sensitive than CT for acute ischemic stroke.
- MRI is better than CT for diagnosis of posterior fossa lesions (2)[B].
- Do not delay emergent treatment (IV thrombolysis) to obtain advanced imaging studies. Generally, if symptomatic, an unenhanced brain CT is emergently performed to exclude hemorrhage, and thrombolytics are initiated immediately, unless contraindicated. A confirmatory MRI is not required in most cases.
- Follow-up carotid imaging (Doppler ultrasound, CTA, or MRA of head and neck) after treatment is initiated.
- Goal is to initiate therapy within 60 minutes of presentation and initial examination.

Diagnostic Procedures/Other
Echocardiogram (transthoracic and/or transesophageal) if there is suspicion for cardioembolic source. In cryptogenic stroke patients, perform prolonged ECG monitoring with a 30-day event monitor.

Test Interpretation
Early CT findings of ischemia: hyperdense MCA sign (increased attenuation of proximal portion of the MCA; associated with MCA thrombosis), loss of gray-white matter differentiation, sulcal effacement, loss of insular ribbon

TREATMENT
- Monitor BP closely in the first 24 hours (1)[A].
  - Withhold antihypertensives unless systolic BP >220 mm Hg or diastolic BP >120 mm Hg. Goal is to lower BP ~15% in the first 24 hours if treatment is undertaken. If thrombolytic therapy is planned, BP must be <185/110 mm Hg prior to administration of thrombolytics.
  - In acute spontaneous intracranial hemorrhagic stroke, goal BP is 160/90 mm Hg or MAP of 110 (see topic “Subarachnoid Hemorrhage” for details
on BP management).

– If there is suspicion of elevated ICP, reduce BP to a target cerebral perfusion pressure of between 61 mm Hg and 80 mm Hg.
– Restart antihypertensive medications 24 hours after stroke onset for patients with a history of hypertension who are neurologically stable.

**ALERT**

Thrombolysis: individualized discussion about the use of IV thrombolysis with eligible patients who have measurable neurologic deficits that do not clear spontaneously and present within 3 to 4.5 hours of stroke symptom onset

**Exclusion criteria for thrombolysis within 3 hours of onset include:**

– Symptoms suggestive of SAH
– Head trauma or prior stroke within 3 months
– MI within 3 months
– GI or gastric ulcer hemorrhage within 21 days
– Major surgery within 14 days
– Arterial puncture at noncompressible site within 7 days
– Any history of intracranial hemorrhage
– Elevated BP (systolic >185 mm Hg and diastolic >110 mm Hg)
– Active bleeding or evidence of acute trauma on examination
– Taking anticoagulant and INR ≥1.7
– Activated PTT not in normal range if heparin received during previous 48 hours; platelet count <100,000 mm$^3$
– Blood glucose concentration <50 mg/dL
– Seizure with postictal residual neurologic impairment
– Multilobar infarction on CT (hypodensity >1/3 cerebral hemisphere)
– Patient or family members not able to provide input and understand potential harms and benefits of treatment

**Extended AHA/ASA exclusion criteria for thrombolysis within 4.5 hours include:**

– Age >80 years
– All patients taking oral anticoagulants regardless of INR
– National Institutes of Health (NIH) Stroke Scale >25
– History of stroke and diabetes

**Antiplatelet agents:** Start oral aspirin (initial dose, 325 mg) within 24 to 48 hours (1)[A].

**MEDICATION**
**First Line**

- BP management options include:
  - Labetalol 10 to 20 mg IV over 1 to 2 minutes, which may be repeated once
  - Nicardipine infusion 5 mg/hr, titrate up by 2.5 mg/hr at 5- to 15-minute intervals to maximum of 15 mg/hr; reduce to 3 mg/hr when target BP is reached.
- Thrombolysis, IV administration of rtPA: Infuse 0.9 mg/kg, maximum dose 90 mg over 60 minutes with 10% of dose given as bolus over 1 minute.
  - Admit to ICU or stroke unit, with neurologic exams every 15 minutes during infusion, every 60 minutes for next 6 hours, and then hourly until 24 hours after treatment.
  - Discontinue infusion and obtain emergent CT scan if severe headache, angioedema, acute hypertension, or nausea and vomiting develop.
  - Measure BP every 15 minutes for first 2 hours, every 30 minutes for next 6 hours, and then every hour until 24 hours after treatment. Maintain BP <185/105 mm Hg; follow-up CT at 24 hours before starting anticoagulants or antiplatelet agents.
- Antiplatelet: aspirin 325 mg/day within 48 hours or 24 to 48 hours after thrombolytic therapy (1)[A]

**Second Line**

Carotid endarterectomy (CEA) for carotid artery stenosis rarely is indicated emergently. CEA is indicated for >70% ipsilateral stenosis. CEA for TIA or incomplete stroke lesion may be indicated for 50–69% stenosis in carefully selected patients, depending on risk factors, and skill and experience of surgeons.

**ISSUES FOR REFERRAL**

Follow-up with neurologist 1 week after discharge, with subsequent follow-up based on individual circumstances.

**ADDITIONAL THERAPIES**

- Prophylactic antibiotics are *not* recommended.
- Deep vein thrombosis (DVT) prophylaxis for immobilized patients
- Corticosteroids are *not* recommended for cerebral brain edema.
- Statin use should be continued without interruption following acute stroke (1) [B].
- Refer to physical therapy, occupational therapy, and speech therapy, as
SURGERY/OTHER PROCEDURES
- Ventricular drain may be placed for patients with acute hydrocephalus secondary to stroke (most commonly cerebellar stroke).
- Decompressive surgery is recommended for major cerebellar infarction; consider for malignant middle cerebral artery infarction, especially in those <60 years of age.
- Consider mechanical embolectomy in carefully selected patients who have evidence of salvageable tissue on advanced imaging.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture within 30 days of stroke onset may improve neurologic functioning.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Observe closely within first 24 hours for neurologic decline, particularly due to cerebral edema.
- Elevate bed to at least 30 degrees if elevated ICP is suspected. Patients with ischemic stroke may benefit from a horizontal bed position during the acute phase.
- Monitor cardiac rhythm for at least 24 hours to identify arrhythmias.
- Airway support and ventilatory assistance may be necessary due to diminished consciousness or bulbar involvement; reserve supplemental oxygen for hypoxic patients. Consider elective intubation for patients with malignant edema.
- Correct hypovolemia with normal saline.
- Keep patients NPO until a formal swallow evaluation has been performed; to reduce risk of aspiration pneumonia, elevate head of bed to 30 degrees.
- Hypoglycemia can cause neurologic dysfunction; correct during initial evaluation.
- Hyperglycemia within first 24 hours after stroke is associated with poor functional outcomes: insulin recommended for patients with glucose levels >140 to 180 mg/dL (1)[C].
- In patients with ICH secondary to anticoagulant use, correct an elevated INR with IV vitamin K and fresh frozen plasma or prothrombin concentrate...
complex; factor VII infusion for patients requiring urgent surgical intervention (i.e., those with cerebellar hemorrhage who are neurologically deteriorating)

- DVT prophylaxis (1)[B]
- Maintain oxygen saturation >94% (1)[C].
- Early physical therapy and discharge planning for rehabilitation and placement
- Maintenance IV hydration with normal saline until swallowing status is assessed; monitor fluid balance closely.
- Frequent neurologic exams in first 24 hours (every 1 to 2 hours)
- Fall precautions; frequent repositioning to prevent skin breakdown
- Discharge criteria: medically stable, adequate nutritional support, neurologic status stable, or improving

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Secondary prevention of stroke with aggressive management of risk factors
- Platelet inhibition using aspirin, clopidogrel, or aspirin plus extended-release dipyridamole (Aggrenox) based on physician and patient preference

**Patient Monitoring**
Follow-up every 3 months for 1st year and then annually

**DIET**
Patients with impaired swallowing should receive nasogastric or percutaneous endoscopic gastrostomy feedings to maintain nutrition and hydration.

**PATIENT EDUCATION**
National Stroke Association (800-STROKES or http://www.stroke.org)

**PROGNOSIS**
Variable depends on subtype and severity of stroke; NIH Stroke Scale may be used for prognosis.

**COMPLICATIONS**
- Acute: brain herniation, hemorrhagic transformation, MI, congestive heart failure, dysphagia, aspiration pneumonia, UTI, DVT, pulmonary embolism,
malnutrition, pressure sores
- Chronic: falls, depression, dementia, orthopedic complications, contractures

REFERENCES

ADDITIONAL READING

CODES

ICD10
- I63.9 Cerebral infarction, unspecified
- I61.9 Nontraumatic intracerebral hemorrhage, unspecified
- I63.50 Cereb infrc due to unsp occls or stenos of unsp cereb artery

CLINICAL PEARLS

- Unless stroke is hemorrhagic or patient is undergoing thrombolysis, do not lower BP acutely. This helps to maintain perfusion of penumbra region.
- Consider IV thrombolysis in eligible patients with neurologic deficits that do not clear spontaneously within 3 to 4.5 hours of symptom onset.
DW-MRI is more sensitive than conventional CT for the diagnosis of acute ischemic stroke. MRI is also superior for diagnosing posterior fossa lesions.
SUBCONJUNCTIVAL HEMORRHAGE

Carrie Valenta, MD, FACP • Colin E. Brown, MD

BASICS

DESCRIPTION
- Subconjunctival hemorrhage (SCH) is bleeding from small blood vessels underneath the conjunctiva, the thin clear skin covering the sclera of the eye.
- SCH is diagnosed clinically:
  - Flat, well-demarcated areas of extravasated blood can be seen just under the surface of the conjunctiva of the eye (red patch of blood sign).
  - SCH is more common in the inferior and temporal regions of the eye (1).
- Typically, SCH resolves spontaneously within 2 weeks.

EPIDEMOLOGY
- Male = female; no gender predilection
- Common; 3% rate of diagnosis in ophthalmology clinics (2)

Incidence
Incidence increases
- With increasing age
- In contact lenses wearers (5% of cases) (3)
- With systemic diseases such as diabetes, hypertension (HTN), and coagulation disorders
- During summer months, possibly due to trauma (2)

ETIOLOGY AND PATHOPHYSIOLOGY
- Direct trauma to the blood vessels of the conjunctiva from blunt or penetrating trauma to the eye
- Direct trauma to the conjunctiva from improper contact lens placement or improper cleaning
- Increased blood pressure (BP) in the vessels of the conjunctiva from HTN or from the temporary increase in BP from a Valsalva type maneuver (e.g., vomiting, sneezing)
- Damaged vessels from diabetes or atherosclerotic disease
- Increased bleeding tendencies from either thrombocytopenia or elevated
prothrombin time (PT)/elevated international normalized ratio (INR) (4)

- Valsalva maneuvers causing sudden severe venous congestion such as coughing, sneezing, vomiting, straining, severe asthma or COPD exacerbation, weightlifting or childbirth/labor (1)
- In patients age >60 years, HTN is the most common etiology.
- In patients age <40 years, trauma/Valsalva and contact lenses use are the most common etiologies.
- In patients age >40 years, conjunctivochalasis (redundant conjunctival folds) and presence of pinguecula are strongly associated (3).

**RISK FACTORS**
- Age
- Contact lenses wearer
- Systemic diseases (HTN, diabetes)
- Bleeding disorders (2)
- Recent ocular surgery (cataract, laser-assisted in situ keratomileusis [LASIK])

**GENERAL PREVENTION**
- Correct cleaning and maintenance of contact lenses
- Protective eyewear in sports and hobbies
- Optimizing control of systemic diseases such as HTN, diabetes, and atherosclerotic disease
- Control of PT/INR in patients on warfarin therapy (5)

**DIAGNOSIS**

**HISTORY**
- Generally asymptomatic; usually, the patient notices redness in the mirror or another person mentions it to the patient.
- May complain of irritation or foreign body sensation
- Little to no pain involved (5)[C]
- Obtain history of trauma. SCH can occur 12 to 24 hours after orbital fracture (1).
- Obtain history of contact lenses usage or recent cataract, LASIK, or other ocular surgery (2)[C].
- Comprehensive past medical history to evaluate if at risk for systemic diseases or taking medications that might increase risk
● Obtain history for current systemic symptomatology.

**PHYSICAL EXAM**
● Measure BP to evaluate control of HTN (2)[C].
● Assess visual acuity; this should be normal in a simple SCH (5)[C].
● Verify that the pupils are equal and reactive to light and accommodation; this should be normal with SCH (5)[C].
● There should be no discharge or exudate noted (5)[C].
● Look at sclera for a bright-red demarcated patch.
  – Demarcated area is most often on inferior aspect of eye due to gravity (3)[C].
● If penetrating trauma is a consideration, perform a gentle digital assessment of the integrity of the globe (4)[C].
● Slit-lamp exam should be performed if there is a history of trauma (1).

**Geriatric Considerations**
In older adults, the area of SCH will be more widespread across the sclera (3). Elastic and connective tissues are more fragile with age, and underlying conditions such as HTN and diabetes may contribute.

**DIFFERENTIAL DIAGNOSIS**
● Viral, bacterial, allergic, or chemical conjunctivitis (enterovirus and coxsackievirus most common) (1)[B]
● Foreign body to conjunctiva
● Penetrating trauma
● Recent ocular surgery/injection
● Contact lenses induced
● Child abuse (particularly if bilateral in an infant or toddler) (1)
● Occasionally found in newborns following vaginal delivery

**DIAGNOSTIC TESTS & INTERPRETATION**
● Typically no testing is indicated; SCH is a clinical diagnosis. If a foreign body is suspected, perform a fluorescein exam.
● Fluorescein exam of a patient with an SCH should show no uptake of staining (5)[C].
● If an orbital fracture is suspected, may obtain plain facial bone films or CT scan (4)[C]
Follow-Up Tests & Special Considerations

If history and physical exam suggest a bleeding disorder (5)[C]

- CBC
- PT/INR

### ALERT

- If a penetrating injury is suspected, may obtain a CT scan of the orbits
- Do not perform MRI if foreign object may be metal (4)[C].

---

**TREATMENT**

**GENERAL MEASURES**

- Control BP.
- Control blood glucose.
- Control INR.
- Wear protective eyewear.

**MEDICATION**

No prescription medications are useful in treatment of SCH.

**ISSUES FOR REFERRAL**

- If a penetrating eye injury is suspected, seek emergent ophthalmology consultation.
- If the patient complains of any decreased visual acuity or visual disturbances, refer to an ophthalmologist as soon as possible.
- If there is no resolution of SCH within 2 weeks or if SCH are recurrent, patient may need referral to an ophthalmologist.

**ADDITIONAL THERAPIES**

- Warm compresses
- Eye lubricants (5)[C]

---

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Follow up only if the area does not resolve within 2 weeks.
If SCH recurs, then work up patient for systemic sources such as bleeding disorders (5)[C].

PATIENT EDUCATION
- Reassurance of the self-limited nature of the problem and typical time frame for resolution
- Education to return to clinic if the area does not heal or recurs
- Correct cleaning and maintenance of contact lenses
- Eye lubricants for ocular irritation

PROGNOSIS
Excellent

COMPLICATIONS
Rare

REFERENCES

ADDITIONAL READING
**CODES**

**ICD10**
- H11.30 Conjunctival hemorrhage, unspecified eye
- H11.31 Conjunctival hemorrhage, right eye
- H11.32 Conjunctival hemorrhage, left eye

**CLINICAL PEARLS**
- SCH is a clinical diagnosis. The condition is typically asymptomatic and will resolve spontaneously within 2 weeks.
- Always check BP in a patient with SCH, as HTN is a known risk factor.
- Indications for immediate referral to an ophthalmologist include eye pain, changes in vision, lack of pupil reactivity, and/or penetrating eye trauma.
- Reassurance and comfort measures (i.e., ocular lubrication) are mainstays of treatment.
- Contact lenses wearers should not wear contact lenses until the SCH resolves completely.
SUBSTANCE USE DISORDERS
S. Lindsey Clarke, MD, FAAFP

BASICS

DESCRIPTION

Any pattern of substance use causing significant physical, mental, or social dysfunction

- Substances of abuse include:
  - Alcohol
  - Tobacco
  - Prescription medications
    - CNS depressants (barbiturates, benzodiazepines, hypnotics)
    - Opioids and morphine derivatives (codeine, fentanyl, hydrocodone, hydromorphone, oxymorphone [Opana], meperidine, methadone, morphine, oxycodone)
    - Stimulants (amphetamines, methylphenidate)
    - Dextromethorphan (“Robo-tripping”)
  - Cannabinoids (marijuana)
  - Synthetic cannabinoids (Spice, K2, others); note: Increasingly, these are sold as liquid in eyedropper bottles for use with vaporizing devices (e-cigarettes/vape pens).
  - Stimulants (cocaine, amphetamines, methamphetamines, Khat)
  - “Club drugs” (MDMA [ecstasy, Molly], PMMA [Superman], flunitrazepam, γ-hydroxybutyrate [GHB])
  - Opioids (heroin, opium, kratom, desomorphine [Krokodil])
  - Dissociative drugs (ketamine, phencyclidine [PCP])
  - Hallucinogens (lysergic acid diethylamide [LSD], salvia, ayahuasca, N,N-dimethyltryptamine [DMT])
  - Synthetic cathinones (bath salts, α-PVP [Flakka])
  - Inhalants (glue, paint thinners, nitrous oxide)
  - Anabolic steroids

See also www.drugabuse.gov/drugs-abuse.

- System(s) affected: cardiovascular, endocrine/metabolic, CNS
- Synonym(s): drug abuse; drug dependence; substance abuse
Geriatric Considerations
- Alcohol is the most commonly abused substance, and abuse often goes unrecognized.
- Higher potential for drug interactions

Pregnancy Considerations
Substance abuse may cause fetal abnormalities, morbidity, and fetal or maternal death.

ALERT
The prevalence of opioid use in pregnancy and associated neonatal abstinence syndrome have increased significantly in recent years. Screening for substance use at the first prenatal visit with a brief intervention, and referral for treatment can improve maternal and neonatal outcomes.

Epidemiology

Incidence
- Predominant age: 16 to 25 years
- Predominant sex: male > female

Prevalence
- 27 million Americans reported illicit drug use in 2015.
- 9% of 12 to 17 year-olds; 22% of 18 to 25 year-olds
- 1 in 5 young adults currently use marijuana.

Etiology and Pathophysiology
Multifactorial, including genetic, environmental

Genetics
Substances of abuse affect dopamine, acetylcholine, γ-aminobutyric acid, norepinephrine, opioid, and serotonin receptors. Variant alleles may account for differences in susceptibility to misuse of different substances.

Risk Factors
- Male gender, young adult
- Depression, anxiety
- Other substance use disorders
Family history
Peer or family use or approval
Low socioeconomic status
Unemployment
Accessibility of substances of abuse
Family dysfunction or trauma
Antisocial personality disorder
Academic problems, school dropout
Criminal involvement

GENERAL PREVENTION
Early identification and aggressive early intervention improve outcomes.
Universal school-based interventions are modestly effective for preventing drug use among adolescents.

COMMONLY ASSOCIATED CONDITIONS
Depression
Personality disorders
Bipolar affective disorder

ALERT
Prescription narcotic overdose is the leading cause of accidental death in patients between the ages of 25 and 65 years in the United States; this correlates with increased prescribing of long-acting oxycodone (see http://www.cdc.gov/injury/wisqars/leading-causes-death.html).

DIAGNOSIS
Substance use disorder (DSM-5 criteria): ≥2 of the following in past year, with severity based on number of criteria present:
Missed work or school
Use in hazardous situations
Continued use despite social or personal problems
Craving
Tolerance (decreased response to effects of drug due to constant exposure)
Withdrawal on discontinuation
Using more than intended
Failed attempts to quit

mebooksfree.com
Increased time spent obtaining, using, or recovering from the substance
Interference with important activities
Continued use despite health problems

HISTORY
- History of infections (e.g., endocarditis, hepatitis B or C, TB, STI, or recurrent pneumonia)
- Social or behavioral problems, including chaotic relationships and/or employment difficulties
- Frequent visits to emergency department
- Criminal incarceration
- History of blackouts, insomnia, mood swings, chronic pain, repetitive trauma
- Anxiety, fatigue, depression, psychosis

PHYSICAL EXAM
- Vital sign abnormalities (changes in HR, RR, BP, and temperature all manifest with misuse of different substances)
- Abnormally dilated or constricted pupils
- Cutaneous needle marks
- Nasal septum perforation (with cocaine use)
- Cardiac dysrhythmias, pathologic murmurs
- Malnutrition with severe dependence

DIFFERENTIAL DIAGNOSIS
- Depression, anxiety, or other mental states
- Metabolic delirium (hypoxia, hypoglycemia, infection, thiamine deficiency, hypothyroidism, thyrotoxicosis)
- ADHD
- Medication toxicity

DIAGNOSTIC TESTS & INTERPRETATION

ALERT
Screening with a single question: “How many times in the past year have you used an illegal drug or used a prescription medication for nonmedical reasons?”: sensitivity of 100% and specificity of 74% in primary care setting (1)[B]

CRAFFT questionnaire is superior to CAGE (Cut down, Annoyed by
criticism, Guilty about drinking, Eye-opener) for identifying alcohol use disorders in adolescents and young adults; sensitivity is 94% with ≥2 “yes” answers.

- C: Have you ever ridden in a CAR driven by someone (including yourself) who was “high” or who had been using alcohol or drugs?
- R: Do you ever use alcohol or drugs to RELAX, feel better about yourself, or fit in?
- A: Do you ever use alcohol or drugs while you are ALONE?
- F: Do you ever FORGET things you did while using alcohol or drugs?
- F: Do your FAMILY or FRIENDS ever tell you that you should cut down on your drinking or drug use?
- T: Have you gotten into TROUBLE while you were using alcohol or drugs?

- American Academy of Pediatrics also recommends the following brief screening tools for adolescents:
  - S2B1 (Screening to Brief Intervention)
  - BSTAD (Brief Screener for Tobacco, Alcohol, and Other Drugs)

- Blood alcohol concentration
- Urine drug screen (UDS) (order qualitative UDS, and if specific drug is in question, a quantitative analysis for specific drug; order confirmatory serum tests if false positive suspected)

- Approximate detection limits
  - Alcohol: 6 to 10 hours
  - Amphetamines and variants: 2 to 3 days
  - Barbiturates: 2 to 10 days
  - Benzodiazepines: 1 to 6 weeks
  - Cocaine: 2 to 3 days
  - Heroin: 1 to 1.5 days
  - LSD, psilocybin: 8 hours
  - Marijuana: 1 to 7 days; up to 1 month with chronic/heavy use
  - Methadone: 1 day to 1 week
  - Opioids: 1 to 3 days
  - PCP: 7 to 14 days
  - Anabolic steroids: oral, 3 weeks; injectable, 3 months; nandrolone, 9 months

- Liver transaminases
- HIV, hepatitis B and C screens
- Echocardiogram for endocarditis
- Head CT scan for seizure, delirium, trauma
TREATMENT
Determine substances abused early (may influence disposition).

GENERAL MEASURES
- Nonjudgmental, medically oriented attitude
- Motivational interviewing and brief interventions can overcome denial and promote change.
- Behavioral and cognitive therapy
- Community reinforcement
- Interventional counseling
- Self-help groups to aid recovery (Alcoholics Anonymous, other 12-step programs)
- Support groups for family (Al-Anon/Alateen)

MEDICATION
- Alcohol withdrawal: See “Alcohol Use Disorder (AUD)” and “Alcohol Withdrawal.”
- Benzodiazepine or barbiturate withdrawal
  - Gradual taper preferable to abrupt discontinuation
  - Substitution of long-acting benzodiazepine (e.g., clonazepam) or phenobarbital
- Nicotine withdrawal: See “Tobacco Use and Smoking Cessation.”
- Opioid dependence
  - Methadone: 15 to 40 mg/day PO; use restricted to inpatient settings and specially licensed clinics (2,3)[A].
  - Buprenorphine: 8 to 16 mg/day sublingually or as 6-month subdermal implant; may precipitate a more severe withdrawal if initiated too soon; use restricted to licensed clinics and certified physicians (3,4)[A].
  - Naltrexone: 50 mg PO daily, 100 mg PO every 2 days, or 150 mg PO every 3 days; must be opioid-free for 7 to 10 days
- Opioid withdrawal
  - Clonidine: 0.1 to 0.2 mg PO BID or TID for autonomic hyperactivity (5) [A]
- Stimulant withdrawal
  - No agent with clear benefit
  - Vaccine to treat cocaine addiction in development
  - Methylphenidate ER: titrated up to 54 mg/day PO might enhance
abstinence in amphetamine-dependent patients

- Adjuncts to therapy
  - Use all medications in conjunction with psychosocial behavioral interventions.
  - Antiemetics, nonaddictive analgesics for opioid withdrawal.
  - Nonhabituating antidepressants, mood stabilizers, anxiolytics, and hypnotics for comorbid mood and anxiety disorders and insomnia that persist after detoxification
- Contraindications
  - Buprenorphine in lactation
  - Naltrexone in pregnancy, liver disease
- Precautions: Clonidine can cause hypotension.
- Significant possible interactions
  - Buprenorphine and ketoconazole, erythromycin, or HIV protease inhibitors
  - Naltrexone and opioid medications (may precipitate or exacerbate withdrawal)

**ISSUES FOR REFERRAL**
- Consider addiction specialist, especially for opioid and polysubstance abuse.
- Maintenance therapy for opioid dependence (e.g., methadone) only in FDA-licensed clinics.
- Psychiatrist for comorbid psychiatric disorders
- Social services

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Indications for inpatient detoxification
  - History of withdrawal symptoms (e.g., seizures)
  - Disorientation
  - Hallucinations or psychotic features
  - Threat of harm to self or others
  - Obstacles to close monitoring (follow-up)
  - Comorbid medical illness
  - Pregnancy
- For narcotic addiction and withdrawal
- Look for signs of severe infection (e.g., bacterial endocarditis).
- Take frequent vital signs during withdrawal.
- Monitor for signs of drug use in the hospital.
Discharge criteria
– Detoxification complete
– Rehabilitation plan in place

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Initially frequent visits to monitor for medical stability and adherence and then progressive follow-up intervals

Patient Monitoring
Verify patient’s adherence with the substance abuse treatment program.

Diet
Patients often are malnourished.

PATIENT EDUCATION
- Substance Abuse and Mental Health Services Administration: http://www.samhsa.gov or 800-662-HELP (4357) for information, treatment facility locator
- National Institute on Drug Abuse: http://www.drugabuse.gov/patients-families
- Alcoholics Anonymous: http://www.aa.org

PROGNOSIS
- Patients in treatment for longer periods (≥1 year) have higher success rates.
- Behavioral therapy and pharmacotherapy are most successful when used in combination.

COMPLICATIONS
- Serious harm to self and others: accidents, violence
- Overdoses resulting in seizures, arrhythmias, cardiac and respiratory arrest, coma, death
- Hepatitis, HIV, tuberculosis, syphilis
- Subacute bacterial endocarditis
- Malnutrition
- Social problems, including arrest
Poor marital adjustment and violence
- Depression, schizophrenia
- Sexual assault (alcohol, flunitrazepam, GHB)

- Committee on Obstetric Practice. Committee Opinion No. 711: opioid use and

**SEE ALSO**

Alcohol Use Disorder (AUD); Alcohol Withdrawal; Tobacco Use and Smoking Cessation

**CODES**

**ICD10**

- F19.10 Other psychoactive substance abuse, uncomplicated
- F10.10 Alcohol abuse, uncomplicated
- F12.10 Cannabis abuse, uncomplicated

**CLINICAL PEARLS**

- Substance use disorders are prevalent, serious, and often unrecognized in clinical practice. Comorbid psychiatric disorders are common.
- Substance abuse is distinguished by family, social, occupational, legal, or physical dysfunction that is caused by persistent use of the substance.
- Dependence is characterized by tolerance, withdrawal, compulsive use, and repeated overindulgence.
- Motivational interviewing, brief interventions, and a nonjudgmental attitude can help to promote a willingness to change behavior.
- There is benefit of referring patients with alcohol dependence to an addiction specialist or treatment program.
Suicide and attempted suicide are significant causes of morbidity and mortality.

**EPIDEMIOLOGY**

- Predominant sex
  - Women attempt suicide 1.5 times more often than men. Men complete suicide 3 times more often than women. Men are more likely to choose a means with high lethality, such as firearms.
- Predominant age: adolescent (second leading cause of death), 10th leading cause of death overall, per 2015, CDC statistics ([latest available])
- Marital status: single > divorced; widowed > married
- Worldwide, suicide is the 17th leading cause of death per World Health Organization reports from 2017. Youths (ages 15 to 29 year olds) are the highest risk group.

**Incidence**

In 2013, 10th leading cause of death in adults in the United States. Military service (not specifically active duty) is associated with increased risk. A 2017 Veteran’s Administration study reported that veterans had a 22% increased rate of suicide, over civilians.

**RISK FACTORS**

- “Human understanding is the most effective weapon against suicide. The greatest need is to deepen the awareness and sensitivity of people to their fellow man” (Shneidman, American Association of Suicidology [AAS]).
- Be alert to a combination of “perturbation” (increased emotional disturbance) and “lethality” (having the potential tools to cause death).
- 80% who complete suicides had a previous attempt.
- 90% who complete suicide meet Diagnostic and Statistical Manual criteria for Axis I or II disorders: major depression, bipolar disorder, anorexia nervosa, panic disorder, borderline and antisocial personality disorders. Schizophrenia
or acute onset of psychosis is also risk factor, due to command hallucinations or even the negative affect or hopelessness that can accompany these states.

- Substance use and withdrawal (alcohol; hallucinogens; opioids)
- Family history of suicide
- Physical illness
- Despair: emotional pain and without hope and, consciously or unconsciously, unworthy of help
- Among teenagers: not feeling “connected” to their peers or family; being bullied; gender identity issues; poor grades
- Psychosocial: recent loss: What may seem to be a small loss (to a medical provider) may be a devastating loss to the patient. Patient-specific factors need to be taken into account; social isolation; anniversaries and holidays. Patients who attempt suicide also seem to have impaired decision-making skills and risk awareness and increased impulsivity, compared with patients who have never attempted suicide (1).
- If a patient is incompetent (e.g., too delusional) to alert providers about the potential for suicide, the patient at increased risk for self-harm and providers should consider hospitalization.
- Access to lethal means: firearms, poisons (including prescription and nonprescription drugs; pesticides) (common method of self-harm in developing countries)

**GENERAL PREVENTION**

- Know how to access resources 24/7 within and outside of the health care institution.
- Screen for risk: use screening instruments BUT keep in mind risks particular to each patient, which could lead to increased risks not captured in some screening tools. Screening instruments include the Patient Health Questionnaire-2 (PHQ-2), the PHQ-9, the Columbia Suicide Severity Rating Scale, Beck Scale for Suicidal Ideation, Linehan Reasons for Living Inventory, and Risk Estimator for Suicide.
- Treat underlying mental illness and substance abuse.
- Screen for possession of means of harm, including prescribed/unprescribed drugs, poisons, and firearms (encourage the removal of guns from the home and the relinquishment of gun licenses).
- Keep in mind that patients with risk factors (see prior section) may be at risk for suicide, even without a prior history of depression.
- Create a safety plan for patients at risk for suicide and their families, including education about how to access emergency care 24 hours a day.
Public education about how to help others access emergency psychiatric care. Suicidal people may initially confide in those they trust outside health care (e.g., family members, religious leaders, “healers,” or to retail service providers, such as hairdressers, and bartenders).

For the military: multiple resources: www.realwarriors.net. Suggested treatments include cognitive restructuring techniques (that their experience with adversity can be a source of strength) and help with problem-solving (so the service member does not feel like a “burden”), therapeutic martial arts training, focus on Vets’ helping others: “Power of 1” initiative (any “one” helpful contact could save a life).

For teens, young adults, and their educators: suggestions and advice for students/families and educators: www.cdc.gov/healthyyouth/adolescenthealth; http://www.stopbullying.gov

In developing world countries, pesticide ingestion is a common method of suicide. Limiting free access has led to reduced suicide rates.

 DIAGNOSIS

HISTORY

Depressed patients should be asked about suicidal ideation and a potential plan:
- “Have you ever felt that life isn’t worth living? Do you ever wish you could go to sleep and not wake up? Are you having thoughts about killing yourself?”

Use psychodynamic formulation, which combines mental-state exam (i.e., behavior, mood, mental content, judgment), past history (i.e., What resources has the patient used in the past for support, and are they currently available?), and history of current illness. If the patient is experiencing a loss, or is under stress, and does not have access to a previously sustaining resource (e.g., a significant other, a pet, sports ability, a job), that patient is under increased risk for suicide.

Prior attempts: precipitants, lethality, intent to die, precautions taken to avoid being rescued, reaction to survival (a patient who is upset that the suicide was not completed is at increased risk for a subsequent attempt)

History of psychiatric symptoms, substance abuse

Also note strengths, such as reasons to live, hopes for future, social supports. A patient without these is at increased risk.
- Gather collateral history (from friends, family, physicians). It may be appropriate to break confidentiality if patient is at imminent risk of suicide.

**PHYSICAL EXAM**
- Medical conditions: delirium, intoxication, withdrawal, medication side effects
- Psychosis: Observe for signs of/ask about command auditory hallucinations to kill oneself, delusional guilt, and persecutory delusions.
- In adults: Observe for signs of hopelessness/despair (see “Risk Factors”).
- In teens: may not appear to be depressed; therefore, screen for risk factors: substance abuse, bullying and social isolation (commonly through electronic media), poor grades

**DIFFERENTIAL DIAGNOSIS**
Suicidal threats and gestures need to be immediately triaged to assess patient safety, although it could be useful as part of a patient’s mental health diagnosis, to differentiate between patients and pseudopatients (i.e., those who would use suicide threats and gestures to manipulate others).

**DIAGNOSTIC TESTS & INTERPRETATION**

*Diagnostic Procedures/Other*
Brief tests that could be part of any medical/mental health assessment:
- Suicide Trigger Scale version 3, (STS-3), which measures a patient’s “ruminative flooding” (self-critical, repetitive thoughts) and “frantic hopelessness” (feeling trapped, suicide is the only choice): [http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3443232/](http://www.ncbi.nlm.nih.gov/pmc/articles/PMC3443232/)

**TREATMENT**

*GENERAL MEASURES*
- Patients expressing active suicidal thoughts or who made an attempt require immediate evaluation for risk factors, mental status, and capacity (to
determine if they are able/or willing to inform treaters about suicidal intentions) as well as a formal psychiatric consultation. Careful primary care screening can be as effective at identifying risk as a psychological assessment.

- Cognitive therapy decreased reattempt rate in prior suicide attempters by half. (i) Establish therapeutic alliance. Have patient tell a story about recent suicidal thought or action. (ii) Help patient develop the skills needed to deal with the thoughts or feelings that trigger suicidal crises. (iii) Have patient imagine being in the situation that brought on the earlier crisis, but this time, guide that patient to practice problem-solving strategies—reinforcing the use of coping skills, rather than suicidal actions (2,3).
- Psychotherapy with suicidal patients is a challenge even for the most experienced clinicians. The countertransference, a clinician’s feelings toward a patient, can evolve into wanting to be rid of the patient. If the patient detects this, the risk of suicide is heightened. The clinician can avoid this by recognizing countertransference and bearing it within so that the patient remains unaware (4).
- Among military personnel: ACE campaign: Ask about suicidal thoughts; Care for the person, including removing access to lethal weapons; “Escort” the soldier/vet to help: an emergency room, a 911 call; call to a support hotline such as (800) 273-TALK (8255); text: 838255.

MEDICATION

- Psychopharmacology “is not a substitute for getting to know the patient” (5).
- Patients are at increased risk of suicide at the outset of antidepressant treatment and when it is discontinued. Consider tapering/switching medical therapies rather than sudden discontinuation. Monitor carefully at these times.
- Anxiety, agitation, and delusions increasing in intensity are risk factors for suicide and should be treated aggressively.
  - In patients with mood disorders, a meta-analysis of randomized, controlled trials found that lithium reduced the risk of death by suicide by 60% (5)[A].
- Agitated or combative patients may require sedation with IV or IM benzodiazepines and/or antipsychotics. Clinical response is typically seen within 20 to 30 minutes if given IM/IV.

Pediatric Considerations

FDA posted black box warning for antidepressant use in the pediatric population after increased suicidality was noted. If risk of untreated depression is sufficient to warrant treatment with antidepressants, treat, but monitor for suicidality.
First Line
ECGs before prescribing or continuing antidepressants or antipsychotics to look for QT prolongation

ISSUES FOR REFERRAL
Consider a psychiatric consult. All decisions regarding treatment must be carefully documented and communicated to all involved health care providers.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Inpatient hospitalization if patient is suicidal with a plan to act or is otherwise at high risk; if immediate risk for self-harm, may be hospitalized involuntarily
- Immediately after a suicide attempt, treat the medical problems resulting from the self-harm before attempting to initiate psychiatric care.
- Order lab work (e.g., solvent screen, blood and urine toxicology screen, aspirin and acetaminophen levels). Patients may not disclose ingestions if they wish to succeed in their attempt or if they are undergoing mental status changes.
- Risk for self-harm continues even in the hospital. As soon as patients arrive at a hospital, they should be searched and potentially dangerous objects removed, they should be under 1-to-1 constant observation, offered medication to ease symptoms; mechanical restraints only if necessary for patient safety
- The period after transfer from involuntary to voluntary hospitalization and post discharge, are times of high risk.
- Discharge criteria
  - No longer considered a danger to self/others
  - Clinicians should be aware that a patient may claim that he or she is no longer suicidal in order to facilitate discharge—and complete the act. Look for clinical and behavioral signs that the patient truly is no longer in despair and is hopeful, such as improved appetite, sleep, engagement with staff, and group therapy. Clinicians should check with family and ancillary staff because patients may share more information with them than with doctors.
  - Provide information about 24/7 resources.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Increase monitoring at the beginning of treatment, when changing medications, and on discharge.
- Educate family members and other close contacts/confidants to the warning signs of suicidality. For adults, despair/hopelessness, isolation, discussing suicide, stating that the world would be a “better place” without them, losses in areas key to the patient’s self-worth. For youths, may exhibit the same signs and symptoms, but one should be aware of these additional risks: history of abuse (e.g., sexual, physical), bullying in person or via electronic media (e.g., text messages or social Web sites), family stress, changes in eating and sleeping patterns, suicidality of friends, and giving away treasured items.
- Make sure that the patient is willing to accept the type of follow-up offered. Do not assume that just setting it up is sufficient protection.
- Curtail access to firearms.
- Limiting the number of pills may be appropriate for an impulsive patient. However, clinicians may believe that by simply limiting the number of pills they prescribe, they are preventing further suicide attempts, an example of “magical thinking.” Clinicians who find themselves thinking this way can take it as a warning sign that their patients may actually be at increased risk of suicide.

PATIENT EDUCATION

Patients who feel they are in danger of hurting themselves should consider one or several of these options:

- Call 911.
- Go directly to an emergency room.
- If already in counseling, contact that therapist immediately.
- Call the National Suicide Prevention Hotline at (800) 273-TALK (8255).
- Servicemen and servicewomen and their families can call (800) 796-9699; if there is no immediate answer, call (800) 273-TALK (8255); text 838255.

PROGNOSIS

The key to a favorable course and prognosis is early recognition of risk factors, early diagnosis and treatment of a psychiatric or medical disorder (which is leading to distress), and appropriate intervention and follow-up.
COMPLICATIONS

- According to the AAS, the grief process for significant others of suicide victims can be lifelong and can be expressed in emotions ranging from anger to despair. Survivors often attempt to shoulder the burden on their own because of the added guilt and shame of the nature of the attempted death or death.
- The AAS recommends the following:
- Counseling: could include short-term behavioral therapy as well as psychotherapy; some therapy should focus on the survivors’ relationships to their current and future significant others. Survivors often seek out life partners as “replacements” for those they lost—could interfere with mourning (W. J. Massicotte, National Scientific Program Committee, written communication, April 24, 2009).
- Sympathetic listening by friends
- Support during holidays
- More self-help strategies: www.survivorsofsuicide.com

REFERENCES

ADDITIONAL READING

- Gutheil TG, Bursztajn H, Brodsky A. The multidimensional assessment of dangerousness: competence assessment in patient care and liability

**CODES**

**ICD10**

- R45.851 Suicidal ideations
- T14.91 Suicide attempt
- Z91.5 Personal history of self-harm

**CLINICAL PEARLS**

- Key preventative measure is to listen to a patient and take steps to keep him or her safe. This could include immediate hospitalization. Questions to explore include, “Are you thinking of killing yourself?” “Who do you have to live for?” and “What should change so that you could live with your suffering?”
- Clozapine, lithium, and cognitive-behavioral therapy are associated with a reduction in the risk of suicide.
- Family members and contacts of people who have attempted or committed suicide suffer from reactions ranging from rage to despair. Their grief is often longer lasting and less well-treated because of the shame and guilt associated with the act. Encourage them to discuss this and consider counseling.
- Resources for clinicians: [www.suicidology.com](http://www.suicidology.com); [www.suicideassessment.com](http://www.suicideassessment.com)
SUPERFICIAL THROMBOPHLEBITIS

Emily M. Culliney, MD, FAAFP

BASICS

DESCRIPTION

- Superficial thrombophlebitis is venous inflammation with secondary thrombosis of a superficial vein.
- Most common in the lower extremities (60–80%), but can occur in the upper extremities/neck
- Generally a benign and self-limiting process, but can be painful
- Traumatic thrombophlebitis types:
  - Injury
  - IV catheter related
  - Intentional (i.e., sclerotherapy)
- Aseptic thrombophlebitis types:
  - Primary hypercoagulable states: disorders with measurable defects in the proteins of the coagulation and/or fibrinolytic systems
  - Secondary hypercoagulable states: clinical conditions with a risk of thrombosis (venous stasis, pregnancy)
- Septic (suppurative) thrombophlebitis types:
  - Iatrogenic, long-term IV catheter use
  - Infectious, mainly syphilis and psittacosis
- Mondor disease
  - Rare presentation of anterior chest/breast veins of women
- System(s) affected: cardiovascular
- Synonym(s): phlebitis; phlebothrombosis

Geriatric Considerations

Septic thrombophlebitis is more common; prognosis is poorer.

Pediatric Considerations

Subperiosteal abscesses of adjacent long bone may complicate the disorder.

Pregnancy Considerations

- Associated with increased risk of aseptic superficial thrombophlebitis,
especially during postpartum
• NSAIDs are contraindicated during pregnancy.

EPIDEMIOLOGY
• Predominant age
  – Traumatic/IV related has no predominant age/sex.
  – Aseptic primary hypercoagulable state
    o Childhood to young adult
• Aseptic secondary hypercoagulable state
  – Mondor disease: women, ages 21 to 55 years
  – Thromboangiitis obliterans onset: ages 20 to 50 years
• Predominant sex
  – Suppurative: male = female
  – Aseptic
    o Spontaneous formation: female (55–70%)
    o Mondor: female > male (2:1)

Incidence
• Septic
  – Incidence of catheter-related thrombophlebitis is 88/100,000 persons per year.
  – Develops in 4–8% if cutdown is performed
• Aseptic primary hypercoagulable state: Antithrombin III and heparin cofactor II deficiency incidence is 50/100,000 persons.
• Aseptic secondary hypercoagulable state
  – In pregnancy, 49-fold increased incidence of phlebitis
  – Superficial migratory thrombophlebitis in 27% of patients with thromboangiitis obliterans

Prevalence
• Superficial thrombophlebitis is common.
• 1/3 of patients in a medical ICU develop thrombophlebitis that eventually progresses to the deep veins.

ETIOLOGY AND PATHOPHYSIOLOGY
• Similar to deep venous thrombosis; virchow triad of vessel trauma, stasis, and hypercoagulability (genetic, iatrogenic, or idiopathic)
• Varicose veins play a primary role in etiology of lower extremity phlebitis.
Mondor disease pathophysiology not completely understood
Less commonly due to infection (i.e., septic)
  – *Staphylococcus aureus*, *Pseudomonas*, *Klebsiella*, *Peptostreptococcus* sp.
  – *Candida* sp.
Aseptic primary hypercoagulable state
  – Due to inherited disorders of hypercoagulability
Aseptic secondary hypercoagulable states
  – Malignancy (Trousseau syndrome: recurrent migratory thrombophlebitis):
    most commonly seen in metastatic mucin or adenocarcinomas of the GI tract (pancreas, stomach, colon, and gallbladder), lung, prostate, and ovary
  – Pregnancy
  – Estrogen-based oral contraceptives
  – Behçet, Buerger, or Mondor disease

**Genetics**
Not applicable other than hypercoagulable states

**RISK FACTORS**

- Nonspecific
  - Varicose veins
  - Immobilization
  - Obesity
  - Advanced age
  - Postoperative states
- Traumatic/septic
  - IV catheter (plastic > coated)
  - Lower extremity IV catheter
  - Cutdowns
  - Cancer, debilitating diseases
  - Burn patients
  - AIDS
  - IV drug use
- Aseptic
  - Pregnancy
  - Estrogen-based oral contraceptives
  - Surgery, trauma, infection
  - Hypercoagulable state (i.e., factor V, protein C, or S deficiency, others)
- Thromboangiitis obliterans: persistent smoking
- Mondor disease
– Breast cancer or breast surgery

**GENERAL PREVENTION**
- Avoid lower extremity cannulations/IV.
- Insert catheters under aseptic conditions, secure cannulas, and replace every 3 days.
- Avoid stasis and use usual deep vein thrombosis (DVT) prophylaxis in high-risk patients (i.e., ICU, immobilized).

**COMMONLY ASSOCIATED CONDITIONS**
- Frequently seen with concurrent DVT (6–53%)
- Symptomatic pulmonary embolism can also be seen concurrently (0–10%).
- Both DVT/PE can occur up to 3 months after onset of phlebitis.

**DIAGNOSIS**

**HISTORY**
Pain along the course of a vein

**PHYSICAL EXAM**
- Swelling, tenderness, redness along the course of a vein or veins
- May have a palpable cord along the course of the vein
- May look like localized cellulitis or erythema nodosum
- Fever in 70% of patients in septic phlebitis
- Sign of systemic sepsis in 84% of suppurative cases

**DIFFERENTIAL DIAGNOSIS**
- Cellulitis
- DVT
- Erythema nodosum
- Cutaneous polyarteritis nodosa
- Lymphangitis

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
Often none necessary if afebrile, otherwise healthy
Small or distal veins (i.e., forearms or below the knee): no recommended imaging

If concern for more proximal extension: venous Doppler US to assess extent of thrombosis and rule out DVT (1)[A]

**Follow-Up Tests & Special Considerations**

- If suspicious for sepsis
  - Blood cultures (bacteremia in 80–90%)
  - Consider culture of the IV fluids being infused.
  - CBC demonstrates leukocytosis.
- Aseptic: evaluation for coagulopathy if recurrent or without another identifiable cause (e.g., protein C and S, lupus anticoagulant, anticardiolipin antibody, factor V and VIII, homocysteine)
- In migratory thrombophlebitis, have a high index of suspicion for malignancy.
- Repeat venous ultrasound to assess effectiveness of therapy.
  - If thrombosis is extending, more aggressive therapy required

**Test Interpretation**

The affected vein is enlarged, tortuous, and thickened with endothelial damage and necrosis.

**TREATMENT**

**GENERAL MEASURES**

- Suppurative: consultation for urgent surgical venous excision
- Local, mild (2)[C]
  - Conservative management, antibiotics not useful
  - For varicosities
    - Compression stockings; maintain activities.
  - Catheter/trauma associated
    - Immediately remove IV and culture tip.
    - Elevate with application of warm compresses.
    - If slow to resolve, consider LMWH.
- Large, severe, or septic thrombophlebitis
  - Inpatient care or bed rest with elevation and local warm compress
  - When the patient is ambulating, then start compression stockings or Ace bandages.
**MEDICATION**

**First Line**
- Best medication(s) and duration of treatment are not well-defined (1)[A].
- Localized, mild thrombophlebitis (usually self-limited)
  - NSAIDs and ASA for inflammation/pain to reduce symptoms and local progression
  - Use of compression stockings can also provide symptomatic relief (3).

**Second Line**
- Septic/suppurative
  - May present or be complicated by sepsis
  - Requires IV antibiotics (broad spectrum initially) and anticoagulation
- Increasing evidence shows that LMWH/fondaparinux treatment can prevent extension of superficial venous thrombosis in addition to venous thromboembolism (VTE) prevention.
- Consider if thrombus is large, close to the junction with deep veins, or involves the long saphenous vein
  - To prevent VTE, 4 weeks of LMWH, such as enoxaparin
  - 45 days of fondaparinux was found to reduce DVT and VTE by 85% (relative risk reduction) in one large study (4)[B].
- Superficial thrombophlebitis related to inherited or acquired hypercoagulable states is addressed by treating the related disease.

**ISSUES FOR REFERRAL**

Severely inflamed or very large phlebitis should be evaluated for excision.

**SURGERY/OTHER PROCEDURES**
- Septic
  - Surgical consultation for excision of the involved vein segment and involved tributaries
  - Drain contiguous abscesses.
  - Remove all associated cannula and culture tips.
- Aseptic: Manage underlying conditions.
  - Evaluate for saphenous vein ligation to prevent deep vein extension after acute phase resolved.
  - Consider referral for varicosity excision.
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Septic: inpatient
- Aseptic: outpatient

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Septic: routine WBC count and differential. Target treatment based on culture results.
- Severe aseptic
  - Repeat venous Doppler US in 1 to 2 weeks to ensure no DVT and assess treatment effectiveness: Do not expect resolution, just nonprogression.
  - Repeat clotting studies.
- Local, mild thrombophlebitis typically resolves with conservative therapy and does not require specific monitoring unless there is a failure to resolve.

DIET

No restrictions

PATIENT EDUCATION

Review local care, elevation, and use of compression hose for acute treatment and prevention of recurrence.

PROGNOSIS

- Septic/suppurative
  - High mortality (50%) if untreated
  - Depends on treatment delay or need for surgery
- Aseptic
  - Usually benign course; recovery in 2 to 3 weeks
  - Depends on development of DVT and early detection of complications
  - Aseptic thrombophlebitis can be isolated, recurrent, or migratory.
  - Recurrence likely if related to varicosity or if severely affected vein not removed
COMPLICATIONS
- Septic: systemic sepsis, bacteremia (84%), septic pulmonary emboli (44%), metastatic abscess formation, pneumonia (44%), subperiosteal abscess of adjacent long bones in children
- Aseptic: DVT (6–53%), VTE (up to 10%), thromboembolic phenomena

SEE ALSO
Deep Vein Thrombophlebitis

CODES
ICD10
- I80.9 Phlebitis and thrombophlebitis of unspecified site
- I80.00 Phlbts and thombophlb of superfic vessels of unsp low extrm
- I80.8 Phlebitis and thrombophlebitis of other sites

**CLINICAL PEARLS**

- Mild superficial thrombophlebitis is typically self-limiting and responds well to conservative care.
- Lower extremity disease involving large veins or proximal saphenous vein may benefit from anticoagulation to prevent DVT.
- Septic thrombophlebitis requires admission for antibiotics and anticoagulation. If severe, consider surgical consultation for venous excision.
SYNCOPE

Taylor S. Howard, MD • Santiago O. Valdes, MD, FAAP

 BASICS

DESCRIPTION

- Transient loss of consciousness characterized by unresponsiveness, loss of postural tone, and spontaneous recovery; usually brief and caused by cerebral hypoperfusion
- System(s) affected: cardiovascular, nervous

EPIDEMIOLOGY

Incidence

- Overall incidence is 6.2/1,000 patient-years.
- Annual incidence of fainting spells resulting in medical evaluation was 9.5/1,000 inhabitants.
- Accounts for 1–3% of emergency room visits and 1% of hospital admissions
- There is an increased incidence after the age of 70 years, and annual incidence in institutionalized elderly (>75 years of age) is 7%.

Prevalence

- Approximately 20% of adults report ≥1 episode during their lifetime; 15% of children <18 years of age
- The prevalence in institutionalized elderly (>75 years of age) is 23%.

ETIOLOGY AND PATHOPHYSIOLOGY

- Systemic hypotension secondary to decreased cardiac output and/or systemic vasodilation leads to a drop in cerebral perfusion and resulting loss of consciousness.
- Cardiac
  - Obstructions to outflow
    - Aortic stenosis
    - Hypertrophic cardiomyopathy: most common cause of sudden cardiac death during exercise in young athletes
  - Pulmonary embolus
  - Cardiac arrhythmias
Sustained ventricular tachycardia (VT)
- Supraventricular tachycardia (SVT) (atrial fibrillation, atrial flutter, reentrant SVT)
- Torsades de pointes (TdP)
- Bradyarrhythmia
  - 2nd- and 3rd-degree AV block
  - Sick sinus syndrome

Noncardiac
- Reflex-mediated vasovagal (neurally mediated syncope [NMS]/neurocardiogenic): inappropriate vasodilation leading to neurally mediated systemic hypotension and decreased cerebral blood flow, situational (micturition, defecation, cough, pain, emotions, hair combing)
- Orthostatic hypotension: Consider volume depletion, pregnancy, anemia, medications.
- Drug/Alcohol induced
- Primary autonomic failure: pure autonomic failure, Parkinsons
- Secondary autonomic failure: diabetes, amyloidosis
- Carotid sinus hypersensitivity

NMS is most common cause in adult cases.

Vast majority of pediatric cases represent benign alterations in vasomotor tone.

Strokes, seizures, and psychogenic nonepileptic seizures may mimic syncope but are a distinct diagnosis.

**Genetics**
Specific cardiomyopathies and arrhythmias may be inherited (i.e., long QT syndrome, catecholaminergic polymorphic VT, Brugada syndrome, hypertrophic cardiomyopathy). Primary and secondary autonomic failure syndromes and NMS may also have genetic links.

**RISK FACTORS**
- Heart disease (acquired or structural)
- Dehydration
- Drugs
  - Antihypertensives
  - Vasodilators (including calcium channel blockers, ACE inhibitors, and nitrates)
  - Phenothiazines
  - Antidepressants
– Antiarrhythmics  
– Diuretics

**GENERAL PREVENTION**

See “Risk Factors.”

**COMMONLY ASSOCIATED CONDITIONS**

See “Etiology and Pathophysiology.”

---

**DIAGNOSIS**

**HISTORY**

- Careful history, physical exam, and an ECG are more important than other investigations in determining the diagnosis (1)[B].
- Make sure that the patient or witness (if present) is not talking about vertigo (i.e., sense of rotary motion, spinning, and whirling), seizure, or causes of fall without loss of consciousness. Onset of syncope is usually rapid, and recovery is spontaneous, rapid, and complete. Duration of episodes are typically brief (<60 seconds).
- Circumstances: Prolonged standing, urinating, coughing, defecation, postprandial, intense emotions are more likely to be associated with NMS. Abrupt neck movements consider carotid sinus hypersensitivity. Exertional syncope considers cardiac.
- Number of previous episodes: Benign causes of syncope tend to be associated with a single episode.
- Presence of prodromal symptoms: Consider NMS.
  – Elderly patients less likely to experience a prodrome
- Palpitations: Consider cardiac.
- Position (supine: arrhythmia; erect: NMS, supine → erect: orthostatic hypotension)
- Prolonged syncope: Consider psychiatric, neurologic.
- Delayed recovery: Consider neurologic (postictal).
- Ask for family history of long QT syndrome, implantable cardioverter-defibrillator (ICD), hypertrophic cardiomyopathy, or unexplained sudden cardiac death in young family members.
- Even after careful evaluation, including diagnostic procedures and special tests, the cause will be found in only 50–60% of the patients.
PHYSICAL EXAM

- BP and pulse, both lying and standing
  - Orthostatic: drop in systolic BP > 20 mm Hg or rise in HR of > 30 bpm (> 40 bpm in those aged 12 to 19 years)
- Check for cardiac murmur or focal neurologic abnormality.

DIFFERENTIAL DIAGNOSIS

- Drop attacks
- Coma
- Vertigo
- Seizure disorder
- Stroke/transient ischemic attacks
- Psychiatric (conversion, somatization): lack hemodynamic and/or autonomic changes

DIAGNOSTIC TESTS & INTERPRETATION

- Goal is to identify life-threatening conditions or those associated with significant risk of injury (2).
- Comprehensive medical and family history, physical examination, and ECG should guide future testing (2).
- No one single test defines the cause of syncope (2).

Initial Tests (lab, imaging)

- ECG should be obtained in most patients.
  - Consider cardiac if there are ischemic changes, bifascicular block, AV block, sinus bradycardia < 40 bpm or sinus pause > 3 seconds, prolong QTc, preexcitation, alternating BBB.
- Other testing should be guided by history and physical:
  - CBC
  - Electrolytes, BUN, creatinine, glucose (rarely helpful if asymptomatic or presenting hours later)
  - BNP level
  - Cardiac enzymes (only if history suggestive of MI)
  - D-dimer (for pulmonary embolism [PE] workup)
  - Urine pregnancy and urine drug screen
  - Initial cardiac or neuroimaging only if indicated
  - Lung scan or helical CT scan of chest if concern for PE
## Follow-Up Tests & Special Considerations

- Injuries may occur in up to 1/3 of adult patients.
- If history and physical suggest ischemic, valvular, or congenital heart disease (1,2)[B]
  - Exercise stress test (if syncope with exertion) (1,2)[C]
  - Echocardiogram (1,2)[B]
- ECG monitoring, either in hospital or ambulatory (1)[B]
  - Consider when concerned for cardiac cause.
  - Choice of outpatient device (i.e., Holter, loop recorder, implantable monitor) should be determined by frequency of symptoms.
- Electrophysiologic studies (1,2)[B]
  - Consider when concerned for cardiac cause.
  - Positive results seen in 22–82% of patients with preexisting heart disease and/or abnormal ECG.

- Head imaging, carotid US, and EEG are not recommended in routine evaluation of syncope but may be useful if history and physical is concerning for neurologic issues (1)[C].
- Carotid hypersensitivity evaluation (2)[B]
  - Carotid hypersensitivity should be considered in patients >40 years old or with syncope during head turning, especially while wearing tight collars, and with neck tumors and neck scars.
  - The technique is not standardized; one side at a time is compressed gently for 20 seconds with constant monitoring of pulse and BP/ECG. Avoid in patients with history of TIA or stroke.
  - Atropine should be readily available.
- Tilt-table testing (1,2)[B]
  - Provocative test for vasovagal syncope
  - Often results are not reproducible
  - High false-positive rate
- Psychiatric evaluation (2)[C]: Indicated when syncope is thought to be psychogenic. Psychiatric disease and substance abuse may be associated with syncope.

## Diagnostic Procedures/Other

External event recorders or implantable loop recorders may be more helpful than short-term ambulatory monitoring; helpful in selective patients with recurrent syncope, with yield of ~55% (1)[B]
Test Interpretation
Depends on etiology and presence of underlying cardiac or neurologic conditions

TREATMENT
- Maintaining good hydration status and normal salt intake are initial therapy.
  Educate patients of the premonitory signs of syncope (1,3)[B].
- Majority of pediatric patients improve with nonpharmacologic measures.

GENERAL MEASURES
- NMS: reassurance, education, behavior modification
- Elderly patients without previously recognized heart disease should be admitted if the physician thinks that the cause of syncope is likely cardiac.
- Patients without heart disease, especially young patients (age <60 years), can be worked up safely as outpatients.
- Prescribe antiarrhythmics for documented arrhythmias occurring simultaneously with syncope or symptoms of presyncope. Asymptomatic arrhythmias do not necessarily require treatment.
- The decision to treat patients on basis of arrhythmias or conduction abnormalities provoked or detected during EPS is problematic: Does the arrhythmia or conduction abnormality have anything to do with the patient’s symptoms?
- Most would treat patients with provoked sustained VT with an antiarrhythmic drug that suppressed arrhythmia during study.
- Rationale for such treatment: Recurrent syncope is less frequent in patients with positive EPS who are treated than it is in those who have negative EPS.

MEDICATION
First Line
- Geared toward specific underlying cardiac or neurologic abnormalities
- In cases of recurrent NMS (1,4)[B]
  – Mineralocorticoids (fludrocortisone)
  – α-Adrenergic agonists (midodrine)

Second Line
- SSRIs (1)[C] (paroxetine, sertraline, fluoxetine)
• Vagolytics (disopyramide)

**ISSUES FOR REFERRAL**
When cardiac or neurologic etiologies are suspected, obtain appropriate consultation, as indicated.

**ADDITIONAL THERAPIES**
For vasovagal/neurocardiogenic/NMS
• Counterpressure maneuvers and exercise have improved vasovagal symptoms and recurrence (1,3)[C].
• Head-up tilt sleeping (2)[C]
• Abdominal binders and/or support stockings (1,2)[C]
• Increased fluid and salt intake to maintain intravascular volume in cases of recurrent NMS

**SURGERY/OTHER PROCEDURES**
• ICD placement for patients with cardiac conditions with high risk of sudden death and/or recurrent syncope on medications (i.e., long QT syndrome, Brugada, catecholaminergic polymorphic VT, hypertrophic cardiomyopathy) (1,2)[B]
• Many recommend pacemaker implantation in patients with the following:
  – 2nd- (Mobitz type II) and 3rd-degree heart block
  – Bifasicular block
  – HV intervals >100 ms
  – Pacing-induced infranodal block
  – Sinus node recovery time ≥3 seconds

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
• Patients with benign etiologies of syncope with negative ED workups are associated with benign outcomes, even in the presence of other risk factors (5) [B].
• Overwhelming majority of children who have completely recovered and without red flags for cardiac or neurologic syncope can be followed as outpatients.
• Patients with suspected cardiac, or those with significant comorbidities (anemia, associated trauma, or persistent vital sign changes) should be admitted.
In adults: ROSE rule recommends hospital admission if any of the following is present: BNP level ≥300 pg/mL, bradycardia ≤50, + fecal occult blood, anemia with hemoglobin ≤9 g/dL, chest pain associated with syncope, ECG showing Q wave (not in lead III) or oxygen saturation ≤94% on room air (6).

- Close monitoring of BP and heart rate during initial presentation
- Discharge criteria
  - Attainment of hemodynamic stability
  - Satisfactory completion of workup for etiology
  - Adequate control of specific arrhythmia or seizure, if present

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Frequent follow-up visits for patients with cardiac causes of syncope, especially patients on antiarrhythmics
- Patients with an unknown cause of syncope rarely (5%) are diagnosed during the follow-up.

**DIET**

No specific diet unless the patient has heart disease or NMS (see “Additional Therapies”)

**PATIENT EDUCATION**

- Reassure the patient that most cardiac causes of syncope can be treated, and patients with noncardiac causes do well, even if the cause of syncope is never discovered.
- Physical counterpressure maneuvers can prevent recurrences of vasovagal syncope.
- Physician and patient should carefully consider whether the patient should continue to drive while syncope is being evaluated. Physicians should be aware of pertinent laws in their own states.

**PROGNOSIS**

- Cumulative mortality at 2 years
  - Low: young patients (<60 years of age) with noncardiac or unknown cause
of syncope
- Intermediate: older patients (>60 years of age) with noncardiac or unknown cause of syncope
- High: patients with cardiac cause of syncope

**Independent predictors of poor short-term outcomes (5,6)[B]**
- Abnormal ECG
- Shortness of breath
- Systolic BP <90 mm Hg
- Hematocrit <30%
- Congestive heart failure

**COMPLICATIONS**
- Trauma from falling
- Death (see “Prognosis”)

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**
- Aortic Valvular Stenosis; Atrial Septal Defect; Carotid Sinus Hypersensitivity; Patent Ductus Arteriosus; Pulmonary Arterial Hypertension; Pulmonary Embolism; Seizure Disorders; Stokes-Adams Attacks
- Algorithms: Syncope; Transient Ischemic Attack and Transient Neurologic Defects

**CODES**

**ICD10**
- R55 Syncope and collapse

**CLINICAL PEARLS**
- Careful history and physical exam is key to a diagnosis.
- Use the ECG/event-recorder to evaluate for arrhythmia.
- NMS is most common cause in children and adults.
- Injuries due to syncope are common.
- True neurologic causes of syncope are very rare.
- <2% of cases are caused by hyponatremia, hypocalcemia, hypoglycemia, or renal failure.
SYNCOPE, REFLEX (VASOVAGAL SYNCOPE)

Melinda Y. Kwan, DO, MPH • Norton Winer, MD

BASICS
A reversible loss of consciousness and postural tone secondary to systemic hypotension and cerebral hypoperfusion due to vasodilation and/or bradycardia (rarely, tachycardia) with spontaneous recovery and no neurologic sequelae. The term syncope excludes seizures, coma, shock, or other states of altered consciousness.

DESCRIPTION
- Derived from the Greek *syncopa*, “to cut short”
- Sudden, transient loss of consciousness characterized by unresponsiveness, falling, and spontaneous recovery
- Common cause of syncope in all age groups, especially in patients with no evidence of neurologic or cardiac disease
- Five main types: vasovagal or neurocardiogenic syncope, situational syncope, orthostatic hypotension, carotid sinus hypersensitivity, and glossopharyngeal/trigeminal neuralgia syncope (uncommon) (1)

EPIDEMIOLOGY
- Mortality: cardiac-related syncope 20–30% and 5% in idiopathic syncope
- Age: any age

Incidence
- Ranges from 7% in children aged <18 years and 15% in adults aged >70 years
- 36–62% of all syncopal episodes
- 30% recurrence rate

Prevalence
22% in the general population

ETIOLOGY AND PATHOPHYSIOLOGY
Cause: an abnormal interaction of the normal mechanisms for maintaining BP
and upright posture
- In normal individuals, upright posture results in venous pooling and transient decrease in BP.
- Neurally induced syncope may result from a cardioinhibitory response, a vasodepressor response, or a combination of the two.
- Increased cardiovagal tone leads to bradycardia or asystole, and decreased peripheral sympathetic activity leads to venodilation and hypotension (2).
- Vasovagal syncope usually has a precipitating event, often related to fright, pain, panic, exercise, noxious stimuli, or heat exposure (2).
- Carotid sinus syncope is precipitated by position change, turning head, or wearing a tight collar (possible neck tumors or surgical scarring).
- Situational syncope is related to micturition, defecation, postexercise, cough, or swallow (3).
- Glossopharyngeal syncope is related to throat or facial pain.

**Genetics**
Vasovagal syncope: strong heritable component

**RISK FACTORS**
- Low-resting BP
- Age: older age
- Prolonged supine position with resulting deconditioning of autonomic control

**GENERAL PREVENTION**
Avoid precipitating events or situations. Optimize diabetes control, use of elastic stockings, adequate hydration.

**COMMONLY ASSOCIATED CONDITIONS**
- Cardiopulmonary disorders: CHF, MI, arrhythmias, hypertrophic obstructive cardiomyopathy, HTN, pulmonary embolism (PE)
- Neurologic disorders: autonomic dysfunction, Shy-Drager syndrome, Parkinson disease, multiple system atrophy, transient ischemic attack, vertebrobasilar insufficiency, peripheral neuropathy
- Psychiatric disorders:
  - Generalized anxiety disorder
  - Panic disorder
  - Major depression
  - Alcohol dependence
**DIAGNOSIS**

**HISTORY**
- Rule out cardiac syncope.
- Neurally mediated syncope is preceded by blurred vision, palpitations, nausea, warmth, diaphoresis, or light-headedness, or there may be history of nausea, warmth, diaphoresis, or fatigue after syncope.
- Vasovagal syncope
  - Three phases: prodrome, loss of consciousness, and postsyncope
  - Precipitating event or stimulus is usually identified, such as panic, fright, pain, or exercise.
  - May be postexertional in athletes (diagnosis of exclusion)
  - Position: can be preceded by prolonged standing but can occur from any position; generally resolves when the patient becomes supine
    - Preceding events: as discussed above
    - Prodrome: as listed above for neurally mediated syncope
  - Duration: generally brief (seconds to minutes)
  - Recovery: may be prolonged with persistent nausea, pallor, and diaphoresis but without neurologic change or confusion
- Carotid sinus syncope is precipitated by position change, after turning head, or wearing a tight collar.
- Situational syncope is related to micturition, defecation, or coughing.
- Glossopharyngeal syncope (less common) is related to throat or facial pain.
  - Precipitating events or situations may include panic, pain, exercise, micturition, defecation, coughing, or swallowing.

**PHYSICAL EXAM**
- Vital signs, including orthostatics and bilateral BP
- Cardiac exam: volume status, murmurs, rhythm, carotid bruits
- Neurologic exam: signs of focal deficit
- Assess for occult blood loss, including guaiac.
- Dix-Hallpike to rule out benign paroxysmal vertigo

**DIFFERENTIAL DIAGNOSIS**
- Seizure
- Arrhythmia
- Hypoglycemia
- Cardiac syncope
DIAGNOSTIC TESTS & INTERPRETATION
Guided by history and physical, includes basic tests to rule out three primary causes of syncope: hypoglycemia, arrhythmia, and anemia

Initial Tests (lab, imaging)
- Blood glucose (hypoglycemia)
- ECG should be ordered for all patients. Abnormal ECG findings are common in patients with cardiac syncope (arrhythmia).
- CBC (rule out anemia)
- Head CT, MRI/MRA, carotid ultrasound only if history or physical exam suggests a neurologic cause
  - Radiology studies are not indicated for insignificant trauma in the presence of a normal neurologic exam (4).

Follow-Up Tests & Special Considerations
- 24-hour Holter monitoring only if a high probability of cardiac cause and/or abnormal ECG findings is present
- A low hemoglobin without obvious cause of bleed warrants stool guaiac, head CT (rule out subarachnoid hemorrhage), abdominal CT (rule out retroperitoneal bleed).
- Negative imaging prompts workup for alternative causes.
- Stroke, bleed, or carotid stenosis require appropriate disease-oriented management.
- EEG only if history or physical exam suggests seizure
- Implantable loop recorder

Diagnostic Procedures/Other
- Head-up tilt table testing:
  - Contraindicated in patients with known cardiac or neurovascular disease or in pregnancy
  - Indicated for recurrent syncope or single episode accompanied by injury or risk to others (e.g., pilots, surgeons)
  - Uses positional changes to reproduce symptoms
– Positive test diagnostic for vasovagal syncope

- Carotid sinus massage, only in a monitored setting (i.e., BP and HR monitoring, IV access):
  - Contraindicated in patients with carotid disease (careful auscultation prior to massage is essential)
  - Pressure at the angle of the jaw for 5 seconds with simultaneous ECG monitoring
  - Positive tests (causing syncope or cardiac pause >3 seconds) are diagnostic of carotid sinus syncope.

- Psychiatric evaluation: to rule out anxiety, depression, and alcohol abuse

**TREATMENT**

Therapy is primarily for recurrent syncope. Situational syncope does not warrant specific treatment.

**GENERAL MEASURES**

Identify and avoid precipitating events or situations

**First Line**

- Nonpharmacologic treatment
  - Patient counseling
    - Development of coping skills
    - Increased salt and fluid intake
  - Moderate exercise training
    - Isometric muscle contractions
      - Leg crossing and buttocks clenching
      - Intense gripping of the hands and tensing of the arms
      - These maneuvers increase cardiac output and arterial blood pressure (5).
  - Tilt-table training
    - Progressively prolonged periods of enforced upright posture

**Second Line**

- $\alpha$-Agonists mainly used for orthostatic hypotension
  - Midodrine is commonly used. It increases peripheral vascular resistance and venous return. Side effects include HTN, paresthesia, urinary retention, “goose bumps,” hyperactivity, dizziness, tremor, and nervousness.
SSRIs: Paroxetine and fluoxetine are useful in treating neurocardiogenic/vasovagal syncope.
- Serotonin affects BP and HR via the central nervous system. Serotonin decreases a sympathetic withdrawal response to rapid increases in serotonin levels.
- Side effects include weight gain, nausea, anxiety, sexual dysfunction, and insomnia.

Mineralocorticoids: Fludrocortisone has been found helpful mainly in orthostatic hypotension.
- Helpful in renal sodium absorption and increasing the vasoconstrictive peripheral vascular response
- Adverse reactions include fluid retention, HTN, CHF, peripheral edema, and hypokalemia.

β-Blockers: metoprolol, atenolol, or pindolol mainly for postural orthostatic tachycardia syndrome (POTS)
- Block peripheral vasodilators and ventricular mechanoreceptor stimulation
- Stabilization of HR and BP
- Side effects: hypotension and bradycardia (with worsening of syncope), fatigue, depression, and sexual dysfunction
- Contraindicated in asthma

ISSUES FOR REFERRAL
Neurology or cardiology, as needed

ADDITIONAL THERAPIES
Use of support/pressure stockings

COMPLEMENTARY & ALTERNATIVE MEDICINE
Treatments for underlying heart disease or precipitating factors (e.g., anxiety); none are proven therapies
- Nutrition and supplements: omega-3 fatty acids, multivitamin, CoQ10, acetyl-L-carnitine, α-lipoic acid, and L-arginine
- Herbs: green tea (Camellia sinensis), bilberry (Vaccinium myrtillus), ginkgo (Ginkgo biloba)
- Homeopathy: carbo vegetabilis, opium, sepia
- Acupuncture: It may precipitate fainting.
SURGERY/OTHER PROCEDURES
Pacemaker placement may be of use in patients with frequent neurocardiogenic/vasovagal syncope that is refractory to other therapies (3)[C].
- Prevents prolonged bradycardia or asystole during syncopal episodes
- Long-term effect
- Invasive placement procedure

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Hospital admission or intense evaluation for (6):
- Severe coronary artery disease or structural heart disease (severe CHF, low ejection fraction or previous myocardial infarction, aortic stenosis)
- Arrhythmic syncope:
  - ECG may show bifascicular block, sinus bradycardia <40 without SA block or β-blockers, Brugada syndrome, abnormal QT interval, etc.
- Severe anemia or electrolyte abnormalities
- Family history of sudden death
- Isotonic crystalloids, as needed
- Vital sign monitoring
- Discharge when hemodynamically stable and workup satisfactory

ONGOING CARE
DIET
- Increased salt intake may help if not otherwise contraindicated (2)[C].
- Maintain fluid intake.

PATIENT EDUCATION
- Identify and avoid precipitating events or situations.
- Avoid dehydration, alcohol consumption, warm environments, tight clothing, and long periods of standing motionless.
- Recognize presyncopeal symptoms.
- Use behaviors, such as lying down, to avoid syncope.

PROGNOSIS
May be recurrent but not life-threatening
COMPLICATIONS
May result in injury from fall

REFERENCES

ADDITIONAL READING

SEE ALSO
Algorithms: Syncope; Transient Ischemic Attack and Transient Neurologic Defects

CODES
ICD10
CLINICAL PEARLS

- A careful history of the events preceding the syncopal episode helps guide evaluation and management.
- Rule out cardiac or neurogenic syncope.
- Prodrome is common with reflex syncope.
- Recovery may be prolonged, with persistent symptoms but there is no residual neurologic deficit or confusion.
- Patients should avoid precipitating situations or events as a first-line treatment.
- Pregnant women can have reflex syncope when moving from supine to lateral decubitus or upright positions.
SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE SECRETION (SIADH)
Elise J. Barney, DO

BASICS

DESCRIPTION

- A syndrome of abnormal production of antidiuretic hormone (ADH), despite low serum osmolality, leading to hyponatremia and inappropriately elevated urine osmolality
  - Decreased urinary electrolyte-free water excretion leads to dilutional hyponatremia (total body sodium [Na] levels may be normal or near normal, but the patient’s total body water is increased).
  - Often secondary to medications but may be associated with an underlying disorder, such as neoplasm, pulmonary disorder, or CNS system disease
- Synonym(s): syndrome of inappropriate secretion of ADH; syndrome of inappropriate antidiuresis

EPIDEMIOLOGY

Incidence

- Often found in the hospital setting, where incidence can be as high as 35%
- Predominant age: elderly
- Predominate sex: females > males

ETIOLOGY AND PATHOPHYSIOLOGY

- Drugs:
  - Antidepressants (e.g., SSRIs, tricyclics, monoamine oxidase inhibitors [MAOIs]),
  - Antineoplastic drugs (e.g., vincristine, vinblastine, cisplatin, cyclophosphamide)
  - Antipsychotic agents (e.g., phenothiazines, thioridazine, haloperidol)
  - Analgesics (e.g., NSAIDs)
  - Antiepileptics (e.g., carbamazepine, oxcarbazepine, valproic acid)
– Oral hypoglycemics (e.g., chlorpropamide, metformin)
– Others (e.g., vasopressin, DDAVP, oxytocin, ciprofloxacin, α-interferon, ecstasy)

Neoplasms (ectopic ADH production):
– Bronchogenic carcinoma
– Small cell carcinoma of the lung
– Oat cell carcinoma of the lung, mesothelioma
– Pancreatic carcinoma
– Hodgkin disease
– Thymoma

Pulmonary conditions:
– Asthma/COPD
– Atelectasis
– Cystic fibrosis
– Positive pressure mechanical ventilation
– Pneumonia
– Pulmonary tuberculosis (TB)
– Sarcoidosis

Neurologic causes:
– Acute porphyria
– CNS injury (i.e., SAH, trauma, stroke)
– CNS lupus
– Encephalitis
– Epilepsy
– Guillain-Barré syndrome
– Meningitis
– Multiple sclerosis

Other:
– HIV infection
– Hypothyroidism, myxedema
– Rocky Mountain spotted fever

Genetics
– 10% of patients have X-linked mutation of V2R.
– Polymorphisms in TRPV4 gene

RISK FACTORS
– Use of predisposing drugs
Advanced age
Postoperative status
Institutionalization

GENERAL PREVENTION
- Search for cause, if unknown.
- Reduce/change medications, if drug-induced.
- Lifelong restriction of fluid intake

COMMONLY ASSOCIATED CONDITIONS
See “Etiology and Pathophysiology.”

DIAGNOSIS

HISTORY
Symptoms:
- Fatigue
- Anorexia
- Nausea
- Vomiting
- Diarrhea
- Headaches
- Unsteady gait
- Falls
- Myalgias/weakness
- Increased thirst
- Confusion
- Seizures, coma

PHYSICAL EXAM
- Euvolemic state
- Mild/moderate hyponatremia (serum Na 125 to 135 mEq/L)
  - Slow cognition and reaction times
  - Hyporeflexia
  - Ataxia
- Severe hyponatremia (serum Na <125 mEq/L)
  - Altered mental status
– Lethargy
– Seizures
– Psychosis
– Coma
– Death

**DIFFERENTIAL DIAGNOSIS**

- Intravascular volume depletion and thiazide-induced
- Appropriate ADH secretion secondary to decreased effective arterial blood volume (e.g., congestive heart failure [CHF], nephrotic syndrome, liver cirrhosis)
- Low solute intake hyponatremia
  - “Tea and toast” diet
  - Beer potomania
- Psychogenic polydipsia
  - Intake usually >10 L/day
  - Diuresis occurs when intake is stopped.
- Endocrinopathies
  - Addison disease
  - Hypothyroidism
- Translocational hyponatremia: caused by hyperglycemia, mannitol, sucrose, glycine
- Pseudohyponatremia
  - Lab artifact caused by hyperlipidemia, paraproteinemias, administration of IVIG
  - Labs using flame photometry or indirect potentiometry susceptible
- Postoperative complications:
  - Caused by nonosmotic release of ADH, probably mediated by pain afferents
  - ADH stimulated by pain, nausea, vomiting, and hypotension
- Cerebral salt-wasting syndrome (hyponatremia, extracellular fluid depletion, CNS insult)

**DIAGNOSTIC TESTS & INTERPRETATION**

- Serum Na level: low
- Serum urea level: normal to low
- Serum osmolality: low
- Urine osmolality: high; urine osmolality >100 mOsm/kg H₂O (1)
Urine Na concentration: high; urine Na >30 mEq/L (1)
Fractional excretion of Na >0.5 % (1)
Serum ADH level: high (not clinically useful)
Not usually required for diagnosis but to assist in diagnosis and assess for other causes:
- Serum uric acid
- Serum glucose; creatinine
- Thyroid function
- Morning cortisol

TREATMENT

GENERAL MEASURES
- Treatment of the underlying cause is essential.
- Requires frequent monitoring (see “Patient Monitoring”)
- Fluid restriction (usually <1,000 mL/day) is the main treatment (2)[C].
- Avoid isotonic saline, as this can worsen the hyponatremia.
- Mild asymptomatic hyponatremia (serum Na >125 mEq/L [>125 mmol/L]):
  Restrict fluid and treat underlying cause.
- Moderate hyponatremia (serum Na 120 to 125 mEq/L):
  - Restrict free water intake.
  - Increase oral solute intake.
  - Calculate urine/plasma electrolyte ratio ([urine Na + K] / [serum Na + serum K]) to determine efficacy of fluid restriction; ineffective if ratio >1 (3) and may need pharmacologic therapy
  - Loop diuretic
  - Treat underlying cause/remove offending agent.
- Severe or with neurologic manifestations
  - Hypertonic saline (3% sodium chloride [NaCl] IV bolus
  - Increase serum Na slowly with hypertonic saline by 4 to 6 mEq/L over 4 to 6 hours (not to exceed 8 mEq/L in a 24-hour period) (1,4).
- Acute (<48 hours duration)
  - Can initially correct rapidly but 24-hour goal is same as in chronic hyponatremia (4)

MEDICATION
- If severe or neurologic symptoms: IV 3% NaCl to increase serum Na
cautiously (5)[B]:
- If serum Na <120 mEq/L or severe neurologic symptoms, consider bolus of hypertonic saline to increase serum Na by 4 to 6 mEq/L over the first 4 to 6 hours.
- NaCl oral tablets
- Oral urea is an option but limited due to bitter taste.
- Loop diuretics: furosemide + potassium (K) replacement
- Vasopressin-2 receptor antagonist (the vaptans: tolvaptan, conivaptan) (5)
  - Good efficacy and safety profiles in the treatment of moderate hyponatremia due to SIADH
  - Liberal fluid intake encouraged
  - Must be initiated in hospital setting
  - Cost may limit long-term use.
  - Avoid tolvaptan in patients with liver disease.
- Demeclocycline (limited use)
  - Blocks ADH at renal tubule; produces nephrogenic diabetes insipidus
  - Dosage for long-term management: 300 to 600 mg PO BID
  - Onset of action within 1 week; therefore, not best for acute management
  - Adverse effects of GI intolerance and nephrotoxicity limit its use.
  - Paucity of evidence for efficacy
- Contraindications: Avoid fluids in CHF, nephrotic syndrome, or cirrhosis. Avoid tolvaptan in patients with cirrhosis due to possible liver injury.
- Precautions: Overly rapid correction (>10 mEq/L/day) can increase risk for osmotic demyelination syndrome (ODS):
  - Permanent CNS damage in pons leading to quadriplegia and pseudobulbar palsy
  - Increased risk in women, alcoholics, malnutrition, hypoxia, chronic hyponatremia of <110 mEq/L, and hypokalemia

**ALERT**
Increase Na levels slowly, no >8 mEq/L/24 hr, to prevent ODS (1)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Careful continuous clinical and laboratory monitoring of hyponatremic state
during acute phase:
- Hourly urine output
- Urine Na, urine osmolality
- Serum Na and K every 4 to 6 hours if moderate/severe, then daily once stable
- Goal Na increase is <8 mEq/L/24 hr until Na reaches 130 mEq/L (1,4)[C].
- If moderate/severe, check serial serum chemistry every 4 to 8 hours to ensure appropriate rate of correction.

- Chronic management: Treat underlying cause; continue fluid restriction and NaCl tablets as needed.

**DIET**
Increase protein/solute intake and decrease water intake.

**PATIENT EDUCATION**
Diet and fluid restrictions

**PROGNOSIS**
- Higher morbidity and mortality in hospitalized patients with hyponatremia (6)
- Higher risk of ICU admission and increased risk of 30-day hospital readmission in hyponatremic patients (6)
- If symptomatic (seizure, coma): high mortality due to cerebral edema if serum Na <120 mEq/L

**COMPLICATIONS**
- Falls and hip fractures
- Cerebral edema (see “Prognosis”)
- Osmotic demyelination with overcorrection (see “Treatment” precautions):
  central pontine and extrapontine irreversible myelinolysis (4)
- Chronic hyponatremia
- Chronic hyponatremia is associated with osteoporosis (6)[C].

**REFERENCES**

**SEE ALSO**

Hyponatremia

**CODES**

**ICD10**

E22.2 Syndrome of inappropriate secretion of antidiuretic hormone

**CLINICAL PEARLS**

- Treatment of the underlying cause is a key. Review all medications for potential culprits.
- Nephrology consultation is recommended in moderate to severe hyponatremia or if hypertonic saline indicated.
- Fluid restriction is the mainstay of treatment in SIADH. Fluid restriction fails to correct hyponatremia and Na wasting in salt-losing renal disease.
- Cerebral salt wasting is a controversial disease entity and is similar to SIADH. However, patients with SIADH are euvoletic, whereas patients with cerebral salt wasting are hypovolemic. The only real way to establish the diagnosis is through fluid restriction. Serum urate and fractional excretion of urate will be corrected with fluid restriction in SIADH but will not correct in cerebral salt wasting.
- ODS is a cerebral demyelination syndrome that causes quadriplegia, pseudobulbar palsy, seizures, coma, and death. It is caused by an overly rapid rate of Na correction. Increase Na levels slowly, no >8 mEq/L/24 hr, to
prevent ODS.

- Safe correction of hyponatremia is important. Online calculators are available: www.medcalc.com/sodium.html.
SYPHILIS

Melissa Badowski, PharmD, MPH • Mahesh C. Patel, MD

BASICS

DESCRIPTION

- A chronic, systemic infectious disease caused by *Treponema pallidum*
- Transmitted sexually by direct contact with an active lesion, vertically (maternal–fetal), and via blood transfusions
- Untreated disease includes four overlapping stages.
  - Primary: single (usually) painless chancre at point of entry; appears in 10 to 90 days; chancre heals without treatment in 3 to 6 weeks.
  - Secondary: appears 2 to 8 weeks after primary chancre; nonpruritic rash on palms or soles of feet, mucous membrane lesions, headache, fever, lymphadenopathy, alopecia
  - Latent: seroreactive without evidence of disease
    - Early latent: acquired within the last year
    - Late latent: exposure >12 months prior to diagnosis
  - Tertiary (late): Serology may be negative (fluorescent treponemal antibody absorption [FTA-ABS] test typically positive)
    - Gumma, cardiovascular, and late neurosyphilis; may be fatal
  - Neurosyphilis: any type of CNS involvement; can occur at any stage
    - Psychosis, delirium, dementia
- Syphilis can affect nearly every organ/tissue

Pediatric Considerations

In noncongenital cases, consider child abuse.

Pregnancy Considerations

- Screen all pregnant patients with venereal disease research laboratory (VDRL) test or rapid plasma reagin (RPR) test early in pregnancy. If high risk, repeat at 28 weeks and at delivery (1,2)[A].
- Use the same nontreponemal test used for initial screening and for follow-up (1,2)[A].
EPIDEMIOLOGY

Incidence

- Syphilis rate decreased until 2000; has since increased (primarily in men who have sex with men-MSM) (3)[A]
- Syphilis rates increased 19% from 2014 to 2015 (7.5/100,000); highest for men aged 25 to 29 years and women aged 20 to 24 years (3)[A]
  - Men: 14/100,000
  - Women: 1.4/100,000
- Congenital: 12/100,000 live births (3)[A]
- Ocular: estimated to be 0.65% of syphilis cases
- Primary and secondary syphilis rates (3)[A]
  - Male (per 100,000 population)
    - Whites, non-Hispanic: 7.6
    - Blacks, non-Hispanic: 39.0
    - Hispanics: 16.6
    - Asians: 5.9
    - American Indians/Alaska natives: 9.1
    - Native Hawaiians/Pacific Islanders: 19.1
    - Multirace: 10.6
  - Female (per 100,000 population)
    - Whites, non-Hispanic: 0.6
    - Blacks, non-Hispanic: 5.3
    - Hispanics: 1.4
    - Asians: 0.3
    - American Indians/Alaska natives: 2.1
    - Native Hawaiians/Pacific Islanders: 1.6
    - Multirace: 0.6

Prevalence

- Predominant sex: male (90%) > female (10%) (3)[A]
- Greatest increase in MSM (3)[A]

ETIOLOGY AND PATHOPHYSIOLOGY

*T. pallidum* enters through intact mucous membranes or breaks in skin. The organism quickly enters the lymphatics to cause systemic disease. Highly infectious; exposure to as few as 60 spirochetes is associated with ~50% chance of infection.
RISK FACTORS
MSM, multiple sexual partners, exposure to infected body fluids, IV drug use, transplacental transmission, adult inmates, high-risk sexual behavior, HIV-positive

GENERAL PREVENTION
Education regarding safe sex; condoms reduce but do not eliminate transmission (4)[A].

COMMONLY ASSOCIATED CONDITIONS
HIV infection, hepatitis B, other STIs

DIAGNOSIS

HISTORY
- As a “great imitator,” a high index of suspicion is often required for accurate diagnosis.
- Previous sexual contact with partner with known infection or high-risk sexual behavior
- Genital lesions (chancre—primary syphilis)
- Rash, alopecia, malaise, headache, anorexia, nausea, fatigue (secondary syphilis)
- Mental status changes (tertiary syphilis)

PHYSICAL EXAM
Signs/symptoms depend on stage.
- Primary: single (occasionally multiple), usually painless ulcer (chancre) in groin or at other point of entry; regional adenopathy
- Secondary
  - Rash: skin/mucous membranes
    - Rough, red-brown macules, usually on palms and soles
    - May appear with chancre or after it has healed
    - Condylomata lata
  - Alopecia
  - Nonspecific symptoms: fever, adenopathy, malaise, headache, hair loss
- Tertiary
  - Focal neurologic findings (hearing loss, vision loss)
– Gummas (skin, mucous membranes, other organ systems)

DIFFERENTIAL DIAGNOSIS

- Primary: chancroid, lymphogranuloma venereum, granuloma inguinale, condylomata acuminata, herpes simplex, Behçet syndrome, trauma, carcinoma, mycotic infection, lichen planus, psoriasis, fungal infection
- Secondary: pityriasis rosea, drug eruption, psoriasis, lichen planus, viral exanthema, Stevens-Johnson syndrome
- Positive serology, asymptomatic: previously treated syphilis/other spirochetal disease (yaws, pinta)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Dark-field microscopy demonstrating *T. pallidum* spirochetes in lesion exudate/tissue biopsy is gold standard but difficult and not very sensitive (5) [A].
- Nontreponemal tests (VDRL/RPR) (3,5) [A]
  - Primary screening test: positive within 7 days of exposure
  - Nonspecific false-positive results are common; must confirm diagnosis with treponemal tests
  - Positive test should be quantified and titers followed regularly after treatment
    - Titors usually correlate with disease activity; 4-fold change is clinically significant.
    - Titors decrease with time/treatment; following adequate treatment for primary/secondary disease, a 4-fold decline is typical in 6 to 12 months.
    - Absence of a 4-fold decline suggests potential treatment failure.
    - ~15% of appropriately treated patients do not have a 4-fold decline in titer 12 months after treatment. Management is unclear; repeat HIV testing and/or CSF examination and continue to follow titers.
    - With appropriate treatment, titers should become negative (see serofast reaction).
    - Titors of patients treated in latent stages decline more gradually.
  - Prozone phenomenon: negative results from high titers of antibody; test with diluted serum
  - Serofast reaction: persistently positive results years after successful treatment; new infection diagnosed by 4-fold rise in titer
  - Conditions that may alter treponemal testing (All stages of syphilis can
have a false-negative RPR result, especially in primary syphilis.)
  - Pregnancy, autoimmune disease, mononucleosis, malaria, leprosy, viral
    pneumonia, cardiolipin antigens, injection drug use, acute febrile illness,
    HIV infection; elderly can have false-positive results.

- **Treponemal tests (confirmatory test after positive nontreponemal screening
test):** FTA-ABS, TP-PA (*T. pallidum particle agglutination*)

  - Confirmatory test; not used for screening
  - Usually positive for life after treatment
  - Titers of no benefit
  - 15–25% of patients treated during primary stage revert to serologic
    nonreactivity after 2 to 3 years.

- **Lumbar puncture (LP) indicated for**

  - Neurologic, ocular, or auditory manifestations
  - Some advise LP in all secondary and early latent cases—even without
    neurologic symptoms.
  - HIV-positive patients with late latent/latent disease of unknown duration
  - Patients with late latent/latent disease of unknown duration if nonpenicillin
    therapy planned
  - Treatment failures
  - Other evidence of active tertiary syphilis is present (e.g., aortitis, gumma,
    iritis)
  - Children to rule out neurosyphilis
  - VDRL, not RPR, used on CSF; may be negative in neurosyphilis; highly
    specific but insensitive
  - Send CSF for protein, glucose, and cell count.
  - Monitor resolution with cell count at 6 months along with serologies (see
    “Patient Monitoring”).
  - Negative FTA-ABS or microhemagglutination (MHA)-TP on CSF excludes
    neurosyphilis (highly sensitive).
  - Positive FTA-ABS or MHA-TP on CSF is not diagnostic because of high
    false-positive rate.
  - Traumatic tap, tuberculosis (TB), pyogenic/aseptic meningitis can all result
    in false-positive VDRL.

---

**TREATMENT**

**GENERAL MEASURES**
Advise patients to notify partner(s) and to avoid intercourse until treatment is complete (5)[A].
Test for HIV infection (3,5)[A].
Management of sexual contacts (5)[A]
- Presumptively treat partners exposed within 90 days of diagnosis.
- Presumptively treat partners exposed >90 days before diagnosis if serologic results are not available immediately and follow-up is uncertain.
- Presumptively treat those exposed to a patient diagnosed with syphilis of unknown duration who has high treponemal titers (>1:32).
- Long-term sex partners of patients with latent infection should be evaluated clinically (including serologies) and treated accordingly.

MEDICATION

ALERT
Use bicillin L-A instead of bicillin C-R (combination benzathine–procaine penicillin)

First Line
Parenteral penicillin G is the drug of choice. The formulation is determined by the disease stage and clinical presentation.

- Primary, secondary, and early latent <1 year (5)[A]
  - Penicillin G benzathine 2.4 million units IM × 1 dose
  - Penicillin-allergic patients: doxycycline 100 mg PO BID for 2 weeks, or tetracycline 500 mg PO QID for 2 weeks, or ceftriaxone 1 to 2 g IM or IV daily for 10 to 14 days
    - Azithromycin 2 g PO for 1 dose (early syphilis only; should not be used in HIV, MSM, or pregnancy)
    - Resistance and treatment failures have been noted in several U.S. regions.
- Late latent/latent of unknown duration and tertiary without evidence of neurosyphilis (5)[A]
  - Penicillin G benzathine 2.4 million units IM weekly × 3 doses
  - Penicillin-allergic patients: Attempt desensitization and treatment with penicillin or doxycycline 100 mg PO BID for 28 days, or tetracycline 500 mg PO QID for 28 days; compliance may be an issue.
- Ocular or neurosyphilis (5)[A]
  - Aqueous crystalline penicillin G 3 to 4 million units IV q4h as continuous infusion for 10 to 14 days
– Alternative: Penicillin G procaine 2.4 million units IM daily in conjunction
with probenecid 500 mg PO QID for 10 to 14 days (if compliance can be
ensured)
– Penicillin-allergic patients: Attempt desensitization and treat with
penicillin; ceftriaxone 2 g/day IM or IV for 10 to 14 days
– If late latent, latent of unknown duration, or tertiary in addition to
neurosyphilis, consider also treating as recommended for late latent after
completion of neurosyphilis treatment.

Congenital (5)[A]
– Aqueous crystalline penicillin G 50,000 U/kg/dose IV q12h for the first 7
days of life and q8h thereafter for a total of 10 days, or penicillin G
procaine 50,000 U/kg/dose IM daily for 10 days
– If negative CSF serologies, normal physical exam, and maternal titer and
then 50,000 U/kg penicillin G benzathine IM in single dose
– If >1 day of drug is missed, restart course.
– Children (after newborn period): aqueous crystalline penicillin G 50,000
U/kg/dose IV q4–6h for 10 days; late latent, 50,000 U/kg IM as 3 doses at
1-week intervals
– For contacts without symptoms: Treat as primary disease after serologies
are obtained.
– HIV-infected and pregnant patients may show poor response to
recommended IM doses. Use IV therapy for all treatment failures in these
patients.
– Do not give benzathine or procaine penicillins IV.

Children (after newborn period) (5)[A]: aqueous crystalline penicillin G
50,000 U/kg/dose IV q4–6h for 10 days; late latent, 50,000 U/kg IM as 3
doses at 1-week intervals

Pregnancy (5)[A]
– Treatment is the same as for nonpregnant patients.
– Some recommend 2nd dose of penicillin G benzathine 2.4 million units IM
1 week after initial dose in 3rd trimester or with primary, secondary, or
early latent syphilis.
– Penicillin sensitivity: no proven alternatives to penicillin available for
treatment during pregnancy
– Penicillin-allergic patients: Desensitize and treat with penicillin.
– HIV-infected pregnant patients may show poor response to recommended
IM doses. Use IV therapy for all treatment failures in these patients.

Treat contacts without symptoms as primary disease after obtaining
serologies.
• History of penicillin allergy:
  – Confirmed IgE-mediated reaction: desensitization
  – Questionable history of IgE-mediated hypersensitivity: penicillin skin testing if major and minor penicillin determinants available

• Precautions (5)[A]
  – HIV-infected and pregnant patients may show poor response to recommended IM doses. Use IV therapy for all treatment failures in these patients.
  – Do not give benzathine or procaine penicillins IV.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

• Clinical and serologic evaluation 6 to 12 months after treatment; if >1 year duration, check at 24 months (5)[A].
• In HIV-infected persons, clinical and serologic evaluation at 3, 6, 9, 12, and 24 months after therapy (5)[A]

*Patient Monitoring*

• Use VDRL or RPR test to monitor therapy: 4-fold rise (two dilutions) in titer indicates new infection, whereas failure to decrease 4-fold (two dilutions) in 6 to 12 months may indicate treatment failure (although definitive criteria for cure not established); always use same test (preferably same lab) (5)[A].
• Retreatment for persistent clinical signs or recurrence, 4-fold rise in titers, or failure of initially high titer to decrease 4-fold by 6 to 12 months
• Neurosyphilis: Repeat LP every 6 months to check for normalization of CSF cell count (± CSF-VDRL and protein evaluation) (5)[A].

**PATIENT EDUCATION**

No intimate contacts until 4-fold titer drop

**PROGNOSIS**

• Excellent in all cases except patients with late syphilis complications and with HIV infection
• Syphilis in HIV-infected patient
  – Treatment same as for HIV-negative patients
  – More often false-negative treponemal and nontreponemal tests or unusually
high titers
- Response to therapy less predictable
- Early syphilis: increased risk of neurosyphilis and higher rates of treatment failure
- Late neurosyphilis: harder to treat; can occur up to 20 years or more after infection

COMPLICATIONS
- Membranous glomerulonephritis
- Paroxysmal cold hemoglobinemia
- Meningitis and tabes dorsalis
- Cardiovascular aneurysms; valvular damage
- Irreversible organ damage
- Jarisch-Herxheimer reaction
  - Fever, chills, headache, myalgias, new rash
  - Common when starting treatment (of primary/secondary disease; less common with tertiary) owing to lysis of treponemes
  - Should not be confused with drug reaction
  - Managed with analgesics and antipyretics

REFERENCES

Chlamydia Infection (Sexually Transmitted); Gonococcal Infections

CODES

ICD10
● A53.9 Syphilis, unspecified
● A51.0 Primary genital syphilis
● A53.0 Latent syphilis, unspecified as early or late

CLINICAL PEARLS
● Screen all HIV-positive patients and patients with high-risk sexual behaviors for syphilis.
● Penicillin remains the treatment of choice for syphilis.
● Syphilis rates are rising—particularly among MSM.
TARSAL TUNNEL SYNDROME

Caitlin G. Waters, MD • J. Herbert Stevenson, MD

BASICS

DESCRIPTION

Tarsal tunnel syndrome occurs when there is compression neuropathy of the posterior tibial nerve as it passes behind the medial malleolus and under the flexor retinaculum (laciniate ligament) in the medial ankle (the tarsal tunnel).

EPIDEMIOLOGY

- Women are slightly more affected than men (56%).
- All postpubescent ages are affected.

ETIOLOGY AND PATHOPHYSIOLOGY

- Contents within the tarsal tunnel from the anterior medial to the posterior lateral side include the following: the posterior tibial tendon, the flexor digitorum longus tendon, the posterior tibial artery and veins, the posterior tibial nerve, and the flexor hallucis tendon.
- The posterior tibial nerve passes through the tarsal tunnel, which is formed by three osseus structures—sustentaculum tali, medial calcaneus, and medial malleolus—covered by the laciniate ligament.
- Compression of the posterior tibial nerve within the tarsal tunnel results in decreased blood flow, ischemic damage, and resultant symptoms (1).
- Chronic compression can destroy endoneurial microvasculature, leading to edema and (eventually) fibrosis and demyelination (2).
- Increased pressure in the tarsal tunnel is caused by a variety of mechanical and biochemical mechanisms. The specific cause for compression is identifiable in only 60–80% of patients (1).
- Three general categories: trauma, space-occupying lesions, deformity (1)
  - Trauma including displaced fractures, deltid ligament sprains, or tenosynovitis
  - Varicosities
  - Hindfoot varus or valgus
  - Fibrosis of the perineurium
- Other causes:
– Osseous prominences
– Ganglia; lipoma; neurilemmoma
– Inflammatory synovitis
– Pigmented villonodular synovitis
– Tarsal coalition
– Accessory musculature
• In patients with systemic disease (e.g., diabetes), the “double crush” syndrome refers to the development of a second compression along the same nerve at a site of anatomic narrowing in patients with previous proximal nerve damage (3).

**RISK FACTORS**
• Tarsal tunnel syndrome is associated with certain occupations and activities involving repetitive weight bearing on the foot and ankle (jogging, dancing).
• Other possible risk factors include (4):
  – Diabetes
  – Systemic inflammatory arthritis
  – Connective tissue disorders
  – Obesity
  – Varicosities
  – Heel varus or valgus
  – Bifurcation of the posterior tibial nerve into medial and lateral plantar nerves proximal to the tarsal tunnel

**DIAGNOSIS**
Tarsal tunnel syndrome is largely a clinical diagnosis, characterized by pain and paresthesias in a predictable distribution along the medial aspect of the ankle and plantar surface of the foot (1).

**HISTORY**
• History of trauma (may be trivial) to the foot precipitating pain
• Pain behind medial malleolus radiating to the longitudinal arch and plantar aspect of foot including the heel
• Tightness, burning, tingling, and numbness (1)
• Pain usually worsens during standing or activity.
• Pain radiates proximally up the medial leg (Valleix phenomenon) in 33% of patients with severe compression.
Some patients have substantial night pain (may be related to venostasis). 
Symptoms improve with rest, wearing loose footwear, and elevation. 
In advanced nerve compression, motor involvement may cause weakness, atrophy, and digital contractures of the intrinsic foot muscles (4).

**ALERT**
Other systemic neuropathies (diabetes, alcoholism, HIV, drug reactions) present with similar symptoms.

**PHYSICAL EXAM**
- Inspect: foot alignment
  - Examine for hindfoot varus or valgus deformity.
  - Exaggerating heel dorsiflexion, inversion, or eversion may reproduce symptoms by stretching or compressing the posterior tibial nerve.
- Palpate the tarsal tunnel and the course of the tibial nerve for tenderness and swelling.
- Tinel sign: Percussion over the tibial nerve may reproduce paresthesias that radiate distally.
- Valleix sign: Percussion over the tibial nerve may produce paresthesias that radiate proximally.
- Cuff test: Inflating a pneumatic cuff engorges varicosities and reproduces symptoms.
- Compression test: Applying pressure to the tarsal tunnel for 60 seconds may reproduce symptoms.
- Sensory examination
  - The medial calcaneal nerve usually is spared, but numbness and altered sensation may be present in the distribution of the medial or lateral plantar nerves.
  - Vibratory sensation and two-point discrimination are decreased early in the disease process.
- Motor examination
  - Intrinsic foot muscle weakness (difficult to assess)
  - Rarely, weakness of toe plantar flexion may be present.
  - Atrophy of the abductor hallucis or abductor digiti minimi may be seen late in the disease process.

**DIFFERENTIAL DIAGNOSIS**
- Peripheral neuropathies (diabetes, alcoholism, HIV, or drug related)
- Inflammatory arthritis (rheumatoid arthritis)
Morton neuroma
Metatarsalgia
Subtalar joint arthritis
Tibialis posterior tendinitis/dysfunction
Plantar fasciitis
Plantar callosities
Peripheral vascular disease
Lumbar radiculopathy
Proximal injury or compression of the tibial branch of the sciatic nerve

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Routine lab tests help rule out other conditions that may mimic tarsal tunnel syndrome, including diabetic neuropathy, rheumatoid arthritis, thyroid dysfunction, or other systemic illnesses (5).
- Routine weight-bearing radiographs, followed by CT (if necessary) to assess for fracture or structural abnormality
- Consider evaluation of lumbar spine x-ray if double crush (injury to lumbar nerve results in compensatory injury to posterior tibial nerve) is suspected (5).
- MRI: helps assess the tarsal tunnel for soft tissue masses or other sources of nerve compression before surgery (1)
- Ultrasound: gaining importance and with several advantages over MRI; can assess for tenosynovitis, ganglia, varicose veins, or lipomas (1)

Pregnancy Considerations
- Tarsal tunnel syndrome can occur during pregnancy, typically secondary to local compression caused by fluid retention and volume changes (1).
- Care is supportive. Most cases resolve after pregnancy.

Pediatric Considerations
MRI is recommended for evaluating pediatric tarsal tunnel syndrome to exclude neoplastic mass.

Diagnostic Procedures/Other
Electrodiagnostic studies
- Electromyography (EMG) of the intrinsic muscles of the foot can confirm the diagnosis of tarsal tunnel syndrome. A normal EMG does not exclude the diagnosis (false-negative rate is ~10%) (1).
Nerve conduction studies may reveal slowed conduction of the tibial nerve. Evaluate for proximal nerve compression, including a lumbar radiculopathy or a double crush phenomenon.

**TREATMENT**

- Conservative management is recommended, except for acute onset tarsal tunnel syndrome or in the setting of a known space-occupying lesion (excluding synovitis).
- Tarsal tunnel decompression may improve sensory impairment and restore protective sensation in diabetic peripheral neuropathies if there is nerve entrapment at the tarsal tunnel.

**MEDICATION**

*First Line*

- Analgesics and anti-inflammatory medications
- Local corticosteroid injection
- Medications that alter neurogenic pain (tricyclic antidepressants, antiepileptic drugs, nerve blockers)

**ADDITIONAL THERAPIES**

- Rest/immobilization
- Taping and bracing
- Orthotics or shoe modification
- Physical therapy to strengthen the intrinsic and extrinsic muscles of the foot and to restore the medial longitudinal arch
- Other modalities (stretching, US, massage, icing)
- Compression stockings to decrease swelling
- Weight loss for obese patients

**SURGERY/OTHER PROCEDURES**

- Surgery is indicated (1,2).
  - If nonoperative measures fail following a 3- to 6-month trial
  - In the setting of acute tarsal tunnel syndrome
  - If a space-occupying lesion is identified
- The surgical outcome is dependent on technique and postoperative management. 50–95% of cases have good to excellent outcomes.
At the time of surgery, assess focal swelling, scarring, or nerve abnormalities and look for a pathologic source of compression.

Postoperative management includes:
- Non-weight-bearing splint until incision heals (2 to 3 weeks), followed by progressively increased weight-bearing and range of motion exercises
- Rest, ice, compression, elevation to limit swelling

ONGOING CARE

PATIENT EDUCATION

- Discuss conservative and surgical options based on individual patient circumstance and preference.
- A decision about surgical intervention should be made with a clear understanding risks, benefits, and potential adverse outcomes.

PROGNOSIS

Surgery is most helpful for:
- Patients with a positive Tinel sign
- Young patients
- Short period between occurrence of symptoms and surgery <1 year
- Localized space-occupying lesion
- No motor neuron involvement

COMPLICATIONS

- The main adverse outcome is an unsuccessful surgical intervention characterized by lack of improvement or recurrence of symptoms.
- Causes for a failed tarsal tunnel release include:
  - Incorrect diagnosis
  - Incomplete release
  - Adhesive neuritis (external scar formation)
  - Intraneural damage (systemic disease, direct nerve injury)
  - Failure to treat all sources of nerve compression in a double crush phenomenon
- Electrodiagnostic studies are rarely helpful in determining the cause of a failed tarsal tunnel release.
- Results with surgical revision are poorer than those for the primary surgical release.

Algorithm: Foot Pain

CODES

ICD10
- G57.50 Tarsal tunnel syndrome, unspecified lower limb
- G57.51 Tarsal tunnel syndrome, right lower limb
- G57.52 Tarsal tunnel syndrome, left lower limb

CLINICAL PEARLS
- Tarsal tunnel syndrome typically presents with pain and tingling of the medial ankle and plantar foot.
- Tinel sign is the most sensitive and specific physical examination test for diagnosing tarsal tunnel.
- EMG cannot independently diagnose tarsal tunnel syndrome; it is used to confirm a clinical diagnosis.
- Conservative management is recommended, except for patients with an acute onset tarsal tunnel syndrome or known space-occupying lesion.
TELOGEN EFFLUVIUM

Quratulanne H. Jan, MD • Arham K. Barakzai, MD

BASICS
Diffuse hair loss or hair thinning; most often an acute self-limited process

DESCRIPTION
Telogen effluvium (TE) is a transient condition in which there is a premature conversion of a significant proportion of anagen (growth phase) hairs into telogen (resting phase) hairs resulting in increased shedding of these resting hair follicles and the clinical appearance of moderate to severe hair thinning.

- Five proposed types of TE
  - Immediate anagen release: a highly common form, lasting 3 to 4 weeks, in which follicles meant to remain in anagen phase enter telogen prematurely due to a signal, including high fever, drug induced, or stress
  - Delayed anagen release: occurs most often postpartum, in which a large group of hair follicles that have remained in the anagen phase for an extended period all together enter the telogen phase, resulting in hair loss
  - Short anagen: a somewhat speculative type, in which at least 50% of the hair follicles have an idiopathic shortening of the anagen phase, resulting in a corresponding doubling of the follicles in the telogen phase
  - Immediate telogen release: Normal resting club hairs remain within the hair follicle until an unknown signal causes their release, initiating the anagen stage to begin. In this type, the resting club hairs are prematurely released, ending the telogen phase abruptly and causing diffuse shedding.
  - Delayed telogen release: In this type, the presence of increased visible light, whether it be a seasonal or environmental change, is thought to end a prolonged telogen phase and initiate the anagen phase, resulting in diffuse shedding of hair follicles.

EPIDEMIOLOGY

Incidence
Second most common cause of alopecia

Prevalence
ETIOLOGY AND PATHOPHYSIOLOGY

- The hair cycle consists of two predominant phases. The anagen (growth phase) and the telogen (resting phase), lasting ~3 years and 3 months, respectively. On the scalp, ~10–15% of hairs are in the telogen phase normally. Due to the presence of some types of external/internal stress, there may be an increase in the percentage of telogen hairs. As new anagen hairs emerge, these telogen hair follicles are forced out. The preceding event usually occurs 2 to 3 months prior to the appearance of hair loss.
- It is hypothesized that substance P plays a key role in the pathogenesis of TE through various mechanisms (1). Studies have been conducted on human hair follicles in vitro and mice hair follicles in vivo, which support this theory.
- Role of substance P includes the following (2):
  - Upregulation of substance P receptor, NK1, at the gene and protein level, leading to premature catagen development and hair growth inhibition
  - Upregulation of nerve growth factor (NGF) and subsequently its hair apoptosis–producing receptor, p75NTR
  - Downregulation of hair growth–promoting receptor, TrkA
  - Upregulation of major histocompatibility class (MHC) I and β2-microglobulin resulting in loss of hair follicle immune-privilege
  - Increase in tumor necrosis factor-α release by mast cells resulting in hair keratinocyte apoptosis
- Decreased cortisol levels in chronic stress states may also enhance the effects of substance P.

RISK FACTORS

- Infection
- Trauma
- Major surgery
- Thyroid disorder
- Febrile illness
- Malignancy
- Allergic contact dermatitis (3)
- Iron deficiency anemia (4)
- Excess vitamin A
- Protein-calorie restriction
- End-stage liver or renal disease
- Hormonal changes (including pregnancy, delivery, and estrogen-containing medications)
- Chronic stress
- Drug induced (β-blockers, anticonvulsants, antidepressants, anticoagulants, retinoids, ACE-inhibitors, etc.)
- Immunizations

**DIAGNOSIS**

**HISTORY**
- Commonly, an inciting event 2 to 6 months previous
- Fear of becoming bald
- Patients often present with bags of hair to emphasize the severity of their hair loss.

**PHYSICAL EXAM**
- Decreased density of hair on the scalp, most commonly involving the crown
- In rare cases of chronic TE, there is hair loss of eyebrows and pubic region.
- May be able to demonstrate diffuse shedding of hair when running fingers through scalp
- Shed hairs are telogen hairs, which have a small bulb of unpigmented or pigmented keratin on the root end.
- May affect nail growth, resulting in the appearance of Beau lines, which are transverse grooves on the nails of the hands and feet

**DIFFERENTIAL DIAGNOSIS**
- Hypothyroidism
- Hyperthyroidism
- Alopecia areata (diffuse pattern)
- Androgenetic alopecia
- Drug-induced alopecia
- Systemic lupus erythematosus
- Secondary syphilis
- Trichotillomania

**DIAGNOSTIC TESTS & INTERPRETATION**
Most often, TE is a clinical diagnosis of exclusion. Blood work may be collected
primarily to rule out other possible causes of hair loss and/or to identify a possible cause for TE.

**Initial Tests (lab, imaging)**
If indicated:
- CBC, ferritin
- TSH
- Creatinine
- Consider hepatic enzymes.
- Consider RPR/VDRL.

**Diagnostic Procedures/Other**
- Hair pull test: unreliable; performed by gently pulling 25 to 30 hairs from various sites on a patient’s scalp. Each pull should elicit <5 normal club hairs; increased quantity may indicate possibility of TE.
- Hair clip test: performed by cutting 25 to 30 hairs from the patient’s scalp and examining them under a microscope. A negative test (not indicative of TE) will demonstrate <10% of hair shafts of small diameter. A positive test will demonstrate >10% of hair shafts of small diameter.
- Trichogram: ~50 hairs are plucked from the patient’s scalp, and the number of telogen and anagen hairs present are counted. In TE, there will be >10% of hairs in the telogen phase.
- Scalp biopsy: rarely needed; it is recommended that several 4-mm punch biopsies be obtained, all horizontally embedded to determine an accurate anagen-to-telogen ratio. Histologically, catagen-to-telogen hairs have numerous apoptotic cells in the outer sheath epithelium. >12–15% of hair follicles in telogen phase is consistent with TE.

**TREATMENT**
TE is a benign, self-limited process. Identify and correct underlying cause. Patient should be reassured that full hair growth will occur in ~6 months to 1 year. No treatment is required.

**MEDICATION**
- Minoxidil stimulates hair regrowth via arteriolar smooth muscle vasodilation; not effective in TE
- Oral zinc therapy: new medication that may have benefits for patients with TE
through various mechanisms all essential to hair growth, including the following (5)[C]:
– Cofactor for enzymes needed in nucleic acid and protein synthesis and cell division
– Inhibition of the catagen phase by blocking certain enzymes involved in hair apoptosis
– Involved in hair growth regulation via hedgehog signaling

COMPLEMENTARY & ALTERNATIVE MEDICINE
Nigella sativa (black cumin) essential oil has also been studied and may be beneficial (6).

REFERENCES

ADDITIONAL READING
ICD10
L65.0 Telogen effluvium

CLINICAL PEARLS

- TE is a self-limited form of nonscarring alopecia; most often acute.
- TE is due to a premature conversion of a significant proportion of anagen (growth phase) hairs into telogen (resting phase) hairs, resulting in increased shedding of these resting hair follicles and the clinical appearance of moderate to severe hair thinning and loss when growth resumes.
- There are many potential causes of TE, both emotional and physiologic. Often it is hard to determine the etiology, but eliminating the stressor often is the key to resolving TE and stimulating new hair growth.
- No treatment is needed. Patient should be reassured that complete hair regrowth will occur in 6 months to 1 year.
TEMPOROMANDIBULAR JOINT DISORDER (TMD)

Jessica Johnson, MD, MPH • Benjamin N. Schneider, MD

BASICS

DESCRIPTION

● Syndrome characterized by
  – Pain and tenderness involving the muscles of mastication and surrounding tissues
  – Sound, pain, stiffness, or grating in the temporomandibular joint (TMJ) with movement
  – Limitation of mandibular movement with possible locking or dislocation
  – Recent research suggests that TMD is a complex disorder with multiple causes consistent with a biopsychosocial model of illness (1)[B].

● System(s) affected: musculoskeletal

● Synonym(s): TMJ syndrome; TMJ dysfunction; myofascial pain–dysfunction syndrome; bruxism; orofacial pain

EPIDEMIOLOGY

Incidence

● Annual first-onset incidence is 3.9%.
● Peak incidence in ages 30 to 50 years

Prevalence

● 6–12% in both adults and older children
● Twice as common in female patients
● Up to 1/2 the population may have at least one sign or symptom of TMD, but most are not limited by symptoms, and <1:4 seek medical or dental treatment.

ETIOLOGY AND PATHOPHYSIOLOGY

● Pathophysiology is multifactorial, involving anatomic, behavioral, emotional, and cognitive factors.
The American Academy of Orofacial Pain categorizes TMD according to three anatomic origins of pain. The change in name from TMJ to TMD emphasizes that many do not suffer from true articular pain.

- Muscle disorders involving the muscles of mastication
  - Occlusomuscular dysfunction (bruxism)
  - Masticatory muscle spasm
  - Myositis
  - Myofibrosis
  - Poorly fitting oral devices (dentures, splints, etc.)
  - Contracture
  - Neoplasia

- Articular disorders of the joint
  - Congenital disorders
  - Inflammatory disorders: synovitis, arthritides, capsulitis, ankyloses
  - Avascular necrosis (rare)
  - TMJ disk derangement, osteoarthritis
  - Hyper- or hypomobile TMJ
  - TMJ trauma: condylar fractures, dislocation

- Cranial bone disorder including the mandible
  - Congenital and developmental disorders
  - Acquired disorders (fracture, neoplasm)

Current consensus is that TMD is not only a local condition, so much as a family of complex disorders that can lead to chronic pain, and often overlap with other chronic pain conditions that reflect CNS sensitization.

- OPPERA study (Orofacial Pain: Prospective Evaluation and Risk Assessment) is assessing the heterogeneity in these disorders.

**Genetics**

Research is ongoing in gene polymorphisms associated with TMD and other pain disorders. These include the catechol O-methyltransferase gene (COMT), which is thought to be associated with changes in pain responsiveness.

**RISK FACTORS**

- Macrotrauma to the face, jaw, and neck, including cervical whiplash injuries and hyperextension of jaw
- Rheumatologic and degenerative conditions involving the TMJ
- Psychosocial stress and poor adaptive capabilities
- Repetitive microtrauma from dental malocclusion, including inappropriate dental treatment
Link with bruxism and jaw/teeth clenching is inconsistent.

**GENERAL PREVENTION**
- Elimination of tension-causing oral habits
- Reduction in overall muscle tension

**COMMONLY ASSOCIATED CONDITIONS**
Craniomandibular disorders, somatization disorder, somatoform pain disorder, other chronic pain syndromes, fibromyalgia, juvenile idiopathic arthritis, tension headache, sleep disturbance, tobacco use

**DIAGNOSIS**
- TMD is a clinical diagnosis, and localized pain is the unifying feature.
- Several research classification systems exist. Most share several of the history and physical findings listed below.

**HISTORY**
- Facial and/or TMJ pain
- Locking/catching of jaw; decreased range of motion
- TMJ noises: clicking, grinding, popping
- Headache, earache, neck pain

**PHYSICAL EXAM**
- Muscle tenderness and restricted pain-free opening are most consistent distinguishing signs.
- Check facial symmetry, muscle hypertrophy, intraoral exam including tooth wear.
- Palpation of muscles of mastication may reproduce pain.
- There may be tenderness over the TMJ.
- Test jaw range of motion (opening, closing, lateral, protrusive) and masticatory muscle strength
  - Maximal (pain-free) jaw opening with interincisal distance <40 mm is suggestive of joint rather than muscle pathology if accompanied by other signs and symptoms (normal 35 to 55 mm).
  - Deviation to the affected side is common.
- Clicking or crepitus of jaw with opening
DIFFERENTIAL DIAGNOSIS
- Condylar fracture/dislocation
- Trigeminal neuralgia
- Dental or periodontal conditions
- Neoplasm of the jaw, orofacial muscles, or salivary glands
- Acute, nondental infection: parotitis, sialadenitis, otitis, mastoiditis
- Jaw claudication: giant cell arteritis
- Migraine or tension type headache
- Ramsay Hunt syndrome (zoster auricular syndrome)

DIAGNOSTIC TESTS & INTERPRETATION
- There are no labs to rule in TMD.
- Blood work may be useful to rule out other conditions (CBC, CMP, ESR, CRP).

Initial Tests (lab, imaging)
- TMD is a clinical diagnosis based primarily on history and physical exam.
- Often, a poor correlation is found between pain severity and pathologic changes seen in joint or muscle tissues. Consider the following for traumatic, infectious, severe, or treatment-resistant cases, with MR or CT more useful as part of surgical workup:
  - Panoramic dental radiographs are a good first-line screen.
  - CT scan allows fine detail of bony structures, preferred for trauma.
  - US: Effusion and findings correlate with MRI and subjective pain.
  - MRI: noninvasive study for disc position; more sensitive than US; can help determine need for surgical management

Diagnostic Procedures/Other
- Local anesthetic nerve block can differentiate orofacial pain of articular versus muscular origin.
- Arthroscopy can be diagnostic for cartilage and bony pathology.

Test Interpretation
Positive findings include:
- Condylar head displacement
- Anterior disc displacement
- Posterior capsulitis
- Loosening of disc and capsular attachments
Chondroid metaplasia of disc leading to disc perforation and degeneration

**TREATMENT**

Signs and symptoms will abate without intervention in most patients. 50% report improvement in 1 year and 85% by 3 years. With conservative therapy, symptoms resolve in 75% of cases within 3 months. Only 5–10% will require surgical intervention.

- Patient education and setting expectations is important as there is no “cure” for TMD, yet most patients will improve with limited interventions.
- Psychosocial interventions, including cognitive-behavioral therapy with or without biofeedback (2)[A]
- Behavior modification to eliminate tension-relieving oral habits including heavy chewing of food and nonfood items as well as potential strain from playing musical instruments that stress or strain the jaw (wind, brass, or string) (2)[A]
- Therapeutic exercises, especially if displacement is present, including formal physical therapy
- Occlusal adjustment cannot be recommended for the management or prevention of TMD, as there is an absence of evidence from RCTs that occlusal adjustment treats or prevents TMD (3)[A].
- Insufficient evidence exists either for or against the use of stabilization splint therapy for the treatment of TMD.
- The American Dental Association recommends a “less is often best” stepwise approach and offers the following stepwise progression for therapy:
  - Eating softer foods
  - Avoiding chewing gum and nail biting
  - Modifying pain with heat or ice
  - Relaxation techniques including meditation and biofeedback
  - Exercises to strengthen jaw muscles
  - Medications
  - Night guards and orthotics

**MEDICATION**

**First Line**
- Acetaminophen
- Naproxen: 500 mg BID stronger evidence than for other NSAIDs (4)[B]
• Topical methylsalicylate
• Gabapentin
• Ibuprofen, if osteoarthritis is suspected (4)[B]

**Second Line**

• Cyclobenzaprine 10 mg nightly more effective than placebo for pain reduction (4)[B]
• Tricyclic antidepressants, SSRIs, or SNRIs; however, SSRIs and some SNRIs may also induce bruxism.

### Acupuncture

• Opiates should be reserved for perioperative or severe or recalcitrant cases (5)[B].

• DMARDs may benefit inflammatory arthropathies such as rheumatoid or psoriatic arthritis.

### Ineffective medications (5)[B]

- The following medications when compared with placebo in RCTs were shown to be ineffective in improving pain and should not be used for the treatment of TMD:
  - Benzodiazepines
  - Topical capsaicin
  - Diclofenac
  - Celecoxib

**ADDITIONAL THERAPIES**

### Joint and muscle injections

- There is very limited evidence to recommend for or against injections into or around the TMJ. Proposed therapies include steroids, hyaluronic acid, local anesthetics, and recently, botulinum toxin.
- Steroids given >3 times annually may accelerate degenerative changes.
- Injections into inferior space or double spaces have better effect than superior space injections alone.
- Recent studies suggest that botulinum toxin type A (Botox) injections may be successful in cases that have failed first-line pharmacologic therapy (4)[B].
- For advanced structural abnormalities, referral for disectomy, arthroplasty, or joint replacement may be warranted. However, strong evidence is lacking for lavage or surgical treatments.

**COMPLEMENTARY & ALTERNATIVE**
MEDICINE

- Glucosamine may be effective if pain is secondary to osteoarthritis of the TMJ (5)[B].
- Multiple electronic diagnostic and treatment modalities are currently marketed to patients; however, the scientific literature does not support the use of electronic diagnostic and treatment devices for TMD at this time.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Relax jaw by disengaging teeth.
- Avoid wide, uncontrolled opening, such as yawning.
- Stress management and behavior modification counseling may be helpful.
- Be aware of any teeth-clenching or grinding habits.

Patient Monitoring

- Ongoing assessment of clinical response to conservative therapies (NSAIDs, behavior modification, occlusal splints) is necessary.
- Surgical procedure (arthroplasty, joint replacement) to correct disc displacement or replace a damaged disc may be indicated only if the patient has not responded to conservative treatment.

DIET

Soft diet to reduce chewing

PROGNOSIS

- With conservative therapy, symptoms resolve in 75% of cases within 3 months.
- Patients benefit most from a comprehensive treatment approach including the following (4):
  - Restoration of normal muscle function
  - Pain control
  - Stress management
  - Behavior modification

COMPLICATIONS
Secondary degenerative joint disease
Chronic TMJ dislocation
Loss of joint range of motion
Depression and chronic pain syndromes
Secondary headache disorder

Headache, Tension

CODES

ICD10

- M26.60 Temporomandibular joint disorder, unspecified
- M26.62 Arthralgia of temporomandibular joint
- M26.63 Articular disc disorder of temporomandibular joint

CLINICAL PEARLS

- The condition called TMD actually designates a number of potential underlying joint and muscle conditions involving the jaw.
- Characteristics of all conditions are pain and functional limitation.
- TMD is a clinical diagnosis; imaging and labs are often of limited utility.
- Cognitive-behavioral therapy reduces pain, depression, and limitation of function.
- Exercises may improve function and pain.
- Evidence is lacking to support occlusion correction or splinting.
- Naproxen, gabapentin, topical methylsalicylate, glucosamine, amitriptyline, acupuncture, and botulinum toxin injections have some evidence of efficacy.
TESTICULAR MALIGNANCIES

Huy T. Tran, MD

BASICS

DESCRIPTION
- Testicular cancer accounts for 1% of all cancers in men; it is the most common solid malignancy in men aged 15 to 34 years (1).
- An estimated 8,850 new cases were diagnosed, and an estimated 410 deaths occurred in the United States in 2016 (2).
- Rates for new cases have been rising 0.8% each year over the last 10 years, but death rates have been stable.
- The median age at diagnosis is 33 years. The median age at death is 41 years.
- Treatment produces an overall 5-year survival of 95.1%; for African American patients, this 5-year survival rate is alarmingly lower but has improved from 86% to 90% (2).

ETIOLOGY AND PATHOPHYSIOLOGY
95% of all malignant tumors arising in the testes are germ cell tumors (GCTs), which are subclassified as follows:
- Seminomatous GCTs: most common type overall
- Nonseminomatous GCTs (NSGCTs): These include embryonal cell carcinoma, choriocarcinoma, yolk sac tumor, teratomas, or often multiple cell types; these are more clinically aggressive tumors.

RISK FACTORS
- Cryptorchidism is the most firmly established risk factor: Relative risk of testicular cancer in all patients with cryptorchidism is 3 to 8, with a lower relative risk of 2 to 3 in those undergoing orchiopexy by age 12 years; in patients with unilateral cryptorchidism, the relative risk of testicular cancer in the contralateral normally descended testis is negligible (3).
- Personal history of testicular cancer
- Use of muscle building supplements
- Positive family history for testicular cancer
- Testicular dysgenesis
- Klinefelter syndrome
Caucasian race
HIV infections

GENERAL PREVENTION
No evidence that screening for testicular cancer is effective (4)

DIAGNOSIS

HISTORY
- A painless solid testicular mass is pathognomonic for testicular cancer.
- Clinical symptoms of epididymitis or orchitis that do not respond to treatment warrant further evaluation.
- Gynecomastia can be a rare systemic endocrine manifestation of testicular neoplasm.

PHYSICAL EXAM
- Testicular exam: Palpate for size, consistency, and nodules; masses do not transilluminate; a firm, hard, or fixed area should be considered suspicious.
- Lymph node and abdominal exam
- Gynecomastia

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- α-Fetoprotein (AFP), β-human chorionic gonadotropin (β-hCG), lactate dehydrogenase (LDH), creatinine, chemistry profile, complete blood count, liver enzymes, chest x-ray (CXR), and testicular ultrasound (US)
- Tumor markers AFP, β-hCG, and LDH are used to assist with diagnosis, prognosis, assessing treatment outcome, and monitoring for relapse:
  - AFP
    - Produced by nonseminomatous testicular cancer and is therefore associated with this histologic type
    - Those with a histologically “pure” testicular seminoma and an elevated AFP are assumed to possess an undetected focus of nonseminoma tumor.
  - β-hCG
    - May be associated with both seminomatous or nonseminomatous tumors
    - Hypogonadism and marijuana use may cause benign elevations of β-hCG.
- LDH is less specific than AFP.
Testicular US is the initial study.
If an intratesticular mass is identified, measure serum AFP, LDH, and β-hCG and order a CXR.
CT scan of the abdomen/pelvis, positron emission tomography (PET) scan, MRI of the brain, and bone scan are used for staging and metastases evaluation as clinically indicated.

Diagnostic Procedures/Other
- Radical inguinal orchietomy is the primary procedure for diagnosis and treatment.
- Testicular biopsy may be rarely considered if a suspicious intratesticular abnormality is identified on US; however, testicular microcalcification on US without any other abnormality can simply be observed and does not demand a biopsy.
- For those with unilateral testicular cancer, contralateral testicular biopsy is not routinely performed but should be considered when there is a cryptorchid testis, marked testicular atrophy, or a suspicious US for intratesticular abnormalities.

Test Interpretation

Clinical staging (5):
- Stage 0: carcinoma in situ
- Stage IA: tumor limited to testis and epididymis without vascular/lymphatic invasion; tumor may invade into the tunica albuginea but not the tunica vaginalis; normal serum tumor markers
- Stage IB: tumor limited to testis and epididymis with vascular/lymphatic invasion or tumor extending through tunica albuginea with involvement of tunica vaginalis; tumor invades the spermatic cord with or without vascular/lymphatic invasion; tumor invades the scrotum with or without vascular/lymphatic invasion; no lymph node involvement or distant metastasis; normal serum tumor markers
- Stage IS: any tumor with elevated serum tumor markers but no nodal involvement or metastasis
- Stage IIA: any tumor with lymph node mass/masses <2 cm
- Stage IIB: any tumor with lymph node mass/masses 2 to 5 cm
- Stage IIC: any tumor with lymph node mass >5 cm
- Stage IIIA: any tumor/lymph node presence; with nonregional nodal or pulmonary metastasis; either serum tumor markers normal or with mild
Stage IIIB: any tumor/lymph node presence; no distant metastasis or nonregional nodal involvement or pulmonary metastasis; with moderately elevated serum tumor markers

Stage IIIC: any tumor/lymph node presence; with or without any metastasis; with greatly elevated serum tumor markers

DIFFERENTIAL DIAGNOSIS
Epidermoid cyst, epididymitis, hernia, hydrocele, hematoma, lymphoma, orchitis, spermatocele, testicular torsion, varicocele

TREATMENT
GENERAL MEASURES

Seminoma: Specifics are noted in the National Comprehensive Cancer Network guidelines (1):

- Stages IA, IB: Options may include surveillance (preferred) (for low tumor load malignancy, i.e., pT1–pT3), single-agent carboplatin, or radiotherapy (2)[A].
- Stage IS: Repeat elevated serum tumor marker and abdominal/pelvic CT scan (2)[A].
- Stage IIA: radiotherapy to include paraaortic and ipsilateral iliac lymph nodes (preferred) or primary chemotherapy (2)[A]
- Stage IIB: primary chemotherapy (preferred) or radiotherapy in select nonbulky cases to include paraaortic and ipsilateral iliac lymph nodes (2)[A]
- Stages IIC, III
  - Good risk (any primary site and no nonpulmonary visceral metastases and normal AFP with any β-hCG or LDH): primary etoposide and cisplatin (EP) or bleomycin, etoposide, and cisplatin (BEP) chemotherapy (1)
  - Intermediate risk (any primary site and nonpulmonary visceral metastases and normal AFP with any β-hCG or LDH): primary BEP chemotherapy (1)

Nonseminoma: Tumors with both seminomatous and nonseminomatous histology are managed as nonseminomatous. See “National Comprehensive Cancer Network guidelines” (1):

- Stage IA: nonseminomatous surveillance protocol (preferred) or nerve-
sparing retroperitoneal lymph node dissection (RPLND) (2)[A]

- Stage IB: nerve-sparing RPLND or primary BEP chemotherapy (2)[A]; for T2 only can enter nonseminomatous surveillance protocol (2)[B]

- Stage IS: primary chemotherapy followed by response evaluation:
  - Complete response, negative tumor markers: nonseminomatous surveillance protocol (2)[A]
  - Partial response, negative tumor markers: surgical resection of all residual masses (2)[A]
  - Incomplete response: consider second-line therapy (2)[A]

- Stage IIA
  - Negative tumor markers: nerve-sparing RPLND (2)[A] or primary chemotherapy (2)[B]
  - Persistent marker elevation: primary chemotherapy followed by response evaluation
    - Complete response, negative tumor markers: nonseminomatous surveillance protocol (2)[A] or bilateral RPLND +/- nerve-sparing in select cases (2)[B]
    - Partial response, negative tumor markers: surgical resection of all residual masses (2)[A]
    - Incomplete response: Consider second-line therapy (2)[A].

- Stage IIB
  - Negative tumor markers: primary chemotherapy or nerve-sparing RPLND in highly selected cases (2)[A]
  - Persistent marker elevation: primary chemotherapy followed by response evaluation
    - Complete response, negative tumor markers: nonseminomatous surveillance protocol (2)[A] or bilateral RPLND +/- nerve-sparing in selected cases (2)[B]
    - Partial response, negative tumor markers: surgical resection of all residual masses (2)[A]
    - Incomplete response: Consider second-line therapy (2)[A].

- Stage IIC: primary chemotherapy followed by response evaluation as per stages IIA and IIB (2)[A]

- Stages IIIA, IIIB, and IIIC: primary chemotherapy depending on risk profile, which is based on tumor, metastases, and postorchiectomy serum tumor markers (2)[A]

- Brain metastases: primary chemotherapy +/- radiotherapy, +/- surgery, as clinically indicated
MEDICATION

First Line
Primary chemotherapy regimens for GCTs:

- EP: Etoposide 100 mg/m²/day IV on days 1 to 5, cisplatin 20 mg/m²/day IV on days 1 to 5; repeat every 21 days (1)[A].
- BEP: Etoposide 100 mg/m²/day IV on days 1 to 5, cisplatin 20 mg/m²/day IV on days 1 to 5; bleomycin 30 U/dose IV weekly on days 1, 8, and 15 or days 2, 9, and 16; repeat every 21 days (1)[A].
- VIP: Etoposide 75 mg/m²/day IV on days 1 to 5; mesna 120 mg/m² slow IV push before ifosfamide on day 1 and then mesna 1,200 mg/m² IV continuous infusion on days 1 to 5; ifosfamide 1,200 mg/m²/day on days 1 to 5; cisplatin 20 mg/m²/day IV on days 1 to 5, repeat every 21 days (1)[A].

Second Line
- These agents are considered in patients who do not respond to first-line therapy or those who experience a recurrence: carboplatin, cisplatin, etoposide, ifosfamide, mesna, paclitaxel, and vinblastine (1)[A].
- Gemcitabine, oxaliplatin, and paclitaxel are used in palliative chemotherapy regimens (1)[A].

ADDITIONAL THERAPIES
Consider sperm banking before treatment that may compromise fertility; rarely covered by insurance

SURGERY/OTHER PROCEDURES
- Radical inguinal orchiectomy: primary treatment for testicular cancer for all patients; prosthesis can be inserted at this time.
- RPLND identifies nodal metastases and provides accurate pathologic staging of the retroperitoneum.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Pure seminoma: Specifics are noted in the National Comprehensive Cancer Network guidelines (1,2)[A]:
– Stages IA, IB: in general, H&P, optional tumor markers, every 3 to 6 months for 1 year, every 6 to 12 months for years 2 to 3 and then annually for years 4 to 5; abdominal/pelvic CT at 3, 6, and 12 months then every 6 to 12 months for years 2 to 3, every 12 to 24 months for years 4 to 5; CXR, as clinically indicated; less frequent if adjuvant therapy is given
– Stage IS: Repeat elevated serum tumor marker and assess with abdominal/pelvic CT scan for evaluable disease.
– Stages IIA, IIB (select): in general, H&P, optional tumor markers every 3 months for year 1, every 6 months for years 2 to 5; abdominal/pelvic CT at 3 and 6 to 12 months, then annually for years 2 to 3 and then as clinically indicated; CXR every 6 months for years 1 to 2
– Stages IIB (select), IIC, and III: Check all serum tumor markers along with chest, abdominal, and pelvic CT:
  o Residual mass 0 to 3 cm and normal serum tumor markers: H&P, AFP, β-hCG, LDH, CXR every 2 months for year 1, every 3 months for year 2, every 6 months for years 3 to 4 and then annually; abdominal/pelvic CT scan at 3 to 6 months then as clinically indicated, PET scans as clinically indicated
  o Residual mass >3 cm and normal serum tumor markers: PET scan 6 weeks after chemotherapy:
    ■ Negative PET scan: abdominal/pelvic CT scans every 6 months for year 1 and then annually for 5 years
    ■ Positive PET scan: Consider RPLND or second-line chemotherapy or radiotherapy.
– Any recurrence: Treat according to extent of disease at relapse.
• Nonseminoma: Specifics are noted in the National Comprehensive Cancer Network guidelines (1):
  – Stages IA and IB on surveillance only: H&P, AFP, β-hCG, LDH, every 2 months for year 1, every 3 months for year 2, every 4 to 6 months for year 3, every 6 months for year 4, annually thereafter; CXR and abdominal/pelvic CT depending on stage IA or stage IB
  – Follow-up after complete response to chemotherapy and RPLND in general: H&P, AFP, β-hCG, LDH every 2 to 3 months for years 1 to 2, every 6 months for years 3 to 5, annually thereafter; abdominal/pelvic CT every 6 months for year 1, annually for year 2, as clinically indicated thereafter
  – Follow-up after RPLND only: H&P, AFP, β-hCG, LDH, CXR every 2 months for year 1, every 3 months for year 2, every 4 months for year 3, every 6 months for year 4, annually thereafter; abdominal/pelvic CT at 3 to
4 months and, as clinically indicated, thereafter; CXR every 2 to 4 months for year 1, 3 to 6 months for year 2, annually thereafter

**PROGNOSIS**

>90% of patients diagnosed are cured, including 70–80% with advanced tumors (1).

**COMPLICATIONS**

- Surgical: hematoma, hemorrhage, infection, and infertility
- Radiotherapy: radiation enteritis and infertility
- Late complications (6):
  - Cardiovascular toxicity and second malignancies each have a 25-year risk of about 16% in those treated with chemotherapy and/or radiotherapy.
  - Risk for secondary malignancies remains increased for at least 35 years after treatment.
  - Increased incidence of metabolic syndrome occurs and is likely associated with lower testosterone levels.
  - Other late complications associated with chemotherapy, depending on the regimen, include chronic neurotoxicity, ototoxicity, renal function impairment, and pulmonary fibrosis.
- The incidence of late relapse in treated testicular cancer is now estimated to be 2–6%; the time to late relapse ranges from 2 to 32 years, with a median of 6 years (6).

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
- C62.00 Malignant neoplasm of unspecified undescended testis
- C62.10 Malignant neoplasm of unspecified descended testis

**CLINICAL PEARLS**

- Testicular cancer is the most common solid organ tumor in men aged 15 to 34 years.
- Testicular US is initial imaging of choice for testicular pathology.
- Radical inguinal orchiectomy is used for both diagnosis and treatment, with possible radiotherapy or chemotherapy as adjuvant treatment.
- 96% overall survival at 10 years after diagnosis and treatment
TESTICULAR TORSION

Jonathan Green, MD, MSCI • Michael P. Hirsh, MD, FACS, FAAP

BASICS

DESCRIPTION

• Twisting of testis and spermatic cord, resulting in acute ischemia and loss of testis if unrecognized:
  – Intravaginal torsion: occurs within tunica vaginalis, only involves testis and spermatic cord
  – Extravaginal torsion: involves twisting of testis, cord, and processus vaginalis as a unit; typically seen in neonates

• System(s) affected: reproductive

Geriatric Considerations
Rare in this age group

Pediatric Considerations
Peak incidence at age 14 years

EPIDEMIOLOGY

Incidence

• ~1/4,000 males before age 25 years

• Predominant age:
  – Occurs from newborn period to 7th decade
  – 65% of cases occur in 2nd decade, with peak at age 14 years.
  – Second peak in neonates (in utero torsion usually occurs around week 32 of gestation)

ETIOLOGY AND PATHOPHYSIOLOGY

• Twisting of spermatic cord causes venous obstruction, edema of testis, and arterial occlusion.

• “Bell clapper” deformity is most common anatomic anomaly predisposing to intravaginal torsion:
– High insertion of the tunica vaginalis on the spermatic cord, resulting in increased testicular mobility within tunica vaginalis
– Bilateral in ~80% of patients
• No clear anatomic defect is associated with extravaginal testicular torsion:
  – In neonates, the tunica vaginalis is not yet well attached to scrotal wall, allowing torsion of entire testis including tunica vaginalis.
• Usually spontaneous and idiopathic
• 20% of patients have a history of trauma.
• 1/3 have had prior episodic testicular pain.
• Contraction of cremasteric muscle or dartos may play a role and is stimulated by trauma, exercise, cold, and sexual stimulation.
• Increased incidence may be due to increasing weight and size of testis during pubertal development.
• Possible alterations in testosterone levels during nocturnal sex response cycle; possible elevated testosterone levels in neonates
• Testis must have inadequate, incomplete, or absent fixation within scrotum.
• Torsion may occur in either clockwise or counterclockwise direction.

**Genetics**
• Unknown
• Familial testicular torsion, although previously rarely reported, may involve as many as 10% of patients.

**RISK FACTORS**
• May be more common in winter
• Paraplegia
• Previous contralateral testicular torsion

**DIAGNOSIS**

**HISTORY**
• Acute onset of pain, often during period of inactivity
• Onset of pain usually sudden but may start gradually with subsequent increase in severity
• Nausea and vomiting are common:
  – Presence may increase the likelihood of testicular torsion versus other differential diagnoses.
Prior history of multiple episodes of testicular pain with spontaneous resolution in an episodic crescendo pattern may indicate intermittent testicular torsion.

**PHYSICAL EXAM**
- Scrotum is enlarged, red, edematous, and painful.
- Testicle is swollen and exquisitely tender.
- Testis may be high in scrotum with a transverse lie.
- Absent cremasteric reflex

**DIFFERENTIAL DIAGNOSIS**
- Torsion appendix testis (this may account for 35–67% of acute scrotal pain cases in children)
- Epididymitis (8–18% of acute scrotal pain cases)
- Orchitis
- Incarcerated or strangulated inguinal hernia
- Acute hydrocele
- Traumatic hematoma
- Idiopathic scrotal edema
- Acute varicocele
- Epididymal hypertension (venous congestion of testicle or prostate due to sexual arousal that does not end in orgasm)
- Testis tumor
- Henoch-Schönlein purpura
- Scrotal abscess
- Leukemic infiltrate

**DIAGNOSTIC TESTS & INTERPRETATION**
- Doppler US may confirm testicular swelling but is diagnostic by demonstrating lack of blood flow to the testicle; PPV of 89.4% (1,2)[B]
- In boys with intermittent, recurrent testicular torsion, both Doppler US and radionuclide scintigraphy findings will be normal (2)[B].

**Diagnostic Procedures/Other**
- Doppler US flow detection demonstrates absent or reduced blood flow with torsion and increased flow with inflammatory process (reliable only in first 12 hours) (2)[B].
- Radionuclide testicular scintigraphy with technetium-99m pertechnetate
demonstrates absent/decreased vascularity in torsion and increased vascularity with inflammatory processes (including torsion of appendix testes) (3)[C].

**Test Interpretation**
- Venous thrombosis
- Tissue edema and necrosis
- Arterial thrombosis
- Decreased Doppler flow also seen in hydrocele, abscess, hematoma, or scrotal hernia (2)
- Sensitivity of radionuclide testicular scintigraphy is decreased relative to ultrasonography because hyperemia in the torsed testicle can mimic flow (3).

**TREATMENT**
- Manual reduction: best performed by experienced physician; may be successful, facilitated by lidocaine 1% (plain) injection at level of external ring:
  - Difficult to determine success of manual reduction, especially after giving local anesthesia
  - Even if successful, must always be followed by surgical exploration, urgently but not emergently (4)[C]
- Surgical exploration via scrotal approach with detorsion, evaluation of testicular viability, orchidopexy of viable testicle, orchiectomy of nonviable testicle (1)[B]
- In boys with a history of intermittent episodes of testicular pain, scrotal exploration is warranted with testicular fixation if abnormal testicular attachments are confirmed (1)[B].

**GENERAL MEASURES**
Early exam is crucial because necrosis of the testicle can occur after 6 to 8 hours (5)[C].

**SURGERY/OTHER PROCEDURES**
Operative testicular fixation of the torsed testicle after detorsion and confirmation of viability:
- At least 3- or 4-point fixation with nonabsorbable sutures between the tunica
albuginea and the tunica vaginalis (1)[B]
- Excision of window of tunica albuginea with suture to dartos fascia (1)[B]
- Any testis that is not clearly viable should be removed (1)[B].
- Testes of questionable viability that are preserved and pexed invariably atrophy (1)[B]
- Bilateral testicular fixation is recommended by many surgeons (1)[B].
- Contralateral testicle frequently has similar abnormal fixation and should be explored (1)[B],(4)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Postoperative visit at 1 to 2 weeks
- Yearly visits until puberty may be needed to evaluate for atrophy.

DIET
Regular

PATIENT EDUCATION
Possibility of testicular atrophy in salvaged testis with depressed sperm counts. Importantly, fertility rates in patients with one testicle remain excellent.

PROGNOSIS
- Testicular salvage:
  - Salvage is related directly to duration of torsion (85–97% if within 6 hours, 20% after 12 hours <10% if >24 hours) (5).
  - The degree of torsion is related to testicular salvage:
    o The median degree of torsion is <360 in patients who are explored and orchidopexy performed.
- 80–94% may have depressed spermatogenesis related to duration of ischemic injury (possibly related to autoimmune-mediated injury) (5).
- Up to 45% of patients undergoing orchiopexy for testicular torsion will develop atrophy of testicle.

COMPLICATIONS
- Possible testicular atrophy
- Abnormal spermatogenesis
- Infertility:
  - Fertility rates with one testicle remain excellent.
  - Nearly 36% of patients who experience torsion have sperm counts <20 million/mL (3).

REFERENCES

CODES

ICD10
- N44.00 Torsion of testis, unspecified
- N44.01 Extravaginal torsion of spermatic cord
- N44.03 Torsion of appendix testis

CLINICAL PEARLs

- The diagnosis of testicular torsion is usually made by physical exam. Patients with suspected torsion should be taken to the OR without delay. If diagnosis is in question, a testicular Doppler US may be done to evaluate blood flow.
- Although testicular necrosis may be present within 6 to 8 hours of torsion, this is highly variable.
Infertility can be a problem even if the testicle is viable. Autoimmune antibodies may be produced, and they may affect subsequent fertility.
**TESTOSTERONE DEFICIENCY**

*Michael Lao, MD • Gregory P. Murphy, MD • Stanton C. Honig, MD*

---

**BASICS**

**DESCRIPTION**

- Testosterone (T) is a critical anabolic hormone involved in various key metabolic pathways.
- It is the principle circulating androgen in males.
- Critical in bodily processes of the cardiovascular, reproductive, and central nervous systems.
- Testosterone deficiency (TD), or hypogonadism, is characterized by low levels of T, often in addition with signs and symptoms attributed to low T levels.
- No universally accepted threshold of T concentration to distinguish eugonadal from hypogonadal men, but the FDA definition is T <300 ng/dL.
- T levels can be affected by disruptions to the hypothalamic–pituitary–testis axis, age, and medical comorbidities.
- T levels correlate with overall health and may be associated with sexual dysfunction.
- T levels decline by 1% per year after age 40 years.
- Special consideration is needed for men with low T who desires future fertility.
- Synonym(s): hypogonadism, hypoandrogenism, androgen deficiency, and low T.

---

**EPIDEMIOLOGY**

**Incidence**

- Overall incidence increases with age.
- Symptomatic TD in United States ages 30 to 79 years is 5.6%.
- 481,000 new cases in United States in men 40 to 69 years.

**Prevalence**

- Estimates of TD vary widely, but typically 20% of men >60 years, 30% >70 years, and 50% >80 years of age.
2 to 4 million men in United States

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Normal hypothalamic–pituitary–testis axis:
  - Hypothalamus produces GnRH, which stimulates pituitary to produce follicle-stimulating hormone (FSH) and luteinizing hormone (LH).
  - LH stimulates Leydig cells to produce T; responsible for 90% of the body’s T
  - T inhibits LH and GnRH through negative feedback at level of hypothalamus and pituitary.
- Primary hypogonadism: Testes produces insufficient amount of T; FSH/LH levels are elevated.
- Secondary hypogonadism: low T from inadequate production of LH
- Congenital syndromes: cryptorchidism, Klinefelter, hypogonadotropic hypogonadism
- Acquired: cancer, trauma, orchiectomy, steroid use
- Infectious: mumps orchitis, HIV, tuberculosis
- Systemic: Cushing, hemochromatosis, autoimmune, severe illness (e.g., renal and liver disease), metabolic syndrome, obesity, obstructive sleep apnea
- Drugs and medications: LHRH agonists (leuprolide), corticosteroids, ethanol, ketoconazole, spironolactone, marijuana, opioids, cimetidine, SSRIs
- Elevated prolactin: prolactinoma, dopamine antagonists (neuroleptics and metoclopramide)

**Genetics**

- Usually normal
- Klinefelter: XXY karyotype
- Kallmann syndrome: abnormal GnRH secretion due to abnormal hypothalamus development

**RISK FACTORS**

- Obesity, diabetes, COPD, depression, thyroid disorders, malnutrition, alcohol, stress
- Chronic infections or inflammatory diseases
- Medications that affect T production or metabolism
- Undescended testicles
- Trauma, cancer, testicular radiation, chemotherapy, disorders of the pituitary and/or hypothalamus
GENERAL PREVENTION
- General health maintenance and treatment of obesity
- Recent data suggests in men with low T and unexplained anemia; T replacement can significantly increase hemoglobin levels (1).
- Recent data suggests men with low bone mineral density and low T can increase bone density and bone strength with T replacement.
- Older men with low T and age-associated memory impairment; T replacement was not seen as beneficial.

COMMONLY ASSOCIATED CONDITIONS
- Infertility, erectile dysfunction, low libido
- Poorer health outcomes
- Osteopenia/osteoporosis and fractures
- Diabetes and insulin resistance, metabolic syndrome
- Increased body weight, adiposity
- Depressed mood, poor concentration, irritability

DIAGNOSIS

HISTORY
Check for
- Congenital and developmental abnormalities
- **Infertility, loss of libido, erectile dysfunction** (2)[A]
- Depression, fatigue, difficulty with concentration
- Decreased muscle strength, energy level
- Increase in body fat, development of diabetes
- Bone fractures from relatively minor trauma
- Testicular trauma, infection, radio- or chemotherapy
- Decrease in testicle size or consistency
- Headaches or vision changes
- Medications

PHYSICAL EXAM
- Infancy: ambiguous genitalia
- Puberty
  - Impaired growth of penis, testicles
  - Lack of secondary male characteristics
– Gynecomastia, eunuchoid habitus

• Adulthood
  – Decreased muscular development, visceral fat distribution
  – Presence of gynecomastia
  – Skin changes to suggest hemochromatosis
  – Eunuchoid habitus
• Genitourinary exam
  – Small and/or soft testicles

DIFFERENTIAL DIAGNOSIS

• Delayed puberty
• Obesity
• Normal aging
• Prior anabolic steroid abuse

DIAGNOSTIC TESTS & INTERPRETATION

• T levels vary widely; they are subject to diurnal, seasonal, and age-related variations. There are multiple assays, each with unique characteristics. Measurement should be obtained between 6 and 10 AM. Confirmation with a second measurement may be necessary. Free T with total T is generally preferred. Measurements should not be obtained during acute illness. T circulates in blood primary bound to SHBG or albumin. Only 2–3% of total T is found free. Free and albumin-bound T is considered bioavailable. Laboratory findings must be interpreted in the appropriate clinical setting. Bioavailable T is considered most important.

• Lower limit of normal in most reference laboratories for total testosterone is 280 to 300 ng/dL (9.8 to 10.4 nmol/L). The lower limit of normal for free testosterone is 5 to 9 pg/mL (0.17 to 0.31 nmol/L).

Initial Tests (lab, imaging)

• In symptomatic individuals, morning T level is initial test. Morning timing is more important for younger men in whom there is more diurnal variation. If initial AM testosterone is low, and confirmed on repeat test, further evaluation is appropriate (3)[A].

• Endocrine evaluation should include LH and FSH to differentiate between primary versus secondary hypogonadism. Consider estradiol and prolactin levels.

• If primary hypogonadism of unknown origin and physical exam reveals
abnormalities, consider obtaining karyotype (e.g., Klinefelter).
- If secondary hypogonadism, evaluation may consist of prolactin, iron saturation, pituitary function testing, and/or MRI of pituitary.
- Imaging is not helpful in the initial diagnosis of TD.
- No evidence to support screening for TD in the general population

**Follow-Up Tests & Special Considerations**
- Routine blood work to measure T response to interventions (e.g., hematocrit, prostate-specific antigen [PSA])
- Dual energy x-ray absorptiometry (DEXA) to measure bone mineral density in men with severe TD or fracture from minimal trauma
- Pituitary MRI: if there is elevation of prolactin more than twice the upper limit of normal or LH/FSH below normal range

**TREATMENT**
Testosterone replacement therapy (TRT) has been shown to effectively ameliorate many symptoms of TD. TRT is recommended for symptomatic men (e.g., low libido and/or erectile dysfunction, low energy level, constitutional symptoms, etc.) with low T levels ≤300 ng/dL obtained in the morning; not recommended for older men with low T levels in absence of signs or symptoms

**GENERAL MEASURES**
- Confirm suspicion.
- Obtain hematocrit, PSA in men >40 years, prolactin, LH/FSH, SHBG, estradiol if obese.
- Baseline physical exam including digital rectal exam, and International Prostate Symptom Score (IPSS)
- Correction of underlying cause
- Considerations
  - Is future fertility an issue? Different treatment strategies are used in men of reproductive age.
  - Current evidence fails to demonstrate that higher serum T is associated with greater risk of prostate cancer development (4)[A].
  - Safety of TRT in existing prostate cancer is still uncertain and contraindicated in package insert.
  - 2010 Endocrine Guidelines: Patients with organ-confined prostate cancer who have undergone radical prostatectomy and have been disease-free for
≥2 years after surgery with undetectable PSA may be considered for T replacement on an individualized basis. Lack of data from randomized trials precludes a general recommendation.

- TRT should not be used in men with hematocrit >54%, untreated obstructive sleep apnea, uncontrolled CHF, severe lower urinary tract symptoms with an IPSS >19 (5)[A].
- TRT is not recommended for mood or strength improvement in otherwise healthy men, or asymptomatic men with low T measurements (5)[A].
- Carefully weigh risks and benefits in men at elevated cardiovascular risk (5,6)[A].
- Clinicians can consider starting short-term TRT as an adjunctive in men with HIV and low T to promote weight maintenance and gains in lean body mass and strength.

**MEDICATION**

**ALERT**

Avoid contact with females or children (see package insert) in patients applying gel preparations.

- Oral therapy is not recommended due to significant hepatotoxicity.
- The FDA has cautioned that T is approved for men with confirmed low T by laboratory testing and caused by certain medical conditions, NOT solely due to aging.
- Despite prior data showing no clear association between TRT and CV disease, there have been several recent papers suggesting that TRT use puts patients at an increased risk for CV disease. These papers have been criticized widely for being flawed due to comparison of unequal groups, short and inaccurate endpoints, flawed laboratory testing, erroneous exclusion criteria, and atypical statistical analysis. Despite this, an FDA panel concluded that there is a possible increased CV risk associated with testosterone use.
- TRT (FDA-approved)
  - Topical gels/solutions: most common
    - Multiple FDA-approved formulations
    - Most frequently prescribed in United States
    - Mimics normal daily circadian rhythm
    - Good absorption, but 15–20% are nonresponders
    - Transfer concern to children and women.
    - Gel application: arms, back, axilla, and groin
– Testosterone pellets (Testopel)
  o Minor office procedure with mild discomfort
  o Long-acting formulation, 3 to 4 months
  o 1–2% risk of infection or pellet extrusion

– Transdermal patch (Androderm)
  o Achieves less robust levels
  o Convenient over gels, no risk of transference
  o High incidence of skin irritation

– Testosterone cypionate and enanthate (short-acting)
  o Injectable (IM), inexpensive
  o Inconvenient: injections every 1 to 3 weeks
  o Starting dose: 100 mg/week, or 200 mg/2 weeks
  o Roller coast effect: Levels rise and fall.

– Testosterone undecanoate (long-acting)
  o Injectable, expensive, convenient
  o Small risk of oil embolism, needs observation in office for 30 minutes postinjection
  o Given approximately every 8 to 12 weeks

– Buccal application (Striant)
  o Adheres to gum line, irritation in 16.3%
  o Poor compliance, every 12 hours application

– Nasal gel (Natesto)
  o Levels overdosing schedule are variable.
  o TID dosing, nasal irritation

• Off-label treatment
  – Human chorionic gonadotropin (hCG)
    o Structure similar to LH, mimics its actions
    o 3 times per week starting at 1,500 IU SC
    o Poor compliance
    o Maintenance of testicular volume and fertility
    o Used in men wanting to preserve fertility

  – Clomiphene citrate: oral agent
    o Increases T by interfering with negative feedback, resulting in increased LH and FSH
    o Starting dose of 25 mg daily 3 to 7 times weekly
    o Used in men wanting to preserve fertility

  – Aromatase inhibitors (Arimidex): oral agent
    o Blocks conversion of T to estradiol
    o Does not negatively impact spermatogenesis and testicular volume
Utilized in cases of low T/estradiol ratio
– Combination TRT with low dose hCG may preserve and support fertility in hypogonadal men hoping for future paternity.

ISSUES FOR REFERRAL

- PSA >4 ng/ml or >3 ng/ml in high-risk individuals, and/or abnormal prostate exam, worsening symptoms of BPH (IPSS>19) should be referred to urology.
- Worsening CHF, OSA, polycythemia should be referred to the appropriate providers.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Necessary to monitor effectiveness of therapy as well as for adverse effects: initially 3 to 6 months after treatment initiation and then annually
- Measure hematocrit at baseline, at 3 to 6 months, and then annually. If hematocrit >54% or symptomatic, stop therapy until hematocrit decreases to a safe level. Treatment includes phlebotomy, blood donation, or adjustment of dose.
- Evaluate patient for hypoxia and sleep apnea.
- Bone mineral density after 1 to 2 years of therapy in men with osteoporosis or low trauma fracture
- Recent meta-analysis of randomized trials did not show aggravation of LUTS after TRT. Men with mild to moderate IPSS did not have significant changes compared to placebo. However, most men with IPSS >19 (severe) were excluded.
- Prostate exam done regularly every 6 to 12 months
- Refer to urology when increase in PSA >0.7 ng/mL within any 12-month period of T treatment or detection of prostatic abnormality on prostate exam.

DIET

Healthy diet and weight reduction if obese

PATIENT EDUCATION

- TD is chronic and likely to need lifelong therapy.
T replacement comes with many risks, and it is very important to regularly monitor outcomes.
Women and children must not be allowed to come in contact with TRT gel products.

PROGNOSIS
- Sustained reversal of symptoms can be achieved when serum levels of T fall in the normal range.
- Adverse health outcomes seen in many with chronically low levels of T such as osteoporosis

COMPLICATIONS
Complications of T replacement
- Decreased testicular volume, azoospermia in 40% of patients on TRT, infertility
- Fluctuations in mood or libido
- Gynecomastia and growth of breast cancer
- Acne and oily skin
- Erythrocytosis (increased hematocrit)
- Exacerbation of sleep apnea
- Hepatotoxicity with prolonged oral use
- Possible prostate enlargement with or without worsening symptoms of BPH
- Unknown cardiovascular risks

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**
- E29.1 Testicular hypofunction
- E89.5 Postprocedural testicular hypofunction

**CLINICAL PEARLS**

- T deficiency is common and prevalence increases with age.
- T deficiency can have negative adverse impact on many bodily systems.
- Symptomatic men with sexual dysfunction, obesity, and metabolic diseases should be tested for T deficiency and treated.
- Initial test of choice is a morning total and free T; if low, repeat measurements.
- TRT in the appropriately selected population can increase lean mass, reduce fat mass, increase bone mineral density, improve libido, improve unexplained anemia, and improved erections. It, however, has not been shown to improve cognition or memory impairment in the elderly.
A group of inherited hematologic disorders that affect the synthesis of adult hemoglobin tetramer (HbA) \((1,2)[C]\)

\(\alpha\)-Thalassemia is due to a deficient synthesis of \(\alpha\)-globin chain, whereas \(\beta\)-thalassemia is due to a deficient synthesis of \(\beta\)-globin chain:

- The synthesis of the unaffected globin chain proceeds normally.
- This unbalanced globin chain production causes unstable hemoglobin tetramers, which leads to hypochromic, microcytic RBCs, and hemolytic anemia.

\(\alpha\)-Thalassemia is more common in persons of Mediterranean, African, and Southeast Asian descent, whereas \(\beta\)-thalassemia is more common in patients of African and Southeast Asian descent.

**Types**
- Thalassemia (minor) trait (\(\alpha\) or \(\beta\)): absent or mild anemia with microcytosis and hypochromia
- \(\alpha\)-Thalassemia major with hemoglobin Barts usually results in fatal hydrops fetalis (fluid in \(\geq 2\) fetal compartments secondary to anemia and fetal heart failure).
- \(\alpha\)-Thalassemia intermedia with hemoglobin H (hemoglobin H disease): results in moderate hemolytic anemia and splenomegaly
- \(\beta\)-Thalassemia major: results in severe anemia, growth retardation, hepatosplenomegaly, bone marrow expansion, and bone deformities. Transfusion therapy is necessary to sustain life.
- \(\beta\)-Thalassemia intermedia: milder disease; transfusion therapy may not be needed or may be needed later in life.

Other variants include hemoglobin E/\(\beta\)-thalassemia in Southeast Asians, which often mimics the severity of \(\alpha\)-thalassemia major; delta thalassemia; hemoglobin H Constant Spring.

System(s) affected: hematologic/lymphatic/immunologic, cardiac, hepatic

Synonym(s): Mediterranean anemia; hereditary leptocytosis; Cooley anemia
**Pediatric Considerations**
- β-Thalassemia major causes symptoms during early childhood, usually starting at 6 months of age, and requires periodic transfusions to sustain life.
- Newborn’s cord blood or heel stick should be screened for hemoglobinopathies with hemoglobin electrophoresis or comparably accurate test, although this primarily detects sickle cell disease.

**Pregnancy Considerations**
- Preconception genetic counseling is advised for couples at risk for having a child with thalassemia and for parents or other relatives of a child with thalassemia.
- Once pregnant, a chorionic villus sample at 10 to 11 weeks’ gestation or an amniocentesis at 15 weeks’ gestation can be done to detect point mutations or deletions with polymerase chain reaction (PCR) technology.

**EPIDEMIOLOGY**

**Incidence**
- Occurs in ~4.4/10,000 live births
- Predominant age: Symptoms start to appear 6 months after birth with β-thalassemia major.
- Predominant sex: male = female

**Prevalence**
- Worldwide, ~200,000 people are alive with β-thalassemia major and <1,000 patients are in the United States.
- In the worldwide population, an estimated 1.5% are β-thalassemia carriers and 5% α-thalassemia carriers.

**ETIOLOGY AND PATHOPHYSIOLOGY**
Unknown; it is unclear how the imbalance of β-globulin in α-thalassemia and α-globin in β-thalassemia results in ineffective red blood cell genesis and hemolysis.

**Genetics**
- Inherited in an autosomal recessive pattern
- α-Thalassemia results from a deletion of ≥1 of the 4 genes, 2 on each chromosome 16, responsible for α-globin synthesis. 1-gene deletion is a silent
carrier state, 2-gene deletion is the trait, 3-gene deletion results in hemoglobin H, and 4-gene deletion results in hemoglobin Bart, causing fatal hydrops fetalis.

- Nondeletional forms do occur rarely. Hemoglobin H Constant Spring is the most common nondeletional form.
- \( \beta \)-Thalassemia is caused by any of >200-point mutations and, very rarely, deletions on chromosome 11; 20 alleles account for >80% of the mutations.
- Significantly disparate phenotype with the same genotype occurs because \( \beta \)-globin chain production can range from near-normal to absent.

**RISK FACTORS**

Family history of thalassemia

**GENERAL PREVENTION**

- Prenatal information: genetic counseling regarding partner selection and information on the availability of diagnostic tests during the pregnancy
- Complication prevention
  - For offspring of adult thalassemia patients, an evaluation for thalassemia by 1 year of age
  - Severe forms
    - Avoid exposure to sick contacts.
    - Keep immunizations up to date.
  - Promptly treat bacterial infections. (After splenectomy, patients should maintain a supply of an appropriate antibiotic to take at the onset of symptoms of a bacterial infection.)
  - Dental checkups every 6 months
  - Avoid activities that could increase the risk of bone fractures.

**COMMONLY ASSOCIATED CONDITIONS**

See “Complications.”

**DIAGNOSIS**

Thalassemia (minor) trait has no signs or symptoms.

**HISTORY**

- Poor growth
- Excessive fatigue
- Cholelithiasis
- Pathologic fractures
- Shortness of breath

**PHYSICAL EXAM**
- Pallor
- Splenomegaly
- Jaundice
- Maxillary hyperplasia/frontal bossing due to massive bone marrow expansion
- Dental malocclusion

**DIFFERENTIAL DIAGNOSIS**
- Iron deficiency anemia
- Other microcytic anemias: lead toxicity, sideroblastic
- Other hemolytic anemias
- Other hemoglobinopathies

**DIAGNOSTIC TESTS & INTERPRETATION**

**Special tests**
- Bone marrow aspiration to evaluate for causes of microcytic anemia is rarely needed.

- Multiple indices have been evaluated to discriminate β-thalassemia trait from iron deficiency anemia, yet none is sensitive enough to exclude β-thalassemia.
- Hemoglobin: usual range 10 to 12 g/dL with thalassemia trait and 3 to 8 g/dL with β-thalassemia major before transfusions
- Hematocrit
  - 28–40% in thalassemia trait
  - May fall to <10% in β-thalassemia major
- Peripheral blood
  - Microcytosis (MCV <70 fl)
  - Hypochromia (MCH <20 pg)
  - High percentage of target cells
  - Reticulocyte count is elevated.
- Red cell distribution width (RDW)
  - A normal RDW with a microcytic hypochromic anemia is almost always thalassemia trait.
  - The RDW can be elevated in ~50% of thalassemia trait patients. This is in
contrast to iron deficiency anemia, where the RDW is almost always elevated (90%).

- Hemoglobin electrophoresis
  - In α-thalassemia trait, no recognizable electrophoretic pattern occurs in adults.
  - However, in the neonatal period, 3–10% of trait patients will have hemoglobin H or hemoglobin Bart at birth, which would confirm α-thalassemia.
  - If HbA₂ is below normal (<2.5%) with a normal HbF level, the diagnosis is α-thalassemia intermedia (HbH disease).
  - In the neonatal period with β-thalassemia trait, the electrophoresis is normal. However, in adults, elevated HbA₂ levels (>4%) may be present but are usually normal (3)[C].
  - β-Thalassemia major or intermedia has elevated HbA₂, elevated HbF, and reduced or absent HbA.

- DNA analysis
  - α-Thalassemia can definitively be diagnosed with genetic testing of hemoglobin A1 and A2 (for deletions and point mutations), but this is not routinely done due to the high cost.
  - High-performance liquid chromatography
  - Cost-effective primary screening tool for children and adolescents (4)[C]
  - Equivocal results should be confirmed with DNA analysis.

**Pediatric Considerations**

For children, calculate Mentzer index (mean corpuscular volume/RBC count).

- <13: suggests thalassemia
- >13: suggests iron deficiency anemia
- Liver iron concentrations can be assessed with MRI (FerriScan).

**TREATMENT**

- Outpatient for mild cases
- Inpatient for transfusion therapy

**GENERAL MEASURES**

- Mild cases (trait or minor) require no therapy.
- Thalassemia intermedia: No therapy is necessary unless hemoglobin falls to a
level that causes symptoms; then transfusion therapy is needed. Decision is based on patient’s quality of life.

- Iron supplements should not be given unless iron deficiency occurs and is confirmed with low ferritin. Supplements increase the risk of iron overload (1) [C].
- Thalassemia major
  
  - A regular transfusion schedule to increase posttransfusion hemoglobin to 13.0 to 14.0 g/L and maintain a mean hemoglobin level of at least 9.3 g/dL (1.4 mmol/L) (1)[B]
  
  - Patients require >8 transfusion events per year. An event may be multiple transfused units.
  - Iron overload
    - Patients receiving transfusion therapy increase total body iron 4 times the normal amount.
    - Therapy is iron chelation. (See “Medication.”)

**MEDICATION**

Thalassemia intermedia and major: folic acid supplements (1 mg/day)

**First Line**

- **β-Thalassemia major**
  - Iron chelation with deferoxamine (Desferal)
    - Usually continuous SC or IV infusion
    - Acute toxicity: initial—1,000 mg IV, may be followed by 500 mg every 4 hours for 2 doses; subsequent doses of 500 mg every 4 to 12 hours based on response (max 6,000 mg/day)
    - Chronic: 20 to 40 mg/kg over 8 to 12 hours daily
    - Usually started by 5 to 8 years of age
    - Treatment lasts 3 to 5 years to reach serum ferritin <1,000 ng/mL.
  - Deferasirox (Exjade): 20 to 30 mg/kg/day PO acceptable alternative; approved for transfusion and non–transfusion-dependent patients with hepatic iron concentrations ≥5 mg/g of dry weight and serum ferritin >300 μg/L; renal and hepatic monitoring is recommended.

**Second Line**

Chelation with deferiprone (Ferriprox) 25 mg/kg TID PO initially is an acceptable alternative for patients who have not responded to deferoxamine; may provide more cardioprotection. A drawback is weekly CBC because ~1% of
patients develop agranulocytosis.

**ISSUES FOR REFERRAL**
Thalassemia major usually requires hematology consult.

**ADDITIONAL THERAPIES**

$\beta$-Thalassemia intermedia

- Hydroxyurea may improve hemoglobin 1 to 2 g/dL.
- Psychological support seems appropriate for this chronic disease. However, no conclusions can be made regarding specific psychological therapies.

**SURGERY/OTHER PROCEDURES**

- Splenectomy
  - May be needed if hypersplenism causes an increase in the transfusion requirements (>180 to 200 mL/kg/year) (5)[C]
  - Defer surgery until patient is at least 4 years of age (due to increased infection risk).
  - Administer pneumococcal polyvalent-23 vaccine 1 month before splenectomy. Children should complete their pneumococcal conjugate vaccine series before surgery.
  - Daily penicillin prophylaxis, 250 mg BID, after splenectomy for 2 years for all patients and for children until age 16 years
- Bone marrow transplantation with HLA-identical related donor stem cells in children before developing hepatitis or iron overload has high likelihood of remission but may impair fertility.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Thalassemia trait requires no restrictions.
- $\beta$-Thalassemia major
  - Avoid strenuous activities (e.g., football, soccer).
  - Acceptable activity levels will be determined on an individual basis depending on the severity of the disorder.

**Patient Monitoring**

- Thalassemia-trait patients require no special follow-up.
For β-thalassemia major, lifelong monitoring is necessary because the therapy and disease progression have numerous potential complications.

**Diet**
- Thalassemia trait requires no restrictions.
- β-Thalassemia major
  - Limit intake of iron-rich foods (e.g., red meats such as liver and some cereals).

**Patient Education**

**Prognosis**
- Outlook varies depending on type.
- Thalassemia-trait patients live a normal lifespan.
- β-Thalassemia major patients live an average of 17 years and usually die by age 30 years.
- Iron overload causes most of the morbidity and mortality:
  - Cardiac events are the primary cause of death.
  - Myocardial iron deposition is best assessed with MRI T2.
  - Effective iron chelation improves longevity.

**Complications**
- Chronic hemolysis
- Susceptibility to infections after splenectomy
- Infections from blood transfusion
- Jaundice
- Leg ulcers
- Cholelithiasis
- Osteoporosis and low-trauma fractures
- Impaired growth rate
- Delayed or absent puberty
- Hypogonadism
- Hepatic siderosis
- Splenomegaly
- Cardiac disease from iron overload
• Thromboembolic phenomenon
• Aplastic and megaloblastic crises
• Increased risk of hematologic and abdominal cancer (6)
• Increased risk of dementia (7)

REFERENCES

ADDITIONAL READING

CODES

ICD10
• D56.9 Thalassemia, unspecified
• D56.1 Beta thalassemia
• D56.0 Alpha thalassemia
CLINICAL PEARLS

- Thalassemia (group of inherited hematologic disorders that affect the synthesis of adult hemoglobin tetramer) is a genetic condition; hemoglobin will not improve over time.
- α-Thalassemia is due to a deficient synthesis of the α-globin chain, whereas β-thalassemia is due to a deficient synthesis of the β-globin chain.
- Hemoglobin electrophoresis is needed for genetic counseling but not to make the diagnosis of thalassemia minor when evaluating a patient with mild hypochromic, microcytic anemia, and normal serum ferritin.
- Anemia from thalassemia minor is not due to inadequate iron availability or iron storage. Therefore, iron supplements will not improve the anemia and could be harmful due to GI distress and iron overload. If coexisting iron deficiency is proven, then iron therapy is appropriate.
THORACIC OUTLET SYNDROME

Robert A. Baldor, MD, FAAFP

BASICS

DESCRIPTION

- This syndrome consists of a constellation of symptoms that affect the head, neck, shoulders, and upper extremities caused by compression of the neurovascular structures (brachial plexus and subclavian vessels) at the thoracic outlet, specifically in the area superior to the 1st rib and posterior to the clavicle.
- Three forms of thoracic outlet syndrome (TOS) have been described: neurogenic, vascular (with venous and arterial symptoms), and nonspecific (includes traumatic and secondary to certain provocative movements).
- Synonym(s): scalenus anticus syndrome; cervical rib syndrome; costoclavicular syndrome

Pregnancy Considerations

Generalized tissue fluid accumulations and postural changes may aggravate symptoms.

EPIDEMIOLOGY

Incidence

- Predominant age
  - Neurogenic type (95%): 20 to 60 years
  - Venous type (4%): 20 to 35 years
  - Arterial type (1%; atherosclerosis): young adult or >50 years
- Predominant sex
  - Neurogenic type: female > male (3.5:1)
  - Venous type: male > female
  - Arterial type: male = female
- No objective confirmatory tests available to measure true incidence
- Estimated 3 to 8/1,000 cases for neurogenic type
- Incidence of other TOS types is unclear.

ETIOLOGY AND PATHOPHYSIOLOGY
The interscalene triangle area is reduced in TOS and may become smaller during certain shoulder and arm movements. Fibrotic bands, cervical ribs, and muscle variations may further narrow the triangle. Trauma or provocative movements affecting the lower brachial plexus have strong implications in TOS pathogenesis.

- Three known causes of TOS: anatomic, traumatic/repetitive movement activities, and neurovascular entrapment
  - Anatomic: Variations in the anatomy of the neck scalene muscles may be responsible for presentations of the neurologic type of TOS and may involve the superior border of the 1st rib. Cervical ribs also have been implicated as a cause of neurologic TOS, with subsequent neuronal fibrosing and degeneration associated with arterial hyalinization in the lower trunk of the brachial plexus. Fibrous bands to cervical ribs are often congenital.
  - Trauma or repetitive movement activities: Motor vehicle accidents with hyperextension injury and resulting fibrosis, including fibrous bands to the clavicle; musicians who maintain prolonged positions of shoulder abduction or extension may be at increased risk.
  - Neurovascular entrapment: occurring in the costoclavicular space between the 1st rib and the head of the clavicle

**RISK FACTORS**

- Trauma, especially to the shoulder girdle
- Presence of a cervical rib
- Posttraumatic, exostosis of clavicle or 1st rib, postural abnormalities (e.g., drooping of shoulders, scoliosis), body building with increased muscular bulk in thoracic outlet area, rapid weight loss with vigorous physical exertion and/or exercise, pendulous breasts
- Occupational exposure: computer users; musicians; repetitive work involving shoulders, arms, hands
- Young, thin females with long necks and drooping shoulders

**GENERAL PREVENTION**

Consider workplace evaluation for proper occupational ergonomics.

**COMMONLY ASSOCIATED CONDITIONS**

- Paget–von Schrötter syndrome: thrombosis of subclavian vein
- Gilliatt-Sumner hand: neurogenic atrophy of abductor pollicis brevis
DIAGNOSIS

HISTORY

- Neurologic type, upper plexus (C4–C7)
  - Pain and paresthesias in head, neck, mandible, face, temporal area, upper back/chest, outer arm, and hand in a radial nerve distribution
  - Occipital and orbital headache
- Neurologic type, lower plexus (C8–T1)
  - Pain and paresthesias in axilla, inner arm, and hand in an ulnar nerve distribution, often nocturnal
  - Hypothenar and interosseous muscle atrophy
- Venous type: arm claudication, cyanosis, swelling, distended arm veins
- Arterial type: digital vasospasm, thrombosis/embolism, aneurysm, gangrene

PHYSICAL EXAM

- Positive Adson maneuver (head rotation to the affected side with cervical extension and then deep inhalation); test is positive if paresthesias occur or if radial pulse is not palpable during maneuver.
- Tenderness to percussion or palpation of supraclavicular area
- Worsening of symptoms with elevation of arm, overhead extension of arms, or with arms extended forward (e.g., driving a car, typing, carrying objects); prompt disappearance of symptoms with arm returning to neutral position
- Morley test
  - Brachial plexus compression test in the supraclavicular area from the scalene triangle
  - Positive with reproduction of an aching sensation and typical localized paresthesia
- Hyperabduction test: diminishment of radial pulse with elevation of arm above the head
- Military maneuver (i.e., costoclavicular bracing): When patient elevates chin and pushes shoulders posteriorly in an extreme “at-attention” position, symptoms are provoked.
- 1-minute Roos test
  - A thoracic outlet shoulder girdle stress test
  - Shoulders and arms are braced in a 90-degree abducted and externally rotated position; patient is required to clench and relax fists repetitively for 1 minute.
  - A positive test reproduces the symptom.
DIFFERENTIAL DIAGNOSIS
- Cervical disk or carpal tunnel syndrome
- Orthopedic shoulder problems (shoulder strain, rotator cuff injury, tendonitis)
- Cervical spondylitis
- Ulnar nerve compression at elbow and hand
- Multiple sclerosis
- Spinal cord tumor/disease
- Angina pectoris
- Migraine
- Complex regional pain syndromes
- C3–C5 and C8 radiculopathies

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
CBC, ESR, and C-reactive protein (CRP) determination may rule out underlying inflammatory conditions.
- Radiograph (chest, C-spine, shoulders) may reveal elongated C7 transverse process or a cervical rib, Pancoast tumor, or healed clavicle fracture.
- Nerve conduction studies and electromyography (EMG)
- CT scan or MRI, although MRI is the method of choice when searching for nerve compression
- Improved high-resolution MRN and tractography are valuable tools for identifying the source of nerve compression in patients with neurogenic TOS and can augment current diagnostic modalities for this syndrome (1)[B]
- Contrast-enhanced 3D MRA using provocative arm positioning allows excellent imaging of the arteries and veins on both sides and thus provides a noninvasive imaging alternative to digital subtraction angiography in patients with suspected vascular TOS (2)[B]
- Doppler and duplex US if vascular obstruction is suspected
- Arteriogram and venogram have limited roles; useful when symptoms suggestive of arterial insufficiency or ischemia, or in planning surgical intervention (3)[C]

Diagnostic Procedures/Other
No indicated procedures; anesthetic anterior scalene block may relieve pressure by scalene muscles on the brachial plexus, making this type of block diagnostic and potentially therapeutic, but it poses the risk of procedural damage to the brachial plexus.
TREATMENT

GENERAL MEASURES

- Conservative management usually involves approaches to reduce and redistribute pressure and traction through the use of physiotherapy or prosthesis.

  - Physical therapy is first-line treatment (4)[B].
  - Interscalene injections of botulinum toxin have been shown to decrease symptoms of TOS (5)[C]. A single, CT-guided Botox injection into the anterior scalene muscle may offer an effective, minimally invasive treatment for NTOS (6)[A].

  - Physical therapy will develop strength in pectoral girdle muscles and achieve normal posture.

  - Severe cases may use taping, adhesive elastic bandages, moist heat, TENS, or US but should not substitute active exercise and correction of posture and muscle imbalance (4)[B].

MEDICATION

No firm evidence exists for any specific approach to the four types of TOS.

- Anti-inflammatory (ibuprofen)
  - Adult dose: 400 to 800 mg PO q8h; not to exceed 3,200 mg/day
  - Pediatric dose
    - <12 years: 10 mg/kg/dose every 6 to 8 hours
    - >12 years: as in adults
  - Contraindications: documented hypersensitivity, active PUD, renal or hepatic impairment, recent use of anticoagulants, hemorrhagic conditions

- Neuropathic pain: Tricyclic antidepressants, carbamazepine, gabapentin, phenytoin, pregabalin; muscle relaxants such as baclofen, metaxalone, or tizanidine may be helpful.

- Severe pain: Consider opiates for brachial plexus nerve block, steroid injections.

ISSUES FOR REFERRAL

- Neurologic, anesthesiologic, orthopedic, vascular surgery referral(s) may be indicated depending on the type of pathologic condition.

- Physical and rehabilitation physicians
SURGERY/OTHER PROCEDURES

- Operative if vascular involvement is present and/or loss of function or lifestyle occurs secondary to severity of symptoms and if conservative therapy fails after 2 to 3 months
- Resection of 1st rib or cervical ribs via transaxillary (preferred with good to excellent outcome 80% of patients), supraclavicular (good to excellent outcome 80% of patients), posterior approaches (reserved for complicated TOS due to necessity of large muscle incision). Excellent results were seen in patients who underwent first rib resection in all three forms of TOS (7)[A].
- Transaxillary approach provides a good exposure and cosmetics in patients with TOS. It should be considered as the gold standard in the management of TOS (8)[B].
- Supraclavicular scalenectomy (9)[C]
- Isolated pectoral minor tenotomy (PMT) is a low-risk outpatient procedure that is effective for the treatment of selected patients with disabling NTOS, with early outcomes similar to supraclavicular decompression + PMT (10)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Conservative, outpatient, nonpharmacologic treatment is reasonable first-line therapy except in cases of thromboembolic phenomena and acute ischemia, symptoms of chronic vascular occlusion, stenosis, arterial dilatation, or progressive neurologic deficit (6)[B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Correct improper posture, practice proper posture, exercises to strengthen shoulder elevator and neck extensor muscles, stretching exercises for scalene muscles, support bra for women with pendulous breasts, breast reduction surgery in selected cases; sleep with arms below chest level, avoid/reduce prolonged hyperabduction.

Patient Monitoring

Office follow-up visits every 3 to 4 weeks
PATIENT EDUCATION
Physical therapy, postural exercises, ergonomic workstation

PROGNOSIS
Durable long-term functional outcomes can be achieved predicated on a highly selective approach to the surgical management of patients with TOS. A majority of operated patients will not require adjunctive procedures or chronic narcotic use (11)[C].

COMPLICATIONS
- Postoperative shoulder, arm, hand pain, and paresthesias in 10%
- Patients who will have symptomatic recurrences at 1 month to 7 years postoperatively (usually within 3 months): 1.5–2%
- Patients who will have brachial plexus injury, probably due to intraoperative traction: 0.5–1%
- Reoperation is indicated for symptomatic recurrence with long posterior remnant of 1st rib (posterior approach) or with disrupted fibrous adhesions (transaxillary approach).
- Venous obstruction or arterial emboli; usually responds to thrombolytics

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

G54.0 Brachial plexus disorders

**CLINICAL PEARLS**

- This syndrome is caused by compression of the neurovascular structures (brachial plexus and subclavian vessels) at the thoracic outlet, specifically in the area superior to the 1st rib and posterior to the clavicle.
- Conservative management involves approaches to reduce and redistribute pressure and traction through the use of physiotherapy or prosthesis.
- Physical therapy is first-line treatment.
- Avoid opiate dependence.
- Consider pain clinic referral if there are nonsurgical causes.
THROMBOPHILIA AND HYPERCOAGULABLE STATES

Kirsten Vitrikas, MD

BASICS

DESCRIPTION

- An inherited or acquired disorder of the coagulation system predisposing an individual to thromboembolism (the formation of a venous, or less commonly, an arterial blood clot) (1).
- Venous thrombosis typically manifests as deep venous thrombosis (DVT) of the lower extremity in the legs or pelvis and pulmonary embolism (PE) (1).
- System(s) affected: cardiovascular, nervous, pulmonary, reproductive, hematologic
- Synonym(s): hypercoagulation syndrome; prothrombotic state

EPIDEMIOLOGY

- An inherited thrombophilic defect or risk can be detected in up to 50% of patients with venous thromboembolism (VTE).
- Factor V Leiden is the most common inherited thrombophilia (1/2 of all currently characterizable inherited thrombophilia cases involve the factor V Leiden mutation), and it is present in its heterozygous form in up to ~20% of patients with a first VTE.
- Heterozygous prothrombin G20210A mutation, the second most common inherited thrombophilia, is present in up to ~8% of patients with VTE.

Incidence

First-time thromboembolism

- ~100/100,000/year among the general population
- <1/100,000/year in those age <15 years
- ~1,000/100,000/year in those age ≥85 years

Prevalence

- 40–80% of lower extremity orthopedic procedures can result in DVT if prophylaxis is not used.
VTE accounts for ~1.2 to 4.7 deaths per 100,000 pregnancies.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Virchow triad as a cause of VTE includes blood stasis, vascular endothelial injury, and abnormalities in circulating blood constituents (i.e., hypercoagulability).
- An imbalance between the hemostatic and fibrinolytic pathways leads to thrombus formation.
- VTE is considered to be the result of genetic tendencies with other acquired risks.
- Upper extremity DVT: >60% are associated with venous catheters. Malignancy is an additional significant risk (2).

**Genetics**
- The most common genetic thrombophilias (factor V Leiden, prothrombin G20210A, proteins C and S, and antithrombin III deficiency) are inherited in an autosomal dominant pattern.
- Homozygous mutations generally have a higher risk of VTE.
- Factor V Leiden/activated protein C (aPC) resistance is the most common inherited thrombophilia.
  - 2–5% prevalence among Caucasians; rare in African Americans or Asians
  - aPC does not cleave factor Va, so thrombin formation continues.
  - Other acquired risks are synergistic (3).
- Prothrombin gene mutation G20210A: prevalence 6% among Caucasians. Heterozygous carriers have increased risk of thrombosis.
- Hyperhomocysteinemia: 5–6% among the general population; increases risk of coronary artery disease/myocardial infarction, cerebrovascular accident, and DVT/PE; acquired in those with folate, vitamin B\textsubscript{12}, and vitamin B\textsubscript{6} deficiencies
- Antithrombin deficiency: <0.2% among the general population; produced in the liver; acquired deficiency in disseminated intravascular coagulation (DIC), sepsis, liver disease, nephrotic syndrome
- Protein C and S deficiencies: 0.5% and 1% incidences, respectively, among the general population. Homozygotes and heterozygotes are hypercoagulable. Vitamin K–dependent, produced in the liver. Protein C inactivates Va and VIIIa. Protein C may become an acquired deficiency in liver disease, sepsis, DIC, acute respiratory distress syndrome, and after surgery. Protein S is a cofactor for protein C, and it may become an acquired deficiency with oral
contraceptive pill (OCP) use, pregnancy, liver disease, sepsis, DIC, HIV, and nephrosis.

**RISK FACTORS**

- **Acquired risk factors**
  - Immobilization or prolonged travel
  - Trauma
  - Surgery, especially orthopedic
  - Malignancies (especially pancreatic, ovarian, brain, and lymphoma)
  - Pregnancy
  - Acute medical illness
  - Exogenous female hormones/oral contraceptives
  - Obesity
  - Nephrotic syndrome
  - Antiphospholipid syndrome (APS) and lupus anticoagulant
  - Myeloproliferative disorders (polycythemia vera, essential thrombocythemia)
  - Hyperviscosity syndromes (sickle cell, paraproteinemias)
  - Hyperhomocysteinemia secondary to vitamin deficiencies ($B_6$, $B_{12}$, folic acid)
  - Tamoxifen, thalidomide, lenalidomide, bevacizumab, L-asparaginase, erythropoiesis-stimulating agents
  - Previous thromboembolism

- **Established genetic factors**
  - Factor V Leiden
  - Prothrombin G20210A mutation
  - Protein C deficiency
  - Protein S deficiency
  - Antithrombin III deficiency

- **Rare genetic factors**
  - Dysfibrinogenemia
  - Hyperhomocysteinemia (methylenetetrahydrofolate reductase mutation)

- **Indeterminate factors**
  - Elevated factor VIII

- **Age:** >60 years
- **Gender:** men
- **Race:** Incidence is higher among African Americans.
GENERAL PREVENTION
- Consider medication prophylaxis in any hospitalized patient with VTE risk factors; hospitalized patients should be encouraged to ambulate as soon as possible (4)[A].
- Consider mechanical prophylaxis in patients at increased risk for VTE in whom anticoagulation may be contraindicated (4)[A].
- Consider prophylaxis with low-molecular-weight heparin (LMWH) plus aspirin in pregnant patients with APS or other thrombophilia.
- Consider prophylaxis using LMWH in patients with solid tumors who have additional risk factors for VTE.
- Prophylaxis with unfractionated heparin (UFH) or LMWH should be considered in patients with genetic or acquired risks of thrombosis and an anticipated additional risk, such as the immobilization associated with surgery.
- Use caution with procoagulant medicines (e.g., OCPs) in asymptomatic individuals who have a known hereditary predisposition.

COMMONLY ASSOCIATED CONDITIONS
Advanced age, cancer, pregnancy, obesity, prior history of thrombosis, surgery, immobilization

DIAGNOSIS

HISTORY
Consider prothrombotic assessment for the following:
- Thrombosis at an unusual anatomic site or recurrent thromboses
- Family history suggesting multiple individuals affected with VTE
- Recurrent pregnancy loss

PHYSICAL EXAM
- DVT: swelling, pain, warmth, and redness, usually of one extremity
- PE: dyspnea, pleurisy, hemoptysis, hypoxia, tachycardia
- Postthrombotic syndrome: pain, swelling, pigmentation, and/or ulceration

DIAGNOSTIC TESTS & INTERPRETATION
Testing for thrombophilias is not recommended unless it will affect management (2,5,6)[B]. Testing should be delayed until after the initial 3 months of anticoagulation (2,5,6)[B].
**Initial Tests (lab, imaging)**

- CBC
- aPC profile: ≤2.0 implies factor V Leiden mutation; 95–100% are factor V Leiden-positive; false-positive finding in pregnancy or with use of OCPs, confirm with factor V Leiden mutation testing or consider factor V Leiden mutation testing up front.
  - aPC resistance may be unreliable while taking LMWH or UFH.
- Prothrombin G20210A genetic assay
- ATIII functional assay
  - Will be low with acute thrombosis and on heparin therapy; may be falsely high on dabigatran, apixaban, edoxaban, and rivaroxaban
- Protein C functional assay
  - May be low with acute thrombosis; will be lower on warfarin, dabigatran, apixaban, edoxaban, and rivaroxaban
- Protein S antigen and functional assay and free S
  - May be low with acute thrombosis; will be lower on warfarin, dabigatran, apixaban, edoxaban, and rivaroxaban
- Antiphospholipid antibodies: phospholipid-dependent tests and anticardiolipin antibodies, lupus anticoagulant
  - May be unreliable on heparin
- Consider evaluation for subclinical malignancy in an unprovoked thrombosis in those >40 years of age or at greater risk.
- Consider homocysteine level, although treatment of hyperhomocysteinemia (vitamins B_{12} and B_{6}, folate) does not alter the thrombophilic risk.

**Follow-Up Tests & Special Considerations**

Dysfibrinogenemia and plasminogen deficiency are very rare causes of thrombophilia.

---

**TREATMENT**

**MEDICATION**

**First Line**

- Newer oral anticoagulants: apixaban, dabigatran, edoxaban, and rivaroxaban are now recommended over vitamin K antagonists for long-term oral
anticoagulation (6)[B].

- **Parenteral anticoagulation:** LMWH has largely replaced UFH as first-line therapy for VTE.
  - Enoxaparin (Lovenox): 1 mg/kg SC BID for at least 5 days (with concomitant warfarin) until international normalized ratio (INR) has reached 2 for at least 24 hours; adjust dose for renal disease.
    - Enoxaparin is preferred in patients with active cancer for a minimum of 6 months (can dose at 1.5 mg/kg SC daily), after which time the patient can be reevaluated to continue treatment (4).
    - Adverse reactions: bleeding, heparin-induced thrombocytopenia (HIT) <0.5% incidence, bone loss (uncommon)
    - Reversal: Stop LMWH.
  - UFH: 80 U/kg or 5,000 U IV bolus, then 18 U/kg/hr or 1,000 U/hr to target the activated partial thromboplastin time (aPTT) to a corresponding anti-Xa level of 0.3 to 0.7 U/mL. The first aPTT should be checked 6 hours after initial therapy and adjusted per standard heparin nomograms, aiming for an adequate level within 24 hours. Transition to warfarin is similar to the recommendations for enoxaparin.
    - SC UFH is an alternative and can be given as 5,000 U IV (once) followed by 250 U/kg SC BID, or 250 U/kg bolus followed by 250 U/kg BID (monitored as for IV UFH), or 333 U/kg once followed by 250 U/kg SC BID (unmonitored).
    - Adverse reactions: bleeding, HIT 3% incidence, bone loss (long-term use)
    - Reversal: Stop heparin, protamine.

- **Oral factor Xa inhibitors**
  - Rivaroxaban (Xarelto): 15 mg twice daily for 21 days then 20 mg once daily; not recommended in morbidly obese patients due to lack of data (6) [C]
  - Apixaban (Eliquis): 10 mg twice daily for 7 days, then 5 mg twice daily; can be used without need for preceding heparin therapy, less renal clearance than other oral anticoagulants
  - Edoxaban (Savaysa): 60 mg daily. Requires treatment with heparin for 5 days prior to initiation, needs adjustment for renal impairment. Not recommended if creatinine clearance >95 mL/min. Adjust dose to 30 mg in patients <60 kg or if using verapamil, quinidine, macrolides, or oral antifungals.

- **Direct thrombin inhibitors**
  - Dabigatran (Pradaxa): 150 mg twice daily after 5 to 10 days of parenteral
anticoagulation. Reversal agent: idarucizumab (Andexanet) newly available; may be dialyzable (6)[C]

- **Vitamin K antagonist**
  - Warfarin (Coumadin): 10 mg/day initially and adjust to INR 2 to 3 for at least 3 months, potentially indefinitely in those with high risk of recurrence, recurrent or unprovoked VTE
    - Warfarin requires careful and frequent monitoring because of many drug–drug and drug–diet (e.g., vitamin K) interactions.
    - Adverse reactions: bleeding, skin necrosis (rare and early in course)
  - Reversal: four-factor prothrombin complex concentrate (PCC); fresh frozen plasma and/or vitamin K
- Pregnancy: low-dose aspirin and/or LMWH or UFH; warfarin is contraindicated.

**Second Line**

Usually indicated when contraindication to heparin or LMWH, such as heparin-associated thrombosis and thrombocytopenia, if there is an inability to use IV drugs, or renal failure. Direct oral anticoagulants may become first line as more clinical experience is developed.

- **Factor Xa inhibitors**
  - Fondaparinux (Arixtra): acute VTE/PE. Weight <50 kg: 5 mg/day SC; weight 50 to 100 kg: 7.5 mg/day SC; weight >100 kg: 10 mg/day SC; use for 5 to 9 days until oral anticoagulation is therapeutic.
    - Prophylaxis: 2.5 mg/day SC
    - Dose adjustments: needed for renal insufficiency; if creatinine clearance is <30 mL/min, use is contraindicated.
- **Direct thrombin inhibitors:**
  - Argatroban: liver metabolized; may be dose-adjusted in liver dysfunction; therapeutic dose based on aPTT

**SURGERY/OTHER PROCEDURES**

- Consider systemic thrombolysis for unstable cases (e.g., massive PE with hypotension).
- Inferior vena cava filter
  - Reduces short-term risk of PE in those with contraindications to anticoagulation (e.g., GI bleeding, cerebral hemorrhage)
  - May increase long-term risk of recurrent DVT
  - Used for patients with multiple episodes of recurrent thromboembolism
despite therapeutic anticoagulation and contraindication to anticoagulation

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Avoid significant risk for trauma (e.g., contact sports, climbing a ladder).

Patient Monitoring
Monitor warfarin as frequently as needed to maintain an INR goal of 2 to 3.

DIET
Vitamin K–stable diet if patient is taking warfarin

PATIENT EDUCATION
- Assume that any drug may enhance or attenuate the warfarin effect.
- Increase the frequency of monitoring following any medication change to ensure therapeutic anticoagulation and to avoid overanticoagulation, especially with antibiotics.
- Many drugs may modulate warfarin effect: alcohol, antibiotics, aspirin, NSAIDs, acetaminophen.

PROGNOSIS
- Anticoagulation should be continued for 3 months and consideration of longer in those with unprovoked VTE.
- Patients with a provoked VTE (i.e., surgery, hospitalization) not receiving chronic anticoagulation have risks of recurrence of 7% (year 1), 16% (year 5), and 23% (year 10).
- Patients with an unprovoked VTE not receiving chronic anticoagulation have risks of recurrence of 15% (year 1), 41% (year 5), and 53% (year 10).
- Currently, there are no data from randomized, controlled trials or controlled clinical trials about the benefits of thrombophilia testing to decrease the risk of recurrent VTE (1).

COMPLICATIONS
Venous or arterial thrombosis; bleeding in anticoagulated patients

REFERENCES

mebooksfree.com

**ADDITIONAL READING**

**CODES**

**ICD10**

- D68.59 Other primary thrombophilia
- D68.51 Activated protein C resistance
- D68.2 Hereditary deficiency of other clotting factors

**CLINICAL PEARLS**

- Factor V Leiden (resistance to aPC) is the most common inherited thrombophilia, with a prevalence of 2–7% in the U.S. Caucasian population.
- Test patients for thrombophilias only if it will affect management of the condition.
- Rule out malignancy, especially in those >50 years of age.
THROMBOTIC THROMBOCYTOPENIC PURPURA

Erin M. Connor, MD • Keith E. Petersen, DO • Stephanie E. Rosen, MD

BASICS

DESCRIPTION

- An acute syndrome of microangiopathic hemolytic anemia (MAHA) and consumptive thrombocytopenia with deposition of hyaline thrombi in terminal arterioles and capillaries leading to ischemic multiorgan damage
- Thrombotic thrombocytopenic purpura (TTP) is characterized by MAHA (schistocytes on peripheral smear) and thrombocytopenia (generally <30K), with or without the following signs and symptoms (1):
  - Neurologic symptoms
  - Renal dysfunction
  - Fever
  - Most patients do not show the historic pentad of MAHA, thrombocytopenia, renal dysfunction, neurologic abnormalities, and fever because treatment is initiated before the pentad can develop.

EPIDEMIOLOGY

Incidence

- Predominant age: 18 to 49 years
- Predominant sex: female > male (3:1)
- Incidence ratio in blacks to whites is 7:1.
- The age–sex–race standardized incidence of clinically suspected TTP is 8 million/year and 2 million/year in those with ADAMTS13 levels <10% (2).

ETIOLOGY AND PATHOPHYSIOLOGY

- In TTP, the aggregating agent responsible for platelet thrombi is unusually large von Willebrand factor (UL vWF) multimers, which are far larger than those found in normal plasma.
- A metalloproteinase, ADAMTS13, which normally enzymatically cleaves UL
vWF multimers to prevent clumping within vessels, is deficient, defective, or absent, allowing UL vWF to react with platelets. This leads to the endothelial cell damage and disseminated thrombi characteristic of TTP.

- Arterioles most often affected are in the brain, kidney, pancreas, heart, and adrenal glands. Lungs and liver are relatively spared.
- In familial TTP, patients have an inherited deficiency of ADAMTS13 (1).
- In acquired idiopathic TTP, autoantibodies are directed against the metalloproteinase ADAMTS13 (1,3).
- Endothelial injury, either directly from a drug/toxin or indirectly via platelet/neutrophil activation, has been proposed as a cause of secondary TTP especially in those without ADAMTS13 deficiency.
  - Drug induced (see “Risk Factors”)
  - Hematopoietic cell transplantation

**Genetics**

- TTP is most often an acquired disorder. A congenital form of inherited TTP (Upshaw-Schulman syndrome) is due to a mutation at the ADAMTS13 metalloproteinase gene locus on chromosome 9q34. This rare form of TTP has an autosomal-recessive pattern of inheritance.
- SUS typically presents in infancy and is rarely diagnosed after 10 years of age, it does not have the female predominance seen in idiopathic TTP, more often has notable renal impairment, and there is some heterogeneity among siblings although parents who are carriers of a single heterozygous ADAMTS13 mutation are typically asymptomatic.

**RISK FACTORS**

- Pregnancy and oral contraceptives
- AIDS and early symptomatic HIV infection
- Bacterial infection/sepsis
- Autoimmune disease
  - Antiphospholipid antibody syndrome
  - Systemic lupus erythematosus
  - Scleroderma
- Cancer
- Hematopoietic stem cell transplantation
- Solid organ transplant
- Drug toxicity
  - Cancer chemotherapy
    - Mitomycin C and gemcitabine
COMMONLY ASSOCIATED CONDITIONS

- TTP/hemolytic uremic syndrome (HUS)/atypical HUS have similar presentations with MAHA and thrombocytopenia and multiorgan involvement.
- TTP generally presents with minimal renal involvement and may have neurologic abnormalities, whereas the opposite is more characteristic of HUS/atypical HUS. Creatinine of >2.3 is suggestive against TTP.
- However, patients with HUS and TTP may have both prominent renal and neurologic manifestations, often making the diagnosis unclear, hence the historical hybrid name “TTP-HUS.”
- ADAMTS13 levels are diminished (generally <10%) in adults with familial or acquired idiopathic TTP but are normal in children diagnosed with HUS following infection with *Escherichia coli* (particularly type O157:H7), so-called Shiga toxin-HUS, and in “atypical HUS,” is also called complement-mediated thrombotic microangiopathy reflecting the pathophysiology which is related to complement dysregulation.

DIAGNOSIS

- Most common symptoms are nonspecific: nausea, vomiting, weakness, abdominal pain, fatigue, fever.
- Related to thrombocytopenia
  - Easy bruising, purpura, or petechiae
  - Epistaxis, menorrhagia, bleeding gums
  - GI bleeding
  - Intracranial hemorrhage
  - Visual symptoms due to retinal hemorrhage
- Related to hemolytic anemia (MAHA): jaundice, fatigue
- Related to end-organ ischemia
  - Neurologic: CNS symptoms occur in 50%.
- Often fluctuating symptoms
  - Headache
  - Altered mental status: Spectrum runs from behavioral/personality changes to obtundation/stupor/coma.
  - Seizures
  - Stroke
  - Renal: hematuria, oliguria, or anuria
  - Cardiac: arrhythmia, myocardial infarction, heart failure

**HISTORY**
- Generally acute onset of symptoms but subacute in about 1/4 of patients
- It is important to assess for potential underlying causes or risk factors (see discussion earlier).
- In about 50% of cases, a trigger/risk factor of some kind is identified (4).

**PHYSICAL EXAM**
- Fever
- Mental status/neurologic: confusion, coma, stupor, weakness
- HEENT: retinal hemorrhage, scleral icterus, epistaxis
- Abdomen/GI: nonspecific tenderness
- Skin: jaundice, petechiae, purpura, ecchymoses

**DIFFERENTIAL DIAGNOSIS**
- HUS and atypical HUS
- Antiphospholipid antibody syndrome: prolonged partial thromboplastin time (PTT) and presence of lupus anticoagulant
- Systemic lupus erythematosus
- Malignant hypertension (HTN): diastolic >130 mm Hg, papilledema, retinal hemorrhages
- Pregnancy-associated preeclampsia/eclampsia or hemolysis, elevated liver enzyme levels, and low platelet HELLP levels: low ATIII levels
- Disseminated intravascular coagulation
  - Prolonged prothrombin time (PT)/PTT, low fibrinogen
  - Low factors V and VIII
  - Secondary to sepsis/shock or widely disseminated malignancy
- Idiopathic thrombocytopenic purpura (ITP)
  - No hemolysis, normal lactate dehydrogenase (LDH) and bilirubin
  - Presence of antiplatelet antibodies
Malignancy-associated microangiopathy
Evan syndrome (autoimmune hemolytic anemia and thrombocytopenia): positive direct Coombs test
Sclerodermal kidney

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- **CBC**
  - Hemoglobin (decreased): Average is 8 to 10 g/dL.
  - Platelets decreased: typically in the 10 to 30,000 range
- Reticulocyte count (increased)
- Haptoglobin decreased (hemolysis)
- Peripheral smear
  - Schistocytes (prominent, >1% of RBCs)
  - Helmet cells, RBC fragments
  - Nucleated RBCs
  - Polychromasia (reticulocytosis)
- Coagulation studies
  - Normal in most; mild elevation in 15%
  - Fibrinogen normal
- Coombs test: negative direct Coombs test
- Electrolytes, BUN/creatinine: mild elevation of BUN and creatinine (creatinine <3 mg/dL)
- Liver function studies: increased indirect bilirubin (hemolysis)
- LDH: 5 to 10 times normal
- Urinalysis
  - Proteinuria, microscopic hematuria
  - Positive dipstick for large blood but minimal RBCs on microscopic exam
- ECG: sinus tachycardia, heart block
- Troponin: increased if cardiac involvement
- HIV, hepatitis A, B, C testing: Exclude underlying viral precipitant.
- Pregnancy test
- Pretreatment ADAMTS13 activity level of <10% is useful in distinguishing acquired or familial TTP from other disorders.
- Head CT/MRI scan: performed if mental status changes are present to rule out possible intracranial hemorrhage or ischemic changes

*Test Interpretation*
Biopsy of affected organs shows platelet thrombi within or beneath damaged endothelium. However, biopsy is rarely obtained because the diagnosis is made on clinical grounds and laboratory findings.

**TREATMENT**

**ALERT**
- Prompt treatment of TTP is necessary due to the high mortality (90%).
- In the absence of another apparent cause, the dyad of MAHA and thrombocytopenia is sufficient to begin treatment for TTP while the workup proceeds (1,3):
  - Plasma exchange (PEX) transfusion is the cornerstone of treatment of classic TTP (3)[A].
  - PEX replaces deficient or defective metalloproteinase (ADAMTS13) and removes UL vWF and antimetalloproteinase antibodies.
  - PEX should begin immediately and continued daily until symptoms and evidence of end-organ damage have resolved.
  - Optimal PEX duration is variable. Convention is to continue for 2 days after platelet count is ≥150,000, and then consider tapering (5)[C].
  - Fresh frozen plasma: temporary measure until PEX can be initiated (3)[B]; should be reserved for those with active bleeding.

**MEDICATION**

**First Line**
- Glucocorticoids may be of benefit in some patients. British guidelines recommend its use for all patients (6)[B].
  - Steroids may work by suppressing the autoantibodies inhibiting ADAMTS13 activity.
  - Use may be in patients with severe ADAMTS13 deficiency, in the setting of exacerbation when PEX is stopped or in relapse after remission.
  - Little benefit of steroids when used as monotherapy.
  - Doses: prednisone 1 to 2 mg/kg/day and taper once in remission or methylprednisolone 1 g/day IV for 3 days.
- Rituximab, an anti-CD20 antibody that deletes B cells, may reduce relapse when given in conjunction with PEX and steroids.
  - Dose: 375 mg/m$^2$ IV weekly for 4 weeks.
Second Line
The following medications are used in refractory cases:

- Rituximab (6)[B]
- Vincristine, cyclophosphamide, cyclosporine
- Intravenous immunoglobulin (IVIG) (3)
- Bortezomib (6)[C]

ISSUES FOR REFERRAL
- Hematology or blood bank for PEX
- Nephrology for dialysis
- Cardiology for presence of significant heart block or ischemia
- Neurosurgery for intracranial hemorrhage

SURGERY/OTHER PROCEDURES
Splenectomy is reserved for severe, refractory cases.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- ABCs, oxygen, IV access, telemetry
- Volume resuscitation if hypotensive/actively bleeding
- Packed RBCs can be transfused safely.
- Platelet transfusion may be used for the treatment of hemorrhage.
- Discharge on normalization and stabilization of neurologic symptoms, LDH, platelets, and renal function

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- No maintenance therapy is required. After PEX is discontinued, blood counts should be monitored over a few months. If testing results remain normal, testing interval can be lengthened.
- Promptly evaluate any symptoms of relapse.

PATIENT EDUCATION
- On discharge, advise patients to self-monitor for signs of relapse (e.g., fever, headache, bruising).
 Patients should be advised about prolonged periods of fatigue following the acute phase.
See National Heart, Lung and Blood Institute Web site: http://www.nhlbi.nih.gov/health/health-topics/topics/ttp

PROGNOSIS

Most patients recover fully from idiopathic TTP when treated promptly:
- 30-day mortality is 10% in those who receive PEX.
- 70% respond within 14 days; 90% respond within 28 days.
- 80% survival in patients with idiopathic TTP treated with PEX (7)

Prior to widespread treatment with PEX TTP carried up to a 90% mortality rate

Initial LDH and platelet counts are not predictive of the patient’s response to treatment.
Final platelet count and LDH or the length or intensity of treatment does not predict relapse.
Low levels of ADAMTS13 activity during remission are associated with higher risk of relapse (7).
In patients with severe ADAMTS13 deficiency, the risk of relapse is estimated to be 41% at 7.5 years, with the greatest risk being in the 1st year.
In patients with autoimmune TTP, there is a 40% relapse rate (4).

COMPLICATIONS

Patients may experience mild cognitive impairments in attention, concentration, and memory following ≥1 episodes of TTP.
Complications of PEX include the following:
- Central line infections and hemorrhage
- Citrate toxicity
- Hypersensitivity reactions to frequent plasma exposure
- Electrolyte abnormalities

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**
- M31.1 Thrombotic microangiopathy
- D69.42 Congenital and hereditary thrombocytopenia purpura
- D69.3 Immune thrombocytopenic purpura

**CLINICAL PEARLS**
- The diagnosis of TTP is made clinically; common symptoms are nonspecific: nausea; vomiting; weakness; abdominal pain; fatigue; fever; and easy bruising, purpura, or petechiae.
- The historical pentad of fever, neurologic symptoms, renal dysfunction, MAHA, and thrombocytopenia is not present in most patients.
- The dyad of MAHA (schistocytes on peripheral smear) and severe thrombocytopenia (<30K) is sufficient to initiate treatment with PEX.
• Do not wait for results of ADAMTS13 determination to initiate therapy.
THYROID MALIGNANT NEOPLASIA

Mohannad Al-Tarakji, MD • Jowhara Al-Qahtani, MD • AbdulHakeem AlTabib, MD

BASICS

DESCRIPTION

Thyroid malignant neoplasia is an autologous growth of thyroid nodules with potential for metastases. There are several types:

- Papillary thyroid carcinoma (PTC)
  - Most common variety, 60–70% of thyroid tumors
  - Peak incidence in the 3rd to 4th decades
  - 3 times more common in women
  - May be associated with radiation exposure
  - Metastasizes by lymphatic route (30% at time of diagnosis)
  - Multicentric in ≥20%, especially in children
  - Higher risk in patients with Hashimoto thyroiditis
  - Evidence for overdetection “overdiagnosis” of PTC includes increased numbers of smaller size tumors and improved or unchanged survival.
  - Many different histologic variants have been described for the thyroid PTC.
  - Thyroid tumors currently diagnosed as noninvasive encapsulated follicular variant of papillary thyroid carcinoma (EFVPTC) have a very low risk of adverse outcome and should be termed “noninvasive follicular thyroid neoplasms with papillary-like nuclear features” (NIFTP). This reclassification will affect a large population of patients worldwide and result in a significant reduction in psychological and clinical consequences associated with the diagnosis of cancer.

- Follicular carcinoma
  - 10–20% of thyroid tumors
  - Peak incidence in 5th decade of life
  - Incidence has been decreasing because of the addition of dietary iodine.
  - Metastasizes by the hematogenous route

- Hürthle cell carcinoma (variant of follicular with poorer prognosis)
  - 2–3% of thyroid malignancies
  - Usually in patients >60 years old
  - No gender difference
Radioresistant
Variant of follicular carcinoma with worse prognosis

Medullary thyroid carcinoma (MCT)
- Arises from parafollicular cells, C cells
- Multiple endocrine neoplasia (MEN) syndromes (MEN2A, MEN2B, FMTC). Prevalence of MEN2 is 1:30,000.
- MCT associated with MEN2B occur in childhood, those with MEN2A occur in young adults, and those with FMTC occur at middle age.
- 3–4% of all thyroid tumors
- 25–35% are associated with MEN syndromes (2A more common than 2B), which can be familial or sporadic.
- Calcitonin is a chemical marker.
- RET proto-oncogene mutation is screened; family members who carry the RET gene should consider early prophylactic thyroidectomy.

Anaplastic carcinoma
- 3% of thyroid tumors
- Most aggressive form of thyroid neoplasia
- More common in females
- Usually in patients >60 years old

Other: lymphoma, sarcoma, or metastatic (renal, breast, or lung)
System(s) affected: endocrine/metabolic
Synonym(s): follicular carcinoma of the thyroid; papillary carcinoma of the thyroid; Hürthle cell carcinoma of the thyroid; anaplastic cell carcinoma of the thyroid

Geriatric Considerations
Risk of malignancy increases at >60 years old.

Pediatric Considerations
- >60% of thyroid nodules are malignant.
- <2% of thyroid malignancies occur in children and adolescents.
- Increasing tumor size, extrathyroidal extension, and multifocal disease are independent factors associated with nodal metastases in pediatric differentiated thyroid cancer which require careful preoperative evaluation for evidence of lateral cervical lymph node metastases and intraoperative evaluation of the central compartment, with consideration of central lymphadenectomy (1).
EPIDEMIOLOGY

Incidence
- 12.9/100,000 per year in the United States
- Deaths: 0.5/100,000 per year in the United States
- In 2015, estimated 62,450 new cases and 1,950 deaths from thyroid cancer in the United States
- Predominant age: usually >40 years old
- Predominant sex: female > male (2.6:1) prevalence
- Lifetime risk of developing thyroid cancer is 1.1%.
- In 2011, 566,708 patients living with thyroid cancer in the United States

ETIOLOGY AND PATHOPHYSIOLOGY

Genetics
- Familial polyposis of the colon, Turcot syndrome, and Gardner syndrome with the APC gene (5q21)
- Medullary: autosomal dominant with MEN syndrome
- BRAF mutation (rare in children)
- RET oncogene (more common in children)

RISK FACTORS
- Family history
- Neck irradiation (6 to 2,000 rads): papillary carcinoma
- Iodine deficiency: follicular carcinoma
- MEN2: medullary carcinoma; autosomal dominant
- Previous history of subtotal thyroidectomy for malignancy: anaplastic carcinoma
- Asian race
- Female gender

GENERAL PREVENTION
- Physical exam in high-risk group
- Calcium infusion or pentagastrin-stimulated calcitonin test screening in high-risk MEN patients
- Screen for RET proto-oncogene in groups at-risk for MCT.

COMMONLY ASSOCIATED CONDITIONS
Medullary carcinoma: pheochromocytoma, hyperparathyroidism,
ganglioneuroma of the GI tract, neuromata of mucosal membranes

**DIAGNOSIS**

**HISTORY**
- Change in voice (hoarseness)
- Positive family history
- Neck mass
- Dysphagia
- Dyspnea
- Cough
- Difficulty swallowing

**PHYSICAL EXAM**
- Neck mass: If fixed to surrounding tissue, this finding suggests advanced disease.
- Cervical adenopathy
- Inspection for mucosal neuromas and marfanoid habitus as this finding is suggestive of MEN2B

**DIFFERENTIAL DIAGNOSIS**
- Multinodular goiter
- Thyroid adenoma
- Thyroglossal duct cyst
- Thyroiditis
- Thyroid cyst
- Ectopic thyroid
- Dermoid cyst

**DIAGNOSTIC TESTS & INTERPRETATION**
- US: Solid mass and microcalcifications are more suspicious of malignancy.
- CT scan and MRI can be useful to evaluate large substernal masses and recurrent soft tissue masses.
- Medullary carcinoma: calcitonin level (normal <30 pg/mL [300 ng/L]), pentagastrin stimulation test, and RET proto-oncogene
- Thyroglobulin (TG) level: postoperative tumor marker
- DNA content of tumors from biopsy specimen: Diploid content has a better
Thyroid function tests usually normal
Thyroid scan: 12–15% of cold nodules are malignant; rate is higher in patients <40 years of age, and those with microcalcifications on US. $^{18}$F-FDG positron-emission tomographic scan can help if the cytology is inconclusive; helpful with recurrent disease when patient has a negative $^{131}$I scan and an elevated TG level (2)[B]

**Diagnostic Procedures/Other**
- Fine-needle aspiration (FNA)
- Surgical biopsy/excision
- Laryngoscopy if vocal cord paralysis is suspected

**Test Interpretation**
- Papillary: psammoma bodies, anaplastic epithelial papillae
- Follicular: anaplastic epithelial cords with follicles
- Hürthle cell: large eosinophilic cells with granular cytoplasm
- Medullary: large amounts of amyloid stroma
- Anaplastic: small cell and giant cell undifferentiated tumors

**TREATMENT**

**MEDICATION**
Postoperatively, will require thyroid hormone replacement: Goal is to keep TSH <0.1 mU/L.
- Levothyroxine ($T_4$, Synthroid) 100 to 200 $\mu g$/day
- Liothyronine ($T_3$, Cytomel) 50 to 100 $\mu g$/day

**GENERAL MEASURES**
- Most cases of thyroid cancer are managed surgically and medically with a good prognosis (3)[C].
- Palliative support has a role in case of advanced thyroid malignancy (3)[C].
  - Papillary/follicular: $^{131}$I thyroid remnant ablation
  - Medullary: Vandetanib has been tried in patients with advanced disease (4) [B].
- Anaplastic: Doxorubicin and cisplatin have achieved partial remission in some
patients.
- Recurrent tumor: Sorafenib has been used in patients with recurrent disease.

**ADDITIONAL THERAPIES**
- External beam radiation for advanced disease
- $^{131}$I is used in high-risk patients with papillary and follicular tumors. The role is to ablate remnant thyroid tissue to improve specificity of future TG assays.

**SURGERY/OTHER PROCEDURES**
- Papillary carcinoma: lobectomy with isthmectomy (if lesion <1 cm) or total thyroidectomy and removal of suspicious lymph nodes; total thyroidectomy for tumors >1 cm (5)[B]
- Follicular carcinoma and Hürthle cell: total thyroidectomy and removal of suspicious lymph nodes
- Medullary carcinoma: total thyroidectomy with central node dissection; unilateral or bilateral modified radical neck dissection if lateral nodes are histologically positive
- Anaplastic carcinoma: aggressive en bloc thyroidectomy; tracheostomy often required; not responsive to $^{131}$I

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*
- 10–30% of initially disease-free patients will develop recurrence and/or metastases. 80% recur in neck and 20% with distant metastases. Lung is most common site of distant metastases.
- Thyroid scan at 6 weeks and administration of $^{131}$I for any visible uptake; any evidence of residual thyroid tissue (after total thyroidectomy) or lymph node disease noted on scan is treated with radioactive iodine.
- At 6 months and then yearly, the patient should have a thyroid scan and chest x-ray.
- Papillary and follicular: A TG level should be done yearly. Recombinant human thyroid-stimulating hormone (rhTSH)—stimulated TG level may be more sensitive (6)[C].
- Medullary: Calcitonin level should be done yearly with pentagastrin
stimulation.
- The thyroid scan and TG level should be done with the patient in the hypothyroid state induced by 6-week withdrawal of levothyroxine or 2- to 3-week withdrawal of liothyronine.
- Decreased incidence of recurrence when TSH is suppressed

**DIET**
Avoid iodine deficiency.

**PATIENT EDUCATION**
National Cancer Institute: (301) 496-5583; http://www.cancer.gov

**PROGNOSIS**
- Taken together: 5-year survival of thyroid cancer is 97.8%.
- Favorable factors: female, multifocality, regional LN involvement
- Adverse factors: age >45 years, follicular histology, primary tumor >4 cm, extrathyroid extension, distant metastases
- Papillary carcinoma: 10-year overall survival is 93%; 30-year cancer-related death rate of 6%
- Follicular carcinoma: 10-year overall survival is 85%; histologically, microinvasive tumors parallel papillary tumor results, whereas grossly invasive tumors do far worse; 30-year cancer-related death rate of 15%
- Hürthle cell carcinoma: 93% 5-year survival rate and 83% survival rate overall; grossly invasive tumor survival <25%
- Medullary carcinoma: negative nodes, 90% 5-year survival rate and 85% 10-year survival rate; with positive nodes, 65% 5-year survival rate and 40% 10-year survival rate. Prognosis worse for MEN2B compared to MEN2A. Overall 10-year survival is 75%.
- Anaplastic carcinoma: survival unexpected. Long-term survivors should have original pathology reexamined.

**COMPLICATIONS**
- Recurrence of tumor is 10–30%; 80% recur in neck, and 20% recur distally.
- Hoarseness from tumor invasion or operative injury to recurrent laryngeal nerve
- Hypoparathyroidism from operative injury to parathyroid glands

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Multiple Endocrine Neoplasia (MEN) Syndromes

**CODES**

**ICD10**

C73 Malignant neoplasm of thyroid gland

**CLINICAL PEARLS**

- Standard workup for a patient suspected of having a thyroid cancer is a physical exam, TSH level, neck US, and FNA.
- TG levels can be elevated in several thyroid disorders. Its usefulness comes
once the diagnosis of cancer has been made. It serves as a better marker for recurrent disease.

- FNA results will be benign, malignant, indeterminate, or nondiagnostic. More helpful in planning initial surgical approach.
THYROIDITIS
Pradeepa P. Vimalachandran, MD, MPH

BASICS

DESCRIPTION

Inflammation of the thyroid gland that may be painful or painless

- Thyroiditis with thyroid pain
  - Subacute granulomatous thyroiditis (nonsuppurative thyroiditis, de Quervain thyroiditis, or giant cell thyroiditis): self-limited; viral URI prodrome, symptoms and signs of thyroid dysfunction (variable)
  - Infectious/suppurative thyroiditis
- Bacterial, fungal, mycobacterial, or parasitic infection of the thyroid
- Most commonly associated with *Streptococcus pyogenes*, *Staphylococcus aureus*, and *Streptococcus pneumoniae*
  - Radiation-induced thyroiditis: from radioactive iodine therapy (1%) or external irradiation for lymphoma and head/neck cancers
- Thyroiditis with no thyroid pain
  - Hashimoto (autoimmune) thyroiditis (chronic lymphocytic thyroiditis): most common etiology of chronic hypothyroidism; autoimmune disease; 90% of patients with high-serum anti-thyroid peroxidase (TPO) antibodies
  - Postpartum thyroiditis: episode of thyrotoxicosis, hypothyroidism, or thyrotoxicosis followed by hypothyroidism in the 1st year postpartum or after spontaneous/induced abortion in women who were without clinically evident thyroid disease before pregnancy
  - Painless (silent) thyroiditis (subacute lymphocytic thyroiditis): mild hyperthyroidism, small painless goiter, and no Graves ophthalmopathy/pretibial myxedema
  - Riedel (fibrous) thyroiditis: rare inflammatory process involving the thyroid and surrounding cervical tissues; associated with various forms of systemic fibrosis; presents as a firm mass in the thyroid commonly associated with compressive symptoms (dyspnea, dysphagia, hoarseness, and aphonia) caused by local infiltration of the advancing fibrotic process with hypocalcemia and hypothyroidism
  - Drug-induced thyroiditis: interferon-α, interleukin-2, amiodarone, kinase inhibitors, or lithium
EPIDEMIOLOGY
- Subacute granulomatous thyroiditis: most common cause of thyroid pain; peaks during summer; incidence: 3/100,000/year; female > male (4:1); peak age: 40 to 50 years
- Suppurative thyroiditis: commonly seen with preexisting thyroid disease/immunocompromised
- Hashimoto thyroiditis: peak age of onset, 30 to 50 years; can occur in children; primarily a disease of women; female > male (7:1)
- Postpartum thyroiditis: female only; occurs within 12 months of pregnancy in 8–11% of pregnancies; occurs in 25% with type 1 diabetes mellitus; incidence is affected by genetic influences and iodine intake.
- Painless (silent) thyroiditis: female > male (4:1) with peak age 30 to 40 years; common in areas of iodine sufficiency
- Riedel thyroiditis: female > male (4:1); highest prevalence age 30 to 60 years

ETIOLOGY AND PATHOPHYSIOLOGY
- Hashimoto disease: Antithyroid antibodies may be produced in response to an environmental antigen and cross-react with thyroid proteins (molecular mimicry). Precipitating factors include infection, stress, sex steroids, pregnancy, iodine intake, and radiation exposure.
- Subacute granulomatous thyroiditis: probably viral
- Postpartum thyroiditis: autoimmunity-induced discharge of preformed hormone from the thyroid
- Painless (silent) thyroiditis: autoimmune

Genetics
Autoimmune thyroiditis is associated with the CT60 polymorphism of cytotoxic T-cell lymphocyte–associated antigen 4; also associated with HLA-DR4, -DR5, and -DR6 in whites

RISK FACTORS
- Hashimoto disease: family history of thyroid/autoimmune disease, personal history of autoimmune disease (type 1 diabetes, celiac disease), high iodine intake, cigarette smoking, selenium deficiency
- Subacute granulomatous thyroiditis: recent viral respiratory infection or HLA-B35
- Suppurative thyroiditis: congenital abnormalities (persistent thyroglossal duct/pyriform sinus fistula), greater age, immunosuppression
Radiation-induced thyroiditis: high-dose irradiation, younger age, female sex, preexisting hypothyroidism
Postpartum thyroiditis: smoking, history of spontaneous/induced abortion
Painless (silent) thyroiditis: iodine-deficient areas

GENERAL PREVENTION
Selenium may decrease inflammatory activity in pregnant women with autoimmune hypothyroidism and may reduce postpartum thyroiditis risk in those positive for TPO antibodies.

COMMONLY ASSOCIATED CONDITIONS
Postpartum thyroiditis: family history of autoimmune thyroid disease; HLA-DRB, -DR4, and -DR5

DIAGNOSIS

HISTORY

- Hypothyroid symptoms (e.g., constipation, heavy menstrual bleeding, fatigue, weakness, dry skin, hair loss, cold intolerance)
- Hyperthyroid symptoms (e.g., irritability, heat intolerance, increased sweating, palpitations, loose stools, disturbed sleep, and lid retraction)
- Subacute granulomatous thyroiditis: sudden/gradual onset, with preceding upper respiratory infection/viral illness (fever, fatigue, malaise, anorexia, and myalgia are common); pain may be limited to thyroid region or radiate to upper neck, jaw, throat, or ears.
- Classic triphasic course (thyrotoxic, hypothyroid, recovery) but variable in the following: subacute, silent, and postpartum thyroiditis (1)[C]

PHYSICAL EXAM

- Examine thyroid size, symmetry, and nodules.
  - Hashimoto disease: 90% have a symmetric, diffusely enlarged, painless gland, with a firm, pebbly texture; 10% have thyroid atrophy.
  - Postpartum thyroiditis: painless, small, nontender, firm goiter (2 to 6 months after delivery)
  - Riedel thyroiditis: rock-hard, wood-like, fixed, painless goiter, often accompanied by symptoms of esophageal/tracheal compression (stridor, dyspnea, a suffocating feeling, dysphagia, and hoarseness)
• Signs of hypothyroid: delayed relaxation phase of deep tendon reflexes, nonpitting edema, dry skin, alopecia, bradycardia
• Signs of hyperthyroid: moist palms, hyperreflexia, tachycardia/atrial fibrillation

DIFFERENTIAL DIAGNOSIS
Simple goiter; iodine-deficient/lithium-induced goiter; Graves disease; lymphoma; acute infectious thyroiditis; oropharynx and trachea infections; thyroid cancer; amiodarone; contrast dye; amyloid

DIAGNOSTIC TESTS & INTERPRETATION
• Thyroid-stimulating hormone (TSH), anti-TPO antibodies
• Hashimoto disease
  – High titers of anti-TPO antibodies
  – New subtype: IgG4 thyroiditis, which is histopathologically characterized by lymphoplasmacytic infiltration, fibrosis, increased numbers of IgG4-positive plasma cells, and high-serum IgG4 levels; more closely associated with rapid progress, subclinical hypothyroidism, higher levels of circulating antibodies, and more diffuse low echogenicity (2)[C]
• Subacute granulomatous thyroiditis
  – High T₄, T₃; low TSH during early stages and elevated later; TSH varies with phase (1)[C].
  – High thyroglobulin; normal levels of anti-TPO and antithyroglobulin antibodies (present in 25%, usually low titers)
  – Elevated erythrocyte sedimentation rate (ESR) (usually >50 mm/hr) and C-reactive protein; mild anemia and slight leukocytosis; LFTs are frequently abnormal during initial hyperthyroid phase and resolve over 1 to 2 months.
• Suppurative thyroiditis
  – In the absence of preexisting thyroid disease, thyroid function is normal, but hyper-/hypothyroidism may occur.
  – Elevated ESR and WBC with marked increase in left shift
  – Fine-needle aspiration (FNA) of the lesion with Gram stain and culture is the most useful diagnostic test.
• Postpartum thyroiditis (3)[B]
  – Anti-TPO antibody positivity is the most useful marker for the prediction of postpartum thyroid dysfunction.
  – Women known to be anti-TPO-Ab+ should have TSH measured at 6 to 12 weeks’ gestation and at 6 months postpartum or as clinically indicated.
Thyrotoxic phase occurs 1 and 6 months postpartum (most commonly at 3 months) and usually lasts only 1 to 2 months.

Hypothyroidism occurs between 3 and 8 months (most commonly at 6 months).

Most patients (80%) have normal thyroid function at 1 year; 30–50% of patients develop permanent hypothyroidism within 9 years.

High thyroglobulin, normal ESR

- Painless (silent) thyroiditis
  - Hyperthyroid state in 5–20%: averages 3 to 4 months, and total duration of illness is <1 year, followed by hypothyroidism and then a return to normal state; some have primary/subclinical hypothyroidism.
  - ~50% have anti-TPO antibodies (1)[C].

- Riedel thyroiditis (4)[C]
  - Hypothyroidism due to extensive replacement of the gland by scar tissue. Anti-TPO antibodies are present in 2/3 of patients along with low radioactive iodine uptake (RAIU).

- Drug-induced thyroiditis
  - Hyper-/hypothyroidism, low RAIU, and variable presence of anti-TPO antibodies

- US: shows variable heterogeneous texture, hypoechogenic in subacute, painless (silent), and postpartum thyroiditis

- Thyroid RAIU scan: decreased in all forms of thyroiditis but not helpful in establishing diagnosis of Hashimoto disease; high RAIU in hashitoxicosis, Graves disease

- Random urine iodine measurement may be helpful to distinguish from other causes of low RAIU.
  - Urine iodine <500 μg/L (subacute granulomatous thyroiditis)
  - Urine iodine >1,000 μg/L (in patients with exposure to excess exogenous iodine/radiocontrast material)

**Diagnostic Procedures/Other**

- Hashimoto with a dominant nodule should have FNA to rule out thyroid carcinoma.

- Open biopsy is necessary for a definitive diagnosis of Riedel thyroiditis.

**Test Interpretation**

- Hashimoto disease: lymphocytic infiltration with formation of Askanazy (Hürthle) cells, oxyphilic changes in follicular cells, fibrosis, thyroid atrophy

- Subacute granulomatous thyroiditis: giant cells, mononuclear cell
Postpartum thyroiditis: lymphocytic infiltration, occasional germinal centers, disruption and collapse of thyroid follicles

Painless (silent) thyroiditis: lymphocytic infiltration, but without fibrosis, Askanazy cells, and extensive lymphoid follicle formation

**TREATMENT**

**GENERAL MEASURES**
Analgesics for pain; corticosteroids for severe granulomatous thyroiditis

**MEDICATION**

- Hashimoto disease (2)[C]
  - If hypothyroid/goitrous: levothyroxine (1.7 μg/kg/day for adults <50 years of age); if no cardiac complications and no adrenal insufficiency, 1/2 replacement dose and increase to full replacement in 10 days
  - If >50 years of age or heart disease and/or adrenal insufficiency, begin with 25 μg/day and titrate to TSH of lower limit normal range.
- If thyrotoxic and symptomatic: propylthiouracil and propranolol
- An elevated TSH level in a woman who is pregnant or attempting to become pregnant is an indication for thyroid replacement.
- Subacute granulomatous thyroiditis
  - Anti-inflammatory agents for 2 to 8 weeks (NSAIDs or aspirin)
  - Pain with no improvement in 2 to 3 days after NSAID use: prednisone 40 mg/day; should result in pain relief in 1 to 2 days; if not, question diagnosis.
  - Severe pain: prednisone 40 to 60 mg/day discontinued over 4 to 6 weeks. If pain recurs, increase dose for several weeks and then taper.
  - Symptomatic hyperthyroidism: \(\beta\)-blockers while thyrotoxic (propranolol 40 to 120 mg/day)
  - Symptomatic hypothyroid phase: Levothyroxine, as mentioned earlier, target TSH in the normal range.
- Suppurative thyroiditis
  - Parenteral empiric, broad-spectrum antibiotics, and surgical drainage
- Painless (silent) thyroiditis
  - No treatment needed
  - If symptomatic during hyperthyroid state, treat with \(\beta\)-blocker (propranolol 40 to 120 mg/day).
– Prednisone shortens the period of hyperthyroidism. Monitor TSH every 4 to 8 weeks to confirm resolution.
– Treat hypothyroid symptoms and asymptomatic patients with TSH >10 mU/L with levothyroxine (50 to 100 μg/day), to be discontinued after 3 to 6 months.

**Postpartum thyroiditis (5)[C]**
– Treat symptomatic hyper-/hypothyroid state. Most do not need treatment.
– Caution in breastfeeding mothers because β-blockers are secreted into breast milk
– For symptomatic hypothyroidism, treat with levothyroxine. Otherwise, remonitor in 4 to 8 weeks. Taper replacement hormone after 6 months if thyroid function has normalized.

**Riedel thyroiditis (4)[C]**
– Corticosteroids in early stages but controversial thereafter; prednisone 10 to 20 mg/day for 4 to 6 months, possibly continued thereafter if effective
– Long-term anti-inflammatory medications to arrest progression and maintain a symptom-free course
– Tamoxifen 10 to 20 mg twice daily as monotherapy or in conjunction with prednisone reduces mass size and clinical symptoms.
– Methotrexate is used with some success.
– Reduction of goiter seen with a combination of mycophenolate mofetil (1 g BID) and 100 mg/day prednisone
– Debunkling surgery is limited to isthmusectomy to relieve constrictive pressure when total thyroidectomy is not possible.

**Drug-induced thyroiditis**
– Discontinue offending drug.

## SURGERY/OTHER PROCEDURES
Enlarged painful thyroid or tracheal compression

## ONGOING CARE

### FOLLOW-UP RECOMMENDATIONS

**Patient Monitoring**

– Hashimoto disease: Repeat thyroid function tests every 3 to 12 months.
– Subacute granulomatous thyroiditis: Repeat thyroid function tests every 3 to 6 weeks until euthyroid and then every 6 to 12 months.
- Postpartum thyroiditis: Check TSH annually.
- Riedel thyroiditis: CT of cervical mediastinal region is recommended.
- TSH every 6 months in patients on amiodarone

**Pregnancy Considerations**
- Avoid radioisotope scanning if possible.
- Keep TSH maximally suppressed.
- If using RAIU scan, discard breast milk for 2 days because RAI is secreted in breast milk.

**PROGNOSIS**
- Hashimoto disease: persistent goiter; eventual thyroid failure
- Subacute granulomatous thyroiditis: 5–15% hypothyroid beyond a year: some with eventual return to normal; remission may be slower in the elderly; recurrence rate: 1–4% after a year
- Painless (silent) thyroiditis: 10–20% hypothyroid beyond a year; recurrence rate 5–10% (much higher in Japan)
- Postpartum thyroiditis: 15–50% hypothyroid beyond a year; women may be euthyroid/continue to be hypothyroid at the end of 1st postpartum year. 70% recurrence rate in subsequent pregnancies; substantial risk exists for later development of hypothyroidism/goiter.

SEE ALSO

Hyperthyroidism; Hypothyroidism, Adult

CODES

ICD10

- E06.9 Thyroiditis, unspecified
- E06.1 Subacute thyroiditis
- E06.0 Acute thyroiditis

CLINICAL PEARLS

- TSH elevation above the normal range indicates a hypothyroid state; suppressed TSH indicates hyperthyroid state. Follow up with free T3/T4 determination.
- Follow patients on thyroid replacement with periodic TSH level.
TINEA (CAPITIS, CORPORIS, CRURIS)

Elisabeth L. Backer, MD

BASICS

DESCRIPTION

- Superficial fungal infections of the skin/scalp; various forms of dermatophytosis; the names relate to the particular area affected (1).
  - Tinea cruris: infection of crural fold and gluteal cleft
  - Tinea corporis: infection involving the face, trunk, and/or extremities; often presents with ring-shaped lesions, hence the misnomer ringworm
  - Tinea capitis: infection of the scalp and hair; affected areas of the scalp can show characteristic black dots resulting from broken hairs.
- Dermatophytes have the ability to subsist on protein, namely keratin.
- They cause disease in keratin-rich structures such as skin, nails, and hair.
- Infections result from contact with infected persons/animals.
  - Zoophilic infections are acquired from animals.
  - Anthropophilic infections are acquired from personal contact (e.g., wrestling) or fomites.
  - Geophile infections are acquired from the soil.
- System(s) affected: skin, exocrine
- Synonym(s): jock itch, ringworm

EPIDEMIOLOGY

Incidence

- Tinea cruris
  - Predominant age: any age; rare in children
  - Predominant sex: male > female
- Tinea corporis
  - Predominant age: all ages
  - Predominant sex: male = female
- Tinea capitis
  - Predominant age: 3 to 9 years; almost always occurs in young children
  - Predominant sex: male = female

Prevalence
Common worldwide

**Pediatric Considerations**
- Tinea cruris is rare prior to puberty.
- Tinea capitis is common in young children.

**Geriatric Considerations**
Tinea cruris is more common in the geriatric population due to an increase in risk factors.

**Pregnancy Considerations**
Tinea cruris and capitis are rare in pregnancy.

**ETIOLOGY AND PATHOPHYSIOLOGY**
Superficial fungal infection of skin/scalp

- Tinea cruris: Source of infection is usually the patient’s own tinea pedis, with agent being transferred from the foot to the groin via the underwear when dressing; most common causative dermatophyte is *Trichophyton rubrum*; rare cases caused by *Epidermophyton floccosum* and *Trichophyton mentagrophytes*
- Tinea corporis: most commonly caused by *T. rubrum*; *Trichophyton tonsurans* most often found in patients with tinea gladiatorum
- Tinea capitis: *T. tonsurans* found in 90% and *Microsporum* sp. in 10% of patients

**Genetics**
Evidence suggests a genetic susceptibility in certain individuals.

**RISK FACTORS**
- Warm climates; summer months and/or copious sweating; wearing wet clothing/multiple layers (tinea cruris)
- Daycare centers/schools/confined quarters (tinea corporis and capitis)
- Depression of cell-mediated immune response (e.g., individuals with atopy or AIDS)
- Obesity (tinea cruris and corporis)
- Direct contact with an active lesion on a human, an animal, or rarely, from soil; working with animals (tinea corporis)

**GENERAL PREVENTION**
Avoidance of risk factors, such as contact with suspicious lesions
Fluconazole or itraconazole may be useful in wrestlers to prevent outbreaks during competitive season.

COMMONLY ASSOCIATED CONDITIONS
Tinea pedis, tinea barbae, tinea manus

DIAGNOSIS
HISTORY
Lesions range from asymptomatic to pruritic.
In tinea cruris, acute inflammation may result from wearing occlusive clothing; chronic scratching may result in an eczematous appearance.
Previous application of topical steroids, especially in tinea cruris and corporis, may alter the overall appearance causing a more extensive eruption with irregular borders and erythematous papules. This modified form is called tinea incognito.

PHYSICAL EXAM
Tinea cruris: well-marginated, erythematous, half-moon–shaped plaques in crural folds that spread to upper thighs; advancing border is well defined, often with fine scaling and sometimes vesicular eruptions. Lesions are usually bilateral and do not include scrotum/penis (unlike with Candida infections) but may migrate to perineum, perianal area, and gluteal cleft and onto the buttocks in chronic/progressive cases. The area may be hyperpigmented on resolution.
Tinea corporis: scaling, pruritic plaques characterized by a sharply defined annular pattern with peripheral activity and central clearing (ring-shaped lesions); papules and occasionally pustules/vesicles present at border and, less commonly, in center
Tinea capitis: commonly begins with round patches of scale (alopecia less common). In its later stages, the infection frequently takes on patterns of chronic scaling with either little/marked inflammation or alopecia. Less often, patients will present with multiple patches of alopecia and the characteristic black-dot appearance of broken hairs. Extreme inflammation results in kerion formation (exudative, pustular nodulation).
DIFFERENTIAL DIAGNOSIS

- Tinea cruris
  - Intertrigo: inflammatory process of moist-opposed skin folds, often including infection with bacteria, yeast, and fungi; painful longitudinal fissures may occur in skin folds.
  - Erythrasma: diffuse brown, scaly, noninflammatory plaque with irregular borders, often involving groin; caused by bacterial infection with Corynebacterium minutissimum; fluoresces coral red with Wood lamp
  - Seborrheic dermatitis of groin
  - Psoriasis of groin (“inverse psoriasis”)
  - Candidiasis of groin (typically involves the scrotum)
  - Acanthosis nigricans

- Tinea capitis
  - Psoriasis
  - Seborrheic dermatitis
  - Pyoderma
  - Alopecia areata and trichotillomania
  - Aplasia cutis congenital

- Tinea corporis
  - Pityriasis rosea
  - Eczema (nummular)
  - Contact dermatitis
  - Syphilis
  - Psoriasis
  - Seborrheic dermatitis
  - Subacute systemic lupus erythematosus (SLE)
  - Erythema annulare centrifugum
  - Erythema multiforme; erythema migrans
  - Impetigo circinatum
  - Granuloma annulare

DIAGNOSTIC TESTS & INTERPRETATION

Wood lamp exam reveals no fluorescence in most cases (Trichophyton sp.); 10% of infections, those caused by T. rubrum, will fluoresce with a green light.

Initial Tests (lab, imaging)

- Potassium hydroxide (KOH) preparation of skin scrapings from dermatophyte leading border shows characteristic translucent, branching, rod-shaped
hyphae.
• Arthrospores can be visualized within hair shafts. Spores and/or hyphae may be seen on KOH exam.

**Follow-Up Tests & Special Considerations**
• Reevaluate to assess response, especially in resistant/extensive cases.
• Fungal culture using Sabouraud dextrose agar/dermatophyte test medium

**Test Interpretation**
• Skin scrapings show fungal hyphae in epidermis.
• Arthrospores found in hair shafts; spores and/or hyphae seen on KOH exam

---

**TREATMENT**

**GENERAL MEASURES**
• Careful hand washing and personal hygiene; laundering of towels/clothing of affected individual; no sharing of towels/clothes/headgear/pillows
• Evaluate other family members, close contacts, or household pets (especially kittens and puppies).
• Use of prophylactic antifungal shampoo by all household members for 2 to 4 weeks in cases of tinea capitis
• Avoid predisposing conditions such as hot baths and tight-fitting clothing (boxer shorts are better than briefs).
• Keep area as dry as possible (talcum/powders may be beneficial).
• Itching can be alleviated by OTC preparations such as Sarna or Prax.
• Topical steroid preparations should be avoided, unless absolutely needed to control itching and only after definitive diagnosis and initiation of antifungal treatment.
• Nystatin should be avoided in tinea infections but is indicated for cutaneous candidal infections.
• Avoid contact sports (e.g., wrestling) temporarily while starting treatment.

**MEDICATION**

**First Line**
• Tinea cruris/corporis (2)[C]
  • Topical azole antifungal compounds
    o Terbinafine 1% (Lamisil): OTC inexpensive and effective compound; can
be applied once or BID for 1 to 2 weeks
  - Econazole 1% (Spectazole), ketoconazole (Nizoral): usually applied BID for 2 to 3 weeks
  - Butenafine 1% (Mentax): applied once daily for 2 weeks; also very effective. To prevent relapse, use for 1 week after resolution.

**Tinea capitis**

- PO griseofulvin for *Trichophyton* and *Microsporum* sp.; microsized preparation available; dosage 10 to 20 mg/kg/day (max 1,000 mg); taken BID or as a single dose daily for 6 to 12 weeks
- PO terbinafine can be used for *Trichophyton* sp. at 62.5 mg/day in patients weighing 10 to 20 kg; 125 mg/day if weight 20 to 40 kg; 250 mg/day if weight >40 kg; use for 4 to 6 weeks.
- PO itraconazole can be used for *Microsporum* sp. and matches griseofulvin efficacy while being better tolerated. Dosage of 3 to 5 mg/kg/day, but most studies have used 100 mg/day for 6 weeks in children >2 years of age.

**Second Line**

Tinea cruris/corporis

- Oral antifungal agents are effective but not indicated in uncomplicated tinea cruris/corporis cases. They can be used for resistant and extensive infections or if the patient is immunocompromised. If topical therapy fails, consider possible oral therapy. Griseofulvin can be given 500 mg/day for 1 to 2 weeks.
- The following oral regimens have been reported in medical literature as being effective but currently are not specifically approved by FDA for tinea cruris:
  - PO terbinafine (Lamisil): 250 mg/day for 1 week
  - PO itraconazole (Sporanox): 100 mg BID once and repeated 1 week later
  - PO fluconazole (Diflucan): 150 mg once per week for 4 weeks
- Topical terbinafine 1% solution has been studied recently and appears effective as a once-daily application for 1 week.
- Oral antifungals have many interactions including warfarin, OCPs, and alcohol; advise checking for drug interactions prior to use; contraindicated in pregnancy. Monitor for liver toxicity when using oral antifungals.

**ISSUES FOR REFERRAL**

Refer if disease is nonresponsive/resistant, especially in immunocompromised host.

**ADDITIONAL THERAPIES**
Treatment of secondary bacterial infections

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Reevaluate response to treatment.

Patient Monitoring
Liver function testing prior to therapy and at regular intervals during course of therapy for patients requiring oral terbinafine, fluconazole,itraconazole, and griseofulvin

PATIENT EDUCATION
Explain the causative agents, predisposing factors, and prevention measures.

PROGNOSIS
• Excellent prognosis for cure with therapy in tinea cruris and corporis
• In tinea capitis, lesions will heal spontaneously in 6 months without treatment but scarring is more likely.

COMPLICATIONS
• Secondary bacterial infection
• Generalized, invasive dermatophyte infection
• Secondary eruptions called dermatophytid reactions may occur at distant sites.

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**

- B35.0 Tinea barbae and tinea capitis
- B35.4 Tinea corporis
- B35.6 Tinea cruris

**CLINICAL PEARLS**

- Tinea corporis is characterized by scaly plaque, with peripheral activity and central clearing.
- Tinea cruris is characterized by erythematous plaque in crural folds usually sparing the scrotum. Treatment of concomitant tinea pedis is advised.
- Tinea capitis is a fungal infection of the scalp affecting hair growth. Topical therapy is ineffective for this infection.
TINEA PEDIS
Elisabeth L. Backer, MD

BASICS

DESCRIPTION

- Superficial infection of the feet caused by dermatophytes
- Most common dermatophyte infection encountered in clinical practice; contagious
- Often accompanied by tinea manuum, tinea unguium, and tinea cruris
- Clinical forms: interdigital (most common), hyperkeratotic, vesiculobullous and rarely ulcerative
- System(s) affected: skin/exocrine
- Synonym(s): athlete’s foot

EPIDEMIOLOGY

- Predominant age: 20 to 50 years, although can occur at any age (1)[C]
- Predominant gender: male > female

Prevalence
4% of population

Pediatric Considerations
Rare in younger children; common in teens

Geriatric Considerations
Elderly are more susceptible to outbreaks because of immunocompromised and impaired perfusion of distal extremities.

ETIOLOGY AND PATHOPHYSIOLOGY

Superficial infection caused by dermatophytes that thrive only in nonviable keratinized tissue

- *Trichophyton interdigitale* (previously *mentagrophytes*) (acute)
- *Trichophyton rubrum* (chronic)
- *Trichophyton tonsurans*
- *Epidermophyton floccosum*
**Genetics**
No known genetic pattern

**RISK FACTORS**
- Hot, humid weather
- Sweating
- Occlusive/tight-fitting footwear
- Immunosuppression
- Prolonged application of topical steroids

**GENERAL PREVENTION**
- Good personal hygiene
- Wearing rubber or wooden sandals in community showers, bathing places, locker rooms
- Careful drying between toes after showering or bathing; blow-drying feet with hair dryer may be more effective than drying with towel.
- Changing socks and shoes frequently
- Applying drying or dusting powder
- Applying topical antiperspirants
- Putting on socks before underwear to prevent infection from spreading to groin

**COMMONLY ASSOCIATED CONDITIONS**
- Hyperhidrosis
- Onychomycosis
- Tinea manuum/unguium/cruris/corporis

**DIAGNOSIS**

**HISTORY**
- Itchy, scaly rash on foot, usually between toes; may progress to fissuring/maceration in toe web spaces.
- May be associated with onychomycosis and other tinea infections
- May be complicated by secondary bacterial infections

**PHYSICAL EXAM**
- Acute form: self-limited, intermittent, recurrent; scaling, thickening, and
fissuring of sole and heel; scaling or fissuring of toe webs; or pruritic vesicular/bullous lesions between toes or on soles
- Chronic form: most common; slowly progressive, pruritic erythematous erosion/scales between toes, in digital interspaces; extension onto soles, sides/dorsum of feet (moccasin distribution); if untreated, may persist indefinitely
- Other features: strong odor, hyperkeratosis, maceration, ulceration
- Tinea pedis may occur unilateral or bilateral.
- Secondary presumably immune-mediated eruptions called dermatophytid reactions may occur at distant sites.

DIFFERENTIAL DIAGNOSIS
- Interdigital type: erythrasma, impetigo, pitted keratolysis, candidal intertrigo
- Moccasin type: psoriasis vulgaris, eczematous dermatitis, pitted keratolysis
- Inflammatory/bullous type: impetigo, allergic contact dermatitis, dyshidrotic eczema (negative KOH examination of scrapings), bullous disease

DIAGNOSTIC TESTS & INTERPRETATION
Wood lamp exam will not fluoresce unless complicated by another fungus, which is uncommon: *Malassezia furfur* (yellow to white), *Corynebacterium* (red), or *Microsporum* (blue-green).

Initial Tests (lab, imaging)
Testing is not needed in typical presentation.
- Direct microscopic exam (potassium hydroxide) of scrapings of the lesions
- Culture (Sabouraud medium)

Test Interpretation
- Potassium hydroxide preparation: septate and branched mycelia
- Culture: dermatophyte

TREATMENT
Treatment is generally with topical antifungal medications for up to 4 weeks and is more effective than placebo:
- Acute treatment
  - Aluminum acetate soak (Burow solution; Domeboro, 1 pack to 1 quart
warm water) to decrease itching and acute eczematous reaction
– Antifungal cream of choice BID after soaks (allyamines slightly more effective than azoles)

● Chronic treatment:
  – Antifungal creams BID, continuing for 3 days after the rash is resolved: terbinafine 1% (possibly most effective topical), clotrimazole 1%, econazole 1%, ketoconazole 2%, tolnaftate 1%, etc. (2)[A]
  – May try systemic antifungal therapy; see below (consider if concomitant onychomycosis or after failed topical treatment).

GENERAL MEASURES
● Soak with aluminum chloride 30% or aluminum subacetate for 20 minutes BID.
● Careful removal of dead/thickened skin after soaking or bathing
● Treatment of shoes with antifungal powders
● Avoidance of occlusive footwear
● Chronic or extensive disease or nail involvement requires oral antifungal medication and systemic therapy.

MEDICATION
For use when topical therapy has failed

First Line
● Systemic antifungals (3)[A]:
  – Itraconazole: 200 mg PO BID for 7 days (cure rate >90%)
  – Terbinafine: 250 mg/day PO for 14 days
● If concomitant onychomycosis:
  – Itraconazole: 200 mg PO BID for 1st week of month for 3 months. Liver function testing is recommended.
  – Terbinafine: 250 mg/day PO for 12 weeks, or pulse dosing: 500 mg/day PO for 1st week of month for 3 months; not recommended if creatinine clearance <50 mL/min
● Pediatric dosing options:
  – Griseofulvin: 10 to 15 mg/kg/day or divided
  – Terbinafine:
    o 10 to 20 kg: 62.5 mg/day
    o 20 to 40 kg: 125 mg/day
    o >40 kg: 250 mg/day
Itraconazole: 5 mg/kg/day
Fluconazole: 6 mg/kg/week
Contraindications: itraconazole, pregnancy Category C
Precautions: All systemic antifungal drugs may have potential hepatotoxicity.
Significant possible interactions: Itraconazole requires gastric acid for absorption; effectiveness is reduced with antacids, H₂ blockers, proton pump inhibitors, etc. Take with acidic beverage such as soda if on antacids.

**Second Line**

- Systemic antifungals: griseofulvin 250 to 500 mg of microsize BID daily for 21 days
- Contraindications (griseofulvin):
  - Patients with porphyria, hepatocellular failure
  - Patients with history of hypersensitivity to griseofulvin
- Precautions (griseofulvin):
  - Should be used only in severe cases
  - Periodic monitoring of organ-system functioning, including renal, hepatic, and hematopoietic
  - Possible photosensitivity reactions
  - Lupus erythematosus, lupus-like syndromes, or exacerbation of existing lupus erythematosus has been reported.
- Significant possible interactions (griseofulvin):
  - Decreases activity of warfarin-type anticoagulants
  - Barbiturates usually depress griseofulvin activity.
  - May potentiate effect of alcohol, producing tachycardia and flush

**ISSUES FOR REFERRAL**
If extensive or resistant disease, especially in immunocompromised host

**ADDITIONAL THERAPIES**
- Treatment of secondary bacterial infections
- Treatment of eczematoid changes

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Avoid sweat buildup along feet.
**Patient Monitoring**
Evaluate for response, recognizing that infections may be chronic/recurrent.

**DIET**
No restrictions

**PATIENT EDUCATION**
See “General Prevention.”

**PROGNOSIS**
- Control but not complete cure
- Infections tend to be chronic with exacerbations (e.g., in hot, humid weather).
- Personal hygiene and preventive measures such as open-toed sandals, careful drying, and frequent sock changes are essential.

**COMPLICATIONS**
- Secondary bacterial infections (common portal of entry for streptococcal infections, producing lymphangitis/cellulitis of lower extremity)
- Eczematoid changes

**REFERENCES**

**ADDITIONAL READING**
SEE ALSO
Dermatitis, Contact; Dyshidrosis

CODES
ICD10
B35.3 Tinea pedis

CLINICAL PEARLS

- Treatment with topical antifungal medications for up to 4 weeks usually suffices.
- Tinea pedis is often recurrent/chronic in nature.
- Careful drying between toes after showering or bathing helps prevent recurrences. (Blow drying feet with hair dryer may be more effective than drying with towel.)
- Socks should be changed frequently. Put on socks before underwear to prevent infection from spreading to groin (tinea cruris).
- Dusting and drying powders (containing antifungal agents) may prevent recurrences.
TINEA VERSICOLOR
Elisabeth L. Backer, MD

BASICS

DESCRIPTION
- Rash due to a common superficial mycosis with a variety of colors and changing shades of color, predominantly present on trunk and proximal upper extremities; macules are usually hypopigmented, light brown, or salmon-colored; fine scale is often apparent. It is not a dermatophyte infection.
- System(s) affected: skin/exocrine
- Synonym(s): pityriasis versicolor

EPIDEMIOLOGY

Incidence
- Common, occurs worldwide, especially in tropical climates, where prevalence can reach 50%
- Predominant age: teenagers and young adults
- Predominant sex: male = female

Pediatric Considerations
Usually occurs after puberty (except in tropical areas); facial lesions are more common in children.

Geriatric Considerations
Not common in the geriatric population

ETIOLOGY AND PATHOPHYSIOLOGY
Inhibition of pigment synthesis in epidermal melanocytes, leading to hypomelanosis; in the hyperpigmented type, the melanosomes are large and heavily melanized (1).
- Saprophytic yeast: Pityrosporum orbiculare (also known as Plasmodium ovale, Malassezia furfur, or Malassezia ovalis), which is a known colonizer of all humans
- Development of clinical disease associated with transformation of Malassezia from yeast cells to pathogenic mycelial form likely multifactorial, due to host
and/or external factors
- Not linked to poor hygiene

**Genetics**
Genetic predisposition may exist.

**RISK FACTORS**
- Hot, humid weather
- Use of topical skin oils
- Hyperhidrosis
- HIV infection/immunosuppression
- High cortisol levels (Cushing, prolonged steroid administration)
- Pregnancy
- Malnutrition
- Oral contraceptives

**GENERAL PREVENTION**
- Recheck and use prophylaxis each spring prior to tanning season.
- Avoid skin oils.

**DIAGNOSIS**

**HISTORY**
- Asymptomatic scaling macules on trunk
- Possible mild pruritus
- More prominent in summer
- Sun tanning accentuates lesions because infected areas do not tan.
- Periodic recurrences common, especially in the warm summer months

**PHYSICAL EXAM**
- *Versicolor* refers to the variety and changing shades of colors. Color variations can exist between individuals and also between lesions.
- Sun-exposed areas: Lesions are usually white/hypopigmented.
- Covered areas: Lesions are often brown or salmon-colored.
- Distribution (sebum-rich areas): chest, shoulders, back (also face and intertriginous areas)
  - Face is more likely to be involved in children.
Appearance: small individual macules/patches that frequently coalesce
Scale: fine, more visible with scraping

DIFFERENTIAL DIAGNOSIS
Other skin diseases with discolored macules and plaques, including the following:
- Pityriasis alba/rosea (“Christmas tree-like” distribution visible in P. rosea)
- Vitiligo (presents without scaling)
- Seborrhoeic dermatitis (more erythematous; thicker scale)
- Nummular eczema
- Secondary syphilis
- Erythrasma
- Mycosis fungoides

DIAGNOSTIC TESTS & INTERPRETATION
Wood lamp: yellow to yellow-green fluorescence or pigment changes

Initial Tests (lab, imaging)
- Direct microscopy of scales with 10% potassium hydroxide (KOH) preparation to visualize hyphae and spores (“spaghetti and meatballs” pattern)
- Routine lab tests are usually not necessary.
- Fungal culture is not useful.

Test Interpretation
- Short, stubby, or Y-shaped hyphae
- Small, round spores in clusters on hyphae

TREATMENT
GENERAL MEASURES
- Apply prescribed topical medications to affected skin with cotton balls.
- Pigmentation may take months to fade or fill in.
- Repeat treatment each spring prior to sun exposure; consider monthly prophylaxis during the summer months.
- Patients who fail topical treatment can be treated with an oral/systemic medication.
MEDICATION

Topical antifungal therapy is the treatment of choice in limited disease and is safe and usually effective. Evidence is generally of poor quality, but data suggest that longer durations of treatment and higher concentrations of active agents produce greater cure rates (2)[A].

First Line
- Ketoconazole 2% shampoo applied to damp skin and left on for 5 minutes for 1 to 3 days or
- Selenium sulfide shampoo 2.5% (Selsun):
  - Allowed to dry for 10 minutes prior to showering: daily for 1 week or
  - Allowed to remain on body for 12 to 24 hours prior to showering: once a week for 4 weeks or
- Clotrimazole 1% topical (Lotrimin) BID for 2 to 4 weeks or
- Miconazole 2% (Micatin, Monistat) BID for 2 to 4 weeks or
- Ketoconazole 2% (Nizoral) cream BID for 2 to 4 weeks or
- Terbinafine (Lamisil) 1% solution BID for 1 week or
- Terbinafine (Lamisil DermGel) once daily for 1 week

Cure rates of topical antiyeast preparations typically 70–80%; healing continues after active treatment. Resumption of even pigmentation may take months.
- Contraindications: Ketoconazole is contraindicated in pregnancy.
- Newer preparations: 2.25% selenium sulfide foam; ketoconazole 2% gel

Second Line
- Use for extensive disease or nonresponders.
- Oral fluconazole 300 mg once weekly for 2 weeks (3)[A]
- Itraconazole 200 mg/day PO for 1 week; cure rate >90% (3)[A]
- Oral ketoconazole is no longer recommended by FDA due to risks of hepatotoxicity, adrenal insufficiency, and drug–drug interactions.
- Oral terbinafine or griseofulvin is not effective.
- Pramiconazole has been studied but is not yet available for clinical use.

ISSUES FOR REFERRAL
- If resistant to treatment
- If extensive disease occurs in immunocompromised host
ONGOING CARE

- Ketoconazole 2% or selenium sulfide 2.5% shampoo can be used weekly for maintenance or monthly for prophylaxis.
- Itraconazole 400 mg once monthly (in 2 divided dosages) during the warmer months of the year can also reduce recurrences.

FOLLOW-UP RECOMMENDATIONS

Warn patients that whiteness will remain for several months after treatment.

Patient Monitoring

- Recheck and treat again each spring prior to tanning season.
- Failure to respond should prompt reassessment or dermatology referral.
- Resistance to treatment, frequent recurrences, or widespread disease may point to immunodeficiency.

PATIENT EDUCATION

For patient education materials favorably reviewed on this topic, contact American Academy of Dermatology, 930 N. Meacham Road, P.O. Box 4014, Schaumberg, IL 60168-4014; (708) 330-0230.

PROGNOSIS

- Duration of lesions months/years
- Recurs almost routinely because this yeast is a known human colonizer
- Pigmentary changes may take months to resolve.

REFERENCES

ADDITIONAL READING

mebooksfree.com

**CODES**

**ICD10**

B36.0 Pityriasis versicolor

**CLINICAL PEARLS**

- Noncontagious macules of varying colors, with fine scale
- Recurrence in summer months
- More apparent after tanning. Skin areas with fungal infection do not tan; thus, hypopigmented areas become more visible.
- Warn patients that whiteness will remain for several months after treatment.
TINNITUS
Donna I. Meltzer, MD

BASICS

DESCRIPTION
- Tinnitus is a perceived sensation of sound in the absence of an external acoustic stimulus; often described as a ringing, hissing, buzzing, or whooshing
- Derived from the Latin word *tinnire*, meaning “to ring”
- May be heard in one or both ears or centrally within the head
- Two types: subjective (most common) and objective tinnitus
- Subjective tinnitus: perceived only by the patient; can be continuous, intermittent, or pulsatile
- Objective tinnitus: audible to the examiner; usually pulsatile; <1% cases (1)
- Primary tinnitus: idiopathic with or without sensorineural hearing loss (SNHL) (2)
- Secondary tinnitus: associated with a specific cause (other than SNHL)

EPIDEMIOLOGY

Prevalence
- Tinnitus reported by 35 to 50 million adults in United States; although underreported, 12 million seek medical care.
- Affects 10–15% of adults
- Prevalence increases with age and peaks in 6th decade.
- Prevalence of 13–53% in general pediatric population
- Ethnic: whites > blacks and Hispanics
- Gender: males > females

Incidence
- Incidence increasing in association with excessive noise exposure
- Higher rates of tinnitus in smokers, hypertensives, diabetics, and obese patients

ETIOLOGY AND PATHOPHYSIOLOGY
- Precise pathophysiology is unknown; numerous theories have been proposed.
Cochlear damage from ototoxic agents or noise exposure damage hair cells so that the central auditory system compensates, resulting in hyperactivity in cochlear nucleus and auditory cortex. Animal models have identified brain abnormalities resulting in increased firing and synchrony in auditory cortex.

- Causes of subjective tinnitus are the following:
  - Otologic: hearing loss, cholesteatoma, cerumen impaction, otosclerosis, Ménière disease, vestibular schwannoma
  - Ototoxic medications: anti-inflammatory agents (aspirin, NSAIDs); antimalarial agents, antimicrobial drugs (aminoglycosides); antineoplastic agents, loop diuretics, miscellaneous drugs (antiarrhythmics, antiulcer, anticonvulsants, antihypertensives); psychotropic drugs; anesthetics
  - Somatic: temporomandibular joint (TMJ) dysfunction, head or neck injury
  - Neurologic: multiple sclerosis, spontaneous intracranial hypertension, vestibular migraine, type I Chiari malformation
  - Infectious: viral, bacterial, fungal

- Causes of objective tinnitus:
  - Vascular: aortic or carotid stenosis, venous hum, arteriovenous fistula or malformation, vascular tumors, high cardiac output state (anemia)
  - Neurologic: palatal myoclonus, idiopathic stapedial muscle spasm
  - Patulous eustachian tube

**Genetics**
Minimal genetic component

**RISK FACTORS**
- Hearing loss (but can have tinnitus with normal hearing)
- High-level noise exposure
- Advanced age
- Use of ototoxic medications
- Otologic disease (otosclerosis, Ménière disease, cerumen impaction)
- Anxiety and depression associated with increased odds of tinnitus

**GENERAL PREVENTION**
- Avoid loud noise exposure and wear appropriate ear protection to prevent hearing loss.
- Monitor ototoxic medications and avoid prescribing more than one ototoxic agent concurrently.
COMMONLY ASSOCIATED CONDITIONS
- SNHL caused by presbycusis (age associated hearing loss) or prolonged loud noise exposure
- Conductive hearing loss due to cerumen, otosclerosis, cholesteatoma
- Psychological disorders: depression, anxiety, insomnia, suicidal ideation
- Despair, frustration, interference with concentration and social interactions, work hindrance

DIAGNOSIS

HISTORY
- Onset gradual (presbycusis) or abrupt (following loud noise exposure)
- Timing: can be continuous (hearing loss) or intermittent (Ménière disease)
- Pattern: nonpulsatile > pulsatile (often vascular cause)
- Location: bilateral > unilateral (vestibular schwannoma, cerumen, Ménière disease)
- Pitch: high pitch (with SNHL) > low pitch (Ménière disease)
- Associated symptoms: hearing loss, headache, noise intolerance, vertigo, TMJ dysfunction, neck pain
- Exacerbating factors: loud noise; jaw, head, or neck movements
- Alleviating factors: hearing aid, position change, medications
- Medication use (prescription, OTC, supplements)
- Hearing and past noise exposure (occupational, military, recreational)
- Psychosocial history (depression, sleep habits)
- Impact of tinnitus: Tinnitus Handicap Inventory, Tinnitus Functional Index

PHYSICAL EXAM
- HEENT, neck, neurologic, and vascular examinations
- Ear: cerumen impaction, effusion, cholesteatoma
- Check hearing; air and bone conduction testing with 512- or 1,024-Hz tuning fork (Weber and Rinne tests)
- Eye: funduscopic exam for papilledema (intracranial hypertension) or visual field change (mass)
- TMJ: Palpate for tenderness and crepitus with movement.
- Cranial nerve, Romberg test (equilibrium), finger to nose, gait; assess for nystagmus.
- Auscultate for bruits or murmurs over ear canal, periauricular areas, orbit,
Differential Diagnosis

- Pulsatile tinnitus: carotid stenosis, aortic valve disease, AV malformation, high cardiac output state (anemia, hyperthyroidism), paraganglioma (glomus tumor)
- Nonpulsatile tinnitus: auditory hallucinations

Diagnostic Tests & Interpretation

- Tinnitus is a symptom; no objective test to confirm diagnosis
- Pure tone audiometry (air and bone conduction)
- Speech discrimination testing
- Tympanometry
- Auditory brainstem response (ABR); less sensitive and specific than MRI for diagnosis of vestibular schwannoma (1)
- Carotid Doppler ultrasonography (neck bruit)

Initial Tests (lab, imaging)

- Little evidence to support lab testing other than targeted lab studies based on history and physical exam. Use clinical judgment and consider the following:
  - CBC
  - BUN/creatinine, fasting glucose, lipid panel
  - Thyroid-stimulating hormone
- Newer guidelines advise against imaging studies unless have one or more of the following: unilateral or pulsatile tinnitus, focal neurologic abnormality, or asymmetric hearing loss (2)
- CT of temporal bone is initial imaging study of middle ear (3).
- Nonpulsatile tinnitus: MRI with or without contrast, MRI auditory canal (for vestibular schwannoma)
- Pulsatile tinnitus: CT, MRI, MRA/MRV, CTA/CTV, carotid ultrasound, and conventional angiography all have been used to work up pulsatile tinnitus (3).

Follow-Up Tests & Special Considerations

Consider HIV, RPR, autoimmune panel, Lyme test, vitamin B\textsubscript{12} level.

Diagnostic Procedures/Other

Electronystagmography (vestibular testing for Ménière disease)
TREATMENT

GENERAL MEASURES

- Individualize treatment based on the severity of tinnitus and impact on function
- Reassure patient.
- Manage treatable pathology.
- Education, relaxation therapy, cognitive-behavioral therapy (CBT)
- Hearing aids (corrects hearing and might mask tinnitus); can be tried if there is hearing loss and bothersome tinnitus (2)[C]
- Protect hearing against future loud noise.
- Masking sound devices or generators on discontinuation might have decreased tinnitus (residual inhibition).
- Discontinue ototoxic medications.

MEDICATION

No pharmacologic agent has been shown to cure or consistently alleviate tinnitus.

First Line

- Antidepressants (SSRIs or TCAs): probably help with psychological distress; insufficient evidence that antidepressant drug therapy improves tinnitus (4)[A]
- Melatonin decreases tinnitus intensity and improves sleep quality; most effective in men, those without depression or prior treatment, and those with more severe bilateral tinnitus (5)[B]

Second Line

- Anticonvulsants: potentially suppress central auditory hyperactivity, but not recommended (2)[C]
- Benzodiazepines help reduce tinnitus distress, but regular use discouraged.
- No difference between gabapentin and control group in patients with isolated tinnitus (6)[B]
- Higher caffeine intake associated with lower incidence of tinnitus in women (7)[B]

ISSUES FOR REFERRAL

- Audiologist for comprehensive hearing evaluation and management
Otolaryngologist, neurologist, or neurosurgeon depending on pathology
Dental referral for TMJ treatment and dental orthotics (splint, night guard)
Therapists for CBT, biofeedback, education, and relaxation techniques

ADDITIONAL THERAPIES
Sound therapy (masking): Patients wear low-level noise generators to mask the tinnitus noise; optional therapy (2)[C]
CBT employs relaxation exercises, coping strategies, and deconditioning techniques to reduce arousal levels and reverse negative thoughts about tinnitus; recommended as beneficial based on randomized controlled trials (2) [C]
Tinnitus retraining therapy (TRT) combines counseling, education, and acoustic therapy (soft music, sound machine) to minimize bothersome nature of tinnitus; often requires a team approach and up to 2 years of therapy; might be more effective than sound masking (8)[B]
Transcranial magnetic stimulation (TMS): a noninvasive method to stimulate neurons in the brain by rapidly changing magnetic fields; not recommended as randomized trials were inconclusive (2)[C]
Botulism toxin (for palatal myoclonus)
Intratympanic steroid injections not recommended (2)[C]
Hyperbaric oxygen: no beneficial effect on tinnitus

SURGERY/OTHER PROCEDURES
Cochlear implants (for severe SNHL)
Ablation of cochlear nerve (destroys hearing)
Epidural stimulation of secondary auditory cortex with implanted electrodes suppressed tinnitus in small subset of patients
Otosclerosis: stapedectomy surgery with implantation of ossicular prosthesis
Severe Ménière disease not alleviated by medications: installation of endolymphatic shunt, labyrinthectomy, or vestibular neurectomy
Auditory neoplasms: surgical resection/radiation
Pulsatile tinnitus due to atherosclerotic carotid artery disease: carotid endarterectomy

COMPLEMENTARY & ALTERNATIVE MEDICINE
Zinc: no evidence that oral zinc supplements improve symptoms of tinnitus in adults (9)[B]
• One evidence-based practice guideline does not recommend Ginkgo biloba, melatonin, zinc, or other dietary supplements for treatment of persistent, bothersome tinnitus [2][C].
• Acamprosate (used to treat alcohol dependence): not recommended [2][C]
• Hypnosis (unknown effectiveness)
• Acupuncture therapy may offer subjective benefits to some patients [10][A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Not applicable

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
• Audiologist: for hearing evaluation and therapy
• Counseling as needed for psychological distress
• Family physician: as needed for support and guidance

PATIENT EDUCATION
• Help patients understand the relatively benign nature of tinnitus.
• Self-help groups
• American Tinnitus Association: (800) 634-8978; http://www.ata.org/
• National Institute on Deafness and Other Communication Disorders: (800) 241-1044; http://www.nidcd.nih.gov/Pages/default.aspx
• American Academy of Family Physicians: http://familydoctor.org

PROGNOSIS
• Tinnitus persisted in 80% of older patients and increased in severity in 50% [1].
• Focus on managing tinnitus and reducing severity, not curing.

REFERENCES

**CODES**

**ICD10**
- H93.19 Tinnitus, unspecified ear
- H93.11 Tinnitus, right ear
- H93.12 Tinnitus, left ear

**CLINICAL PEARLS**
- People have different levels of tolerance to tinnitus. It may affect sleep, concentration, and emotional state. Many patients with chronic tinnitus have depression.
- To keep tinnitus from worsening, avoid loud noises and minimize stress.
- Optimal management may involve multiple strategies.
TOBACCO USE AND SMOKING CESSATION

Felix B. Chang, MD, DABMA, FAAMA • Daniel Molinar, MD

BASICS

DESCRIPTION

- Use of tobacco of any form
- The second leading actual cause of death in the United States
- Smokeless tobacco refers to tobacco products that are sniffed, sucked, or chewed.
- Nicotine sources: cigars, pipes, water pipes, hookahs, and cigarettes

EPIDEMIOLOGY

Incidence

- 2.4 million new smokers annually in the United States (2.6% initiation rate)
- 59% of new smokers are <18 years of age (5.8% initiation rate for teens)
- 9.7 million people age >18 years smoke 20 or more cigarettes daily

Prevalence

- 15% of all adults (36.5 million people): 17% of males, 14% of females are current cigarette smokers.
- Highest among those aged 18 to 25 years (41%)
- Adults aged >25 years (28%)
- Race: highest among whites (22%) and African Americans (21%) and is lower among Hispanics (15%) and Asians (12%)
- Gender: male > female (22% vs. 17%)
- Inversely proportional to education level
- Cigarette smoking is responsible for >480,000 deaths per year in the United States, including >41,000 deaths from secondhand smoke exposure. This is about 1 in 5 deaths annually or 1,300 deaths every day.

ETIOLOGY AND PATHOPHYSIOLOGY
● Addiction due to nicotine’s rapid stimulation of the brain’s dopamine system (teenage brain especially susceptible)
● Atherosclerotic risk due to adrenergic stimulation, endothelial damage, carbon monoxide, and adverse effects on lipids
● Direct airway damage from cigarette tar
● Carcinogens in all tobacco products

RISK FACTORS
● Presence of a smoker in the household
● Easy access to cigarettes
● Comorbid stress and psychiatric disorders
● Low self-esteem/self-worth
● Poor academic performance
● Boys: high levels of aggression and rebelliousness
● Girls: preoccupation with weight and body image
● *International Journal of Environmental Research and Public Health* defined heavy smoking as 20 or more cigarettes per day, or 20 or more pack-years. A pack-year is determined by multiplying the number of cigarettes smoked per day by the number of years of smoking. Twenty pack-years is equivalent to a pack a day for 20 years or 2 packs a day for 10 years. Other common cut-points for heavy smoking include 15 and 25 cigarettes per day.

GENERAL PREVENTION
● Most first-time tobacco use occurs before high school graduation.
● The Tar Wars program of the American Academy of Family Physicians has successfully targeted tobacco use prevention in 4th and 5th graders.
● Smoking bans in public areas and workplaces
● Restriction of minors’ access to tobacco
● Restrictions on tobacco advertisements
● Raising prices through taxation
● Media literacy education
● Tobacco-free sports initiatives

COMMONLY ASSOCIATED CONDITIONS
● Coronary artery disease
● Cerebrovascular disease
● Peripheral vascular disease
● Abdominal aortic aneurysm (AAA)
- COPD
- Cancer of the lip, oral cavity, pharynx, larynx, lung, esophagus, stomach, pancreas, kidney, bladder, cervix, and blood
- Pneumonia, osteoporosis
- Periodontitis
- Alcohol use
- Depression and anxiety
- Reduced fertility

**Pregnancy Considerations**

Women who smoke or are exposed to secondhand smoke during pregnancy have increased risks of miscarriage, placenta previa, placental abruption, premature rupture of membranes, preterm delivery, low-birth-weight infants, and stillbirth.

**Pediatric Considerations**

- Secondhand smoke increases the risk for:
  - Sudden infant death syndrome
  - Acute upper and lower respiratory tract infections
  - More severe exacerbations of asthma
  - Otitis media and need for tympanostomies
- Nicotine passes through breast milk. Effects on growth and development of nursing infants are unknown.

**DIAGNOSIS**

**HISTORY**

- Ask about tobacco use and secondhand smoke exposure at every physician encounter.
- Type and quantity of tobacco used
- Pack-years = packs/day × years
- Awareness of health risks
- Assess interest in quitting.
- Identify triggers for smoking.
- Prior attempts to quit: method, duration of success, reason for relapse

**PHYSICAL EXAM**

- General: tobacco smoke odor
Skin: premature face wrinkling
Mouth: nicotine-stained teeth; inspect for suspicious mucosal lesions.
Lungs: crackles, wheezing, increased or decreased volume
Vessels: carotid or abdominal bruits, abdominal aortic enlargement, peripheral pulses, stigmata of peripheral vascular disease

**DIAGNOSTIC TESTS & INTERPRETATION**
- CXR for patients with pulmonary symptoms or signs of cancer but not for screening
- The USPSTF recommends one-time screening US for AAA in men ≥65 years of age who ever smoked (number needed to screen to prevent one AAA = 500).
- Low-dose CT is more sensitive than chest radiograph for identifying small, asymptomatic lung cancers.
- USPSTF recommends screening for lung cancer with low-dose CT for individuals 55 to 80 years with a 30 pack-years history of smoking; current smokers or those who have quit within past 15 years

*Diagnostic Procedures/Other*
PFTs for smokers with chronic pulmonary symptoms, such as wheezing and dyspnea

**TREATMENT**
Both behavioral counseling and pharmacotherapy benefit patients who are trying to quit smoking especially when used in combination.

**ALERT**
Provider recommending smoking cessation at *every clinical visit* improves cessation rates.

**GENERAL MEASURES**
- Behavioral counseling includes the 5 As:
  - Ask about tobacco use at every office visit.
  - Advise all smokers to quit.
  - Assess the patient’s willingness to quit.
  - Assist the patient in his or her attempt to quit.
  - Arrange follow-up.

mebooksfree.com
Patients ready to quit smoking should set a quit date within the next 2 weeks; no difference in success rates between patients who taper prior to their quit date and those who stop abruptly.

Success increased with a quitting partner, such as a spouse, friend, or coworker, to provide mutual encouragement.

**MEDICATION**

**First Line**

- **Varenicline (Chantix):** 0.5 mg/day PO for 3 days, then 0.5 mg BID for 4 days and then 1 mg BID for 11 weeks (1)[A]:
  - Start 1 to 4 weeks prior to smoking cessation and continue for 12 to 24 weeks.
  - Superior to placebo and to bupropion; number needed to treat = 7
  - May be combined with nicotine replacement therapy (NRT)
  - S/E: nausea, insomnia, headache, depression, suicidal ideation; safety not established in adolescents or patients with psychiatric or cardiovascular disease; pregnancy Category C

- **Bupropion SR (Zyban):** 150 mg PO for 3 days and then 150 mg BID:
  - Start 1 week prior to smoking cessation and continue for 7 to 12 weeks.
  - Twice as effective as placebo
  - Drug of choice for patients with depression or schizophrenia
  - May be combined with varenicline and NRT in men who smoke >1 PPD
    - S/E: tachycardia, headache, nausea, insomnia, dry mouth; contraindicated in patients who have seizure disorders or anorexia/bulimia; pregnancy Category C (1,2)[A]

- **NRT (e.g., patch, gum, lozenge, inhaler, nasal spray) (1,2)[A]:**
  - Improves quit rates by 50–70% versus placebo
  - Over the counter
  - **Patch (NicoDerm CQ 21, 14, and 7 mg):**
    - 1 patch q24h
    - Start with 21 mg if smoking ≥10 cigarettes per day; otherwise, start with 14 mg.
    - 6 weeks on initial dose and then taper
    - 2 weeks each on subsequent doses
    - No proven benefit beyond 8 weeks
  - **E-cigarettes**
    - Contain less nicotine than cigarette
    - Controversial if less “dangerous” than tobacco; not well studied as NRT
Conflicting data on whether teen use increases or decreases risk to cigarette progression

- Gum (Nicorette, 2 and 4 mg):
  - Use 4 mg if smoking ≥25 cigarettes per day.
  - Chew 1 piece q1–2h for 6 weeks, then 1 piece q2–4h for 3 weeks and then 1 piece q4–8h for 3 weeks.
- May use in combination with bupropion; monitor for hypertension.
- S/E: headache, pharyngitis, cough, rhinitis, dyspepsia; all mainly with inhaler and spray forms
- Pregnancy Category D
- NRT is reasonable in hospitalized smokers, as NRT products immediately treat nicotine withdrawal symptoms, whereas varenicline and bupropion take time to reach steady state.

Second Line

- Nortriptyline: 25 to 75 mg/day PO or in divided doses (1)[A]:
  - Start 10 to 14 days prior to smoking cessation and continue for at least 12 weeks.
  - Efficacy similar to bupropion, but side effects more common; pregnancy Category D
  - The antidepressants bupropion and nortriptyline aid long-term smoking cessation (4)[A].

- Clonidine: 0.1 mg PO BID or 0.1 mg/day transdermal patch weekly (1):
  - Side effects: hypotension, bradycardia, depression, fatigue; pregnancy Category C

ADDITIONAL THERAPIES

- Electronic cigarettes: low grade of evidence (5)[A]
- Pharmacotherapy and behavior support increase success compared with minimal intervention or usual care (4)[A].
- Naltrexone: no evidence

COMPLEMENTARY & ALTERNATIVE MEDICINE

Acupuncture, aversive therapy, and hypnosis have not been proven to enhance long-term smoking cessation.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Follow up 3 to 7 days after scheduled quit date and at least monthly for 3 months thereafter.
- Refraining from tobacco products for first 2 weeks is critical to long-term abstinence.
- Encourage patients who relapse to try again.

Patient Monitoring

- Short-term withdrawal symptoms include dysphoria, depressed mood, irritability, anxiety, insomnia, increased appetite, and poor concentration.
- Longer term risks of smoking cessation include weight gain (4 to 5 kg on average) and depression.
- Quitting is also associated with exacerbations of ulcerative colitis and worsening of cognitive function in patients with schizophrenia.
- Nicotine withdrawal syndrome: dysphoric or depressed mood, insomnia, irritability, frustration, or anger; anxiety, difficulty concentrating, restlessness, and increased appetite or weight gain.
- Lung cancer risk by smoking status: heavy smokers 1.00, light smokers 9.44 (0.35 to 0.56), ex-smokers 0.17 (0.13 to 0.23), never smoker 0.09 (0.06 to 0.13); adjusted hazard ratio (95% CI)

DIET

Healthy eating for limiting weight gain

PATIENT EDUCATION

1-800-QUIT-NOW

PROGNOSIS

- Measurable cardiovascular benefits of smoking cessation begin as early as 24 hours after quitting and continue to mount until the risk is reduced to that of nonsmokers by 5 to 15 years.
- People who quit smoking after a heart attack or cardiac surgery reduces their risk of death by 1/3.
- Relapse rates initially >60% but decrease to 2–4% per year after completing 2 years of abstinence.
>16 million Americans are living with a disease caused by smoking or exposure to tobacco smoke.

For every person who dies because of smoking, at least 30 people live with a serious smoking-related illness.

On average, smokers die 10 years earlier than nonsmokers.

Pharmacotherapy for preoperative smokers increases cessation rates and decreases postoperative complications.

COMPLICATIONS

- Disability and premature death due to heart attack, stroke, cancer, COPD
- Smoking more than doubles the risk of coronary artery disease and doubles the risk of stroke.
- Smokers are 12 to 22 times more likely than nonsmokers to die from lung cancer.
- Worldwide, tobacco use causes nearly 6 million deaths per year, and current trends show that tobacco use will cause >8 million deaths annually by 2030.
- Complications with screening by low-dose CT include complications associated with needle biopsy, bronchoscopy, and thoracotomy from false positives.

REFERENCES

ADDITIONAL READING

2017;65(52):1457–1464.

**SEE ALSO**

Nicotine Addiction; Substance Use Disorders

**CODES**

**ICD10**

- F17.210 Nicotine dependence, cigarettes, uncomplicated
- F17.213 Nicotine dependence, cigarettes, with withdrawal
- F17.211 Nicotine dependence, cigarettes, in remission

**CLINICAL PEARLS**

- Tobacco use is the leading cause of preventable disease, disability, and death in the United States.
- Every patient who uses tobacco should be offered smoking cessation.
- Use the 5 As for tobacco cessation efforts: ask, advise, assess, assist, and arrange.
- Depression with suicidal ideations is a contraindication to varenicline use.
- Even brief advice to quit increases quit rates.
- The first-line pharmacologic therapies for smoking cessation include NRT, varenicline, and bupropion.
- Although nicotine replacement (delivered by nicotine polacrilex gum, nicotine lozenges, nicotine nasal spray, and transdermal nicotine) has an effect comparable to cigarette smoking in terms increasing myocardial work. The
risks associated with NRT in patients with cardiac disease are low and much less than the risks of continued smoking.
TOURETTE SYNDROME
Ravin V. Patel, MD • Dustin Creech, MD

BASICS

DESCRIPTION
Tourette syndrome (TS) is a movement disorder most commonly seen in school-age children; a childhood-onset neurobehavioral disorder characterized by the presence of multiple motor and at least one phonic tic (see “Physical Exam”)

- Tics are sudden, brief, repetitive, stereotyped motor movements (motor tics) or sounds (phonic tics) produced by moving air through the nose, mouth, or throat.
- Tics tend to occur in bouts.
- Tics can be simple or complex.
  - Motor tics precede vocal tics.
  - Simple tics precede complex tics.
- Tics often are preceded by sensory symptoms, especially a compulsion to move.
- Patients are able to suppress their tics, but voluntary suppression is associated with an inner tension that results in more forceful tics when suppression ceases.
- System(s) affected: nervous

EPIDEMIOLOGY

Incidence
- The onset occurs before 18 years of age.
- Predominant age
  - Average age of onset: 7 years (3 to 8 years)
  - Tic severity is greatest at ages 7 to 12 years.
    - 96% present by age 11 years
  - Of children with TS, 50% will experience complete resolution of symptoms by age 18 years (based on self-reporting).
- Predominant sex: male > female (3:1)
- Predominant race/ethnicity: clinically heterogeneous disorder, but non-Hispanic whites (2:1) compared with Hispanics and/or blacks
Prevalence
0.77% overall in children
- 1.06% in boys
- 0.25% in girls

ETIOLOGY AND PATHOPHYSIOLOGY
Abnormalities of dopamine neurotransmission and receptor hypersensitivity, most likely in the ventral striatum, play a primary role in the pathophysiology.
- Abnormality of basal ganglia development
- Thought to result from a complex interaction between social, environmental, and multiple genetic abnormalities
- Mechanism is uncertain; may involve dysfunction of basal ganglia–thalamocortical circuits, likely involving decreased inhibitory output from the basal ganglia, which results in an imbalance of inhibition and excitation in the motor cortex
- Controversial pediatric autoimmune neuropsychiatric disorder associated with streptococcal infection (PANDAS)
  - TS/OCD cases linked to immunologic response to previous group A β-hemolytic Streptococcus (GABHS)
  - Thought to be linked to 10% of all TS cases
- Five criteria
  - Presence of tic disorder and/or OCD
  - Prepubertal onset of neuropsychosis
  - History of sudden onset of symptoms and/or episodic course with abrupt symptom exacerbation, interspersed with periods of partial/complete remission
  - Evidence of a temporal association between onset/exacerbation of symptoms and a prior streptococcal infection
  - Adventitious movements during symptom exacerbation (e.g., motor hyperactivity)

Genetics
- Predisposition: frequent familial history of tic disorders and OCD
- Precise pattern of transmission and genetic origin unknown. Recent studies suggest polygenic inheritance with evidence for a locus on chromosome 17q; sequence variants in SLITRK1 gene on chromosome 13q also are associated with TS.
- Higher concordance in monozygotic compared with dizygotic twins; wide
range of phenotypes

**RISK FACTORS**
- Risk of TS among relatives: 9.8–15%
- First-degree relatives of individuals with TS have a 10- to 100-fold increased risk of developing TS.
- Low birth weight, maternal stress during pregnancy, severe nausea and vomiting in 1st trimester

**COMMONLY ASSOCIATED CONDITIONS**
- OCD (28–67%)
- ADHD (50–60%)
- Conduct disorder
- Depression/anxiety including phobias, panic attacks, and stuttering
- Learning disabilities (23%)
- Impairments of visual perception, sleep disorders, restless leg syndrome, and migraine headaches

**DIAGNOSIS**

**HISTORY**
Diagnosis of TS is based on history and clinical presentation (i.e., observation of tics with/without presence of coexisting disorders). Identify comorbid conditions.

**PHYSICAL EXAM**
- Typically, the physical exam is normal.
- Motor and vocal tics are the clinical hallmarks.
- Tics fluctuate in type, frequency, and anatomic distribution over time.
- Multiple motor tics include facial grimacing, blinking, head/neck jerking, tongue protruding, sniffing, touching, and burping.
- Vocal tics include grunts, snorts, throat clearing, barking, yelling, hiccups, sucking, and coughing.
- Tics are exacerbated by anticipation, emotional upset, anxiety, or fatigue.
- Tics subside when patient is concentrating/absorbed in activities.
- Motor and vocal tics may persist during all stages of sleep, especially light sleep.
• Blink-reflex abnormalities may be observed.
• No known clinical measures reliably predict children who will continue to express tics in adulthood; severity of tics in late childhood is associated with future tic severity.
• Diagnostic and Statistical Manual of Mental Disorders (5th ed.; DSM-5) criteria (1)[C]:
  – A. Both multiple motor and one or more vocal tics have been present at some time during the illness, although not necessarily concurrently.
  – B. The tics may wax and wane in frequency but have persisted for >1 year since first tic onset.
  – C. Onset is before age 18 years.
  – D. The disturbance is not attributable to the physiologic effects of a substance (e.g., cocaine) or another medical condition (e.g., Huntington disease, postviral encephalitis).

DIFFERENTIAL DIAGNOSIS
• Chorea/Huntington disease
• Myoclonus
• Seizure
• Ischemic or hemorrhagic stroke
• Essential tremor
• Posttraumatic/head injury
• Headache
• Dementia
• Wilson disease
• Sydenham chorea
• Multiple sclerosis
• Postviral encephalitis
• Toxin exposure (e.g., carbon monoxide, cocaine)
• Drug effects (e.g., dopamine agonists, fluoroquinolones)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• No definitive lab tests diagnose TS; based on clinical features, particularly the presence of multiple motor and vocal tics
• Thyroid-stimulating hormone (TSH) should be measured because of association of tics with hyperthyroidism.
• No imaging studies diagnose TS
EEG shows nonspecific abnormalities; useful only to differentiate tics from epilepsy

**Test Interpretation**
- Smaller caudate volumes in patients with TS
- Striatal dopaminergic terminals are increased, as is striatal dopamine transporter (DAT) density.

---

**TREATMENT**

**GENERAL MEASURES**
- Many patients require no treatment; patient should play an active role in treatment decisions.
- Treatment assessment
  - Yale Global Tic Severity Scale
  - Tourette Syndrome Severity Scale
  - Global Assessment of Functioning scale
  - Gilles de la Tourette Syndrome-Quality of Life scale
- A detailed history is crucial to management, because tics and comorbidities are interrelated. Goal of treatment should be to improve social functioning, self-esteem, and quality of life.
- Educate that tics are neither voluntary nor psychiatric.
- Educate patient, family, teachers, and friends to identify and address psychosocial stressors and environmental triggers.
- No cure for tics: Treatment is purely symptomatic, and multimodal treatment usually is indicated.
- Neurologic and psychiatric evaluation may be useful for other primary disorders and comorbid conditions (especially ADHD, OCD, and depression).
- TS clusters with several comorbid conditions; each disorder must be evaluated for associated functional impairment because patients often are more disabled by their psychiatric conditions than by the tics; choice of initial treatment depends largely on worst symptoms (tics, obsessions, or impulsivity).
- Nonpharmacologic therapy—reassurance and environmental modification, identification and treatment of trigger, and cognitive behavior therapy
- When pharmacotherapy is employed, monotherapy is preferred to polytherapy.
**MEDICATION**

**First Line**
- Atypical antipsychotics
  - Risperidone: now recommended for standard therapy (2)[A]
    - Initiate 0.25 mg BID; titrate to 0.25 to 6.00 mg/day.
    - As effective as haloperidol and pimozide for tics with fewer side effects
    - Effective against comorbidities such as OCD
    - Side effects may limit use: sedation, weight gain, and fatigue.
- α₂-Adrenergic receptor agonists (2)[B]
  - Historically first-line agents due to favorable side-effect profile, but suboptimal efficacy in limited clinical trials
  - Side effects: sedation and hypotension common
    - Initiate therapy gradually and taper when discontinuing to avoid cardiac adverse events.
  - Clonidine 0.1 to 0.3 mg/day given BID–TID
    - Maximum dose: 0.5 mg/day
    - 25–50% of patients report at least some reduction in tics.
  - Guanfacine 1 to 3 mg/day given daily or BID
    - Less sedating and longer duration of action compared with clonidine
    - Improves motor/vocal tics by 30% in some studies; no better than placebo in others

**Second Line**
- Neuroleptics
  - Typical antipsychotics
    - High risk for extrapyramidal symptoms (EPS)
      - Haloperidol: Initiate 0.5 mg/day and titrate 0.5 mg/week up to 1 to 4 mg at bedtime (3)[B].
        - FDA-approved for treating tics
        - Considered last option of typical antipsychotics due to lower efficacy and increased side effects compared to similar medications
      - Pimozide: Initiate 0.5 mg/day and titrate 0.5 mg/week up to 1 to 4 mg at bedtime (4)[A].
        - FDA-approved for treating tics
        - Risk of cardiac toxicity (prolonged QT interval and arrhythmias); must be given under ECG monitoring; long-term use may induce sedation, weight gain, depression, pseudoparkinsonism, and akathisia.
- Found to work better in long-term control of tics versus acute exacerbations
  - Fluphenazine: 2.5 to 10.0 mg/day
    - Effective but less favored due to side effects
  - Atypical antipsychotics (3)[C]
    - Olanzapine: initiate 2.5 to 5.0 mg/day; titrate up to 20 mg/day.
      - Equally effective as haloperidol and pimozide
      - May cause metabolic disturbances and weight gain
    - Quetiapine: initiate 100 to 150 mg/day; titrate to 100 to 600 mg/day.
      - Well tolerated but limited data exists
    - Ziprasidone: 5 to 40 mg/day
    - Aripiprazole: Initiate 2 mg/day; titrate up to 20 or 30 mg/day.
      - Few studies but favorable side-effect profile

- Alternative treatments
  - Topiramate: 25 to 200 mg/day (2)[A]; promising data but not sufficient efficacy so far to recommend as first or second line
  - Tetrabenazine
  - Baclofen

- Treatment of ADHD in patients with tics (5)[A]
  - Stimulants
    - Comorbid tic disorder is not a serious contraindication, as previously held; exacerbation of tics is neither clinically significant nor common.
    - Methylphenidate: 2.5 to 30.0 mg/day
    - Dextroamphetamine: 5 to 30 mg/day
  - $\alpha_2$-Adrenergic agonists
    - Guanfacine
    - Clonidine
      - The combination of methylphenidate and clonidine has shown superior efficacy in treating both ADHD and tic symptoms compared to monotherapy with either agent in one trial.
  - Other medications
    - Atomoxetine
    - Desipramine

- Treatment of OCD in patients with tics (6)[B]
  - SSRIEs
    - First-line treatment of OCD; can be used in TS as well
    - Side effects include nausea, insomnia, sexual dysfunction, headache, and agitation.
- Comorbid tic disorder not a contraindication; exacerbation of tics neither clinically significant nor common
- Black box warning for suicidality with SSRIs
- Fluoxetine: 10 to 80 mg/day
- Fluvoxamine: 50 to 300 mg/day
- Sertraline: 50 to 200 mg/day
  - Tricyclic antidepressants
    - Clomipramine: 25 to 200 mg/day
      - Can be used in patients refractory to SSRIs or to augment SSRI intake in partial responders
      - Side effects: weight gain, dry mouth, lowered seizure threshold, and constipation; ECG changes, including QT prolongation and tachycardia.

**ADDITIONAL THERAPIES**
- Botulinum toxin injections in severe cases or where chronic medication therapy is not preferred
- Habit-reversal training provides a viable tic suppression treatment: works equally for motor and vocal tics.

**SURGERY/OTHER PROCEDURES**
Thalamic ablation and deep brain stimulation have been used experimentally (7)[C].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Nonpharmacologic therapy
- Reassurance and environmental modification
- Identification and treatment of triggers
- Behavioral therapy: Awareness/assertiveness training, relaxation therapy, habit-reversal therapy, and self-monitoring have shown to significantly decrease tic severity.
- Hypnotherapy
- Biofeedback
- Acupuncture
- Cannabinoids: insufficient evidence to recommend; small trials show small positive effects in some parameters (8)[A].
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Observe for associated psychiatric disorders.

PATIENT EDUCATION
- Reassurance that many patients with tics do not need medication; often education and/or therapy is all that is required.
- National Tourette Syndrome Association: http://www.tsa-usa.org

PROGNOSIS
- Symptoms will fluctuate throughout illness.
- Tic severity typically stabilizes by age 25 years.
- 60–75% of young adults show some improvement in symptoms.
- 10–40% of patients will exhibit full remission.

REFERENCES
7. Lombroso PJ, Scahill L. Tourette syndrome and obsessive-compulsive

**ADDITIONAL READING**

**CODES**

**ICD10**

F95.2 Tourette’s disorder

**CLINICAL PEARLS**

- TS is diagnosed by history and witnessing tics; have parent video patient’s tics if not present on exam in your office.
- Many patients require no treatment; patient should play an active role in treatment decisions.
- Nearly 50% of children with tics also have ADHD. Stimulants may be used as first-line treatment for ADHD (tics are not a contraindication, as previously believed).
TOXOPLASMOSIS
Jonathan MacClements, MD, FAAFP

BASICS
- *Toxoplasma gondii* is an obligate intracellular protozoan parasite.
- Most common latent protozoan infection
- Clinically significant disease typically manifests only in pregnancy or in an immunocompromised patient.

DESCRIPTION
- Acute self-limited infection in immunocompetent
- Acute symptomatic or reactivated latent infection in immunocompromised persons
- Congenital toxoplasmosis (acute primary infection during pregnancy)
- Ocular toxoplasmosis

**Pediatric Considerations**
- The earlier fetal infection occurs, the more severe.
- Risk of perinatal death is 5% if infected in 1st trimester.

**Pregnancy Considerations**
- Pregnant immunocompromised and HIV-infected women should undergo serologic testing.
- Counsel pregnant women regarding risks.
- Serologic testing during pregnancy is controversial.

EPIDEMIOLOGY

**Incidence**
- Prevalence of congenital toxoplasmosis in the United States: 10 to 100/100,000 live births
- Predominant sex: male > female

**Prevalence**
- Present in every country. Seropositivity rates range from <10% to >90% (1)
In the United States, 11% of individuals aged 6 to 49 years are seropositive. Age-adjusted prevalence in the United States is 23%. Seroprevalence among women in the United States is 15%.

ETIOLOGY AND PATHOPHYSIOLOGY

Transmission to humans
- Ingestion of raw or undercooked meat, food, or water containing tissue cysts or oocytes that is usually from soil contaminated with feline feces.
- Transplacental passage from infected mother to fetus; risk of transmission is 30% on average.
- Blood product transfusion or solid-organ transplantation.
- Ingested *T. gondii* oocysts enter host’s gastrointestinal tract where bradyzoites/tachyzoites are released, penetrate contiguous cells, replicate and are transported to susceptible tissues causing clinical disease.

Genetics
Human leukocyte antigen (HLA) DQ3 is a genetic marker for susceptibility in HIV/AIDS patients.

RISK FACTORS
- Immunocompromised states, including HIV infection with CD4 cell count <100/μL.
- Primary infection during pregnancy; risk of fetal transmission increases with gestational age at seroconversion. Transmission in the 1st trimester is associated with more severe consequences.
- Chronically infected immunocompromised pregnant women are at increased risk for transmitting congenital toxoplasmosis.

GENERAL PREVENTION
- Avoid eating undercooked meat: Cook to 152°F (66°C) or freeze for 24 hours at ≤−12°C.
- Avoid drinking unfiltered water.
- Wash produce thoroughly.
- Strict hand hygiene after touching soil.
- Wear gloves and wash hands after handling raw meat or cat litter.
- Avoid shellfish (*Toxoplasma* cysts).
COMMONLY ASSOCIATED CONDITIONS

- Chorioretinitis; self-limiting, febrile lymphadenopathy; mononucleosis-like illness
- Potential association with schizophrenia

DIAGNOSIS

HISTORY

- Congenital toxoplasmosis
  - Clinical presentation varies widely; 80% of patients are asymptomatic at birth.
  - Classic triad (*uncommon*): chorioretinitis, hydrocephalus, cerebral calcifications
  - Manifestations may include prematurity, intrauterine growth retardation (IUGR).
  - Jaundice, rash with a mononucleosis-like illness
  - Mental retardation, seizures, visual defects, spasticity, sensorineural hearing loss
- Ocular toxoplasmosis
  - Chorioretinitis: focal necrotizing retinitis
  - Yellowish-white elevated cotton patch
  - Congenital disease usually bilateral; acquired is more often unilateral.
  - Symptoms include blurred vision, scotoma, pain, and photophobia.
- Acute toxoplasmosis (immunocompetent host)
  - ~90% of patients are asymptomatic.
  - Most common manifestation is bilateral, symmetric, nontender cervical lymphadenopathy.
  - Constitutional symptoms such as fever, chills, and sweats are usually mild.
  - Headaches, myalgias, pharyngitis, hepatosplenomegaly, and diffuse nonpruritic maculopapular rash may occur.
  - Pregnant women are often asymptomatic.
  - CNS: encephalitis
  - Headache; focal neurologic deficits and seizures
  - Fever usually present
  - Extracerebral toxoplasmosis: pneumonitis, chorioretinitis; rarely: GI system, liver, musculoskeletal system, heart, bone marrow, bladder, and orchitis
PHYSICAL EXAM
- In adults: fever, lymphadenopathy, nonpruritic rash
- In newborns: hydrocephalus, neurologic abnormalities, hepatosplenomegaly, chorioretinitis, microcephaly, mental retardation

DIFFERENTIAL DIAGNOSIS
Syphilis, lymphoma, progressive multifocal leukoencephalopathy, cryptococcal meningitis, congenital TORCH infections, *Listeria* infection, tuberculosis (TB), erythroblastosis fetalis

DIAGNOSTIC TESTS & INTERPRETATION
- CBC: atypical lymphocytosis, anemia, thrombocytopenia
- Serology interpretation
  - IgM antibodies appear in the 1st week if acute infection
  - Initial test demonstrates positive IgM and negative IgG, with both tests being positive 2 weeks later.
  - If follow-up IgG is negative 2 to 4 weeks later and IgM is positive, this is likely a false positive.
  - Negative IgG rules out prior infection (IgG persists for life).
- Types of serologic tests
  - ELISA: most commonly used
  - Sabin-Feldman dye test: Gold standard against which all other serologic assays are compared.
  - IFA test: more available in commercial labs
  - ISAGA: widely available commercially; more sensitive and specific than IFA for detecting IgM
  - Avidity testing: confirmatory test to establish if positive IgM/IgG reflects recent or chronic infection
- PCR: *T. gondii* DNA amplification in blood or amniotic fluid; used for diagnosis of fetal infection
- Culture (rarely necessary): Organism can be isolated either by cell culture or by mouse inoculation.

*Initial Tests (lab, imaging)*
- Diagnosis of primary infection is typically based on history and confirmed by serology.
- Serum *Toxoplasma*-specific IgG and IgM are first step.
- According to IgM result, determine IgG avidity.
• Diagnosis of maternal infection and congenital toxoplasmosis
  – Test pregnant women who have mononucleosis-like illness but negative heterophile test for toxoplasmosis.
  – Diagnose maternal infection based on two blood samples at least 2 weeks to show seroconversion.
  – High avidity of IgG during 1st trimester argues against maternal primary infection.
  – Fetal ultrasound is useful for prognosis.
  – Routine screening for toxoplasmosis is not recommended in pregnancy.
• Neonatal diagnosis of congenital toxoplasmosis
  – Serology requires repeat testing for IgM and IgA.
  – Sample cord or peripheral blood within 2 weeks
  – Ophthalmologic, auditory, and neurologic examinations; lumbar puncture and head CT
• Diagnosis of toxoplasmic encephalitis
  – Serology for IgG
  – Imaging: MRI is more sensitive than CT scan to identify characteristic ring-enhancing lesions.
• SPECT and PET scans can help distinguish toxoplasmosis from CNS lymphoma.

**Diagnostic Procedures/Other**

• Lymph node biopsy
• Brain biopsy in CNS disease
• Amniocentesis with PCR (risk of false negatives and false positives)
• Placental isolation of *Toxoplasma* is diagnostic.

**Test Interpretation**

• Confirmatory, meningocerebritis ± abscesses with necrosis, Giemsa
• Lymph node histology shows triad of:
  – Reactive follicular hyperplasia
  – Irregular clusters of epithelioid histiocytes blurring margins of germinal centers
  – Distension of sinuses with monocytoid cells
• Sensitivity of triad 63%, specificity 91%
TREATMENT

GENERAL MEASURES
Immunocompetent patients usually require no treatment.

MEDICATION

First Line

**IMPORTANT:** All pyrimethamine-containing regimens should include leucovorin (folinic acid 10 to 25 mg/day PO) during and 1 week after completion of pyrimethamine to prevent drug-induced hematologic toxicity (2)[A].

- Treatment in immunocompromised hosts
  - Initial regimen of choice is pyrimethamine 200 mg loading dose PO, followed by 50 mg/day plus sulfadiazine 4 to 6 g/day PO in 4 divided doses; for those intolerant or allergic to sulfadiazine, clindamycin 600 to 1,200 mg IV or 450 mg PO QID can be used instead.
  - Alternative regimens for patients intolerant to sulfadiazine and clindamycin include the following:
    - Pyrimethamine: 200 mg loading dose PO, followed by 50 mg/day plus azithromycin 900 to 1,200 mg PO once daily
    - Pyrimethamine: 200 mg loading dose PO and then 50 mg/day plus atovaquone 1,500 mg PO BID
    - Sulfadiazine: 1,000 to 1,500 mg QID plus atovaquone 1,500 mg BID
    - Trimethoprim-sulfamethoxazole: 10/50 mg/kg/day PO or IV divided BID (for 30 days) may be a cost-effective alternative.
  - Duration of therapy: typically 6 weeks, lower doses for secondary prophylaxis (2)[A]
  - Use adjunctive steroids in patients with signs of increased intracranial pressure.
  - Anticonvulsants, if there is a history of seizures

- Prophylaxis in immunocompromised patients
  - Primary prophylaxis: indicated for patients with HIV infection and CD4 count <100 cells/μL who are T. gondii IgG–positive
    - Trimethoprim-sulfamethoxazole-DS: 1 tablet PO daily. Alternative for sulfa allergy is dapsone 50 mg/day PO *plus* pyrimethamine 50 mg PO weekly *plus* leucovorin 25 mg PO weekly or atovaquone 1,500 mg PO weekly
daily.
– Secondary prophylaxis: Following 6 weeks of therapy, administer lower doses of drugs:
  o Sulfadiazine 2 to 4 g/day in 2 to 4 divided doses plus pyrimethamine 25 to 50 mg/day is the first choice.
  o Alternative regimens include clindamycin 600 mg PO q8h plus pyrimethamine 25 to 50 mg/day PO or atovaquone 750 mg PO BID to QID ± pyrimethamine 25 mg PO daily.

● Pregnant women (3)[A]
  – Although typically offered, it is unsure if antenatal treatment reduces congenital transmission.
  – <18 weeks’ gestation: spiramycin 1 g PO q8h without food until delivery if amniotic fluid PCR is negative; does not treat infection in the fetus
  – >18 weeks’ gestation: Pyrimethamine and sulfadiazine should be considered only if fetal infection is documented by positive amniotic fluid PCR (pyrimethamine is teratogenic):
    o Pyrimethamine: 50 mg PO q12h for 2 days, then 50 mg/day plus sulfadiazine 75 mg/kg PO × 1 dose and then 50 mg/kg q12h (max 4 g/day)

● Treat infected newborns regardless of clinical manifestations:
  – Pyrimethamine 2 mg/kg/day (max 50 mg) for 2 days; then 1 mg/kg/day (max 25 mg) for 2 to 6 month and then 1 mg/kg (max 25 mg) on Monday, Wednesday, and Friday; sulfadiazine 100 mg/kg/day divided BID; and leucovorin 10 mg 3 times per week during pyrimethamine and 1 week after discontinuation

● Immunocompetent nonpregnant patients generally do not require treatment unless symptoms are severe or prolonged; one of two regimens can be used:
  – Pyrimethamine: 100 mg loading dose PO, followed by 25 to 50 mg/day plus sulfadiazine 2 to 4 g/day in 4 divided doses
  – Pyrimethamine: 100 mg loading dose PO, followed by 25 to 50 mg/day plus clindamycin 300 mg PO QID

Second Line
● Clindamycin: 900 to 1,200 mg TID IV used for ocular and CNS toxoplasmosis alone and in combination with pyrimethamine; as effective as the sulfadiazine-pyrimethamine with fewer adverse effects
● Corticosteroids (prednisone 1 to 2 mg/kg/day) are added for macular chorioretinitis or CNS infection.
● Alternatives: atovaquone (Mepron), azithromycin (Zithromax), clarithromycin
(Biaxin), or dapsone plus pyrimethamine and leucovorin

- Trimethoprim-sulfamethoxazole appears to be equivalent to pyrimethamine-sulfadiazine in AIDS patients with CNS disease.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Precautions

- Monitor for bone marrow, renal, or liver toxicity.
- Good hydration: Sulfadiazine is poorly soluble and may crystallize in the urine.
- Watch for antibiotic-associated diarrhea.
- Sulfonamides may alter phenytoin and warfarin levels or interfere with oral hypoglycemic agents.

**PATIENT EDUCATION**

**PROGNOSIS**

- Immunodeficient patients often relapse if treatment or suppression therapy is stopped.
- Treatment may prevent the development of untoward sequelae in infants with congenital toxoplasmosis.

**REFERENCES**

ADDITIONAL READING

CODES

**ICD10**

- B58.9 Toxoplasmosis, unspecified
- P37.1 Congenital toxoplasmosis
- B58.2 Toxoplasma meningoencephalitis

CLINICAL PEARLS

- Toxoplasmosis is often asymptomatic in immunocompetent patients.
- Primary prevention is important, particularly for pregnant women and immunodeficient patients.
- The most common manifestation of acute toxoplasmosis in immunocompetent host is bilateral, symmetric, nontender cervical lymphadenopathy.
- Universal screening for congenital toxoplasmosis is not currently
recommended.
TRACHEITIS, BACTERIAL
Mary Cataletto, MD, FAAP, FCCP • Margaret J. McCormick, MS, RN, CNE

BASICS
DESCRIPTION
- Acute, potentially life-threatening infraglottic bacterial infection following a primary viral infection, usually parainfluenzae or influenza viruses
  - Direct laryngoscopy reveals marked subglottic edema and thick mucopurulent secretions, sometimes causing pseudomembranes.
- System(s) affected: pulmonary
- Synonym(s): laryngotracheobronchitis; pseudomembranous croup; bacterial croup

EPIDEMIOLOGY
Incidence
- Estimated incidence: 4 to 8 per 1 million (1)
- First cases described prior to 1950; resurgence of cases has been noted since 1979.
- Peak incidence in children: fall and winter
- Mean age: 5 years (1)
- Infections in adolescents and adults have been reported.
- Predominant sex: male > female (2:1)
- Accounts for 5–14% of upper airway obstruction in children requiring critical care services

Prevalence
- Rare illness
- Most common potentially life-threatening upper airway infection in children
- Methicillin-resistant Staphylococcus aureus (MRSA) may contribute to changing epidemiology and virulence.

ETIOLOGY AND PATHOPHYSIOLOGY
- S. aureus (most common pediatric cause): Consider MRSA.
- *Haemophilus influenzae* type B
- *Streptococcus pyogenes* group A
- *Streptococcus pneumoniae*
- *Moraxella catarrhalis* (associated with higher intubation rate; more frequent in younger children)
- Frequently polymicrobial

**Genetics**
No known genetic predisposition

**RISK FACTORS**
- Periods of increased seasonal activity of respiratory viruses
- Reports following adenoidectomy, with chronic tracheal aspiration, with evidence of other concurrent infections, including sinusitis, otitis, pneumonia, or pharyngitis

**GENERAL PREVENTION**
- Standard precautions, with scrupulous attention to hand washing
- Vaccination against viruses that may predispose to bacterial tracheitis
- In children with artificial airways, periodic surveillance of tracheal cultures can be helpful.

**COMMONLY ASSOCIATED CONDITIONS**
- Consider anatomic abnormalities or foreign body as well as recent pharyngeal or laryngeal surgery.
- Predisposing: Down syndrome, immunodeficiency, subglottic hemangioma, tracheoesophageal fistula repair, tracheobronchomalacia
- Viral coinfection may occur.

**DIAGNOSIS**
- May present with fever and systemic toxicity or as more localized disease
- Careful history and physical exam are the best methods to distinguish bacterial tracheitis from croup and other rare causes of upper airway obstruction.

**HISTORY**
- Prodromal upper respiratory tract symptoms
Gradual progression of mild upper airway symptoms over 1 hour to 6 days to acute, febrile phase of rapid respiratory decompensation
- No drooling
- No response to aerosolized epinephrine and/or systemic corticosteroids (1)
- May see more indolent course in patients with artificial airways

**PHYSICAL EXAM**

Fever >38°C (100.4°F)
- Toxic appearance
- Variable degree of respiratory distress (2)
  - Cough
  - Tachypnea
  - Inspiratory stridor (2)
- Voice and cry usually normal
- Drooling uncommon

**DIFFERENTIAL DIAGNOSIS**

- Severe croup (viral)
- Spasmodic croup
- Diphtheria in nonvaccinated patients
- Retropharyngeal abscess
- Epiglottitis
- Bacterial pneumonia
- Foreign body aspiration

**DIAGNOSTIC TESTS & INTERPRETATION**

- Routine laboratory studies are not required to make the diagnosis.
- Radiographs are neither definitive nor diagnostic.
- Tracheal endoscopy provides a definitive diagnosis (1,3)[C].

**Initial Tests (lab, imaging)**

- Bacterial cultures of tracheal secretions are required for culture isolates and sensitivities.
- Rapid antigen or polymerase chain reaction (PCR)-based testing for respiratory viruses may be helpful.
- Routine laboratory studies may not be helpful.
- Blood cultures rarely positive
- CBC results may vary.
– WBC count may show marked leukocytosis or may be normal.
– Increased band cell count

Radiographs may be normal, but exudates may mimic the findings in foreign body aspiration.

– Pneumonic infiltrates are common.
– Anteroposterior (AP) and lateral neck x-rays show subglottic and tracheal narrowing (i.e., steeple sign on AP film) with haziness and radiopaque linear or particulate densities (crusts).
– In patients with risk of acute respiratory obstruction, either do not obtain x-rays or monitor carefully.

Follow-Up Tests & Special Considerations

Follow chest film if suspect pneumonia.

Diagnostic Procedures/Other

– Direct laryngoscopy and tracheoscopy is diagnostic and demonstrates
  – Normal supraglottic structures
  – Marked subglottic erythema and edema
  – Ulcerations
  – Epithelial sloughing
  – Copious mucopurulent secretions ± plaques or pseudomembranes

– Obtain Gram stain and aerobic, anaerobic, and viral cultures of tracheal secretions during the procedure.

– Tracheal biopsy is rarely indicated but may be considered in immunodeficient child or child with ulcerative colitis.

Test Interpretation

– Diffuse inflammation of larynx, trachea, and bronchi
– Mucopurulent exudate; microabscesses may be present.
– Semiadherent membranes (containing numerous neutrophils and cellular debris) may be identified within the trachea.

TREATMENT

– Treat as potentially life-threatening airway emergency.
– Children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU (1)[C].
– Assess and monitor respiratory status; supplemental oxygen may be required.
Airway protection and support, as necessary (at least 50% require intubation; some studies report up to 100%)
- Ventilatory support may be required.
- Suctioning

**MEDICATION**
- Empiric therapy should cover the most common pathogens until sensitivities are available: antistaphylococcal agent (vancomycin or clindamycin) and a 3rd-generation cephalosporin (e.g., ceftriaxone or cefotaxime) (1,3)[C].
- In the case of technology-dependent children with tracheostomy, make initial antibiotic choices based on previous tracheal culture.
- Narrow regimen when pathogens and sensitivities available (1,3)[C]
- Inhaled antibiotics are not routinely recommended either as primary or adjuvant therapy (4)[A].
- Contraindications: Refer to the manufacturer’s literature for each drug.
- Precautions: Refer to the manufacturer’s literature for each drug. Avoid aminoglycosides in patients with previous hearing loss.
- Significant possible interactions: Refer to the manufacturer’s literature for each drug.

**ISSUES FOR REFERRAL**
All children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU; ID and ENT consultation should be considered.

**ADDITIONAL THERAPIES**
- At present, evidence is lacking to establish the effect of heliox inhalation in the treatment of croup in children.
- For technology-dependent children with artificial airway:
  - Initial antibiotic choices should cover most recent tracheal aspirate isolates and then be refined according to culture and sensitivity results.

**SURGERY/OTHER PROCEDURES**
- Tracheostomy is usually not necessary.
- Therapeutic bronchoscopy may be necessary to facilitate removal of inspissated secretions.
- Tracheal membranes may require removal.

**ADMISSION, INPATIENT, AND NURSING**
CONSIDERATIONS

- Aggressive supportive care and airway protection are paramount.
- Initial treatment of choice for bacterial tracheitis is broad-spectrum antibiotic coverage.
- Children with tracheitis and artificial airways present unique challenges: Tracheoscopy is important in establishing diagnosis in this population.
- Be vigilant for possible MRSA.

Pediatric Considerations

- True pediatric emergency
- Admission to ICU
- Maintain airway: often difficult due to copious secretions
  - Endotracheal or nasotracheal intubation usually needed, especially in infants and children <4 years of age
  - Much less likely to need intubation if child >8 years of age
  - Advantage of intubation is the ability to clear trachea and bronchi of secretions and pseudomembranes.
- Vigorous pulmonary toilet to clear airway of secretions
- Hydration, humidification, antibiotics
- Admission criteria/initial stabilization
  - Suspected or confirmed diagnosis of tracheitis
  - Respiratory distress
  - Artificial airway
- Nursing
  - Provide calm, quiet environment for child once endoscopy and cultures are done.
  - Airway monitoring
  - Frequent suctioning
  - Monitor fluid balance.
  - Establish and maintain open lines of communication with child and parents.
- Discharge when no longer in need of acute care

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Children with artificial airways will require ongoing follow-up.

**Diet**

Varies with clinical situation

**Patient Education**

Keep immunizations up to date.

**Prognosis**

- Intubation generally 3 to 11 days
- Usually requires 3 to 7 days of hospitalization
- With effective early recognition and management, complete recovery can be expected.
- Cardiopulmonary arrest and death have occurred.
- Higher recurrence rates in children with artificial airways

**Complications**

- Cardiopulmonary arrest
- Hypotension
- Acute respiratory distress syndrome (ARDS)
- Pneumonia
- Formation of pseudomembranes

**References**

**Additional Reading**

**SEE ALSO**

*Croup (Laryngotracheobronchitis); Epiglottitis*

**CODES**

**ICD10**

- J04.10 Acute tracheitis without obstruction
- J04.11 Acute tracheitis with obstruction
- J05.0 Acute obstructive laryngitis [croup]

**CLINICAL PEARLS**

- Bacterial tracheitis is an acute, potentially life-threatening, infraglottic bacterial infection following a primary viral infection that accounts for 5–14% of upper airway obstructions in children requiring critical care services.
- Children with suspected or actual bacterial tracheitis should be cared for in a pediatric ICU.
- Endoscopy provides a definitive diagnosis (2).
- Initial treatment of choice for bacterial tracheitis is broad-spectrum antibiotic coverage, aggressive airway protection, and supportive care (2).
BASICS

DESCRIPTION

- Society’s growing acceptance of nontraditional lifestyles has, in recent years, made increased room for transgender individuals, as it has for lesbians, gays, and bisexuals, even as these populations continue to suffer unique health care disparities. Better education of physicians and other providers will improve the health of the transgender population. Such education begins with teaching acceptance of all human beings into health care and ensuring a safe office environment for transgendered individuals to speak openly with their clinicians. Once a “safe” space is created, it will be possible to provide appropriate and supportive health care to reduce disparities and the harms that result.
  - At least 1:11,900 males and 1:30,400 females in the United States define themselves as transgender (1).
  - Current conservative estimates indicate 0.3% of U.S. adults, or nearly 1 million people, identify themselves as transgender (2).
- The terms “transgender” and “gender nonconforming” refer to those whose gender identity or presentation differs from the sex assigned at birth (3).
  - Gender identity, the sense of one’s self as male or female, and gender presentation, the outward expression of gender, may or may not reflect the self-identification of a transgender patient.
  - Transgender patients can no more be categorized or thought alike, than any other patients. Race, ethnicity, socioeconomic status, age, and other factors, all play a role in how transgender patients define themselves.
  - Moreover, a patient’s body may or may not match gender identity or presentation. Although a patient’s anatomy may determine treatment, that treatment must also be sensitive to, and respect, gender identity and/or presentation.
  - Transgender people may be sexually oriented toward men, women, other transgender people, or any combination of the above.
  - Transgender patients are further defined by those who have undergone surgical procedures and/or medical treatment to better align gender identity,
by those who plan such procedures in the future, and by others who do not.

- Accordingly, it is important to ask transgender patients how they would describe themselves and to honor terminology acceptable to each patient, specifically preferred name, preferred pronoun, and preferred gender identity, with those attributes ideally reflected within any electronic medical record (EMR).

- Transgender people have a unique set of mental and physical needs (2).
  - Real or imagined stigma and discrimination are barriers to health care (3).
  - Transgender patients are less likely to have health insurance and more likely to encounter discrimination on the part of health care providers, thereby limiting access to health care services.
  - Over 50% of transgender patients delay needed care, compared to 20% in the general population (3,4).

- Evidence-based medicine for transgender patients is lacking or limited to case reports and smaller studies aggravated, perhaps, by social stigma, marginalization, and discrimination (2).

- Transgender patients may also suffer from gender dysphoria, recognized in *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* as the disconnection between gender expression and one’s assigned gender at birth (1).

## DIAGNOSIS

- Specific health concerns
  - Transition-related medical care, or gender-confirming therapy, including hormone therapy and surgical treatment, or sex reassignment surgery (SRS) help patients align primary and secondary sexual characteristics with gender identity (2).
  - The World Professional Association for Transgender Health (WPATH) has published standards of care (SOCs) that include hormone therapy and SRS (2)[C].
    - SOCs are endorsed by American College of Obstetricians and Gynecologists (ACOG), the Endocrine Society, the American Medical Association, and the American Psychological Association (2).
    - Hormone therapy and surgery not only treat symptoms of gender dysphoria but also help transgender patients achieve well-being (1).
    - Hormone therapy does convey a greater risk of thromboembolic disease, liver dysfunction, and cardiovascular (CV) disease (1).
Treatment is associated with a high degree of patient satisfaction, low prevalence of regrets, and significant relief of gender dysphoria (2)[C].

- Specific diseases
  - AIDS
    - Rate of HIV infection among transgender people is 4 times that of general population (4).
    - Requires increased vigilance on the part of health care providers

- Psychosocial considerations
  - Transgender people are at risk of victimization by others, of mental health issues, including depression and anxiety, and of suicide (4).
    - 41% of transgender people have attempted suicide compared to 1.6% of the U.S. general population (1,2,4).
    - One 2012 survey found that 61% of transgender people had been victims of physical assault and abuse; 64% had been victims of sexual assault, mostly not reported (5).
    - Transgender people are at greater risk of societal discrimination, including housing and workforce discrimination, are more likely to be unemployed, homeless, and lacking in social support owing to federal and state laws that inadequately protect transgender people from discrimination (5).
  - Psychosocial assessment is recommended at baseline and at least annually (5)[C].
  - Mental health and substance abuse screening are also indicated (6)[C].

**ALERT**
- Transgender patients are at increased risk of suicidal ideation, suicide attempts, and suicide (1,2,4).
- Improving access to care
  - Barriers to health care
    - Transgender patients are often reluctant to disclose gender identity or expression, owing to the risk of stigma or discrimination.
    - 28% of transgender patients report being verbally harassed and 2% physically assaulted while seeking health care (1).
  - Providers’ lack of education and experience
  - Financial barriers
    - Lack of health insurance
    - Unemployment among transgender people is twice the rate of general population (1).
GENERAL MEASURES

- Care of transgender people, including hormone therapy, is within the scope of primary care providers.
- Education of health care providers, for physicians, and those beginning in medical school, is crucial to providing optimal care to transgender patients (2).

MEDICATION

**First Line**

- **Hormone therapy (7)[A]**

- **Adolescents**
  - Suppress pubertal development using gonadotropin-releasing hormone (GnRH) analogues when girls and boys first exhibit pubertal physical changes (Tanner stage 2).
  - Progestin
  - Cross-sex steroids at about age 16 years
  - Initiate treatment after persistent gender dysphoria/gender incongruence have been confirmed by a multidisciplinary team of medical and mental health providers and the patient has the mental capacity to provide informed consent, generally by age 16 years.
  - Surgical referral

- **Adults**

  - Estrogens, antiandrogens, and/or GnRH agonists for male-to-female patients (7)[A]

    - Estradiol 2 to 6 mg/day, or estradiol transdermal patch 0.025 to 0.200 mg/day, or estradiol valerate or cypionate 5 to 30 mg IM every 2 weeks
    - Add spironolactone 100 to 300 mg/day, cyproterone acetate 25 to 50 mg/day, or GnRH agonists to minimize estrogen requirement.
    - At initial visit, do prostate-specific antigen (PSA), lipid panel, and liver function tests (LFTs); every 3 months, check testosterone levels until stable, monitor estradiol blood level for compliance, repeat lipid panel, and encourage breast exams (6)[A].
    - Every 6 months to 1 year, preoperatively, order visual fields to assess for prolactinoma, check serum prolactin, and repeat lipid panel; if patient is >50 years old, recheck PSA and consider mammogram (6)[A].
    - Every 6 months to 1 year, postoperatively, reduce estrogens to hormone replacement therapy (HRT) doses (conjugated equine estrogens 0.625 mg/day, transdermal ethinyl estradiol 0.05 to 0.10 mg/day, or ethinyl
estradiol 0.02 to 0.05 mg/day) and do dual energy x-ray absorptiometry (DEXA) scan to monitor for osteoporosis (6)[A].

- Testosterone for female-to-male patients (7)[A]
  - Testosterone esters 100 to 200 mg IM every other week or transdermal testosterone 2.5 to 7.5 mg/day or testosterone gel 1.6% 50 to 100 mg/day with goal of serum testosterone in midmale range
  - At initial visit, check weight, lipid panel, and glucose level (6)[A].
  - Every 3 to 6 months, repeat lipid panel and LFTs, do complete blood count to rule out polycythemia, and check testosterone levels.
  - Every 6 months to 1 year, preoperatively, do pelvic exam and Papanicolaou (Pap) smear per current protocols (6)[A].
  - Every 2 years, do endometrial ultrasounds.
  - Every 6 months to 1 year, postoperatively, titrate testosterone to maintain serum testosterone at 500 μg/dL (17.35 SI) and do DEXA scan (6)[A].

SURGERY/OTHER PROCEDURES
- SRS (7)[A]: only after 1 year of hormone therapy
- In adolescents, consider delaying gender-affirming genital surgery until the patient is at least 18 years old.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Interacting with the health care system
- Discrimination on the part of health care providers is a major barrier to care (4).

Patient Monitoring
- Routine medical screening:
  - Pelvic exam (6)
  - Cervical and anal Pap tests (6)
  - Screening for STIs (6)
- Measurement of prolactin levels (7)
- Evaluation of CV risk factors (7)
- Bone mineral density tests, as indicated (7)
- Breast cancer screening per guidelines (7)
- Screening, as indicated, for prostate cancer in transgender females treated with
Estrogens (7)

- In adolescents, monitor clinical pubertal development every 3 to 6 months and check labs (LH, FSH, E2/T, 25[OH]D) every 6 to 12 months; do bone mineral density test every 1 to 2 years (7).
- In adults, monitor physical changes and any adverse changes every 3 months during the 1st year of hormone therapy and then once or twice yearly (7).
- Transgender males: Check serum testosterone every 3 months until levels are in the normal physiologic male range; check hematocrit and hemoglobin at baseline and every 3 months in year 1 and then once or twice a year; monitor lipids as indicated (7).
- Transgender females: Check serum testosterone and estradiol every 3 months; if patient is on spironolactone, check serum electrolytes every 3 months in the 1st year of treatment and then annually.

**PATIENT EDUCATION**

- Hormone therapy and potential health risks
- Counseling for gender-confirming surgery
- Legal issues
  - Under the Affordable Care Act (ACA), denial of treatment of being transgender as a “preexisting condition” is banned (2).
  - Centers for Medicare & Medicaid Services (CMS) considers SRS experimental and denies coverage (2).
  - The U.S. Department of Veterans Affairs (VA), although acknowledging the need to care for transgender veterans, denies coverage of SRS on the basis of a VA regulation that excludes gender alterations from the medical benefits package (2).

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- F64.1 Gender identity disorder in adolescence and adulthood
- Z11.4 Encounter for screening for human immunodeficiency virus
- Z72.52 High risk homosexual behavior

**CLINICAL PEARLS**

- Health care providers must be sensitive to the unique needs of transgender patients; must be open to the care of such patients; and should, as with all patients, display an ethical, principled, and timely approach to care.
- Do use inclusive language in the care of transgender patients, assessing the individuals’ preferences, and respect differences among transgender patients.
- Always address health care needs particular to the transgender population.
- Avoid stigmatization of transgender patients, ensuring gender-blind clinical care.
TRANSIENT ISCHEMIC ATTACK (TIA)

Samuel E. Mathis, MD • Kyu K. Jana, MD

BASICS

DESCRIPTION

• A transient episode of neurologic dysfunction due to focal brain, retinal, or spinal cord ischemia without acute infarction
• Most important predictor of stroke: 15% of patients with stroke report previous TIA.
• Synonym(s): ministroke

EPIDEMIOLOGY

• 200,000 to 500,000 new TIA cases reported each year
  – 83 cases/100,000 people/year in the United States
  – 400 to 800 cases/100,000 persons aged 50 to 59 years
• Prevalence of TIA in general population: ~2.3%
• Predominant age: risk increases >60 years; highest in 7th and 8th decades
• Predominant sex: male > female (3:1)
• Predominant race/ethnicity: African Americans > Hispanics > Caucasians.
  The difference in African Americans is exaggerated at younger ages.

ETIOLOGY AND PATHOPHYSIOLOGY

Temporary reduction/cessation of cerebral blood flow adversely affecting neuronal function

• Carotid/vertebral atherosclerotic disease
  – Artery-to-artery thromboembolism
  – Low-flow ischemia
• Small, deep vessel disease associated with hypertension (HTN)
  – Lacunar infarcts
• Cardiac diseases
  – 1–6% of patients with MI develop stroke.
• Embolism secondary to the following:
  – Valvular (mitral valve) pathology
  – Mural hypokinesias/akinesias with thrombosis (acute anterior MI/congestive cardiomyopathies)
– Cardiac arrhythmia (atrial fibrillation accounts for 5–20% incidence)
  • Hypercoagulable states
    – Antiphospholipid antibodies
    – Increased estrogen (e.g., oral contraceptives)
    – Pregnancy and parturition
  • Arteritis
    – Noninfectious necrotizing vasculitis
    – Drugs
    – Irradiation
    – Local trauma
  • Sympathomimetic drugs (e.g., cocaine)
  • Other causes: spontaneous and posttraumatic (e.g., chiropractic manipulation)
    arterial dissection
  • Fibromuscular dysplasia

**Genetics**
Inheritance is polygenic, with tendency to clustering of risk factors within families.

**RISK FACTORS**
- HTN
- Cardiac diseases (A-fib, MI, valvular disease)
- Diabetes
- Hyperlipidemia
- Atherosclerotic disease (carotid/vertebral stenosis)
- Cigarette smoking
- Thrombophilias

**GENERAL PREVENTION**
- Lifestyle changes: smoking cessation, diet modification, weight loss, regular aerobic exercise, and limited alcohol intake
- Strict control of medical risk factors: diabetes (glycemic control), HTN (thiazide and/or ACE/ARB), hyperlipidemia (statins), anticoagulation when high risk of cardioembolism (e.g., atrial fibrillation, mechanical valves)

**ALERT**
10–20% of patients with TIA have CVA within 90 days; 25–50% of those occur within the first 48 hours.
Geriatric Considerations
- Older patients have a higher mortality rate than younger patients—highest in 7th and 8th decades.
- Atrial fibrillation is a frequent cause among the elderly.

Pediatric Considerations
- Congenital heart disease is a common cause among pediatric patients.
- Other causes include the following:
  – Metabolic: homocystinuria, Fabry disease
  – Central nervous system infection
  – Clotting disorders
  – Genetic: Marfan syndrome, moyamoya, or sickle cell disease

Pregnancy Considerations
- Preeclampsia, eclampsia, and HELLP syndrome
- TTP and hemolytic uremic syndrome
- Postpartum angiopathy
- Cerebral venous thrombosis
- Hypercoagulable states related to pregnancy

COMMONLY ASSOCIATED CONDITIONS
- Atrial fibrillation
- Uncontrolled HTN
- Carotid stenosis
- TIA Mimics
  – Some disease processes mimic TIA presentation.
  – Seizures, migraines, metabolic disturbances, syncope
  – Gradual onset with nonspecific symptoms (headache, memory loss)

DIAGNOSIS
HISTORY
- Emphasis on symptom onset, progression, and recovery
- Carotid circulation (hemispheric): monocular visual loss, hemiplegia, hemianesthesia, neglect, aphasia, visual field defects (amaurosis fugax); less often, headaches, seizures, amnesia, confusion
- Vertebrobasilar (brain stem/cerebellar): bilateral visual obscuration, diplopia,
vertigo, ataxia, facial paresis, Horner syndrome, dysphagia, dysarthria; also headache, nausea, vomiting, and ataxia

- Past medical history, baseline functional status
- **ABCD2 or ABCD3-I score: predicts risk of CVA within 48 hours (1)[A]**
  - Score of 0 to 1: 0%; 2 to 3: 1.3%; 4 to 5: 4.1%; 6 to 7: 8.1%
    - **Age >65 years**: 1 point
    - **BP 140/90 mm Hg**: 1 point
    - **Clinical presentation**
      - Unilateral weakness: 2 points
      - Speech impaired without weakness: 1 point
    - **Duration**: 1 to 2 points based on time
    - **Diabetes**: 1 point
    - **Dual TIA** (within 7 days preceding): 2 points
    - **Imaging** (new lesion or carotid stenosis): 2 points

**PHYSICAL EXAM**
- Vital signs, oxygen saturation
- Thorough neurologic and cardiac exams

**DIFFERENTIAL DIAGNOSIS**
- Evolving stroke
- Migraine (hemiplegic)
- Focal seizure (Todd paralysis)
- Bell palsy
- Neoplasm of brain
- Subarachnoid hemorrhage
- Intoxication
- Glucose or other electrolyte abnormalities
- Head trauma
- Central nervous system infection
- Multiple sclerosis

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Neuroimaging within 24 hours of symptom onset
- MRI, including diffusion-weighted imaging, is the preferred brain diagnostic modality; if not available, then noncontrast head CT (2)[B]
- Noninvasive imaging of the cervicocephalic vessels should be performed
routinely in suspected TIA (2)[A].

- Consider assessment of the extracranial vasculature by carotid US/TCD, MRA, or CTA depending on availability and expertise and characteristics of the patient (2)[B].
- Routine blood tests (CBC, chemistry, PT/PTT, UPT, and fasting lipid panel) are reasonable in evaluation of patient with TIA (2)[B].

**Follow-Up Tests & Special Considerations**

- If only noninvasive testing is performed prior to CEA, it is reasonable to pursue two concordant noninvasive findings; otherwise, catheter angiography should be considered (2)[B].
- Echo is reasonable in evaluation of patients with suspected TIA especially when no other cause is noted (2)[B].
- TEE is useful in identifying PFO, aortic arch atherosclerosis, and valvular disease and is reasonable when this will alter management (2)[B].
- Prolonged cardiac monitoring is useful in patients with an unclear etiology after initial brain imaging and ECG (2)[B].
- EEG: if seizure suspected
- Consider a sleep study due to the high prevalence of sleep apnea among TIA patients; treatment with CPAP has shown to improve patient outcomes (3)[B].

**TREATMENT**

**GENERAL MEASURES**

- TIA is a neurologic emergency. Immediate medical attention should be sought within 24 hours of symptom onset due to increased stroke risk.
- Current evidence suggests that patients with high-risk TIAs require rapid referral and 24-hour admission (ABCD2 score ≥3 g).
- Acute phase
  - Inpatient for high-risk individuals
  - Outpatient investigations may be considered based on patient’s stroke risk, arrangement of follow-up, and social circumstances.
- Antiplatelet therapy to prevent recurrence or future CVA
- Treatment/control of underlying associated conditions

**MEDICATION**

- For patients with TIA, the use of antiplatelet agents rather than oral
anticoagulation is recommended to reduce risk of recurrent stroke and other cardiovascular events, with the exception of cardioembolic etiologies (2)[A].

- Uncertain if switching agent in patients who have additional ischemic attacks while on antiplatelet therapy is beneficial (4)[C].

**First Line**

- Enteric-coated aspirin: 160 to 325 mg/day in the acute phase (4)[A] followed by long-term antiplatelet therapy for noncardioembolic TIA and anticoagulation for cardioembolic etiology

- Antiplatelet therapy
  - Aspirin 50 to 325 mg/day (4)[A]
    - Contraindications: active peptic ulcer disease and hypersensitivity to ASA or NSAIDs
    - Precautions: may aggravate preexisting PUD; or worsen symptoms of asthma
    - Significant possible interactions: may potentiate effects of anticoagulants and sulfonylurea analogues
  - ER dipyridamole–ASA (Aggrenox): 25/200 mg BID (4,5)[B]
    - Combined therapy with dipyridamole and ASA is better than ASA alone (6)[A].
    - More expensive than ASA alone and may have more associated side effects
  - Clopidogrel 75 mg/day (4)[B]
    - Can be used in patients who are allergic to ASA (4)[B]
    - Precautions: Thrombotic thrombocytopenic purpura (TTP) can occur and increases risk of bleeding when combined with aspirin.
    - May be very slightly more effective than aspirin alone (4)[B]; more expensive and more side effects than aspirin

- Combined aspirin and clopidogrel therapy has been demonstrated to reduce the incidence of subsequent stroke by 21% without increased risk of bleeding when used for a duration of 1 month or less immediately following TIA or CVA (5)[A].

- Anticoagulation therapy
  - Direct thrombin inhibitor:
    - Dabigatran (Pradaxa)
    - Idarucizumab (Praxbind) reversal agent
  - Factor Xa inhibitors
    - Apixaban (Eliquis)
- Rivaroxaban (Xarelto)
  - Edoxaban (Savaysa)
    - Noninferior to warfarin in nonvalvular A-fib
    - Precautions: Avoid in CKD (CrCl <30 mL/min).
    - Expensive but no INR needed
    - Not reversible
  - Warfarin (INR-adjusted dose) (4)[A]
    - Contraindications: intolerance/allergy, active liver disease, active bleeding, pregnancy
    - Significant possible interactions: antibiotics, antiepileptics, antifungals, and many others
- ASA 325 mg/day or ASA 81 mg/day plus clopidogrel 75 mg/day (4)[A]
  - Patients who cannot take anticoagulation for reasons other than bleeding risk

**Second Line**
Ticlopidine (Ticlid): 250 mg PO BID
- For patients unable to tolerate other agents
- Contraindications: hypersensitivity, presence of hematopoietic/hemostatic disorders, conditions associated with bleeding, severe liver dysfunction
- Precautions: neutropenia (0.8% severe), which is reversible with cessation of the drug. Monitor blood counts every 2 weeks for first 3 months. TTP can occur.
- Significant possible interactions: Digoxin plasma levels decreased 15%; theophylline half-life increased from 8.6 to 12.2 hours.

**ISSUES FOR REFERRAL**
- Neurology for ongoing workup and treatment
- Cardiology if cardiac cause suspected
- Vascular surgery if carotid endarterectomy appropriate

**ADDITIONAL THERAPIES**
- Secondary prevention of TIA should be initiated; venous thromboembolism (VTE) prophylaxis
- Patients with TIA or ischemic stroke should be started on high dose statin (7).
- BP should be reduced after 24 hours. Thiazides, ACE inhibitors, and ARBs have shown to be of benefit. β-Blockers have not shown benefit in reducing recurrence or stroke.
Patients with DM or pre-DM should be advised to follow ADA guidelines to maintain tight glycemic control (3)[A].

SURGERY/OTHER PROCEDURES
- Consider carotid endarterectomy in patients with a high degree of carotid artery stenosis ≥70%.
- When carotid endarterectomy is indicated for patients with TIA, surgery within 2 weeks is reasonable if there are no contraindications to early revascularization.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Symptoms <72 hours and the following:
- ABCD2 score of >3
- ABCD2 score of 0 to 3 and uncertainty that diagnostic workup can be completed within 2 days as outpatient. Alternatively: If urgent imaging not available through ED or urgent neurology follow-up not available, admit ABCD2 score ≥3 with evidence of focal ischemia.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Outpatient follow-up with neuro support every 3 months for 1st year and then annually
- Close attention to recurrent TIA or subsequent CVA

DIET
- DASH diet or as appropriate for underlying medical problems
- Physical activity
  - Any level of physical activity is beneficial, but at least 30 minutes of moderate-intensity physical activity daily is preferred (150 minutes/week).

PROGNOSIS
- The risk of stroke on the ipsilateral side within 90 days and cumulative thereafter is 10–20%.
- Frequency increases with the addition of multiple risk factors and severity of carotid stenosis.
- Patients with larger artery occlusion or cardioembolic etiology are at increased risk of recurrence.
- The major cause of death in the first 5 years is cardiac disease.
- High mortality risk associated with TIA, up to 25% of patients will die within 1 year of TIA.

**COMPLICATIONS**

- Stroke
- Functional impairment

**REFERENCES**

ADDITIONAL READING

SEE ALSO

Algorithms: Stroke; Transient Ischemic Attack and Transient Neurologic Defects

CODES

**ICD10**

- G45.9 Transient cerebral ischemic attack, unspecified
- G45.1 Carotid artery syndrome (hemispheric)
- G45.0 Vertebro-basilar artery syndrome

CLINICAL PEARLS

- Stress smoking cessation, exercise, weight loss, limited ETOH intake, and control of HTN, hyperlipidemia, and diabetes.
- Antiplatelet therapy (e.g., aspirin, clopidogrel, or aspirin-dipyridamole) should be initiated.
- Warfarin should be initiated in patients with atrial fibrillation or cardioembolic risk factors.
TRANSIENT STRESS CARDIOMYOPATHY

Timothy P. Fitzgibbons, MD, PhD • Gerard P. Aurigemma, MD

BASICS

DESCRIPTION

- Transient stress cardiomyopathy (TSC) is a unique cause of reversible left ventricle (LV) dysfunction with a presentation indistinguishable from the acute coronary syndromes (ACSs), particularly ST-segment elevation myocardial infarction (MI) (1).
- Typically, the patient is a postmenopausal woman who presents with acute chest pain or dyspnea after an identifiable “trigger” (i.e., an acute emotional or physiologic stressor).
- First reported by authors from Japan, TSC was known initially as the takotsubo syndrome because the typical LV morphology (i.e., apical ballooning) resembled that of a Japanese octopus trap or takotsubo.
- Presenting clinical features include the following:
  - Chest symptoms and/or dyspnea
  - ECG changes, including ST-segment elevations or diffuse T-wave inversions
  - Mild elevation in cardiac biomarkers (creatine kinase [CK], troponin)
  - Transient wall motion abnormalities that may involve the base, midportion, and/or lateral walls of the LV.
  - The apex of the right ventricle (RV) may be affected in up to 25% of cases (2)[B].

- Clinical features may vary on a case-by-case basis, and formal diagnostic criteria have not been established.

- Authors from the Mayo Clinic have proposed that 3 of the 4 following criteria establish the diagnosis (1)[A]:
  - Transient akinesia or dyskinesis of the LV apical and midventricular segments with regional wall motion abnormalities extending beyond a single epicardial vascular distribution
  - Absence of obstructive coronary artery disease (CAD) or angiographic
evidence of acute plaque rupture
- New ECG abnormalities, either ST-segment elevation or T-wave inversion
- Absence of
  - Recent significant head trauma
  - Intracranial bleeding
  - Pheochromocytoma
  - Obstructive epicardial CAD
  - Myocarditis
  - Hypertrophic cardiomyopathy
- Synonym(s): takotsubo cardiomyopathy; apical ballooning syndrome; stress cardiomyopathy; broken heart syndrome; ampulla cardiomyopathy

EPIDEMIOLOGY

Incidence
- TSC accounts for a small percentage (1–3%) of ACS.
- In a recent prospective evaluation of patients admitted to the ICU, as many as 28% had apical ballooning, often in association with sepsis.
- Predominant sex: 82–100% of cases occur in women.
- Predominant age: Mean age of patients is 62 to 75 years.

Prevalence
2.2% of patients presenting to a referral hospital with ST-segment MIs were found to have TSC.

ETIOLOGY AND PATHOPHYSIOLOGY
- The exact pathophysiology is not known.
- A perturbation in the brain–heart axis, originating in the insular cortex, may be the inciting event
- Subsequent overwhelming activation of the sympathetic nervous system initiates a cascade of events, including the following:
  - Catecholamine-induced LV dysfunction: “biased agonism” of epinephrine for β2-adrenergic receptors, located predominantly at the cardiac apex
  - Endothelial dysfunction and vasospasm
  - Cellular metabolic injury
    - Myocardial norepinephrine release
    - Calcium overload
    - Contraction band necrosis
Genetics
No genetic associations have been described to date.

RISK FACTORS
- Female sex
- Postmenopausal state
- Emotional stress (i.e., argument, death of family member)
- Physiologic stress (i.e., acute medical illness)
- Chronic neurologic or psychiatric disease

COMMONLY ASSOCIATED CONDITIONS
Death from TSC is rare, and most cases resolve rapidly, within 2 to 3 days. Reported complications include:
- Left-sided heart failure
- Pulmonary edema
- Cardiogenic shock and hemodynamic compromise
- Dynamic LV outflow tract gradient complicated by hypotension
- Mitral regurgitation
- Ventricular arrhythmias
- LV thrombus formation
- LV free wall rupture
- Death (rare, 0–8%)

DIAGNOSIS
Because TSC often is indistinguishable from an ACS, it should be treated initially as such:
- Activate emergency medical services or report to emergency department.
- Oxygen, IV access, and ECG monitoring
- Urgent cardiology consultation

HISTORY
- In 2/3 of patients, there is exposure to a “trigger event.”
  - Emotional stress: argument, death of family member, divorce, public speaking, and so forth
  - Physiologic stress: acute medical condition such as head trauma, asthma attack, seizure, and so forth
In 1/3 of patients, there is no identifiable trigger (3).
- Acute onset of dyspnea or chest pain
- Palpitations
- Syncope

**PHYSICAL EXAM**
Exam may be unremarkable or may include any of the following:
- Tachypnea
- Tachycardia
- Hypotension
- Jugular venous distension
- Bibasilar rales
- S₃ gallop
- Systolic ejection murmur due to dynamic LV outflow tract gradient
- Holosystolic murmur of mitral regurgitation

**DIFFERENTIAL DIAGNOSIS**
- Acute ST-segment elevation MI
- Pulmonary embolism
- Myopericarditis
- Pheochromocytoma
- Hypertrophic cardiomyopathy
- Subarachnoid hemorrhage or stroke

**DIAGNOSTIC TESTS & INTERPRETATION**
- ECG should be done urgently and may show the following:
  - Diffuse ST-segment elevations
  - Diffuse and often dramatic T-wave inversions
  - QTc interval prolongation (4) [B]
  - Q waves
- Laboratory tests typically reveal a mild elevation in cardiac biomarkers such as
  - CK (rarely >500 U/mL)
  - Troponin I
  - B-type natriuretic peptide (BNP)
  - Markers of high filling pressures (e.g., BNP) tend to be higher than markers of necrosis (e.g., CK, troponin).
- TSC can be distinguished from AMI with 95% specificity using a BNP/TnT
ratio $\geq 1,272$ (sensitivity 52%) (5)[B].

- Chest radiograph
  - Cardiomegaly
  - Pulmonary edema

- Echocardiogram
  - Reduced LV systolic function
  - Abnormal diastolic function, including evidence of increased filling pressures
  - Regional wall motion abnormalities in one of the following patterns:
    o Classic or “takotsubo-type” ballooning of the apex with a hypercontractile base
    o “Reverse takotsubo”: apical hypercontractility with basal akinesis
    o “Midventricular” akinesis with apical and basal hypercontractility
    o Focal or localized akinesis of an isolated segment
  - Dynamic intracavitary LV gradient
  - Mitral regurgitation
  - Variable involvement of the RV

- Cardiac MRI
  - Reduced LV function
  - Wall motion abnormalities as described for transthoracic echocardiography
  - Absence of delayed hyperenhancement with gadolinium

**Diagnostic Procedures/Other**

- Because ST-segment elevation MI is the diagnosis of exclusion, patients typically are referred for urgent cardiac catheterization.

- Coronary angiography
  - Nonocclusive CAD
  - Rarely, epicardial coronary spasm
  - Endothelial dysfunction as measured by fractional flow reserve or TIMI frame counts

- Left-sided heart catheterization: increased LV end-diastolic pressure to a similar degree as AMI

- Ventriculography: wall motion abnormalities as described for transthoracic echocardiography

- Right-sided heart catheterization
  - Increased pulmonary capillary wedge pressure
  - Secondary pulmonary hypertension
  - Increased right ventricular filling pressures
  - Reduced cardiac output or cardiogenic shock (cardiac index <2 and mean
arterial pressure [MAP] <60 mm Hg)

**Test Interpretation**
Characteristic pathologic findings of involved myocardium have not been described.

**TREATMENT**
- Activation of emergency medical services
- Advanced cardiac life support therapies as needed
- Oxygen
- IV access
- ECG monitoring

**MEDICATION**
After diagnostic cardiac catheterization, empirical treatment goals are as follows:
- Management of hypotension: differentiation between cardiogenic shock and
dynamic LV cavity gradient
- Management of increased filling pressures and congestive states
- Attenuation of sympathetic drive

**First Line**
- There are no evidence-based treatment recommendations for TSC.
- Although β-blockers are of theoretical benefit, their use has not been associated with improved outcomes in observational cohorts (3)[B].
- If there is evidence of left ventricular systolic dysfunction or pulmonary edema, consider the following:
  - Furosemide: 20 to 40 mg IV/PO BID as needed to reduce LV filling pressures and dyspnea (6)
  - ACE inhibitors or angiotensin receptor blockers: Lisinopril 10 to 40 mg/day PO or equivalent or valsartan 80 to 160 mg PO BID have been associated with improved outcomes in observational cohorts (3)[B].

**Second Line**
Short-term anticoagulation should be considered in patients with severely reduced LV function to prevent LV thrombus formation. Unfractionated heparin 80 U/kg IV bolus followed by 18 U/kg/hr IV or Lovenox 1 mg/kg SC BID.
ISSUES FOR REFERRAL
All patients with TSC generally should be comanaged with cardiology while inpatient and referred to cardiology as an outpatient.

ADDITIONAL THERAPIES
- Urgent cardiology consultation and consideration of cardiac catheterization
- Hypotension may require the following:
  - Vasopressors (e.g., dopamine or Levophed) if there is no LV outflow tract gradient (6)[C]
  - Phenylephrine and IV fluids to increase afterload in the presence of an LV outflow tract gradient (6)[C]
  - Cardiogenic shock that is not due to an LV outflow tract gradient may require placement of an intra-aortic balloon pump.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization
  - 12-lead ECG
  - Chest radiograph
  - Laboratory testing
  - Echocardiography
  - Patients with TSC usually are admitted for observation because the differential diagnosis includes ACS.
- Normal saline infusion to support BP, if necessary, and no evidence of heart failure
- Discharge criteria generally considered after exclusion of ACS and resolution of
  - Congestive state
  - Hypotension
  - Profound impairments of systolic function

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Impairments in systolic function typically resolve in 2 to 3 days but may last as long as 1 month.
• Patients should follow up with cardiology and serial echocardiography to document improved LV function.

PROGNOSIS
• Prognosis is excellent. Inpatient mortality is rare and ranges from 0% to 8%.
• Recurrence is rare; it also has been reported in 0–8% of patients.

Algorithm: Chest Pain/Acute Coronary Syndrome

CODES
ICD10
I51.81 Takotsubo syndrome
CLINICAL PEARLS

- TSC is a cause of reversible LV dysfunction with a clinical presentation indistinguishable from the ACS, particularly ST-segment elevation MI.
- Echocardiography may strongly suggest the diagnosis.
- Treatment is supportive and should include diuretics and ACE inhibitors in patients with CHF.
TRICHOMONIASIS
Michael Arnold, MD, CDR, MC

BASICS

DESCRIPTION
- Sexually transmitted urogenital infection caused by a pear-shaped, parasitic protozoan
- Causes vaginitis/urethritis in women, nongonococcal urethritis in men
- In pregnancy, increases risk of preterm labor, preterm premature rupture of membranes, small for gestational age infant, and possibly stillbirth
- Synonym(s): trich; trichomonal urethritis

EPIDEMIOLOGY

Incidence
- The most common curable sexually transmitted infection (STI); in 2008, >275 million new cases worldwide, over half of curable STIs (1)
- Estimated 1.1 million new cases annually in the United States
- 10–25% of vaginal infections
- 1–17% of cases of NGU in males; reported prevalence among men without urethritis ranges from 0% to 8%
- Predominant age: middle-aged adults
  - Rare until onset of sexual activity
  - Common in postmenopausal women; age is not protective and long-term carriage is common.
- Women have higher prevalence (1.5 to 4.4 times more than men) (2).

Pediatric Considerations
Rare in prepubertal children; diagnosis should raise concern of sexual abuse.

Prevalence
- 3.1% of all U.S. women age 25 to 49 years; 1.5% of U.S. women age 15 to 24 years
- Racial disparity demonstrated
  - 1.3% of white, non-Hispanic women
  - 1.8% of Mexican American women
– 13.3% of black, non-Hispanic women

ETIOLOGY AND PATHOPHYSIOLOGY

- *Trichomonas vaginalis*: a pear-shaped, flagellated, parasitic protozoan
- Grows best at 35–37°C in anaerobic conditions at pH of 5.5 to 6.0
- STI, but nonsexual transmission is possible because organism can survive several hours in moist environment.

**Genetics**
No known genetic considerations

**RISK FACTORS**
- Multiple sexual partners
- Unprotected intercourse
- Lower socioeconomic status
- Other STIs
- Untreated partner with previous infection
- Use of douching or feminine powders

**GENERAL PREVENTION**
- Use of male or female condoms
- Limiting numbers of sexual partners
- Male circumcision may be protective (3)[B].

**COMMONLY ASSOCIATED CONDITIONS**
- Other STIs, including HIV
- Bacterial vaginosis

**DIAGNOSIS**

**HISTORY**
- Women—up to 80% may be asymptomatic (2)
  - Yellow-green, malodorous vaginal discharge
  - Vulvovaginal pruritus
  - Dysuria
  - Symptoms often worsen during menses.
- Men—80% are asymptomatic (2)
– Dysuria
– Urethral discharge, often scant
– Pruritus or burning after intercourse

PHYSICAL EXAM

• Women
  – Vaginal erythema
  – Yellow-green, frothy, malodorous vaginal discharge
  – Cervical petechiae (“strawberry cervix”; seen in <5% of patients) (2)
• Men: penile discharge, spontaneous and with expression

DIFFERENTIAL DIAGNOSIS

• Women (other vaginitides)
  – Bacterial vaginosis
  – Vaginal candidiasis
  – Chlamydial infection
  – Gonorrheal infection
• Men (other urethritides)
  – Chlamydial infection
  – Gonorrheal infection

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

• Wet mounts of vaginal or urethral discharge: direct visualization of motile trichomonads; most common diagnostic method because inexpensive and available
  – Sensitivity: 60–70%; declines rapidly within 1 hour from collection
  – Specificity: 99.8%
• Culture: sensitivity >95%, specificity >99%; takes 4 to 7 days for growth
• Nucleic acid amplification test (NAAT)
  – Gold standard for diagnosis (4)
  – Sensitivity and specificity 95–99%
  – FDA-approved for vaginal, endocervical, or female urine specimens
  – Results in 1 hour
  – Limited clinical availability
• Antigen detection
  – ELISA and direct fluorescent antibody tests: sensitivity of 80–90%
  – Limited clinical availability
Follow-Up Tests & Special Considerations
Detection on cervical Papanicolaou smear
- Treat because highly specific (97–99%)
- Not effective Trichomonas screening test given sensitivity as low as 60%

Diagnostic Procedures/Other
In males, urethral meatal swab increases Trichomonas detection rate by 4 times.

TREATMENT
- Symptomatic individuals require treatment.
- Sexual partners should be treated presumptively.
- Patients should abstain from sexual intercourse during treatment and until they are asymptomatic.

GENERAL MEASURES
The nitroimidazole class is only known effective antimicrobial treatment. If metronidazole resistance is suspected, use tinidazole (5)[A].

MEDICATION
First Line
- Metronidazole: 2 g PO, 1 dose (6)[A]
  - FDA pregnancy risk Category B
  - Cure rate: 84–98%
- Tinidazole: 2 g PO, 1 dose (6)[A]
  - FDA pregnancy risk Category C
  - Abstain from breastfeeding during treatment and for 3 days after the dose.
  - More expensive
  - Reaches higher levels in genitourinary tract
  - Cure rate: 92–100%

Second Line
- Metronidazole: 500 mg PO BID for 7 days
  - Only if still symptomatic after initial treatment
  - Considered first line in HIV-positive individuals
- Can dose with metronidazole or tinidazole 2 g daily for 7 days if infection
persists

- May consider IV dosing of metronidazole based on case report that demonstrated cure after multiple failed oral regimens

**Pregnancy Considerations**

Metronidazole is effective for trichomoniasis infection during pregnancy but may increase the risk of preterm and low-birth-weight babies.

- Studies showed risk in patients receiving 4 times the standard dosing.
- Trichomoniasis is also associated with prematurity.

**ISSUES FOR REFERRAL**

- Multidrug-resistant organism
- Patient allergy to metronidazole: Desensitization to metronidazole is recommended.

**ADDITIONAL THERAPIES**

- Limited clinical trials assessing effectiveness of alternative therapies (4)
- Intravaginal metronidazole gel is not effective.
- Suggested alternative therapies based on small number of case reports
  - Paromomycin 6.25% cream
  - Povidone-iodine douche
  - Boric acid intravaginally
  - Furazolidone intravaginally

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

See “Additional Therapies.”

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- If symptoms persist after initial treatment, repeat wet mount or other testing.
- Retest women for *T. vaginalis* recommended within 3 months of treatment; data insufficient for retesting men (6)[A]
- HIV-positive patients should be screened for *Trichomonas* at time of HIV diagnosis and at least annually (6)[A].
DIET
Abstain from alcohol during treatment and for 24 hours following last dose of metronidazole or 48 to 72 hours following last dose of tinidazole due to disulfiram-like reaction.

PATIENT EDUCATION
Educate about the sexually transmitted aspect.
- Advise patient to notify sexual partner to be treated.
- Discuss STI prevention—condom use can prevent recurrence.
- Abstain from intercourse while undergoing treatment; use condoms if abstention is not feasible.
- Avoid alcohol during treatment with metronidazole or tinidazole.

PROGNOSIS
- Excellent
- Usually eliminated after one course of antibiotics

COMPLICATIONS
Pregnancy Considerations
Linked to low birth weight, preterm premature rupture of membranes, and preterm birth; associations with infertility, but not proven

REFERENCES
2. Menezes CB, Frasson AP, Tasca T. Trichomoniasis—are we giving the deserved attention to the most common non-viral sexually transmitted disease worldwide? Microb Cell. 2016;3(9):404–419.
5. Seña AC, Bachmann LH, Hobbs MM. Persistent and recurrent Trichomonas

**ADDITIONAL READING**

- McClelland RS, Sangare L, Hassan WM, et al. Infection with *Trichomonas*

**CODES**

**ICD10**
- A59.9 Trichomoniasis, unspecified
- A59.03 Trichomonal cystitis and urethritis
- A59.01 Trichomonal vulvovaginitis

**CLINICAL PEARLS**
- Both partners need to be treated for trichomoniasis.
- Retest women within 3 months of treatment.
- Avoid alcohol during treatment with standard agents.
- Treatment does not reduce risk of adverse pregnancy outcomes.
- Male circumcision may be protective.
- Annual screening recommended for HIV-positive patients
- Not a nationally notifiable condition
TRIGEMINAL NEURALGIA
Noah M. Rosenberg, MD, MBA

BASICS

DESCRIPTION
- A painful disorder of the sensory nucleus of the trigeminal nerve (cranial nerve [CN] V) that produces episodic, paroxysmal, severe, lancinating facial pain lasting seconds to minutes in the distribution of ≥1 divisions of the nerve.
- Often precipitated by stimulation of well-defined, ipsilateral trigger zones: usually perioral, perinasal, and, occasionally, intraoral (e.g., by washing, shaving).
- System(s) affected: nervous
- Synonym(s): tic douloureux, Fothergill neuralgia, trifacial neuralgia, prosopalgia

EPIDEMIOLOGY

Incidence
- Women: 5.9/100,000/year
- Men: 3.4/100,000/year
- >70 years of age: ~25.6/100,000/year
- Predominant age:
  - >50 years; incidence increases with age.
  - Rare: <35 years of age (consider another primary disease; see “Etiology and Pathophysiology”)
- Predominant sex: female > male (~2:1)

Prevalence
16/100,000

Pediatric Considerations
Unusual during childhood

Pregnancy Considerations
Teratogenicity limits therapy for 1st and 2nd trimesters.
ETIOLOGY AND PATHOPHYSIOLOGY

- Demyelination around the compression site seems to be the mechanism by which compression of nerves leads to symptoms.
- Demyelinated lesions may set up an ectopic impulse generation causing erratic responses: hyperexcitability of damaged nerves and transmission of action potentials along adjacent, undamaged, unstimulated sensory fibers.
- Compression of trigeminal nerve by anomalous arteries or veins of posterior fossa, compressing trigeminal root.
- Etiologic classification:
  - Idiopathic (classic)
  - Secondary: cerebellopontine angle tumors (e.g., meningioma); tumors of CN V (e.g., neuroma, vascular malformations), trauma, demyelinating disease (e.g., multiple sclerosis [MS])

RISK FACTORS
Unknown

COMMONLY ASSOCIATED CONDITIONS

- Sjögren syndrome; rheumatoid arthritis
- Chronic meningitis
- Acute polyneuropathy
- MS
- Hemifacial spasm
- Charcot-Marie-Tooth neuropathy
- Glossopharyngeal neuralgia

DIAGNOSIS

HISTORY
Paroxysms of pain in the distribution of the trigeminal nerve

PHYSICAL EXAM
All exam findings typically are negative due to the paroxysmal nature of the disorder.

DIFFERENTIAL DIAGNOSIS

- Other forms of neuralgia usually have sensory loss. Presence of sensory loss
nearly excludes the diagnosis of TN (if younger patient, frequently MS).
- Neoplasia in cerebellopontine angle
- Vascular malformation of brain stem
- Demyelinating lesion (MS is diagnosed in 2–4% of patients with trigeminal neuralgia [TN].)
- Vascular insult
- Migraine, cluster headache
- Giant cell arteritis
- Postherpetic neuralgia
- Chronic meningitis
- Acute polyneuropathy
- Atypical odontalgia
- SUNCT syndrome (short-lasting, unilateral, neuralgiform pain with conjunctival injection, and tearing)

**DIAGNOSTIC TESTS & INTERPRETATION**
- The International Headache Society diagnostic criteria for classic TN are as follows:
  - Paroxysmal attacks of pain lasting from a fraction of 1 second to 2 minutes, affecting ≥1 divisions of the trigeminal nerve
  - Pain has at least an intense, sharp, superficial, or stabbing characteristic or is precipitated from trigger areas or by trigger factors.
  - Attacks are stereotyped in the individual patient.
  - No clinically evident neurologic deficit found
  - Not attributed to another disorder
- Secondary TN is characterized by pain that is indistinguishable from classic TN but is caused by a demonstrable structural lesion other than vascular compression.
  - Indicated in all first-time-presenting patients to rule out secondary causes
- MRI versus CT scan: MRI, with and without contrast, offers more detailed imaging and is preferred, if not contraindicated.
- Routine head imaging identifies structural causes in up to 15% of patients.
- No positive findings are significantly correlated with diagnosis.

**Test Interpretation**
- Trigeminal nerve: inflammatory changes, demyelination, and degenerative changes
- Trigeminal ganglion: hypermyelination and microneuromata
TREATMENT

GENERAL MEASURES

- Outpatient
- Drug treatment is first line.
- Invasive procedures are reserved for patients who cannot tolerate, fail to respond to, or relapse after chronic drug treatment.
- Avoid stimulation (e.g., air, heat, cold) of trigger zones, including lips, cheeks, and gums.

MEDICATION

First Line

- Carbamazepine (Tegretol) (1)[A]: Start at 100 to 200 mg BID; effective dose usually 200 mg QID; max dose 1,200 mg/day:
  - 70–90% of patients respond initially (number needed to treat [NNT] = 1.9) (1)[A]
  - By 3 years, 30% are no longer helped.
  - Most common side effect: sedation
- Contraindications: concurrent use of monoamine oxidase inhibitors (MAOIs)
- Precautions: caution in the presence of liver disease
- Significant possible medication interactions: macrolide antibiotics, oral anticoagulants, anticonvulsants, tricyclics, oral contraceptives, steroids, digitalis, isoniazid, MAOIs, methyprylon, nabilone, nizatidine, other H₂ blockers, phenytoin, propoxyphene, benzodiazepines, and calcium channel blockers
- Oxcarbazepine (Trileptal): Start at 150 to 300 mg BID; effective dose usually 375 mg BID; max dose 1,200 mg/day:
  - Efficacy similar to carbamazepine
  - Faster, with less drowsiness and fewer drug interactions than carbamazepine
  - May cause hyponatremia
  - Most common side effect: sedation

Second Line

- Antiepileptic drugs: insufficient evidence from randomized, controlled trials to show significant benefit from antiepileptic drugs in TN (2)[A]
- Phenytoin (Dilantin): 300 to 400 mg/day (synergistic with carbamazepine):
– Potent P450 inducer (enhanced metabolism of many drugs)
– Various CNS side effects (sedation, ataxia)

- Baclofen (Lioresal): 10 to 80 mg/day; start at 5 to 10 mg TID with food (as an adjunct to phenytoin or carbamazepine); side effects: drowsiness, weakness, nausea, vomiting

- Gabapentin (Neurontin): Start at 100 mg TID or 300 mg at bedtime; can increase dose up to 300 to 600 mg TID–QID; can be used as monotherapy or in combination with other medications

- Lamotrigine: Titrate up to 200 mg BID over weeks; side effect: 10% experience rash

- Antidepressants, including amitriptyline, fluoxetine, trazodone:
  – Used especially with anticonvulsants
  – Particularly effective for atypical forms of TN

- Clonazepam (Klonopin) frequently causes drowsiness and ataxia.

- Sumatriptan (Imitrex) 3 mg SC reduces acute symptoms and may be helpful after failure of conventional medical therapy.

- Capsaicin cream topically

- Botulinum toxin injection into zygomatic arch

- Valproic acid (Depakene, Depakote)

**ISSUES FOR REFERRAL**
Initial treatment failure or positive findings on imaging studies

**ADDITIONAL THERAPIES**

- Radiotherapy
  - Stereotactic radiosurgery, such as gamma knife radiosurgery, has been shown to be effective after drug failure:
    – Produces lesions with focused gamma knife radiation
    – Therapy aimed at the proximal trigeminal root
    – Minimal clinically effective dose: 70 Gy
    
    – ~60–80% of patients achieve complete relief within 1 year; by 3 years, ~30–40% maintain complete relief (3)[B].
  – Most common side effect: sensory disturbance (facial numbness)
  – Failure rates are higher in patients with past TN-related invasive procedures.

**SURGERY/OTHER PROCEDURES**

- Microvascular decompression of CN V at its entrance to (or exit from) brain
stem:
- 98% of patients achieve initial pain relief; by 20 months, 86% maintain complete relief (NNT = 2) (4)[B].
- Surgical mortality across studies was 0.3–0.4%.
- Most common side effect: transient facial numbness and diplopia, headache, nausea, vomiting
- Pain relief after procedure strongly correlates with the type of TN pain: Type 1 (shocklike pain) results in better outcomes than type 2 (aching pain between paroxysms).
- **Peripheral nerve ablation (multiple methods):**
  - Higher rates of failure and facial numbness than decompression surgery
  - Radiofrequency thermocoagulation
  - Neurectomy
  - Cryotherapy: high relapse rate
  - Partial sensory rhizotomy
- 4% tetracaine dissolved in 0.5% bupivacaine nerve block (only a few case reports to date; ropivacaine)
- Alcohol block or glycerol injection into trigeminal cistern: unpredictable side effects (dysesthesia and anesthesia dolorosa); temporary relief
- Peripheral block or section of CN V proximal to gasserian ganglion
- Balloon compression of gasserian ganglion
- Evidence supporting destructive procedures for benign pain conditions remains limited (5)[A].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Acupuncture, moxibustion (herb): weak evidence for efficacy (6)[B]

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Regular outpatient follow-up to monitor symptoms and therapeutic failure

**Patient Monitoring**
- Carbamazepine and/or phenytoin serum levels
- If carbamazepine is prescribed: CBC and platelets at baseline, then weekly for a month, then monthly for 4 months and then every 6 to 12 months if dose is
stable (regimens for monitoring vary)

- Reduce drugs after 4 to 6 weeks to determine whether condition is in remission; resume at previous dose if pain recurs. Withdraw drugs slowly after several months, again to check for remission or if lower dose of drugs can be tolerated.

DIET

No special diet

PATIENT EDUCATION

- Instruct patient regarding medication dosage and side effects, risk-to-benefit ratios of surgery, or radiation therapy.
- Support organizations:
  - The Facial Pain Association (formerly the Trigeminal Neuralgia Association): www.fpa-support.org
  - Living with Trigeminal Neuralgia: www.livingwithtn.org

PROGNOSIS

- 50–60% eventually fail pharmacologic treatment.
- After having microvascular decompression surgery, most patients wish they had undergone the procedure sooner.
- Of those, relapse is seen in ~50% of stereotactic radiosurgeries and ~27% of surgical microvascular decompressions.

COMPLICATIONS

- Mental and physical sluggishness; dizziness with carbamazepine
- Paresthesias and corneal reflex loss with stereotactic radiosurgery
- Surgical mortality and morbidity associated with microvascular decompression

REFERENCES

### ADDITIONAL READING

### CODES

**ICD10**

- G50.0 Trigeminal neuralgia
- B02.22 Postherpetic trigeminal neuralgia

### CLINICAL PEARLS

- Patients with TN typically have a normal physical exam.
- The long-term efficacy of pharmacotherapy for TN is 40–50%.
- If pharmacotherapy fails, stereotactic radiosurgery or surgical microvascular decompression often is successful.
TRIGGER FINGER (DIGITAL STENOSING TENOSYNOVITIS)

Alan M. Ehrlich, MD • Robert A. Yood, MD

BASICS

DESCRIPTION
A clicking, snapping, or locking of a finger/thumb with extension movement (after flexion) ± associated pain

EPIDEMIOLOGY

Incidence
- Adult population: 28/100,000/year
  - Rare in children
- 4 times increased risk in diabetics (1)[B]
- Predominant age
  - Childhood form typically involves thumb.
  - Adult form typically presents in the 5th and 6th decades of life and involves thumb/digits.
- Predominant sex
  - Children: female = male
  - Adults: female > male (6:1)

Prevalence
Lifetime prevalence in the general population is 2.6%.

Pediatric Considerations
- The thumb is more commonly involved in children.
- Surgery is often more complicated for children with a trigger finger (as opposed to a trigger thumb).
- Release of the A1 pulley alone is often insufficient, other procedures may be necessary.

ETIOLOGY AND PATHOPHYSIOLOGY
- Narrowing around the A1 pulley from inflammation, protein deposition, or
thickening of the tendon itself. Prolonged inflammation leads to fibrocartilaginous metaplasia of the tendon sheath.

- If the flexor tendon become nodular, the triggering phenomenon is worse because the nodule has difficulty passing under the A1 pulley.
- Because intrinsic flexor muscles are stronger than extensors, the finger can stick in the flexed position.
- No clear association with repetitive movements

RISK FACTORS
- Diabetes mellitus
- Rheumatoid arthritis
- Hypothyroidism
- Mucopolysaccharide disorders
- Amyloidosis

GENERAL PREVENTION
Most cases are idiopathic, and no known prevention exists; no clear association with repetitive movements

COMMONLY ASSOCIATED CONDITIONS
- De Quervain tenosynovitis
- Carpal tunnel syndrome
- Dupuytren contracture
- Diabetes mellitus
- Rheumatoid arthritis
- Hypothyroidism
- Amyloidosis

DIAGNOSIS
Diagnosis is based on clinical presentation.

HISTORY
Clicking, snapping, or locking of a digit while attempting to extend; with or without associated pain

PHYSICAL EXAM
- A palpable nodule may be present.
• Snapping/locking may be present but neither is necessary for the diagnosis.
• Tenderness to palpation is variable.

DIAGNOSTIC TESTS & INTERPRETATION

Test Interpretation
• Thickening of the A1 pulley with fibrocartilaginous metaplasia
• Thickening/nodule formation of flexor tendon

TREATMENT
• Splinting the metacarpophalangeal (MCP) joint at 10 to 15 degrees of flexion for 6 weeks with the distal joints free to move:
  – Splinting is more effective for fingers than thumbs (70% vs. 50%).
  – Splinting is less effective with severe symptoms, symptoms >6 months, or if multiple digits are involved (1)[B].
• Injection of long-acting corticosteroid may provide symptom relief. Subsequent injections are less likely to help.
• Surgery often successful for patients unresponsive to splinting/corticosteroid injections

GENERAL MEASURES
Attempt splinting/steroid injection prior to surgery. Splinting may be more effective for preventing recurrence than as initial treatment (2)[B].

MEDICATION

First Line
• Steroid injection of the tendon sheath/surrounding SC tissue has 57–90% success rate.
• Injection in surrounding tissues is as efficacious as injecting into the tendon sheath (1,3)[B]. Injection into the palmar surface at the midproximal phalanx is associated with less pain than injection of tendon sheath at MCP joint (4) [B].
• Injection using ultrasound guidance does not improve success rate compared to standard injection technique (5)[A]. Corticosteroid injection has higher success rate than splinting (2)[B].
**Second Line**
- Oral NSAIDs may reduce pain and discomfort but have not been shown to alter underlying disease. NSAIDs do not reduce symptoms of snapping/locking.
- Injection with diclofenac may be an alternative to corticosteroid for patients with diabetes mellitus if increase in blood sugar is a concern (6)[A].
- Corticosteroids are more effective than diclofenac during the first 3 weeks postinjection. Efficacy is similar to other modalities by 3 months postinjection (6)[B].
- In one randomized trial, hyaluronic acid (HA) injections were as effective as corticosteroid injections. The optimal frequency, dosage, and molecular weight of HA injections has yet to be adequately studied.

**ISSUES FOR REFERRAL**
Refer to a hand surgeon for release if the patient is not responding to splinting and/or steroid injections.

**ADDITIONAL THERAPIES**
Physiotherapy is helpful, particularly in children.

**SURGERY/OTHER PROCEDURES**
- Surgical release can be done as an open procedure or percutaneously.
- No apparent differences in success or rates of complications between surgical approaches (6)[A].
- Surgery has a lower rate of recurrence than corticosteroid injection (6)[A].
- Most hand surgeons prefer open release because of concern about nerve injury.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Day surgery for trigger finger release
- Discharge criteria: absence of complications

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

mebooksfree.com
Follow-up is needed only if symptoms persist or if complications develop after surgery.

Splinting of the affected digit to minimize flexion/extension of the MCP joint helps symptom resolution (1)[B],(7)[C].

PROGNOSIS

Prognosis is excellent with conservative treatment or surgical intervention. Recurrence following corticosteroid injection is more likely for patients with type 1 diabetes mellitus, younger patients, involvement of multiple digits, and patients with a history of other upper extremity tendinopathies (8)[B].

COMPLICATIONS

- Complications from surgery include infection, bleeding, digital nerve injury, persistent pain, and loss of range of motion of the affected finger. The rate of major complications is low (3%). The rate of minor complications (including loss of range of motion) is higher (up to 28%).
- Injury to the A2 pulley may result in bowstringing (bulging of the flexor tendon in the palm with flexion). This can be painful.
- Diabetic patients may have increased blood sugar levels for up to 5 days following steroid injection.

REFERENCES

7. Ryzewicz M, Wolf JM. Trigger digits: principles, management, and

**ADDITIONAL READING**

**CODES**

**ICD10**

- M65.30 Trigger finger, unspecified finger
- M65.319 Trigger thumb, unspecified thumb
- M65.329 Trigger finger, unspecified index finger

**CLINICAL PEARLS**

- Trigger finger is caused by narrowing of the A1 flexor tendon pulley.
- Splinting the MCP joint at 10 to 15 degrees flexion for 6 weeks is the preferred initial conservative treatment.
- Splinting is more effective for fingers as opposed to thumbs (70% vs. 50%). Splinting is less effective with severe symptoms, longstanding symptoms (>6 months), or if multiple digits are involved.
• Long-acting corticosteroid injections are effective for treatment of trigger finger.
• Open and percutaneous surgical release has high success rates for patients not responsive to splinting or injections.
TROCHANTERIC BURSITIS (GREATER TROCHANTERIC PAIN SYNDROME)

David W. Kruse, MD • David C. Shin, MD

BASICS

*Trochanteric bursitis* is the historical term referring to lateral hip pain and tenderness over the greater trochanter. Because many patients lack an inflammatory process within the trochanteric bursa, this condition has been more recently referred to as *greater trochanteric pain syndrome* (GTPS) (1).

DESCRIPTION

- Bursae are fluid-filled sacs found primarily at tendon attachment sites with bony protuberances:
  - Multiple bursae are in the area of the greater trochanter of the femur.
  - These bursae are associated with the tendons of the gluteus muscles, iliotibial band (ITB), and tensor fasciae latae.
  - The subgluteus maximus bursa is implicated most commonly in lateral hip pain (1).
- Other structures of the lateral hip include the following:
  - ITB, tensor fasciae latae, gluteus maximus tendon, gluteus medius tendon, gluteus minimus tendon, quadratus femoris muscle, vastus lateralis tendon, piriformis tendon
- *Bursitis* refers to bursal inflammation.
- *Tendinopathy* refers to any abnormality of a tendon, inflammatory or degenerative. *Enthesopathy* refers to abnormalities of the zones of attachment of ligaments and tendons to bones.

EPIDEMIOLOGY

**Incidence**

- 1.8/1,000 persons/year
- Peak incidence in 4th to 6th decades

**Prevalence**

- Predominant sex: female > male
More common in running and contact athletes
  – Football, rugby, soccer

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute: Abnormal gait or poor muscle flexibility and strength imbalances lead to bursal friction and secondary inflammation.
  – Tendon overuse and inflammation
  – Direct trauma from contact or frequently lying with body weight on hip can cause an inflammatory response (“hip pointer”) as well.
- Chronic
  – Fibrosis and thickening of bursal sac due to chronic inflammatory process
  – Tendinopathy due to chronic overuse and degeneration: gluteus medius and minimus most commonly involved (1)

Genetics
No known genetic factors

RISK FACTORS
Multiple factors have been implicated (1):
- Female gender
- Obesity
- Tight hip musculature (including ITB)
- Direct trauma
- Total hip arthroplasty
- Abnormal gait or pelvic architecture
  – Leg length discrepancy
  – Sacroiliac (SI) joint dysfunction
  – Knee or hip osteoarthritis
  – Abnormal foot mechanics (e.g., pes planus, overpronation)
  – Neuromuscular disorder: Trendelenburg gait

GENERAL PREVENTION
- Maintain ITB, hip, and lower back flexibility and strength.
- Avoid direct trauma (use of appropriate padding in contact sports).
- Avoid prolonged running on banked or crowned surfaces.
- Wear appropriate shoes.
- Appropriate bedding and sleeping surface
- Maintain appropriate body weight loss.
COMMONLY ASSOCIATED CONDITIONS

- Biomechanical factors (1)
  - Tight ITBs, leg length discrepancy, SI joint dysfunction, pes planus
  - Width of greater trochanters greater than width of iliac wings
- Other associated pathology (1):
  - Low back pain
  - Knee and hip osteoarthritis
  - Obesity

DIAGNOSIS

HISTORY

General history (1)

- Pain localized to the lateral hip or buttock
- Pain may radiate to groin or lateral thigh (pseudoradiculopathy).
- Pain exacerbated by:
  - Prolonged walking or standing
  - Rising after prolonged sitting
  - Sitting with legs crossed
  - Lying on affected side
- Other historical features:
  - Direct trauma to affected hip
  - Chronic low back pain
  - Chronic leg/knee/ankle/hip pain
  - Recent increase in running distance or intensity
  - Change in running surfaces

PHYSICAL EXAM

- Observe gait.
- Point tenderness with direct palpation over the lateral hip is characteristic of GTPS (1)[B].
- Other exam features have lower sensitivity (1)[B]:
  - Pain with extremes of passive rotation, abduction, or adduction
  - Pain with resisted hip abduction and external or internal rotation
  - Trendelenburg sign
- Other tests to rule out associated conditions:
  - Patrick-FABERE (flexion, abduction, external rotation, extension) test for
SI joint dysfunction
- Ober test for ITB pathology
- Flexion and extension of hip for osteoarthritis
- Leg length measurement
- Foot inspection for pes planus or overpronation
- Lower extremity neurologic assessment for lumbar radiculopathy or neuromuscular disorders
- Hip lag sign (2)

DIFFERENTIAL DIAGNOSIS
- ITB syndrome
- Piriformis syndrome
- Osteoarthritis or avascular necrosis of the hip
- Lumbosacral osteoarthritis/disc disease with nerve root compression
- Fracture or contusion of the hip or pelvis—particularly in setting of trauma
- Stress reaction/fracture of femoral neck—particularly in female runners
- Septic bursitis/arthritis

DIAGNOSTIC TESTS & INTERPRETATION
No routine lab testing is recommended.

Initial Tests (lab, imaging)
- Diagnosis can be made by history and exam (3).
- If imaging is ordered:
  - US can aid in diagnosis and guide aspiration and/or injection.
  - Anteroposterior and frog-leg views of affected hip to rule out specific bony pathology (OA, stress fracture, etc.)
  - Consider lumbar spine radiographs if back pain is thought to be a contributing factor.
  - MRI is image of choice in recalcitrant pain or to formally exclude stress fracture.

Follow-Up Tests & Special Considerations
- If there is a concern for a septic bursitis, then aspiration or incision and drainage may be necessary.
- Advanced imaging rarely necessary; detection of abnormalities on MRI is a poor predictor of GTPS (4)[B].
TREATMENT

GENERAL MEASURES
- Physical therapy to address underlying dysfunction and rebuild atrophic muscle
- Correct pelvic/hip instability.
- Correct lower limb biomechanics.
- Low-impact conditioning and aquatic therapy
- Gait training
- Weight loss (if applicable)
- Minimize aggravating activities such as prolonged walking or standing.
- Avoid lying on affected side.
- Runners
  - May need to decrease distance and/or intensity of runs during treatment.
  - Some need to stop running. Amount of time is case specific but may range from 2 to 4 weeks.
  - Avoid banked tracks or roads with excessive tilt.

MEDICATION

First Line
- NSAIDs (1)[B]: Treat for 2 to 4 weeks.
  - Naproxen: 500 mg PO BID
  - Ibuprofen: 800 mg PO TID
- Corticosteroid injection is effective for pain relief (5)[C] and can be considered first-line therapy for selected cases:
  - Dexamethasone: 4 mg/mL or
  - Kenalog: 40 mg/mL, use 1 to 2 mL
  - Consider adding a local anesthetic (short- and/or long-acting) for more immediate pain relief.
  - Can be repeated with similar effect if original treatment showed a strong response
  - Goal is pain relief.

ISSUES FOR REFERRAL
- Septic bursitis
- Recalcitrant bursitis
ADDITIONAL THERAPIES

- Ice
- Low-energy shock wave therapy has been shown to be superior to other nonoperative modalities (6).
- Focus on achieving flexibility of hip musculature, particularly the ITB.
- Address contributing factors:
  - Low back flexibility
  - If leg length discrepancy, consider heel lift
  - If pes planus or overpronation, consider arch supports or custom orthotics

SURGERY/OTHER PROCEDURES

- Surgery rare but effective in refractory cases (6)[A]
- If surgery is indicated, potential options include:
  - Arthroscopic bursectomy
  - ITB release
  - Gluteus medius tendon repair

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Acupuncture
- Prolotherapy
- Growth factor injection techniques
- Platelet-rich plasma injection

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

4 weeks posttreatment, sooner if significant worsening

PATIENT EDUCATION

- Maintain hip musculature flexibility, including ITB.
- Correct issues that may cause abnormal gait:
  - Low back pain
  - Knee pain
  - Leg length discrepancy (heel lift)
  - Foot mechanics (orthotics)
Gradual return to physical activity

PROGNOSIS
Depends on chronicity and recurrence, with more acute cases having an excellent prognosis

COMPLICATIONS
Bursal thickening and fibrosis

REFERENCES

ADDITIONAL READING
- McMahon SE, Smith TO, Hing CB. A systematic review of imaging

**CODES**

**ICD10**

- M70.60 Trochanteric bursitis, unspecified hip
- M70.62 Trochanteric bursitis, left hip
- M70.61 Trochanteric bursitis, right hip

**CLINICAL PEARLS**

- Patients with GTPS often present with an inability to lie on the affected side.
- Femoral neck stress fractures are a do-not-miss diagnosis, particularly in young female runners.
- Corticosteroid injection helps as an initial therapy, particularly for pain relief to allow for aggressive physical therapy.
- Physical therapy is treatment mainstay for correcting biomechanical imbalances and restoring proper function.
BASICS

DESCRIPTION

- Active tuberculosis (TB)
  - Primary infection or reactivation of latent infection
  - Without preventive therapy, affects 10% of infected individuals
  - Risk increases with immunosuppression: Highest risk first 2 years after infection. Reactivation risk increases with comorbidities (e.g., HIV, diabetes).
  - Well-described forms: pulmonary (85% of cases), miliary (disseminated), meningeal, abdominal, lymphadenitis (scrofula)
- Usually acquired by inhalation of airborne bacilli from an individual with active TB. Bacilli multiply in alveoli and spread via macrophages, lymphatics, and blood. Three possible outcomes:
  - Eradication: Tissue hypersensitivity halts infection within 10 weeks.
  - Primary TB
  - Latent TB (See “Tuberculosis, Latent [LTBI].”)

Pediatric Considerations

- Children have a faster rate of progression to disease, higher risk of progression to disease, and more commonly have severe disease.
- Most children with pulmonary TB are asymptomatic.
- Pediatric TB treatment should be directly observed (directly observed therapy [DOT]) using four drugs.

EPIDEMIOLGY

Incidence

- Worldwide (2016): 10.4 million: 133 cases/100,000 population; highest incidence in Asia and Africa (1)
- United States (2014): 9,421 (3/100,000); incidence in foreign-born persons 14 times that of U.S.-born persons (2)
Prevalence
Worldwide (2016): Indirect estimates are uncertain due to variance in reporting systems. Higher burden countries have approximately 150 cases/100,000 population (2).

Mortality
Worldwide (2015): 1.4 million deaths due to TB, 1 of the top 10 causes of death worldwide

ETIOLOGY AND PATHOPHYSIOLOGY
- *Mycobacterium tuberculosis*, *Mycobacterium bovis*, or *Mycobacterium africanum* are causative organisms.
- Cell-mediated response by activated T lymphocytes and macrophages forms a granuloma that limits bacillary replication. Destruction of the macrophages produces early “solid necrosis.” In 2 to 3 weeks, “caseous necrosis” develops and LTBI ensues. In the immunocompetent, granuloma undergoes “fibrosis” and calcification. In the immunocompromised, primary progressive TB develops. Cavitary lesions may form. Necrotic lesions may rupture into bronchioles with resulting aerosolization of tuberculous bacilli.

RISK FACTORS
- For infection: homeless, ethnic minorities, close quarters (correctional facilities, nursing homes, barracks), close contact with infected person, living in areas with high incidence of active TB, health care workers; medically underserved, low income, substance abuse
- For development of disease once infected: HIV; lymphoma; silicosis; diabetes mellitus; chronic renal failure; cancer of head, neck, or lung; children <5 years of age; malnutrition; systemic corticosteroids, immunosuppressive drugs; IV drug abuse, alcohol abuse, cigarette smokers; <2 years since infection with *M. tuberculosis*; history of gastrectomy or jejunal bypass; <90% of ideal body weight

GENERAL PREVENTION
- Screen for and treat LTBI. Report active TB to health department; test and treat all close contacts.
- Bacillus Calmette-Guérin (BCG) vaccine: Live attenuated *M. bovis* prevents 50% of pulmonary disease and 80% of meningitis and miliary disease in children. Relatively ineffective in adults. Use is more common in endemic
In the United States, consider BCG for high-risk children with negative PPD and HIV tests or for health workers at risk for drug-resistant infection.

COMMONLY ASSOCIATED CONDITIONS
Immunosuppression; HIV-coinfection; malignancy

DIAGNOSIS

HISTORY
- Known exposure to individual with active TB
- Immunosuppression
- Tobacco use; recreational drug use
- Signs and symptoms
  - General: fever, night sweats, weight loss, malaise, painless lymph node swelling
  - Pulmonary TB: unexplained cough >2 to 3 weeks, hemoptysis
  - Abdominal TB: presents acutely as surgical abdomen; chronic abdominal TB varies in presentation, vague abdominal symptoms, abdominal mass, "doughy" abdomen.
  - Meningitis: See “Tuberculosis, CNS.”
  - Miliary: See “Tuberculosis, Miliary.”

PHYSICAL EXAM
- Often entirely normal. Specific findings depend on organs involved: adenopathy, rales, or hepatosplenomegaly; poor weight gain in children
- Late findings: renal, bone, or CNS disease

DIFFERENTIAL DIAGNOSIS
- Pulmonary TB: pneumonia (bacterial fungal, atypical), malignancy, tularemia, actinomycosis, Wegener, noninfectious granulomatous diseases (e.g., sarcoidosis)
- Extrapulmonary TB: syphilis, cat-scratch disease, leishmaniasis, leprosy, rheumatologic disease, erythema nodosum, erythema induratum, other mycobacterial infections

DIAGNOSTIC TESTS & INTERPRETATION
**Initial Tests (lab, imaging)**

To determine immune response to mycobacterium

- Tuberculin skin test (TST) (e.g., PPD): 5 U (0.1 mL) intermediate-strength intradermal injection into volar forearm. Measure induration at 48 to 72 hours:
  - PPD positive if induration
    - >5 mm and HIV infection, recent TB contact, immunosuppressed, disease on x-ray
    - >10 mm and age <4 years or other risk factors
    - >15 mm and age >4 years and no risk factors
    - Two-step test if no recent PPD, age >55 years, nursing home resident, prison inmate, or health care worker. Second test 1 to 3 weeks after initial test; interpret as usual.
  - Context of PPD results:
    - False positive: BCG (unreliable, should not affect decision to treat)
    - False negative: HIV, steroids, gastrectomy, alcoholism, renal failure, sarcoidosis, malnutrition, hematologic or lymphoreticular disorder, very recent exposure
    - If positive once, no need to repeat

- Interferon-γ release assays (IGRAs) measure interferon release after stimulation in vitro by *M. tuberculosis* antigens (3)[A]:
  - With very few exceptions do not cross-react with BCG and most nontuberculous mycobacteria
    - IGRA preferred for persons who have had BCG (vaccine or for cancer therapy) and those unlikely to return for TST interpretation (3)[A]
    - TST preferred if age <5 years (3)[A]
    - Either TST or IGRA may be used as periodic screening for persons in high-risk occupations and for recent contacts of persons with known or suspected active TB (3)[A].
    - Cotesting with TST and IGRA may be indicated when the initial test is negative, but the risk for poor prognosis is increased (e.g., HIV-infected persons or children <5 years old) (3)[A].

- TST and IGRA cannot differentiate LTBI and active TB.

**Initial Tests (lab, imaging)**

**Active TB**

- Three sputum samples (8 to 24 hours apart with at least one early morning sample) for acid-fast bacilli (AFB) stain and culture by aerosol induction, gastric aspirate (children), or bronchoalveolar lavage
Positive AFB: Treat immediately; culture and sensitivity guide treatment

Nucleic acid amplification test (NAAT): Utilize as an adjunct to culture and AFB smear. Positive result supports presumptive diagnosis of TB while culture pending. Negative NAAT does not rule out TB.

Chest radiograph
- Primary TB: infiltrate with or without effusion, atelectasis, or adenopathy. Ghon lesion: calcified tuberculous caseating granuloma (tuberculoma); if associated with calcified ipsilateral hilar lymph node, then Ghon (or Ranke) complex
- Recrudescent TB: cavitary lesions and upper lobe disease with hilar adenopathy
- HIV: atypical findings with primary infection, right upper lobe atelectasis

CT chest: good sensitivity, tree-in-bud (centrilobular nodules with branching linear opacities)

Follow-Up Tests & Special Considerations
- Baseline CBC, creatinine, AST, ALT, bilirubin, alkaline phosphatase, visual acuity, and red–green color discrimination (regimens involving EMB)
- Diabetes screen if risk factors present
- HIV: If positive, get baseline CD4 count, viral load.
- Check hepatitis B and C if injection drug users, Africa or Asia born, HIV infected or otherwise high risk.
- Extrapulmonary: urine, CSF, bone marrow, and liver biopsy for culture as indicated
- Nonspecific findings: anemia, thrombocytosis, SIADH, hypergammaglobulinemia, monocytosis, sterile pyuria

Diagnostic Procedures/Other
- Culture: takes several weeks for definitive results
- Xpert MTB/RIF (rapid molecular test): currently the only FDA-approved molecular assay for pulmonary TB diagnosis and detection of rifampicin resistance in areas with high prevalence of MDR TB (3)[A]

TREATMENT

GENERAL MEASURES
- If clinical suspicion, treat immediately. Prescribing physician is responsible
for treatment completion.

- Respiratory and droplet precautions
- Not infectious if favorable clinical response after 2 to 3 weeks of therapy and three negative AFB smears

**MEDICATION**

Use ideal body weight for dosing; DOT recommended for all and required for children, institutionalized patients, nonadherent patients, and nondaily regimens

**First Line**

- **LTBI (4)[A]**
  - Isoniazid (INH) for 9 months at 5 mg/kg/day (max of 300 mg) or 15 mg/kg (max of 900 mg) 2 times per week or
  - INH 15 mg/kg + rifapentine 300 to 900 mg weekly for 12 weeks by DOT for age ≥12 years

- **Active TB Infection (4)[A]**
  - Regimen 1 (preferred)
    - Initial phase:
      - INH 5 mg/kg, rifampin (RIF) 10 mg/kg (max 600 mg), pyrazinamide (PZA) 15 to 30 mg/kg, and ethambutol (EMB) 15 to 20 mg/kg daily for 8 weeks or
      - INH/RIF/PZA/EMB 5 days/week for 8 weeks
    - Continuation phase:
      - INH/RIF daily for 18 weeks; or, if DOT, INH/RIF 5 days/week for 18 weeks
  - Regimen 2 (preferred when more frequent DOT in continuation phase is difficult to achieve)
    - Initial phase:
      - INH/RIF/PZA/EMB daily for 8 weeks or
      - INH/RIF/PZA/EMB 5 days/week for 8 weeks
    - Continuation phase:
      - INH/RIF 3 times per week for 18 weeks
  - Regimen 3 (caution if HIV infected or with cavitary disease; missed doses can lead to treatment failure, relapse, and acquired drug resistance)
    - Initial phase: INH/RIF/PZA/EMB 3 times per week for 8 weeks
    - Continuation phase: INH/RIF 3 times per week for 18 weeks
  - Regimen 4 (do not use if HIV positive, smear positive, or cavitary disease)
    - Initial phase: INH/RIF/PZA/EMB daily for 14 doses and then twice a
week for 12 doses
  ◦ Continuation phase: INH/RIF twice a week for 18 weeks

**Pregnancy Considerations**
- Delay treatment in pregnant patients with LTBI until delivery unless other risk factors (e.g., HIV, immunosuppressed) present.
- Treat TB in pregnancy with INH, RIF, and EMB; add pyridoxine 25 mg/day.
- Streptomycin: ototoxic and nephrotoxic; do not use in pregnancy. PZA is not used in pregnant women in the United States.
- Congenital infection: from maternal miliary or endometrial TB. PPD, CXR, lumbar puncture, and culture placenta. Treat promptly if suspected.
- Breastfeeding: OK while taking TB drugs; supplement with pyridoxine 25 mg/day.

**Pediatric Considerations**
- Children may attend school as long as they are taking the appropriate medications.
- EMB can be used in infants and children. (4)

**ALERT**
- Maximum drug doses: RIF 600 mg all regimens; PZA 2,000 mg/day or 4,000 mg 2 times per week; EMB 600 mg/day or 4,000 mg 2 times per week
- If patient does not receive PZA for all of the first 2 months, extend treatment to 9 months.
- *M. bovis* is resistant to PZA; must be treated 9 months
- Continue EMB until organism susceptibility to INH plus RIF is determined (4)[A].
- Initiation of ART therapy in HIV-positive patients infected with TB carries an increased risk of immune reconstitution inflammatory syndrome (IRIS) (4)[A].

**Second Line**
Fluoroquinolones and injectable aminoglycosides. Use when MDR is suspected or patient intolerance.

**ISSUES FOR REFERRAL**

**ALERT**
Notify public health authorities for all cases of active TB. Consult infectious
disease specialist for drug-resistant TB and HIV-positive patients on antiretroviral therapy.

ADDITIONAL THERAPIES

- Pyridoxine: 50 mg should be given to all persons at risk for INH neuropathy: pregnant women, breastfeeding infants, HIV positive, diabetes, alcoholism, malnutrition, chronic renal failure, or advanced age (4)[A].
- Steroids: recommended for TB meningitis (4)[A]; not recommended for TB pericarditis (4)[B]

SURGERY/OTHER PROCEDURES

For extrapulmonary complications (spinal cord compression, bowel obstruction, constrictive pericarditis)

COMPLEMENTARY & ALTERNATIVE MEDICINE

Vitamin D deficiency may increase susceptibility to TB and development of active TB (5)[C]. Evidence is unclear regarding vitamin D supplementation in TB treatment.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Negative pressure isolation with personal respirators and droplet precautions
  - Three consecutive negative sputum AFB smears are necessary for release from isolation.
- Once TB has been excluded or the patient has demonstrated response to therapy and is not an infectious risk, arrange outpatient follow-up with a provider comfortable managing TB and coordinate case management with local public health authorities.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Monthly sputum for AFB smear and culture until two consecutive cultures are
negative; must confirm this prior to starting continuation phase

- Monthly visits to assess treatment adherence and adverse medication effects; CXR after 2 months of treatment
- For HIV positive: CD4 count, viral load, CBC, and liver enzymes every 3 months
- Liver enzymes monthly for chronic liver disease, alcohol use, pregnant or postpartum patients. Temporarily halt medications for enzyme increase $\geq 5 \times$ ULN if asymptomatic or $\geq 3 \times$ ULN if symptomatic.
- Visual acuity and red–green color monthly if on EMB $>2$ months or doses $>20$ mg/kg/day
- If culture-positive after 2 months of therapy, reassess drug sensitivity, initiate DOT, coordinate care with public health authorities, and consider infectious disease consultation (if not already involved).

PATIENT EDUCATION

- Emphasize medication adherence.
- Screen and treat close contacts.
- Alert patient that health authorities must be notified.

PROGNOSIS

Few complications and full resolution of infection if medications are taken for full course as prescribed

COMPLICATIONS

- Cavitary lesions can become secondarily infected.
- Risk for drug resistance increases with HIV positive, treatment nonadherence, or residence in area with high incidence of resistance.
- MDR-TB: resistance to INH and rifampicin
- XDR-TB: MDR-TB that is also resistant to fluoroquinolones and at least one second-line injectable drug (9% of MDR)

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**
- Tuberculosis, CNS; *Tuberculosis, Latent (LTBI)*; Tuberculosis, Miliary
- Algorithm: *Weight Loss, Unintentional*

**CODES**

**ICD10**
- A15.9 Respiratory tuberculosis unspecified
- A15.0 Tuberculosis of lung
- A19.9 Miliary tuberculosis, unspecified

**CLINICAL PEARLS**
- TB is fully curable when treated appropriately.
- Children and elderly patients exhibit fewer classic clinical features of TB.
- Involve public health authorities early.
- Treatment of pulmonary TB generally involves a four-drug regimen.
- DOT is preferred.
TUBERCULOSIS, LATENT (LTBI)

Kay A. Bauman, MD, MPH

BASICS

DESCRIPTION

- Latent tuberculosis infection (LTBI) is an asymptomatic, noninfectious condition following exposure to an active case of tuberculosis. LTBI is usually detected by a positive skin test (i.e., purified protein derivative [PPD]) or a positive interferon-γ release assay (IGRA) test. In LTBI, acid-fast bacilli smear and culture are negative, and chest x-ray (CXR) does not suggest active TB.
- Active TB occurs in 5–10% of infected individuals who have not received preventive therapy. Chance of active TB increases with immunosuppression and is highest for all individuals within 2 years of infection; 85% of the cases are pulmonary, which is capable of person-to-person spread via aerosol route.
- The majority (68% in 2016) of active TB cases in the United States occur in foreign-born persons. 90% are the result of reactivation of LTBI (1).
- LTBI treatment is a key component of the TB elimination strategy of the United States.

ALERT

After 20 years of annual decreases in the number active TB cases in the United States, the incidence has recently plateaued. Identification and treatment LTBI is crucial to reverse this trend. Test for LTBI (PPD or IGRA) and treat latent infection in high-risk populations.

EPIDEMIOLOGY

- TB is the leading cause of infectious disease mortality worldwide.
- In the United States, high-risk groups include immigrants from Asia, Latin America, Africa, and the Pacific basin; homeless persons; persons with a history of drug use or history of incarceration; HIV-infected individuals; and health care workers.
- Newly exposed (particularly children) are also at high risk.
- In 2016, there were 9,287 new cases of TB in the United States, the lowest number of TB cases on record. Of these cases, 31% were U.S.-born and 68%
Among foreign-born persons, Asians have the highest active TB case rate (27 cases/100,000); non-Hispanic blacks (22/100,000) and Hispanics (10/100,000) (1).

Of active TB cases in ethnic minorities, 95% of Asian cases, 75% of Hispanic cases, 42% of black cases, and 21% of white cases were foreign born (1).

In 2016, 55% of foreign-born persons with TB came from five countries: Mexico (19%), Philippines (13%), India (10%), Vietnam (8%), and China (6%) (1).

In 2016, 6% of active TB cases in the United States were in HIV-positive individuals. TB is the leading cause of death in persons living with HIV (1).

In 2016, the lowest state-specific incidence was 0.2 cases/100,000 in Wyoming and the highest 8.3/100,000 in Hawaii.

**Prevalence**

- 4% of the U.S. population has LTBI (~11 million).
- ~1/3 of the world’s population harbors latent TB.

**ETIOLOGY AND PATHOPHYSIOLOGY**

*Mycobacterium tuberculosis, Mycobacterium bovis,* and *Mycobacterium africanum*

**RISK FACTORS**

- HIV infection, immunosuppression
- Immigrants (from Asia, Latin America, Pacific Islands, Africa, or areas with high rates of TB), including migrant workers
- Close contact with infected individual
- Institutionalization (e.g., prison, nursing home)
- Use of illicit drugs
- Lower socioeconomic or homeless status
- Health care workers
- Chronic medical disease such as diabetes mellitus (DM), end-stage renal disease, cancer, or silicosis; organ transplant (immunosuppression)
- Persons with fibrotic changes on CXR consistent with previous TB infection
- Recent TB skin test (tuberculin skin test [TST]) converters
- Laboratory personnel working with mycobacteria

**GENERAL PREVENTION**
Screen for LTBI and treat individuals with positive tests.

**COMMONLY ASSOCIATED CONDITIONS**
- HIV infection (see “Initial Tests (lab, imaging)”)  
- Immunosuppression

**DIAGNOSIS**

**HISTORY**
Assess risk. History of immigration from a high-risk area including those with temporary visas for school or work (Note: TB screening for this type of visa is not required, unlike regulations for those seeking permanent residence in the United States.) (2), history of IV drug use and/or drug treatment, HIV, homelessness, recent incarceration, immunosuppression

**PHYSICAL EXAM**
No active signs of infection on exam in patients with LTBI

**DIFFERENTIAL DIAGNOSIS**
Fungal infections; atypical mycobacteria or *Nocardia*

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- CXR to rule out active TB  
- No others routinely recommended  
- In higher risk patients: liver profile, hepatitis C virus (HCV), and hepatitis B virus (HBV) screening  
- HIV test recommended to assess risk for active TB in men who have sex with men or persons with a history of IV drug use

*Diagnostic Procedures/Other*
- TST: PPD: 5 U (0.1 mL) intermediate-strength intradermal volar forearm. Measure induration at 48 to 72 hours:  
  - Positive if induration is  
    - >5 mm and patient has HIV infection (or suspected), is immunosuppressed, had recent close TB contact, or has clinical evidence of active or old disease on CXR
>10 mm and patient age <4 years or has other risk factors noted earlier
>15 mm and patient age >4 years and has no risk factors
- Negative if induration <5 mm on initial test and, if indicated, on second test
- Use the two-step test (administer a second intradermal test 1 to 3 weeks after initial test; measure and interpret as usual) if patient has had no recent PPD and is age >55 years or is a nursing home resident, prison inmate, or health care worker.
- Preferred for children <5 years
- The IGRA QuantiFERON-TB and QuantiFERON-TB GOLD; T-SPOT measure the release of interferon by sensitized lymphocytes when exposed to antigens of \textit{M. tuberculosis}. It is unaffected by prior BCG vaccination, requires only one visit, and has improved sensitivity and specificity but is costly (3).
- Special considerations
  - Steroids: false-negative skin test
  - Measles vaccine: may suppress tuberculin activity; simultaneous PPD and measles vaccine recommended; if not simultaneous, defer PPD for 4 to 6 weeks after measles vaccine.
  - The multiple-puncture Tine test is not recommended.
  - The history of BCG vaccination should not alter the management of a positive PPD test.
  - Disorders that may give a false-negative skin test:
    o Recent viral infection
    o New (<10 weeks) infection
    o Severe malnutrition; HIV; anergy
    o Age <6 months
    o Overwhelming TB

\textbf{TREATMENT}

\textbf{GENERAL MEASURES}

- Must exclude active TB
- Treatment for LTBI is critical for the control and elimination of TB disease. LTBI treatment decreases the risk of active TB and decreases risk of potential spread to others. Treat all persons with LTBI.
- High-risk patients: Treat LTBI at any age if patient has HIV, has had close TB contact, is a recent converter (<2 years), is an IV drug user, has an abnormal
CXR, or has a high-risk medical condition.
- Directly observed therapy (DOT) is recommended if patient adherence is not assured.
  - Use isoniazid (INH) (for 9 months).
  - Acceptable alternative: INH for 6 months
  - Use INH 900 mg and rifapentine 900 mg weekly for 12 weeks.
- Treat LTBI during pregnancy if patient has recent infection or is HIV positive (use INH with pyridoxine, and monitor liver enzymes); otherwise, postpone treatment until after delivery.
- Consult public health or infectious disease specialist for suspected INH resistance in HIV patients.
- Note: rifampin and pyrazinamide are less often recommended for LTBI treatment due to side effects.
- Exclusions: cirrhosis, active hepatitis, history of excessive alcohol consumption

**MEDICATION**
- INH alone
  - INH-scored tablets: 100 mg, 300 mg, or syrup 10 mg/Ml
    - Daily: adult 300 mg; pediatric 10 to 15 mg/kg (maximum 300 mg)
    - Twice weekly: adult 900 mg; pediatric 20 to 30 mg/kg (maximum 900 mg)
    - Treatment for 9 months; typical completion rates of ≤60%
  - Precautions
    - Follow liver function if the patient has history of alcoholism, HBV, HCV, or other liver dysfunction or new signs of liver injury.
    - INH: Peripheral neuritis and hypersensitivity are possible. Consider pyridoxine.
- INH and rifapentine
  - Patients >12 years: rifapentine, a rifampin-like drug can be used to treat LTBI. 900 mg weekly (if patient >50 kg) and INH, 15 to 25 mg/kg weekly (rounded to nearest 50 or 100 mg; 900 mg max) for 12 weeks given as direct observation therapy. This new, shorter treatment increased rates of completion compared with 9 months of INH (82% vs. 69%), slightly more adverse effects (5% vs. 4%), more costly (4).
  - Contraindications to INH/rifapentine: HIV patients receiving antiretroviral therapy, pregnancy. Rifapentine may cause hyperuricemia and hematuria (4).
- Alternative: rifampin alone
– Adults 600 mg/day for 4 months; children 10 to 20 mg/kg/day for 6 months (max 600 mg/day). Fewer data exist for efficacy of this regimen but can be considered for contacts of INH-resistant TB or patient with INH contraindications. In one study, the 4-month course increased compliance from 62.6% with INH to 71.6% with rifampin (5).

ADDITIONAL THERAPIES

**Pediatric Considerations**

- Follow public health recommendations for assessing and treating newborns.
- If mother or household contact has LTBI, skin test all household contacts, and treat all positive PPD.
- If contact has abnormal CXR, separate infant until infectious status is known; if not contagious, monitor infant PPD (6).
- If mother has disease and is possibly contagious, evaluate infant for congenital TB and test for HIV; separate newborn until mother is noninfectious (6).
- Treat suspected congenital TB.
- If no congenital disease, start INH and repeat PPD after 3 to 4 months. If positive, reassess infant and finish 9 months of INH. If PPD is negative and source is noninfectious, stop INH and monitor infant (6).
- BCG vaccine, live-attenuated *M. bovis*: used more commonly in developing countries in children to prevent complications of TB

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

**Geriatric Considerations**

- Before entering a chronic care facility, patients should have a PPD using two-step protocols.
- INH side effects are more pronounced.
- Discharge criteria
  – Activity, as tolerated
  – No isolation required

**ONGOING CARE FOLLOW-UP RECOMMENDATIONS**
**Patient Monitoring**
- During preventive therapy for LTBI: monthly visits to assess adherence and monitor for hepatitis and neuropathy; if stable, can monitor less frequently
- If patient asymptomatic, no need to repeat CXR
- Check liver enzymes if patient is symptomatic, is HIV positive, has chronic liver disease, uses alcohol, or is pregnant or postpartum, and modify drugs as needed.

**Diet**
Regular. Consider pyridoxine, 10 to 50 mg/day.

**PROGNOSIS**
- Generally, there are few complications, and treatment is effective if medications are taken as prescribed.
- Retreatment is not necessary.

**COMPLICATIONS**
Recrudescent TB

**REFERENCES**

Tuberculosis; Tuberculosis, Miliary

CODES

ICD10

R76.11 Nonspecific reaction to skin test w/o active tuberculosis

CLINICAL PEARLS

- ~4% of the U.S. population has LTBI.
- Treatment of LTBI is crucial to the control and elimination of TB disease in the United States.
- Screen foreign-born persons for latent TB, and treat those who are positive.
- Screen household contacts of patients who are PPD+.
- A history of BCG vaccination, especially >10 years before PPD testing, should not be considered as the cause of a positive PPD. The interferon-γ blood test is unaffected by prior BCG vaccination.
TYPHOID FEVER
Douglas W. MacPherson, MD, MSc–CTM, FRCPC

BASICS
- A common enteric bacterial disease transmitted by ingestion of contaminated food or water
- Most cases in the United States are imported from endemic areas of South or Southeast Asia and Latin America.

DESCRIPTION
- Typhoid fever is an acute systemic illness in humans caused by Salmonella typhi.
  - Classic example of enteric fever caused by Salmonella bacterium
- Enteric fevers due to Salmonella paratyphi can present in a manner similar to classic typhoid fever.
- Typhoid is endemic in developing nations with poor sanitation. Most cases in North America and other developed nations are acquired after travel to disease-endemic areas.
- Travelers may be at greater risk of typhoid.
- Mode of transmission is fecal–oral through ingestion of contaminated food (poultry or milk) or water.
- Incubation period varies from 7 to 21 days.
- System(s) affected: gastrointestinal; pulmonary; skin/exocrine
- Synonym(s): typhoid; typhus abdominalis; enteric fever; nervous fever; slow fever

Geriatric Considerations
Disease is more serious in the elderly.

Pediatric Considerations
Disease is more serious in infants and milder in children.

EPIDEMIOLOGY
Although typhoid outbreaks have been described in the United States, most cases are reported in international travelers returning from endemic transmission areas.
- Predominant age: all ages
- Predominant sex: male = female

**Incidence**
In the United States, 300 to 500 new cases per year

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Historically, typhoid fever (untreated) occurs in several week-long stages.
- The initial infection is transmitted via the fecal–oral route, with resultant bacteremia and sepsis. Involvement of the bowel wall (Peyer patch) rarely may be associated with bleeding from the bowel or bowel perforation.
- The first stage involves fluctuations in temperature with relative bradycardia (Faget sign). Other symptoms include headache, cough, malaise, epistaxis, and abdominal pain.
- The second stage involves higher fever (with persistent relative bradycardia). Mental status changes are possible (agitation—“nervous fever”). Rose spots appear on the chest and abdomen. In some patients, abdominal pain is common as is constipation or diarrhea (with characteristic malodorous “pea soup” appearance).
- The third week is when most complications occur due to intestinal hemorrhage or encephalitis.
- The final week is defervescence and recovery.
- A chronic carrier state may occur with *S. typhi* shedding in the stools. Potential person-to-person transmission may occur. In a chronic carrier state, *S. typhi* resides in the biliary tract and gallbladder. Chronic suppressive antimicrobials may clear the carrier state; in rare cases, cholecystectomy performed to clear *S. typhi* carrier state

**RISK FACTORS**
Consider in patients presenting with fever after tropical travel or exposure to a chronic carrier.

**GENERAL PREVENTION**
- Food and water precautions help prevent all enteric infections, including typhoid fever.
- Avoid tap water, salad/raw vegetables, unpeeled fruits, and dairy products in tropical travel.
- Avoid undercooked poultry or poultry products left unrefrigerated for
prolonged periods.

- Wash hands before and after food preparation.

- For high-risk travel to an endemic area, consider typhoid vaccination (1,2)A.
  - Parenteral ViCPS or capsular polysaccharide typhoid vaccine (Typhim Vi)
    or
  - Ty21a or live oral typhoid vaccine (Vivotif Berna), particularly if prolonged risk (>4 weeks)

- Consider vaccination for workers exposed to S. typhi or those with close contact with a carrier of S. typhi.

- Occupational health and safety precautions. Consider screening of domestic and commercial food handlers.

**DIAGNOSIS**

Assess clinical presentation and exposure history, including travel and exposures to S. typhi carriers.

**HISTORY**

- Travel history to an endemic region and exposure to contaminated food or water
- Exposure to a chronic S. typhi carrier
- Fever, headache
- Malaise
- Abdominal discomfort/bloating/constipation
- Diarrhea (less common)
- Dry cough
- Confusion/lethargy

**PHYSICAL EXAM**

- Fever with relative bradycardia
- Cervical adenopathy
- Conjunctivitis
- Rose spot (transient erythematous maculopapular rash in anterior thorax or upper abdomen)
- Splenomegaly
- Hepatomegaly

**DIFFERENTIAL DIAGNOSIS**
Enteric fever caused by nontyphoid *Salmonella* spp.
“Enteric fever–like” syndrome caused by *Yersinia enterocolitica*, pseudotuberculosis, and *Campylobacter* spp.
Infectious hepatitis
Malaria, dengue
Atypical pneumonia
Infectious mononucleosis
Subacute bacterial endocarditis
Tuberculosis
Brucellosis; Q fever; typhus
Toxoplasmosis
Viral infections: Epstein-Barr virus (EBV), cytomegalovirus (CMV), viral hemorrhagic agents

**DIAGNOSTIC TESTS & INTERPRETATION**

Enteric fevers/typhoid syndromes are rare in the United States. Therefore, a high level of clinical suspicion is required.

- Definitive diagnosis is by culture of *S. typhi* from blood or other sterile body fluid.
- Isolation of *S. typhi* in sputum, urine, or stool leads to a presumptive diagnosis.
- Serology is nonspecific and typically not useful.
- If there are multiple negative blood cultures or patient has recent been on antibiotic therapy, diagnostic yield is better with bone marrow culture.
- Anemia, leukopenia (neutropenia), thrombocytopenia, or evidence of disseminated intravascular coagulopathy. Elevated liver enzymes are common.
- Suspect intestinal perforation (consider serial plain abdominal films looking for evidence of perforation) in ill patients complaining of persistent abdominal tenderness.

**Diagnostic Procedures/Other**

- Bone marrow aspirate for culture of *S. typhi* is more sensitive than blood cultures but rarely used as a primary investigation.
- Bone marrow aspiration may be done for evaluation of a fever of unknown origin.

**Test Interpretation**
Classically, bowel pathology shows mononuclear lymphoid proliferation, especially Peyer patches of the terminal ileum.

**TREATMENT**

- Treatment of typhoid disease and chronic carrier states must be determined on an individual basis. Factors to consider include age, public health and occupational health risk (e.g., food handler, chronic care facilities, medical personnel), intolerance to antibiotics, and evidence of biliary tract disease.
- Awareness of emerging drug-resistant *S. typhi* strains and the epidemiology of the patient’s exposure help direct primary therapy. Knowledge of local resistance patterns for presumptive treatment or laboratory sensitivity also guides therapy. Fluoroquinolone-resistant *S. typhi* is common in Asia.

**GENERAL MEASURES**

- Fluid and electrolyte support
- Strict isolation of patient’s linen, stool, and urine
- Consider serial plain abdominal films for evidence of perforation, usually in the 3rd to 4th week of illness.
- For hemorrhage: blood transfusion and management of shock

**MEDICATION**

**First Line**

- Chloramphenicol: pediatric 50 mg/kg/day PO QID for 2 weeks; adult dose 2 to 3 g per day PO divided q6h for 2 weeks *or*
- Ampicillin: pediatric 100 mg/kg/day (max 2 g) QID PO for 2 weeks; adults 500 mg q6h for 2 weeks *or*
- Ciprofloxacin: 500 mg PO BID for 2 weeks, *indicated in multiple-drug-resistant typhoid*
  - Has been used safely in children; WHO recommends as first line in areas with drug resistance to older first-line antibiotics.
  - Fluoroquinolones may prevent clinical relapse better than chloramphenicol *[3][A]*.
- Ceftriaxone: pediatric 100 mg/kg/day for 2 weeks; adult dose: 1 to 2 g IV once daily for 2 weeks *or*
- Azithromycin: pediatric 10 to 20 mg/kg (max 1 g) PO daily for 5 to 7 days; adult dose: 1 g PO once followed by 500 mg PO daily for 5 to 7 days
Chronic carrier state
- Ampicillin: 4 to 5 g/day plus probenecid 2 g/day QID for 6 weeks (for patients with normal gallbladder function and no evidence of cholelithiasis)
- Ciprofloxacin: 500 mg PO BID for 4 to 6 weeks is also efficacious.
  Chloramphenicol resistance has been reported in Mexico, South America, Central America, Southeast Asia, India, Pakistan, Middle East, and Africa.
- Contraindications: Refer to manufacturer’s profile.
- Precautions: Rarely, Jarisch-Herxheimer reaction appears after antimicrobial therapy.
- Significant possible interactions: Refer to manufacturer’s profile for each drug.

**Second Line**
- Trimethoprim–sulfamethoxazole one double-strength tablet twice a day for 10 days (Note: Drug resistance is common, local resistance patterns and expert consultation should guide treatment.)
- Furazolidone: 7.5 mg/kg/day PO for 10 days; in uncomplicated multidrug-resistant typhoid; safe in children; efficacy >85% cure

**Pregnancy Considerations**
Ciprofloxacin therapy is relatively contraindicated in children and in pregnant patients.

**ISSUES FOR REFERRAL**
Complications of sepsis, bowel perforation

**SURGERY/OTHER PROCEDURES**
- Complications: bowel perforation
- Cholecystectomy may be warranted in carriers with cholelithiasis, relapse after therapy, or intolerance to antimicrobial therapy.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Inpatient if acutely ill
- Outpatient for less ill patient or for carrier
- Observe enteric precautions.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Bed rest initially and then activity as tolerated

Patient Monitoring
See “General Measures.”

DIET
NPO if abdominal symptoms are severe. With improvement, begin normal low-residue diet, with high-calorie supplementation if malnourished.

PATIENT EDUCATION
- Discuss chronic carrier state and its complications.
- For family members, travelers, or workers at risk, educate about food/water hygiene and provide vaccination.
- Educate patients that the typhoid vaccines do not protect against S. paratyphi infection.
- Typhoid vaccines protect 50–80% of recipients (not 100%). Efficacy wanes over 2 to 4 years.
- CDC patient handout: http://www.cdc.gov/vaccines/hcp/vis/vis-statements/typhoid.html

PROGNOSIS
Overall prognosis is good; with appropriate treatment, <2% mortality rate, 15% relapse rate with some antibiotic treatments, and 3% bowel perforation

COMPLICATIONS
- Intestinal hemorrhage and perforation in distal ileum
- Patients (up to 3%) may become chronic carriers-persistent stool excretor of S. typhi for >1 year.
- Seeding of the biliary tract may become a focus for relapse of typhoid fever: most common in females and older patients (>50 years of age)
- Osteomyelitis is more common in patients with sickle cell anemia, systemic lupus erythematosus, and hematologic neoplasms, as well as in immunosuppressed hosts.
- Endovascular infection in the elderly and in patients with a history of bypass
operation or aneurysm

- Rarely, endocarditis or meningitis

REFERENCES

ADDITIONAL READING

CODES
ICD10
- A01.00 Typhoid fever, unspecified
- Z22.0 Carrier of typhoid
- A01.03 Typhoid pneumonia

CLINICAL PEARLS
- Consider typhoid (along with malaria, dengue, and other travel-associated infections) in febrile travelers returning from endemic areas (Latin America, sub-Saharan Africa, South Asia).
- Routine blood cultures detect S. typhi but may be negative if antibiotics are administered prior to testing.
- A history or documentation of vaccination against S. typhi does not exclude the diagnosis of typhoid fever.
BASICS
An infectious disease syndrome caused by several rickettsial bacterial organisms resulting in acute, chronic, and recurrent disease (1)[C]

DESCRIPTION
- Acute infection caused by three species of Rickettsia
  - Epidemic typhus: human-to-human transmission by body louse; primarily in setting of refugee camps, war, famine, and disaster. Recurrent disease occurs years after initial infection and can be a source of human outbreak. Flying squirrels are a reservoir.
  - Endemic (murine) typhus: spread to humans by rat flea bite
  - Scrub typhus: infection and infestation of chiggers and of rodents to humans by the chigger; primarily in Asia and western Pacific areas
- System(s) affected: endocrine/metabolic; hematologic/lymphatic/immunologic; pulmonary; skin/exocrine
- Synonym(s): louse-borne typhus; Brill-Zinsser disease; murine typhus

EPIDEMIOLOGY
- Epidemic and endemic typhus: rare in the United States (outside of South Texas)
- Scrub typhus: travelers returning from endemic areas only (rare)

Incidence
Endemic typhus: <100 cases annually, primarily in states around the Gulf of Mexico, especially South Texas; underreporting suspected

ETIOLOGY AND PATHOPHYSIOLOGY
- Epidemic typhus by Rickettsia prowazekii
- Endemic typhus by Rickettsia typhi (2)[A]
- Scrub typhus by Rickettsia tsutsugamushi

RISK FACTORS
Vector exposure
Travel to endemic countries

Geriatric Considerations
Elderly may have more severe disease.

GENERAL PREVENTION
Vector control:
- Scrub typhus: Wear protective clothing and use insect repellents.
- Endemic typhus: Practice ectoparasite and rodent control.
- Epidemic typhus: delousing and cleaning of clothing; vaccine for those at high risk of exposure (typhus vaccine production discontinued in the United States)

DIAGNOSIS
Typhus syndromes are rare in the United States. A high level of clinical suspicion is necessary.

HISTORY
Travel or other risk exposure
- Fever, chills
- Intractable headache
- Myalgias, malaise
- Cough, rash, ocular pain

PHYSICAL EXAM
- General
  - Fever
  - Relative bradycardia (scrub typhus)
- Epidemic typhus
  - Incubation period ~1 week
  - Macular or maculopapular rash beginning on trunk ~5th day of illness
  - Nonproductive cough
  - Pulmonary infiltrates
- Endemic typhus
  - Incubation period 1 to 2 weeks
  - Macular or maculopapular rash beginning on trunk 3rd to 5th day of illness
Scrub typhus
- Incubation period 1 to 3 weeks
- Eschar at bite site
- Regional lymphadenopathy
- Generalized lymphadenopathy
- Splenomegaly
- Macular or maculopapular rash beginning on trunk approximately 5th day of illness
- Relative bradycardia early in disease
- Ocular pain
- Conjunctival injection

DIFFERENTIAL DIAGNOSIS
- Other rickettsial disease: Rocky Mountain spotted fever; ehrlichiosis; Mediterranean spotted fever (boutonneuse fever) (*Rickettsia conorii*)
- Bacterial meningitis; meningococcemia
- Measles, rubella
- Toxoplasmosis
- Leptospirosis
- Typhoid fever
- Dengue, malaria
- Relapsing fever
- Secondary syphilis
- Viral syndromes: mononucleosis, acute retroviral syndrome

DIAGNOSTIC TESTS & INTERPRETATION
- Specific serologies with rising antibody titer
- If suspected, isolate *Rickettsia* in qualified laboratory to minimize the risk of laboratory-acquired infection.
- CDC Rickettsial Zoonoses Branch 404-639-1075.

*Initial Tests (lab, imaging)*
- CBC often normal
- Weil-Felix serologic reaction may be positive; test hampered by low sensitivity and nonspecificity; epidemic and endemic typhus, 4-fold titer rise or titer >1/320 to OX19; scrub typhus, 4-fold rise in titer to OXK
- Hyponatremia in severe cases
- Hypoalbuminemia in severe cases
Recent antibiotic exposure may alter lab results.

**Test Interpretation**
Diffuse vasculitis on skin biopsy

**TREATMENT**
Initiate treatment based on epidemiologic risk and clinical presentation.

**GENERAL MEASURES**
- Skin and mouth care
- Supportive care—directed at complications

**MEDICATION**

**First Line**
- Begin treatment when diagnosis is likely and continue until clinically improved and the patient is afebrile for at least 48 hours; usual course is 5 to 7 days.
- Children ≥8 years of age and adults
  - Doxycycline IV/PO: adults 100 mg q12h, children ≤45 kg: 5 mg/kg/day divided twice daily (max of 200 mg/day); >45 kg: adult dosing
  - Children ≤8 years of age: risk of dental staining from tetracyclines minimal with short courses
  - Tetracycline: 25 mg/kg PO initially and then 25 mg/kg/day in equally divided doses q6h
- Children ≤8 years of age, pregnant women, or if typhoid fever is suspected
  - Chloramphenicol: 50 mg/kg PO initially and then 50 mg/kg/day in equally divided doses q6h
  - If severely ill, chloramphenicol sodium succinate: 20 mg/kg IV initially, infused over 30 to 45 minutes and then 50 mg/kg/day infused in equally divided doses q6h until orally tolerable
  - Azithromycin, fluoroquinolones, and rifampin alternatives depending on scenario
- Precautions and interactions: Refer to the manufacturer’s profile for each specific drug.

**Second Line**
Doxycycline: single oral dose of 100 or 200 mg orally for those in refugee camps, victims of disasters, or in the presence of limited medical services
Isolated reports indicate that erythromycin and ciprofloxacin are effective.
Azithromycin 1,000 mg orally once a day for 3-day course is effective for scrub typhus; better tolerated than doxycycline but more expensive
Rifampin may be effective in areas where scrub typhus responds poorly to standard antirickettsial drugs.

ISSUES FOR REFERRAL
Infectious disease consultation is recommended. Contact CDC and local public health authorities.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Outpatient care unless severely ill
- Severely ill or constitutionally unstable (e.g., shock)

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
- Admit severely ill patients.
- If treated as an outpatient, ensure regular follow-up to assess clinical improvement and resolution.

Diet
As tolerated

PATIENT EDUCATION
Travel advice (minimize exposure risks, vector avoidance, vaccination as appropriate)

PROGNOSIS
- Recovery is expected with prompt treatment.
- Relapses may follow treatment, especially if initiated within 48 hours of onset (this is not an indication to delay treatment). Treat relapses the same as
primary disease.

- Without treatment, the mortality rate of typhus is 40–60% for epidemic, 1–2% for endemic, and up to 30% for scrub disease.
- Mortality is higher among the elderly.

**COMPlications**

Organ-specific complications (particularly in the 2nd week of illness): azotemia, meningocerebralitis, seizures, delirium, coma, myocardial failure, hyponatremia, hypoalbuminemia, hypovolemia, shock, and death

**REFERENCES**

**ADDITIONAL READING**

CODES

ICD10
- A75.9 Typhus fever, unspecified
- A75.0 Epidemic louse-borne typhus fever d/t Rickettsia prowazekii
- A75.2 Typhus fever due to Rickettsia typhi

CLINICAL PEARLS
- Consider typhus (along with malaria and dengue) in febrile travelers returning from endemic areas.
- Rickettsial infections typically present within 2 to 14 days. Febrile illnesses presenting >18 days after travel are unlikely to be rickettsial.
- Routine blood cultures do not detect Rickettsia.
- Prior vaccination does not exclude typhus.
ULCER, APHTHOUS

Cynthia Y. Ohata, MD  Chisalu Nchekwube, MD

BASICS

DESCRIPTION

- Self-limited, painful ulcerations of the nonkeratinized oral mucosa, which are often recurrent (1)
- Synonyms: canker sores; aphthae; aphthous stomatitis
- Comes from *aphth* meaning “ulcer” in Greek; used by Hippocrates between 460 and 370 BC to categorize oral disease
- Classification
  - Simple aphthosis (1)
    o Common
    o Episodic
    o Prompt healing, few ulcers
    o 3 to 6 episodes per year
    o Minimal pain, little disability, limited to oral cavity
  - Complex aphthous ulcers (1)
    o Uncommon
    o Episodic or continuous
    o Slow healing
    o Few to many ulcers
    o Frequent or continuous ulceration
    o Marked pain
    o Major disability
- Ulcer morphology
  - Minor aphthous ulcers (2)
    o Usually <10 mm in diameter
    o Self-limited, healing within 4 to 14 days
    o Rarely affect the roof of the mouth
    o Nonscarring
  - Major aphthous ulcers (2)
    o Usually >10 mm in diameter
    o Can affect the roof of the mouth
    o May take weeks to months to heal
Generally, more painful than minor aphthous ulcers
- May cause scarring
  - Herpetiform ulcers (2)
    - Usually 2 to 3 mm in diameter, may coalesce to form larger ulcerations
    - Unrelated to viral-caused herpetic stomatitis
    - Occur in small clusters numbering 10s to 100s, lasting 1 to 4 weeks
    - Generally, more painful than minor aphthous ulcers
    - May cause scarring

**EPIDEMIOLOGY**
- Most frequent chronic disease of the oral cavity, affecting 5–25% of the population (2)
- More common in patients between 10 and 40 years of age, women, and those of higher socioeconomic status (2)
- Less frequent with advancing age (1)
- Minor aphthous ulcers
  - Most common: 70–85% of all aphthae
- Major aphthous ulcers
  - 10–15% of all aphthae
- Herpetiform
  - Least common: 5–10% of all aphthae

**ETIOLOGY AND PATHOPHYSIOLOGY**
Likely multifactorial; association with stress-induced rise in salivary cortisol, multiple HLA antigens, cell-mediated immunity; exact etiology unknown (1). However, tumor necrosis factor-α (TNF-α) is a proinflammatory cytokine and is implied in development of new aphthous ulcers (3).

**RISK FACTORS**
- Genetic factors: 40% of patients with recurrent aphthous stomatitis (RAS) have a family history; most genetic associations with HLA antigen subtypes (1)
- Local trauma: sharp teeth, dental treatments, or mucosal injury secondary to tooth brushing
- Sodium lauryl sulfate–containing toothpaste
- Increased stress and anxiety
- Nutritional deficiencies: iron, vitamin B_{12}, folic acid (3)
- Gluten-sensitive enteropathy/ceeliac disease, inflammatory bowel disease
(IBD) (3)
- Immunodeficiency
- Recent cessation of tobacco use
- Food sensitivity: to benzoic acid/cinnamaldehyde
- Medications
  - NSAIDs
  - β-Blockers
  - Alendronate
  - Methotrexate
  - ACE inhibitors (1)
- Neutropenia
- Anemia
- Endocrine alterations (i.e., menstrual cycle) (2)
- Oral streptococci (3)
- *Helicobacter pylori* infection
- Epstein-Barr virus (1)

**DIAGNOSIS**

Diagnosis is made by history and clinical presentation. Lab work can help identify underlying illness (2)[A].

**HISTORY**

- May experience prodrome of burning sensation of oral mucosa 2 to 48 hours prior to appearance of ulcers
- Patients typically complain of oral ulcerations, which are painful and exacerbated by movement of the mouth. Exacerbation may also be reported with certain foods (hot, spicy, acidic, or carbonated foods or drinks) (2).
- Ask about ulcerative lesions of other anatomic areas, family history, or prior history of aphthous ulcers (2).

**PHYSICAL EXAM**

- Round or ovoid ulcerations generally <10 mm in size covered with a grayish-white pseudomembrane surrounded by an erythematous halo (2)[A]
- Ulcers are typically found in the buccal or lip mucosa, ventral tongue, soft palate, or oral vestibule; rarely on the roof of the mouth or lips
- Evaluate for signs of secondary infection: elevated temperature, increased surrounding edema, or pus drainage.
DIFFERENTIAL DIAGNOSIS

- Oral trauma
  - Biting
  - Dentures
- Infection
  - Herpesvirus (herpetic stomatitis): vesicular lesions on keratinized tissue (dorsal tongue, vermillion border); generally, not present on mucosa (4)[C]
  - HIV: Ulcerations have lengthened healing time and tend to be more painful; history of oral candidiasis/hairy leukoplakia (4)[C]
- Mucocutaneous disease; especially if chronic or nonhealing
  - Lichen planus
  - Pemphigus
- Malignancy: Investigate and closely monitor nonhealing lesions, especially those with leukoplakia or ipsilateral cervical lymphadenopathy.
- Important to evaluate for underlying systemic disease, causing aphthous-like ulcerations
  - Particularly in patients with major aphthae, nonoral lesions, or adults with sudden outbreaks (2)[A]
  - Behçet syndrome: autoimmune systemic vasculitis usually involving mucous membranes
    - Genital and oral ulceration
    - Uveitis
  - Magic syndrome: variation of Behçet with major aphthae and inflamed cartilage (3)
  - Reiter syndrome: reactive arthritis, preceded by infection, usually of the genital tract (2)[A]
    - Uveitis
    - Urethritis
    - HLA-B27–associated arthritis
  - Sweet syndrome: acute neutrophilic dermatosis (4)[C]
    - Fever, sudden onset
    - Erythematous skin plaques/papules, well-demarcated
    - Leukocytosis
    - 50% of patients have an associated malignancy.
    - Most often in middle-aged females
  - IBD: Crohn disease, ulcerative colitis
    - 20–50% of patients with Crohn disease experience recurrent oral ulcers (4)[A].
Bloody or persistent diarrhea
- PFAPA syndrome (1)[C]
  - Periodic fevers, aphthous ulcers, pharyngitis, and adenitis
  - Tonsillectomy may be curative.
- Cyclic neutropenia (1)[C]
  - Recurrent fevers associated with infections, occasionally occurring intraorally
  - Begins in childhood
- Systemic lupus erythematosus (SLE): autoimmune vascular collagen disease
  - Oral lesions have great variability, including recurrent ulceration.
- Gluten-sensitive enteropathy (celiac disease)
  - Weight loss and signs of malabsorption
  - Bloating and diarrhea

DIAGNOSTIC TESTS & INTERPRETATION
May consider complete blood count, zinc, folic acid, ferritin, vitamin B₁₂, B₂, B₆, and B₁₂ to evaluate for systemic causes in severe or recurrent cases (1,5)[A]

Follow-Up Tests & Special Considerations
- HIV is associated with increased amount of ulcers and increased healing time.
- Biopsy and viral cultures for nonhealing ulcers or atypical presentations
- Rheumatologic serology if underlying systemic disease is suspected

TREATMENT
GENERAL MEASURES
- Management is symptomatic. Goal is to reduce inflammation and relieve pain.
- Avoid potentially irritating food or drink:
  - Spicy, acidic, hot
  - Carbonated beverages
  - Abrasive/hard foods (i.e., chips, nuts, etc.)
- Behavior modification to reduce dental trauma with toothbrush or bruxism

MEDICATION
In general, the goals of treatment depend on the extent of ulceration and
frequency of outbreaks.

**First Line**

- **Barriers:** Protect from further insult; soothe.
- **Topical barrier preparations (3)[A]**
  - Hyaluronan gel 0.2%
  - Cyanoacrylate adhesives
  - Sucralfate
- **Topical corticosteroids (to improve healing time and symptoms) (2)[A]**
  - Adverse effects: may increase risk of oral candidiasis (more likely with higher potency formulations)
- **Topical steroid preparations**
  - Hydrocortisone: 2.5 mg pellets applied to ulcer 4 times daily for up to 2 weeks or until resolution
  - Triamcinolone 0.1% dental paste: Apply sparingly to ulcers 3 times daily for up to 2 weeks or until ulcer resolution.
  - Fluocinonide 0.05% gel or ointment: Apply sparingly to ulcer 4 times daily for up to 2 weeks or until ulcer resolution.
  - Dexamethasone 5 mg/5 mL elixir: Rinse for 3 minutes and spit 4 times daily until ulcer resolution.
- **Topical anesthetics/anti-inflammatory/immunomodulators (to reduce symptoms only) (2)[A]**
  - Adverse effects: may cause initial stinging
- **Topical anesthetic/anti-inflammatory/immunomodulators preparations:**
  - Lidocaine 2% gel, apply 4 times daily for up to 2 weeks or until ulcer resolution.
  - Diclofenac 3% topical, 2.5% hyaluronic acid alternating
- **Antimicrobial mouth rinses (improve healing time, decrease pain, and may prevent recurrence)**
- **Antimicrobial preparations (3)[A]**
  - Chlorhexidine: aqueous mouthwash 0.2% mouth rinse or 1% gel
    - Use 4 times daily for up to several months.
    - May cause superficial tooth staining
  - Triclosan: anti-inflammatory, antimicrobial
  - Tetracycline: 5% used as mouth wash, anti-inflammatory as mouthwash
  - Penicillin G troche: 50 mg 4 times a day for 4 days

**Second Line**
Systemic drugs indicated when outbreaks are constant and aggressive, with major aphthae, intense pain, and no relief from topical treatment; should be used with caution due to risk of side effects (2)[A]
- Prednisone 0.75 mg/kg/day, tapered by 0.25 mg/kg/day every 2 weeks, preferred over other systemic agents (1,2)[A]

- Zinc 150 mg/day
- Pentoxifylline 400 mg 3 times per day
- Colchicine 1.5 mg/day
- Dapsone 50 mg/day

ISSUES FOR REFERRAL
Otolaryngology or dental referral if lesions have not resolved as expected

ADDITIONAL THERAPIES
- Vitamin B$_{12}$ supplementation appeared to decrease burden of outbreaks and recurrence, independent of preexisting deficiency in one small study. Multivitamins have not been shown to be effective (1)[B].
- *H. pylori* eradication has been associated with lower number of aphthous lesions (1)[B].

SURGERY/OTHER PROCEDURES
- Help to reduce symptoms such as pain, but do not reduce healing time (5)[A]
  - Chemical cauter with silver nitrate (reduces ulcer pain but not healing time)
  - Low-dense ultrasound
- Laser ablation has been found in some studies to reduce symptoms such as pain and provide lesion resolution, however does not prevent reoccurrence (6)[A].
- Ozone application is an emerging therapy that decreases pain and improves healing time in small studies.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Topicals (2)[B] with potential:
  - *Myrtus communis* (myrtle)
  - Quercetin
  - Damask rose
  - Licorice gel adhesive
Systemic (2)[A], insufficient data to date on homeopathic medicines: borax, mercurius solubilis, natrum muriaticum, phosphorus, sulfuric acid, arsenicum album, nux vomica, lycopodium

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

K12.0 Recurrent oral aphthae

CLINICAL PEARLS

- Aphthous ulcers are the most common chronic disease of the oral cavity.
- Most cases are mild, self-limited episodes.
• Appropriate treatment should be aimed at symptom control and promotion of healing.
• Nonhealing ulcers, extra-oral involvement, and sudden onset in adulthood require additional workup.
ULCERATIVE COLITIS

George Clement, MD • Elise Leisinger, DO

**BASICS**

**DESCRIPTION**
- Chronic relapsing and remitting inflammatory bowel disease causing recurrent episodes of diarrhea that is often bloody and accompanied by abdominal pain, incontinence, fever, and weight loss
- Inflammation limited to the colonic mucosa
- Colonic involvement is universal but may be accompanied by large joint arthritis, ocular inflammation, skin lesions, biliary disease, liver disease, thromboembolic disease, and (rarely) pulmonary complications

**EPIDEMIOLOGY**

**Incidence**
- North America: 19/100,000 person-years (1)
- Europe: 24/100,000 person-years (1)
- Asia and Middle East: 6.3/100,000 person-years (1)

**Prevalence**
- North America: 249/100,000 persons (1)
- Europe: 505/100,000 persons (1)

**Pregnancy Considerations**
- Increased risk of preterm delivery and small for gestational age birth
- 30% with inactive disease relapse in pregnancy
- Management with gastroenterologist and/or maternal–fetal medicine specialist/obstetrician is recommended.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Idiopathic; hypothesized association with autoimmune dysfunction, genetic predisposition, diet, and colonic microbiome
- Almost universally involves terminal colon, >95% of patients have rectal involvement, 50% have disease limited to rectum and sigmoid; 20% have pancolitis.
Genetics
Moderate heritability. Specific genetic markers have not been identified.

RISK FACTORS
- Age: variable, peak incidence 15 to 40 years of age
- First-degree relative with ulcerative colitis (UC)
- Theorized risk factors include disruption of colonic microbiome by diet or infection, dietary factors (Western diet in particular), antibiotic use, lack of breastfeeding in infant, obesity, and NSAID use.

GENERAL PREVENTION
No known preventive measures

Pediatric Considerations
- Breastfeeding may protect against pediatric inflammatory bowel disease.
- UC more likely pancolonic at onset and shorter time from diagnosis to colectomy (median 11.1 years)

COMMONLY ASSOCIATED CONDITIONS
- Arthritis: large joint, sacroiliitis, ankylosing spondylitis
- Pyoderma gangrenosum (rare)
- Erythema nodosum (common)
- Aphthous ulcers
- Episcleritis and uveitis (rare)
- Autoimmune liver disease (rare)
- Fatty liver (common)
- Liver cirrhosis (rare)
- Primary sclerosing cholangitis (rare)
- Bile duct carcinoma (rare)
- Thromboembolic disease (rare)
- Colon cancer (rare)
- Anemia (rare)
- Pulmonary diseases (very rare)

DIAGNOSIS
HISTORY
- Frequent diarrhea, may be bloody or include mucus
- Frequent, small bowel movements, associated with tenesmus, colicky abdominal pain, urgency, and fecal incontinence
- Episodes often accompanied by fever, weight loss, fatigue, anemia, joint swelling/redness, and skin findings
- Onset is gradual and progressive over weeks.
- Predominant age of onset: 15 to 40 years; smaller peak in ages 50 to 80 years

**PHYSICAL EXAM**
- Often normal
- Abdominal tenderness
- Presence of blood on rectal exam
- In severe disease: fever, hypotension, tachycardia, pallor, loss of subcutaneous fat, muscle atrophy, peripheral edema

**DIFFERENTIAL DIAGNOSIS**
- Crohn disease
- Infectious colitis: bacterial, parasitic, or viral (cytomegalovirus [CMV])
- Diverticular colitis
- Diversion colitis in patients with prior bowel surgery
- Medication-induced colitis
- Radiation colitis
- Graft versus host disease
- Celiac disease
- Microscopic colitis

**DIAGNOSTIC TESTS & INTERPRETATION**
- Stool examination to rule out infectious cause
- Confirm diagnosis with sigmoidoscopy or colonoscopy as indicated by clinical severity.

*Initial Tests (lab, imaging)*
- CBC: Leukocytosis and anemia support diagnosis.
- BMP: urea and electrolyte abnormalities; hypokalemia supports diagnosis.
- LFTs: liver function abnormalities; low albumin indicates severe disease (2).
- ESR or CRP elevation supports diagnosis and can help define severity (2).
- Iron studies, vitamin B₁₂, folate if anemic to determine nutrient deficiency versus chronic disease
• Fecal calprotectin: indicates colonic inflammation (3)
• Stool studies to rule out infectious cause: *Clostridium difficile* toxin (four samples), stool cultures, Shiga toxin, ova and parasite microscopy, Giardia antigen
• STI testing to rule out proctitis, particularly in MSM: chlamydia, gonorrhea, HSV, syphilis (3)
• Perinuclear antineutrophil cytoplasmic antibody (pANCA) and anti-*Saccharomyces cerevisiae* antibodies (ASCA) are commonly present in patients with UC; testing not recommended for diagnosis (3)
• Abdominal x-ray to exclude colonic dilation (3)

**Diagnostic Procedures/Other**
• Colonoscopy with 2+ biopsies from each of five sites along the entire colon is an initial diagnostic step (3).
• Complete colonoscopy may be contraindicated in severe UC due to risk of perforation or precipitation of toxic megacolon (3).

**Test Interpretation**
• Endoscopic findings that support UC include mucosal engorgement with vascular markings, mucosal erythema, and mucosal granularity. Affected areas will extend proximally and continuously.
• Histologic findings that support UC include mucosal separation, distortion, and atrophy of the crypts, chronic inflammatory cells in lamina propria, lymphocytes and plasma cells in crypt bases (4)[C].
• If only rectal biopsy, villous mucosal architecture and Paneth cells metaplasia support UC (4)[C].
• Mild ileal inflammation (“backwash ileitis”) may be present in UC (4)[C].

**TREATMENT**

**GENERAL MEASURES**
• Assess for outpatient versus inpatient treatment.
• Approach is either induction during initial presentation/relapses or maintenance between relapses.
• Options determined by response to prior treatments and side effect profile
• Minimize comorbidities: treat infections, stop aspirin and NSAIDs.
• Educate patients about colorectal cancer, surgical options.
Assess for high risk of colectomy: severe findings on colonoscopy, age <40 years, high inflammatory markers, requiring steroids, prior hospitalizations, concomitant *C. difficile* or CMV infection.

Treatment of low risk patients includes only first-line medications.

**MEDICATION**

**First Line**

- Proctitis/distal colitis with mild or moderate severity: 5-ASA (e.g., mesalamine 1 g/day) suppository; 5-ASA foam enemas are a less-effective alternative (5)[C].
- Left-sided UC with mild to moderate severity: topical 5-ASA (e.g., mesalamine 1 g/day) *plus* >2 g/day oral mesalamine (5)[C]
- Left-sided severe UC: hospital admission and systemic steroids (e.g., prednisone 40 to 60 mg/day) in addition to mesalamine/5-ASA (5)[C]
- Extensive UC of mild to moderate severity: oral sulfasalazine titrated up to 4 to 6 g/day or a combination of topical and oral 5-ASA (above) (5)[C]
- Severe UC: necessitates hospitalization for intensive treatment and surveillance for complications; IV steroids (methylprednisolone 60 mg/day or hydrocortisone 400 mg/day) with or without 2 to 6 g/day oral mesalamine (5)[C]

**Second Line**

- Proctitis/distal colitis with mild to moderate severity: first-line therapy *plus* 2 to 6 g/day oral mesalamine. Topical corticosteroids (budesonide 2 to 8 mg/day or hydrocortisone 100 mg/day) may be added (5)[C].
- Left-sided UC with mild to moderate severity: first-line therapy *plus* topical corticosteroids (budesonide 2 to 8 mg/day or hydrocortisone 100 mg/day) may be added. Persistent rectal bleeding despite this regimen can be treated with systemic prednisone at 40 to 60 g/day with a prolonged taper (5)[C].
- Left-sided severe UC: first-line therapy *plus* prednisone at 40 to 60 g/day and long taper; if refractory, azathioprine 2.5 mg/kg/day or 6-mercaptopurine (1.5 mg/kg/day) for induction and maintenance (5)[C]
- Severe UC: TNF-α-blocker (adalimumab, infliximab, golimumab) combined with methotrexate or thiopurine. Patients with severe UC will often need timely colectomy (5)[C].
- Infliximab adult dose: 5 mg/kg IV at weeks 0, 2, and 6 for induction and then maintenance of 5 mg/kg IV is given every 8 weeks.
- Adalimumab: dose: 160 mg SC (given as four injections on day 1 or two
injections daily over 2 consecutive days; limit injections to 40 mg per injection); 2nd dose 2 weeks later: 80 mg, and maintenance: 40 mg every other week (6)[C]

- Other second-line therapies, particularly in refractory disease, include CsA 4 mg/kg/day and tacrolimus 0.1 to 0.2 mg/kg/day PO or 0.01 to 0.02 mg/kg/day IV. Trough concentrations with tacrolimus should be 10 to 15 ng/mL.
- TNF-α-blockers can help maintain remission in steroid-dependent patients with severe UC.
- Immunosuppressive therapy increases risk of opportunistic infections. Chronic steroid use can cause adrenal suppression gastrointestinal bleeding, heart disease, osteoporosis, thinning of skin, and compromised vascular wall integrity. Infusion of biologics carries the risk of anaphylactic reactions during treatment.

**Pediatric Considerations**
Pediatric growth and development can be affected due to malabsorption.

**SURGERY/OTHER PROCEDURES**
- Surgery is indicated for medically refractory disease (particularly in patients on high-dose steroids).
- Emergent surgery (total or subtotal abdominal colectomy with end ileostomy) for massive hemorrhage, perforation, and toxic dilatation
- Total colectomy with ileostomy is curative.
- Total proctocolectomy with ileal pouch anal anastomosis (IPAA) is the most common surgery and an appropriate alternative to ileostomy. Common complications include pouchitis (50%) and need for reoperation in up to 30% (4)[C].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- There is ongoing research into the role of probiotics, dietary changes, and fecal microbiota transplantation as treatment for UC. The current evidence is insufficient to support any particular alternative therapy to achieve or maintain remission.
- Tobacco cessation is associated with 65% reduction in relapse (3)[C].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
● Admission for UC or its complications warrants gastroenterology consultation.
● Consultation with surgery is indicated. Severe UC, particularly involving toxic megacolon, fulminant colitis, or colon cancer, may require emergent surgery.
● Imaging helps assess disease activity and colon size.
● Initiate IV corticosteroids and rule out infection (C. difficile, CMV, shigella, amoebae).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Regular surveillance colonoscopy in patients with prolonged (8 to 10 years) active disease (4)
- Annual surveillance in patients with primary sclerosing cholangitis
- Annual LFTs and cholangiography for cholestasis
- Annual BUN/creatinine for patients on long-term mesalamine

**Pediatric Considerations**

Cumulative risk of cancer increases with duration of disease. Ensure regular surveillance.

**DIET**

- NPO during acute exacerbations
- There are otherwise no specific dietary recommendations. Dietary research is ongoing.

**PATIENT EDUCATION**

**PROGNOSIS**

- Chronic disease with variable severity and rate of recurrence
- Variable; mortality for initial attack is ~5%; 75–85% experience relapse; up to 20% require colectomy.
- Colon cancer risk is the single most important factor affecting long-term prognosis.
• Left-sided colitis and ulcerative proctitis have favorable prognoses with probable normal lifespan.

**Geriatric Considerations**
• Increased mortality if first presentation occurs after 60 years of age.
• Consider lower medication dosages and slower titration due to risks of polypharmacy.

**COMPLICATIONS**
• Perforation: Treat toxic megacolon with prompt surgery. Limit colonoscopies in severe disease.
• Obstruction
• Anemia
• Fulminant colitis
• Toxic megacolon
• Liver disease
• Stricture formation
• Osteoporosis
• Colorectal cancer

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**
- Clostridium Difficile Infection
- Algorithm: Hematemesis (Bleeding, Upper Gastrointestinal)

**CODES**

**ICD10**
- K51.90 Ulcerative colitis, unspecified, without complications
- K51.919 Ulcerative colitis, unspecified with unspecified complications
- K51.80 Other ulcerative colitis without complications

**CLINICAL PEARLS**
- UC is marked by diffuse, uninterrupted colonic mucosal inflammation.
- Hallmark symptom is bloody diarrhea.
- Annual or biannual surveillance colonoscopy after 8 to 10 years of colitis due to increased risk of colorectal cancer
URETHRITIS

Patrick L. McCurdy, PA-C, MS, MBA • Matthew E. Bryant, MD

BASICS

DESCRIPTION

- Inflammation of the urethra
- Common manifestation of sexually transmitted infection
- Frequently associated with dysuria, pruritus, and/or urethral discharge; classified as gonococcal (caused by Neisseria gonorrhoeae) and nongonococcal (caused by other bacteria, or less commonly autoimmune disorders [Reiter syndrome], trauma, or chemical irritation)

EPIDEMIOLOGY

Incidence

- In 2014, there were >395,000 reported cases of gonorrhea, with a rate of 123.9 cases per 100,000 per population (12.8% increase since 2014) (1).
- In 2014, there were >1.5 million reported cases of Chlamydia trachomatis infection, or 478.8 cases per 100,000 per population (5.9% increase since 2014) (1).
- Rate of chlamydial infection in U.S. women was more than twice that of men, reflecting higher rates of screening (1).
- Highest incidences of gonorrhea and chlamydia among young men and women, ages 15 to 24 years (>50% of all cases) (1)
- Chlamydial infections are 5 times more likely in young adult women than gonococcal infections (1).

ETIOLOGY AND PATHOPHYSIOLOGY

- Most common cause is infection via sexual transmission of N. gonorrhoeae, a gram-negative diplococcus.
- N. gonorrhoeae interacts with nonciliated epithelial cells → cellular invasion → inflammation, neutrophil production, bacterial cell phagocytosis (2)
- Sexually transmitted C. trachomatis infection is the most common cause of nongonococcal urethritis.
● Other established pathogens:
  – *Mycoplasma genitalium*
  – *Trichomonas vaginalis*
  – *Ureaplasma urealyticum*
  – Herpes simplex virus (rare)
  – Adenovirus (rare)
● Noninfectious causes (generally rare)
  – Chemical irritants (i.e., soaps, shampoos, douches, spermicides)
  – Foreign bodies
  – Urethral instrumentation

**RISK FACTORS**
● Age 15 to 24 years
● New sex partner
● One or more sex partner(s)
● History of or coexisting STI
● Sex partner with concurrent partner(s)
● Inconsistent condom use outside of a mutually monogamous relationship
● Exchanging sex for money or drugs
● Member of population with increased prevalence of infection, including incarcerated populations, military recruits, black and Latino persons

**GENERAL PREVENTION**
● Use of male condoms, female condoms, or cervical diaphragms
● Abstinence or reduction in the number of sex partners
● Behavioral counseling

**COMMONLY ASSOCIATED CONDITIONS**

**ALERT**
Annual chlamydia and gonorrhea screening is recommended for all sexually active women <25 years, women >25 years with risk factors, and all men who have sex with men. There is insufficient evidence to recommend testing all men <25 year (3).

**DIAGNOSIS**
● Chief complaint
– Urethral discharge (mucopurulent suggestive of *N. gonorrhoeae*)
– Dysuria
– Erythema of the urethral meatus
– Symptom onset 2 to 8 days following exposure

**History**
– Sexual history, including condom use, number of partners, sexual behaviors
– Previous STIs
– Substance abuse
– Recent travel
– Symptoms indicative of complications or additional sites of infection (i.e., men: testicular pain and swelling, anal itching, rectal pain or bleeding; women: lower abdominal pain, dyspareunia, irregular vaginal bleeding)

**Male GU exam (possible findings)**
– Urethral discharge
– Meatal erythema
– Testicular tenderness
– Palpate scrotum to check for epididymitis or orchitis.
– Assess for ulcers.
– Assess for inguinal lymphadenopathy.

**Female GU exam (possible findings)**
– Vaginal discharge
– Endocervical discharge, hyperemia, and/or friability

**Pediatric Considerations**
Pediatric infections with gonorrhea and chlamydia after the neonatal period strongly suggest sexual contact. If indicated, investigations should be initiated promptly (3).

**DIFFERENTIAL DIAGNOSIS**
• Other genitourinary tract diseases
  – Cystitis/urinary tract infection
  – Epididymitis
  – Prostatitis
  – PID
  – Pyelonephritis
• Vaginal atrophy, especially in postmenopausal women
• Stevens-Johnson syndrome
• Reiter syndrome: uveitis, urethritis, arthritis
• Wegener granulomatosis
DIAGNOSTIC TESTS & INTERPRETATION

**ALERT**
Health care providers are required to report all gonorrhea and chlamydia infections in accordance with local and state requirements.

*Initial Tests (lab, imaging)*
- Gram-stain diagnosis of urethritis if: urethral secretions with ≥2 WBC per oil immersion field, mucopurulent or purulent discharge, or first void urine sediment with ≥10 WBC per high-power field (hpf) (3)
- Gonorrhea
  - Nucleic acid amplification test (NAAT): in men: first void urine preferred (90–100% sensitivity, 97–100% specificity for gonorrhea); in women: vaginal swab preferred (patient or clinician collected), end cervical swab acceptable, first void urine may detect 10% fewer infections (3)[A]
  - Culture: traditional gold standard—most commonly used in cases of suspected treatment resistance (3)
- Chlamydia
  - NAAT: in men: first catch urine equal to urethral swab (85–95% sensitivity, 93–99% specificity); in women: vaginal swab preferred (patient or clinician collected), end cervical swab acceptable, first void urine may detect 10% fewer infections (3)[A]
  - Tissue cultures: traditional gold standard, but currently NOT recommended (3)
- If concern for trichomonas: NAAT (urine, urethral, vaginal, or endocervical swab), wet mount, or culture
- There is no FDA-approved diagnostic test available for *M. genitalium*, an emerging pathogen with a greater prevalence than gonorrhea in many populations (4).

**ALERT**
Due to the similarity in clinical symptoms and high rates of coinfection, cotesting for gonorrhea and chlamydia infection is recommended. In addition, given that risk factors for gonorrhea and chlamydia indicate risks for other STIs, screening for HIV, RPR, hepatitis C, and hepatitis B may also be indicated.

*Follow-Up Tests & Special Considerations*
Test of cure (TOC) for chlamydia and gonorrhea is recommended in pregnant women or when treatment noncompliance is suspected (3).

Repeat testing in 3 months recommended due to rates of reinfection (3).

HIV infection: Persons with HIV infection should receive the same treatment as patients without HIV infection (3).

**Diagnostic Procedures/Other**

Urethrocystoscopy for cases with suspected foreign body, intraurethral warts, urethral stricture

**Test Interpretation**

Urethral strictures (untreated gonorrhea), intraurethral lesions (venereal warts, congenital anomalies), PID, or tubo-ovarian abscesses are possible.

---

**TREATMENT**

**GENERAL MEASURES**

- Most cases can be treated in the outpatient setting.
- Single-dose regimens with direct observation preferred (3)

**MEDICATION**

**First Line**

- **Gonorrhea**
  - Ceftriaxone 250 mg IM plus either: azithromycin 1 g PO × 1 dose (preferred) OR doxycycline 100 mg PO BID for 7 days (if azithromycin allergy) (3)[A]
  - For children ≤45 kg: ceftriaxone 25 to 50 mg/kg (max 125 mg) IM × 1 dose. For children >45 kg: Use adult dosing.

- **Chlamydia**
  - Azithromycin: 1 g PO × 1 dose OR
  - Doxycycline: 100 mg PO BID for 7 days (3)[A]
  - Alternative regimens (all for 7 days): erythromycin base 500 mg PO QID, erythromycin ethylsuccinate 800 mg PO QID, levofloxacin 500 mg daily, OR ofloxacin 300 mg PO BID

- **Trichomonas**
  - Metronidazole: 2 g PO × 1 dose

- Recurrent and resistant urethritis
– Metronidazole: 2 mg PO single dose OR tinidazole 2 g PO single dose plus azithromycin 1 g PO × 1 dose

**Contraindications:** sensitivity to any of the indicated medications

**Precautions:** Patients taking tetracyclines may have increased photosensitivity.

**Significant possible interactions**
– Tetracyclines should not be taken with milk products or antacids.
– Oral contraceptives may be rendered less effective by oral antibiotics.
  Patients and partners should use a back-up method of birth control for the remainder of the cycle.

**Pregnancy Considerations**
Chlamydia: All pregnant women <25 years and older women at increased risk should be screened for chlamydia at their first prenatal visit and again in the 3rd trimester. Women with chlamydia infections should be treated, have a documented TOC 3 to 4 weeks after treatment, and retested in 3 months (3).

– Gonorrhea: All pregnant women <25 years and older women at increased risk should be screened for gonorrhea at their first prenatal visit and again in the 3rd trimester. Women with gonorrhea infections should be treated and be retested in 3 months (3).

– Tetracyclines and quinolones are contraindicated.

– Avoid erythromycin estolate because of an increased risk of cholestatic jaundice.

– Single-dose therapy is recommended.

**Second Line**
– Gonorrhea: If ceftriaxone is not an option, cefixime 400 mg PO × 1 dose plus either: azithromycin 1 g PO × 1 dose OR doxycycline 100 mg PO BID for 7 days (if azithromycin allergy); followed by a TOC in 1 week (3)

– Chlamydia alternative regimens (all for 7 days): erythromycin base 500 mg PO QID, erythromycin ethylsuccinate 800 mg PO QID, levofloxacin 500 mg daily, OR ofloxacin 300 mg PO BID (3)

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
– Sexual activity should be avoided for 7 days following administration of single-dose therapy or until completion of multiday regimen.
• All sexual partners who came in contact with the patient within 60 days should be referred for evaluation, testing, and presumptive treatment (3).
• Expedited partner therapy (EPT) is an acceptable alternative. EPT—the practice of treating the diagnosed patient’s sex partner(s) for chlamydia or gonorrhea by providing medications or prescriptions to the patient to provide to the partner(s) without clinical evaluation (3).

**Patient Monitoring**
• Instruct patients to return if symptoms persist or recur after completing treatment.
• TOC in 3 to 4 weeks in pregnant women suspected of nonadherence, reinfection, persistent symptoms
• Screen for reinfection in all patients at 3 months.

**DIET**
Avoid alcohol when taking metronidazole.

**PATIENT EDUCATION**
• Behavioral counseling interventions are recommended. Evidence of benefit increase with intensity of intervention (5).
• Successful approaches include basic information about STIs and transmission, assess risk for transmission, include training skills (i.e., condom use, communication about safe sex, problem solving, goal setting) (5).

**PROGNOSIS**
If the diagnosis is firmly established, appropriate medications are prescribed and the patient is compliant with treatment; relief of symptoms occurs within days and the problem will resolve without sequela.

**COMPLICATIONS**
• Stricture formation
• Epididymitis
• Prostatitis
• PID in women
• Disseminated gonococcal infection
• Gonococcal meningitis
• Gonococcal endocarditis
• Perinatal transmission (chlamydial conjunctivitis, chlamydial pneumonia,
ophthalmia neonatorum)

- Reiter syndrome
- Chronic cervical chlamydial infection has been proposed to increase risk of cervical cancer (6).

CLINICAL PEARLS
- Inflammation of the urethra, frequently associated with dysuria, pruritus, and/or urethral discharge
- Common manifestation of STI
- Classified as gonococcal (caused by *N. gonorrhoeae*) and nongonococcal
- NAAT preferred method of diagnosis for men and women
- Single-dose regimens with direct observation preferred
- In cases of gonorrhea or chlamydia infection, in person or EPT recommended for all partners of patients within the last 60 days
- Given that risk factors for gonorrhea and chlamydia indicate risk for other STIs, screening for HIV, RPR, hepatitis C, and hepatitis B may also be indicated.
- Repeat testing for gonorrhea and chlamydia in 3 months recommended due to rates of reinfection.
- Special considerations in pediatric and pregnant populations
- Treatment in persons with HIV infection is the same as in patients without HIV infection.
- Health care providers are required to report all gonorrhea and chlamydia infections in accordance with local and state requirements.
URINARY TRACT INFECTION (UTI) IN FEMALES

James Steward, MD • Akhil Das, MD, FACS

BASICS

DESCRIPTION

- Urinary tract infection (UTI) is the presence of pathogenic microorganisms within the urinary tract with concomitant symptoms.
- This topic refers primarily to infectious cystitis; other complicated UTIs, such as pyelonephritis, are discussed elsewhere.
- Uncomplicated UTI: occurs in patients who have a normal, unobstructed urinary tract, who have no history of recent instrumentation, and whose symptoms are confined to the lower urinary tract. Uncomplicated UTIs are most common in young, sexually active women.
- Complicated UTI: an infection of the lower or upper urinary tract in the presence of an anatomic abnormality, a functional abnormality, or a urinary catheter
- Recurrent UTI: symptomatic UTIs that follow resolution of an earlier episode, usually after appropriate treatment
  - Three UTIs within 12 months or two within 6 months
  - Most recurrences are thought to represent reinfection rather than relapse.
- No evidence indicates that recurrent UTIs lead to health problems such as hypertension or renal disease in the absence of anatomic or functional abnormalities of the urinary tract (1)[A].

- System(s) affected: renal/urologic
- Synonym(s): cystitis; infectious cystitis

EPIDEMIOLOGY

Incidence

- Accounts for 8 million doctor visits and 1 million emergency room visits and contributes to >100,000 hospital admissions each year (2)
- 11% of women have UTIs in any given year.
- Predominant age: young adults and older
- Predominant sex: female > male
Prevalence
- >50% of females have at least one UTI in their lifetime.
- One in four women has recurrent UTIs.

ETIOLOGY AND PATHOPHYSIOLOGY
- Bacteria and subsequent infection in the urinary tract arise chiefly via ascending bacterial movement and propagation (1).
- Pathogenic organisms (Escherichia coli) possess adherence factors and toxins that allow initiation and propagation of genitourinary infections:
  - Type 1 and P. pili (pyelonephritis-associated pili)
  - Lipopolysaccharide
- Most UTIs are caused by bacteria originating from bowel flora:
  - E. coli is the causative organism in 80% of cases of uncomplicated cystitis.
  - Staphylococcus saprophyticus accounts for 15% of infections.
  - Enterobacteriaceae (i.e., Klebsiella, Proteus, Enterobacter, and Pseudomonas) also contribute.
- Candida is associated with nosocomial UTI (3).

Genetics
Women with human leukocyte antigen 3 (HLA-3) and nonsecretor Lewis antigen have an increased bacterial adherence, which may lead to an increased risk in UTI.

RISK FACTORS
- Previous UTI
- Diabetes mellitus (DM)
- Pregnancy
- Sexual activity
- Use of spermicides or diaphragm
- Underlying abnormalities of the urinary tract such as tumors, calculi, strictures, incomplete bladder emptying, urinary incontinence, neurogenic bladder
- Catheterization
- Recent antibiotic use
- Poor hygiene
- Estrogen deficiency
- Inadequate fluid intake
GENERAL PREVENTION
- Maintain good hydration.
- Women with frequent or intercourse-related UTI should empty bladder immediately before and following intercourse; consider postcoital antibiotic.
- Avoid feminine hygiene sprays and douches.
- Wipe urethra from front to back.
- Cranberry juice (not cranberry juice cocktail) consumption may prevent recurrent infections.

COMMONLY ASSOCIATED CONDITIONS
See “Risk Factors.”

Geriatric Considerations
- Elderly patients are more likely to have underlying urinary tract abnormality.
- Acute UTI may be associated with incontinence or mental status changes in the elderly.

DIAGNOSIS

HISTORY
Note: Any or all may be present:
- Burning or pain during urination (dysuria)
- Urgency (sensation of need to urinate often)
- Frequency
- Sensation of incomplete bladder emptying
- Blood in urine
- Lower abdominal pain or cramping
- Offensive odor of urine
- Nocturia
- Sudden onset of urinary incontinence
- Dyspareunia

PHYSICAL EXAM
- Suprapubic tenderness
- Urethral and/or vaginal tenderness
- Fever or costovertebral angle tenderness indicates upper UTI.
DIFFERENTIAL DIAGNOSIS
- Vaginitis
- Asymptomatic bacteriuria
- STDs causing urethritis or pyuria
- Hematuria from causes other than infection (e.g., neoplasia, calculi)
- Interstitial cystitis
- Psychological dysfunction

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- No lab testing is necessary in women with high likelihood of lower UTI based on classic symptoms. Negative dipstick in the presence of high pretest probability does not rule out UTI.
- Urinalysis
  - Pyuria (>10 neutrophils/high-power field [HPF])
  - Bacteriuria (any amount on unspun urine, or five bacteria/HPF on centrifuged urine)
  - Hematuria (≥3 RBCs/HPF)
- Dipstick urinalysis
  - Leukocyte esterase (75–96% sensitivity, 94–98% specificity, when >100,000 colony-forming units [CFU])
  - Nitrite tests are useful with nitrite-reducing organisms (e.g., enterococci, S. saprophyticus, Acinetobacter).
- Urine culture: only indicated if diagnosis is unclear or patient has recurrent infections and resistance is suspected. It is neither cost-effective nor usually helpful for lower tract, uncomplicated UTI.
  - Presence of 100,000 CFU/mL of organism indicates infection.
  - Identification of a single organism at lower CFU per milliliter likely also represents infection in the presence of appropriate symptoms.
  - Suspect a contaminated specimen when culture shows multiple types of bacteria.
- Imaging studies are often not required in most cases of UTI.

Follow-Up Tests & Special Considerations
- In nonpregnant, premenopausal women with symptoms of UTI, positive urinalysis, and no risks for complicated infection, empirical treatment may be given without obtaining a urine culture.
- Imaging may be indicated for UTIs in men, infants, immunocompromised
patients, febrile infection, signs or symptoms of obstruction, failure to respond to appropriate therapy, and in patients with recurrent infections.

- CT scan and MRI provide the most complete anatomic data in adults.

**Pediatric Considerations**
For infants and children, obtain US; if ureteral dilatation is detected, obtain either voiding cystourethrogram or isotope cystogram to evaluate for reflux.

**Diagnostic Procedures/Other**
- Urethral catheterization may be necessary to obtain a urine specimen from children and adults if the voided urine is suspected of being contaminated.
- Suprapubic bladder aspiration or urethral catheterization techniques can be used to obtain specimens from infants.
- Cystourethroscopy can be used for patients with recurrent UTIs and previous anti-incontinence surgery or hematuria (4)[A].

**TREATMENT**

**GENERAL MEASURES**
- Maintain good hydration.
- Maintain good hygiene.
- 1/4 of women with uncomplicated UTI experience a second UTI within 6 months and 1/2 at some time during their lifetime.
- Many women with uncomplicated UTI clear symptoms without treatment.

**MEDICATION**

**First Line**
- The urinary tract topical analgesic phenazopyridine 100 to 200 mg TID produces rapid relief of symptoms and should be offered to patients with more than minor discomfort; it is available over the counter. This medication is not a substitute for definitive treatment and also may alter urinalysis but not the urine culture.
- Choice of antibiotic should be made with consideration to patient allergy, compliance, local resistance patterns, availability, and cost.
- Uncomplicated UTI (adolescents and adults who are nonpregnant, nondiabetic, afebrile, immunocompetent, and without genitourinary anatomic abnormalities)
– Trimethoprim/sulfamethoxazole (TMP/SMX; Bactrim): 160/800 mg PO BID for 3 days, best where resistance of E. coli strains <20%
– 5-day course of nitrofurantoin should be used in patients with allergy to TMP/SMX and in areas where E. coli resistance to TMP/SMX >20% (4) [A].
– Fosfomycin (Monurol): 3 g PO single dose (expensive)
– Pivmecillinam 400 mg BID for 5 days
• Lower UTI in pregnancy
  – Nitrofurantoin (Macrobid): 100 mg PO BID for 7 days
  – Cephalexin (Keflex): 500 mg PO BID for 7 days
• Postcoital UTI: Single-dose TMP/SMX or cephalexin may reduce frequency of UTI in sexually active women.
• Complicated UTI (pregnancy, diabetes, febrile, immunocompromised patient, recurrent UTIs): Extend course to 7 to 10 days of treatment with antibiotic chosen based on culture results; may begin with fluoroquinolone, TMP/SMX, or cephalosporin while awaiting results (avoid using nitrofurantoin for complicated UTI)
  – Fluoroquinolones are not safe during pregnancy and are usually avoided in treatment of children.
  – FDA black box warning (2016) on fluoroquinolones due to disabling and potentially permanent side effects
  – TMP/SMX use in pregnancy is not desirable (especially in 1st and 3rd trimester) but is appropriate in some circumstances (4)[A].

Second Line
• Uncomplicated UTI
  – β-Lactams (amoxicillin/clavulanate, cefdinir, cefpodoxime proxetil) for 3 to 7 days
• Chronic UTIs
  – Women with recurrent symptomatic UTIs can be treated with continuous or postcoital prophylactic antibiotics. Treatment duration guided by the severity of patient symptoms and by physician and patient preference: Consider 6 months of therapy, followed by observation for reinfection after discontinuing prophylaxis.
    o Continuous antimicrobial prophylaxis involves daily administration of low-dose TMP/SMX 40/200 mg or nitrofurantoin 50 to 100 mg, among others.
  – Another treatment option is self-started antibiotics.
    o Patient is given a specimen cup, UA/culture order, antibiotic script, and
instructed to notify physician when UTI occurs.

**Pediatric Considerations**
Long-term antibiotics appear to reduce the risk of recurrent symptomatic UTI in susceptible children, but the benefit is small and must be considered together with the increased risk of microbial resistance.

**ISSUES FOR REFERRAL**
Men with uncomplicated UTI and most other patients with complicated UTI should be referred to a urologist for evaluation.

**Pediatric Considerations**
UTI in children, especially <1 year of age, should prompt workup for urinary tract anomalies.

**SURGERY/OTHER PROCEDURES**
- Urinary tract obstruction with urosepsis requires urgent drainage of the obstructed system.
- Patients with emphysematous pyelonephritis or pyonephrosis may need immediate surgical intervention.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Preliminary studies indicate that *Vaccinium macrocarpon* (cranberry) juice may help to prevent and treat UTIs by inhibiting bacterial adherence to the bladder epithelium. It may decrease the number of symptomatic UTIs over a 1-year period.
- Methenamine can be used for recurrent UTIs (converts to formaldehyde in urine).
- Vaginal estrogen can be used to prevent recurrent UTIs in postmenopausal women.
- Other complementary therapies, such as urine acidification with vitamin C, alkalinization, and acupuncture, appear to be attractive alternative for prevention of UTIs; however, there is a lack of head-to-head trials to support their use.

**ADMISSION, INPATIENT, AND NURSING**
CONSIDERATIONS
Inpatient evaluation is reserved for patients with complicated or upper tract UTIs. Majority of UTIs are managed in an outpatient setting.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- First or rare UTI: Young or middle-aged, nonpregnant adult females require no follow-up if UTI is clinically cured after 3-day therapy.
- If symptoms persist after 2 to 3 days of therapy, obtain culture/sensitivity and change antibiotic accordingly.

Pregnancy Considerations
- UTI during pregnancy always requires culture/sensitivity and usually requires a 7- to 14-day treatment.
- Following the treatment of acute infection, pregnant women warrant surveillance urine cultures every trimester. They may receive prophylactic antibiotics for the remainder of pregnancy for recurrent or upper tract disease.

PATIENT EDUCATION
- Although no controlled studies support this intervention, postcoital voiding is commonly advised.

PROGNOSIS
Symptoms resolve within 2 to 3 days of antibiotic treatment in almost all patients.

COMPLICATIONS
- Pyelonephritis or sepsis
- Renal abscess
- Acute urinary outlet obstruction

Pregnancy Considerations
Pregnant females, infants, and young children with cystitis are at higher risk of
pyelonephritis.

Algorithm: Dysuria

CODES

ICD10

- N39.0 Urinary tract infection, site not specified
- N30.90 Cystitis, unspecified without hematuria
- N30.91 Cystitis, unspecified with hematuria

CLINICAL PEARLS

- Uncomplicated UTIs cause significant short-term morbidity but generally do not cause renal damage.
- Culture is generally not indicated for women with symptoms of uncomplicated UTI.
- Treatment of uncomplicated UTIs reduces morbidity, but does not reduce risk of recurrence.
- Uncomplicated UTIs should be treated for 3 days (TMP/SMX) or 5 days (nitrofurantoin). All pregnant women with bacteriuria should be treated.
- Health care professionals should avoid treating women with asymptomatic bacteriuria.
- Fluoroquinolones should be reserved for complicated UTI.
URINARY TRACT INFECTION (UTI) IN MALES

Amy L. Wiser, MD

BASICS

DESCRIPTION

- Cystitis is an infection of the lower urinary tract, usually resulting from a single gram-negative enteric bacteria. (See also “Prostatitis,” “Pyelonephritis,” and “Urethritis.”)
- System(s) affected: renal/urologic
- Synonym(s): urinary tract infection (UTI); cystitis
- Conventional consideration of UTI in male newborn, infant, and elderly men is complicated, with associated functional/structural mechanisms.
- In otherwise healthy males ages 15 to 50 years, UTI is uncommon and considered uncomplicated.

EPIDEMIOLOGY

Incidence

- Approximately 20% of UTIs occur in men.
- Predominant age: increases with age
- Uncommon in men <50 years of age
- 6 to 8 infections/10,000 men aged 21 to 50 years (1)

Prevalence

Lifetime prevalence approximately 14%

ETIOLOGY AND PATHOPHYSIOLOGY

- Escherichia coli (majority of infections)
- Klebsiella
- Enterobacter
- Enterococcus
- Proteus
- Serratia
- Citrobacter
- *Providencia*
- *Streptococcus faecalis* and *Staphylococcus* sp.
- *Pseudomonas* and *Morganella* (more common in elderly and catheterized patients)
- Pathogenesis—bacterial entry into urinary tract via ascension or bladder instrumentation

**Genetics**
Not applicable

**RISK FACTORS**
- Age
- Obesity
- History of prior UTI
- Outlet obstruction
  - Benign prostatic hypertrophy (BPH)—incidence of 33% of men with UTIs (2)
  - Urethral stricture
  - Calculi
- Cognitive impairment
- Fecal incontinence
- Urinary incontinence
- Anal intercourse
- Recent urologic surgery
- Infection of the prostate/kidney
- Urinary tract instrumentation, catheterization
- Immunocompromised host
- Diabetes
- Bladder diverticula
- Neurogenic bladder
- Institutionalization
- Uncircumcised
- Engaging in sex with an infected female partner or in anal intercourse (1)

**GENERAL PREVENTION**
- Prompt treatment of predisposing factors
- Use a catheter only when necessary; if needed, use aseptic technique and closed system and remove as soon as possible.
Currently, cranberry products are not recommended for preventing UTIs in men.

**COMMONLY ASSOCIATED CONDITIONS**
- Acute bacterial pyelonephritis
- Chronic bacterial pyelonephritis
- Urethritis
- Prostatitis
- Prostatic hypertrophy
- Prostate cancer

**Geriatric Considerations**
Bacteriuria is common among the elderly; may be related to functional status and usually is transient. Of men >65 years of age, 5–10% have asymptomatic bacteriuria (ASB). If ASB is noted, no treatment is needed (3,4).

**Pediatric Considerations**
Can be associated with obstruction to normal flow of urine, such as vesicoureteral reflux. Unique diagnostic criteria and evaluation recommendations exist (see below).

**DIAGNOSIS**

**HISTORY**
- Urinary frequency
- Urinary urgency
- Dysuria
- Hesitancy
- Slow urinary stream
- Dribbling of urine
- Nocturia
- Suprapubic discomfort or perineal pain
- Low back pain
- Hematuria
- Systemic symptoms (chills, fever) or flank pain, nausea, vomiting present with concomitant pyelonephritis or prostatitis
PHYSICAL EXAM
- Suprapubic tenderness
- Costovertebral angle (CVA) tenderness and/or fever may be present with concomitant pyelonephritis/prostatitis/epididymitis.
- Perform genital examination.
- Consider digital rectal exam, including palpation of the prostate gland, to rule out bacterial prostatitis.

DIFFERENTIAL DIAGNOSIS
- Anatomic/functional pathology of the urinary tract
- Urethritis/STIs
- Infections in other sites of the genitourinary tract (e.g., epididymis, prostatitis). More than 90% of men with febrile UTI have concomitant prostate infection.

DIAGNOSTIC TESTS & INTERPRETATION
- Urine dipstick/manual microscopy of clean catch midstream void showing the following:
  - Pyuria (>10 WBCs)
  - Bacteriuria
  - Positive leukocyte esterase (in males: sensitivity, 78%; specificity, 59%; positive predictive value [PPV], 71%; negative predictive value [NPV], 67%)
  - Positive nitrite (in males: sensitivity, 47%; specificity, 98%; PPV, 96%; NPV, 59%)
  - In general, leukocyte esterase is more sensitive, and nitrite is more specific in detecting UTI (5).
- Automated microscopy/flow cytometry that measures cell counts and bacterial counts can be used to improve screening characteristics (sensitivity, 92%; specificity, 55%; PPV, 47%; NPV, 97%). The high NPV of these screening tests allows for more judicious use of urine culture (5).
- Urine culture: >100,000 colony-forming units (CFU; >10⁵ CFU) of bacteria/mL of urine confirm diagnosis.
- Lower counts, such as >10³ CFU, also may be indicative of infection, especially in the presence of pyuria.
- Diagnosis in infants and children <24 months made on the basis of both pyuria and 50,000 CFU on culture
- Renal and bladder ultrasound recommended in infants and young children
after first confirmed UTI

**Follow-Up Tests & Special Considerations**

- Consider assessing for risk factors for STIs, as chlamydial/gonococcal urethritis can mimic a UTI. If risk factors are present, use urine nucleic acid amplification tests to identify gonococcal and *Chlamydia* infections and treat as necessary.
- Further urologic evaluation is warranted to rule out other disorders in men with recurrent UTI, febrile UTI, or pyelonephritis. This may include the following:
  - Ultrasound
  - Cystoscopy
  - Urodynamics
  - IV pyelography
- Value of a urologic evaluation in a single uncomplicated UTI has not been determined.
- Antibiotics prior to culture or phenazopyridine prior to urine dipstick can alter results.
- Blood cultures are not routine; perform if concern for sepsis or bacteremia.

**Test Interpretation**

Depends on site of infection

**TREATMENT**

**GENERAL MEASURES**

- Hydration
- Analgesia, if required
- Patient with indwelling catheters
  - If asymptomatic bacterial colonization, no need to treat (sterilization of urine is not possible, and resistant organisms may take up residence)
  - If symptomatic of acute infection, institute treatment.

**MEDICATION**

**First Line**

- Acute, uncomplicated cystitis
  - Treat empirically; strongly consider if nitrite positive, using local resistance
patterns or based on culture and sensitivity results for 7 days.
– For empirical therapy, a fluoroquinolone or trimethoprim-sulfamethoxazole DS usually used to treat the most likely pathogens
- Complicated, febrile, or recurrent infection
– Prescribe a minimum of 2 weeks antibiotics based on antimicrobial sensitivities with repeat urine check after the treatment. In men with febrile UTI or pyelonephritis, prostatic involvement also has to be considered. Treatment of concomitant prostatitis requires antimicrobials with good prostatic tissue and fluid penetration (fluoroquinolones).

Second Line
According to culture and sensitivity results and patient’s history

ISSUES FOR REFERRAL
Further urologic evaluation and referral are warranted to rule out other disorders in men with recurrent UTI, febrile UTI, or pyelonephritis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
● Inability to tolerate oral medications
● Acute renal failure
● Suspected sepsis

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Close follow-up until clinically well

DIET
Encourage adequate fluid intake.

PATIENT EDUCATION
For patient education materials about this topic that have been reviewed favorably, contact the National Kidney Foundation, 30 E. 33rd Street, Suite 1100, New York, NY 10016; 212-889-2210.
PROGNOSIS
Clearing of infections with appropriate antibiotic treatment

COMPLICATIONS
- Pyelonephritis
- Ascending infection
- Recurrent infection
- Prostatitis

REFERENCES

ADDITIONAL READING
SEE ALSO

- Prostate Cancer; Prostatic Hyperplasia, Benign (BPH); Prostatitis; Pyelonephritis; Urethritis
- Algorithms: Dysuria; Urethral Discharge

CODES

ICD10

- N39.0 Urinary tract infection, site not specified
- N30.90 Cystitis, unspecified without hematuria
- N30.91 Cystitis, unspecified with hematuria

CLINICAL PEARLS

- Cystitis is an infection of the lower urinary tract, usually resulting from a single gram-negative enteric bacteria.
- Risk factors/causes: age, history of UTI, obesity, BPH, cognitive impairment, fecal incontinence, urinary incontinence, anal intercourse, recent urologic surgery, catheterization, infection of the prostate/kidney, urinary tract instrumentation, immunocompromised host, diabetes, neurogenic bladder, outlet obstruction, sex with infected female partner
- Evaluation: urinalysis, urine culture, STI testing (e.g., gonorrhea, Chlamydia by culture/DNA probe)
- Treat empirically with fluoroquinolones or trimethoprim-sulfamethoxazole DS for 7 days.
UROLITHIASIS
Phillip Fournier, MD

BASICS

DESCRIPTION

- Stone formation within the urinary tract: Urinary crystals bind to form a nidus which grows to form a calculus (stone).
- Range of symptoms: asymptomatic to obstructive; febrile morbidity if result of infection

EPIDEMIOLOGY

- The worldwide epidemiology differs according to both geographic area (higher prevalence in hot, arid, or dry climates) and socioeconomic conditions (dietary intake and lifestyle). Radiolucent stones and stones secondary to infection are less influenced by environmental conditions.
- Vesical calculosis (bladder stones) due to malnutrition during early life is frequent in Middle East and Asian countries.
- Incidence in industrialized countries seems to be increasing, probably due to improved diagnostics as well as to increasingly rich diets.
- Increased incidence in patients with surgically induced absorption issues, such as Crohn disease and gastric bypass surgery (1)[B]

Incidence

- In industrialized countries: 100 to 200/100,000/year
- Predominant age: Mean age is 40 to 60 years.
- Predominant sex: male > female (~2:1) (2)

ETIOLOGY AND PATHOPHYSIOLOGY

- Supersaturation and dehydration lead to high salt content in urine which congregates.
- Stasis of urine
  - Renal malformation (e.g., horseshoe kidney, ureteropelvic junction obstruction)
  - Incomplete bladder emptying (e.g., neurogenic bladder, prostate enlargement, multiple sclerosis)
Crystals may form in pure solutions (homogeneous) or on existing surfaces, such as other crystals or cellular debris (heterogeneous).

- Balance of promoters and inhibitors: organic (Tamm-Horsfall protein, glycosaminoglycan, uropontin, nephrocalcin) and inorganic (citrate, pyrophosphate)
- Calcium oxalate and/or phosphate stones (80%)
  - Hypercalciuria
    - Absorptive hypercalciuria: increased jejunal calcium absorption
    - Renal leak: increased calcium excretion from renal proximal tubule
    - Resorptive hypercalciuria: mild hyperparathyroidism
  - Hypercalcemia
    - Hyperparathyroidism
    - Sarcoidosis
    - Malignancy
    - Immobilization
    - Paget disease
- Hyperoxaluria
  - Enteric hyperoxaluria
    - Intestinal malabsorptive state associated with irritable bowel disease, celiac sprue, or intestinal resection
    - Bile salt malabsorption leads to formation of calcium soaps.
  - Primary hyperoxaluria: autosomal recessive, types I and II
  - Dietary hyperoxaluria: overindulgence in oxalate-rich food
- Hyperuricosuria
  - Seen in 10% of calcium stone formers
  - Caused by increased dietary purine intake, systemic acidosis, myeloproliferative diseases, gout, chemotherapy, Lesch-Nyhan syndrome
  - Thiazides, probenecid
- Hypocitraturia
  - Caused by acidosis: renal tubular acidosis, malabsorption, thiazides, enalapril, excessive dietary protein
- Uric acid stones (10–15%): hyperuricemia causes as discussed earlier
- Struvite stones (5–10%): infected urine with urease-producing organisms (most commonly Proteus sp.)
- Cystine stones (<1%): autosomal recessive disorder of renal tubular reabsorption of cystine
- Bladder stones: seen with chronic bladder catheterization and some medications (indinavir)
- In children: usually due to malnutrition
Genetics

- Up to 20% of patients have a family history. However, spouses of those who form stones have higher calcium excretion rates than controls, suggesting strong dietary–environmental factors.
- Autosomal dominant: idiopathic hypercalciuria
- Autosomal recessive
  - Cystinuria, Lesch-Nyhan syndrome, hyperoxaluria types I and II
  - Ehlers-Danlos syndrome, Marfan syndrome, Wilson disease, familial renal tubular acidosis

RISK FACTORS

- White > African American in regions with both populations
- Family history
- Previous history of nephrolithiasis
- Diet rich in protein, refined carbohydrates, and sodium, carbonated drinks
- Occupations associated with a sedentary lifestyle or with a hot, dry workplace
- Incidence rates peak during summer secondary to dehydration.
- Obesity
- Surgically/medically induced malabsorption (Crohn disease, gastric bypass, celiac)

GENERAL PREVENTION

- Hydration (3)[A]
- Decrease salt and meat intake
- Avoid oxalate-rich foods.

Pediatric Considerations

Rare: more common in men with low socioeconomic status

Pregnancy Considerations

- Pregnant women have the same incidence of renal colic as do nonpregnant women.
- Most symptomatic stones occur during the 2nd and 3rd trimesters, heralded by symptoms of flank pain/hematuria.
- Most common differential diagnosis is physiologic hydronephrosis of pregnancy. Use ultrasound to avoid irradiation. Noncontrast-enhanced CT scan also is diagnostic.
- Treatment goals
– Control pain and avoid infection and preserve renal function until birth or stone passage.
– 30% require intervention, such as stent placement.

**DIAGNOSIS**

**HISTORY**

- Pain
  - Renal colic: acute onset of severe groin and/or flank pain
  - Distal stones may present with referred pain in labia, penile meatus, or testis.
- Microscopic/gross hematuria occurs in 95% of patients.
- Nonspecific symptoms of nausea, vomiting, tachycardia, diaphoresis
- Low-grade fever without signs of infection
- Infectious origin: associated with high-grade fevers require more urgent treatment (see the following text)
- Frequency and dysuria especially occur with stones at the vesicoureteric junction (VUJ).
- Asymptomatic: nonobstructing stones within the renal calyces

**PHYSICAL EXAM**

Tender costovertebral angle with palpation/percussion and/or iliac fossa

**DIFFERENTIAL DIAGNOSIS**

- Appendicitis
- Ruptured aortic aneurysm
- Musculoskeletal strain
- Pyelonephritis (upper UTI)
- Pyonephrosis (obstructed upper UTI; emergency)
- Perinephric abscess
- Ectopic pregnancy
- Salpingitis

**DIAGNOSTIC TESTS & INTERPRETATION**

- Urinalysis for RBCs, leukocytes, nitrates, pH (acidic urine <5.5 is associated with uric acid stones; alkaline >7 with struvite stones)
- Midstream urine for microscopy, culture, and sensitivity
Blood: urea, creatinine, electrolytes, calcium, and urate; consider CBC.
Parathyroid hormone only if calcium is elevated
Stone analysis if/when stone passed

**Initial Tests (lab, imaging)**
- Noncontrast-enhanced helical CT scan of the abdomen and pelvis has replaced IV pyelogram as the investigation of choice (4)[A].
  - Stone is found most commonly at levels of ureteric luminal narrowing: pelviureteric junction, pelvic brim, and VUJ.
  - Acute obstruction: Proximal ureter and renal pelvis are dilated to the level of obstruction, and perinephric stranding is possible on imaging.
- Renal ultrasound may be as effective with lower radiation at diagnosis as well as identifying obstruction (5)[B].
- X-ray of kidneys, ureter, and bladder to determine if stone is radiopaque or lucent
  - Calcium oxalate/phosphate stones are radiopaque.
  - Uric acid stones are radiolucent.
  - Staghorn calculi (that fill the shape of the renal calyces) are usually struvite and opaque.
  - Cystine stones are faintly opaque (ground-glass appearance).
- Ultrasound has low sensitivity and specificity but is often the first choice for pregnant women and children.

**TREATMENT**

**GENERAL MEASURES**
- 75% of patients are successfully treated conservatively and pass the stone spontaneously.
- Stones that do not pass usually require surgical intervention.
- 30–50% of patients will have recurrent stones.
- Increased fluid intake; eliminate carbonated drinks.

**MEDICATION**
- Medical expulsive therapy: $\alpha_1$-Antagonists (e.g., tamsulosin) (6) and calcium channel blockers (e.g., nifedipine) improve likelihood of spontaneous stone passage with a number needed to treat (NNT) of ~5.
- Category C in pregnancy
Adequate pain control can be achieved with NSAIDs.

**ISSUES FOR REFERRAL**
- Urgent referral of patients with UTI/sepsis or acute renal failure/solitary kidney
- Early referral of pregnant patients, large stones (>8 mm), chronic renal failure, children
- Refer patients if no passage at 2 to 4 weeks or poorly controlled pain.

**ADDITIONAL THERAPIES**
- Uric acid stone dissolution therapy
  - Alkalinize urine with potassium citrate C; keep pH >6.5.
  - Allopurinol 100 to 300 mg/day PO (for those who continue to form stones despite alkalinization of urine)
- Cystine stone dissolution/prevention
  - Alkalinize urine with potassium citrate; keep pH >6.5.
  - Chelating agents: captopril, α-mercaptopropionylglycine, D-penicillamine
- Consider altering medications that increase risk of stone formation:
  probenecid, loop diuretics, salicylic acid, salbutamol, indinavir, triamterene, acetazolamide.
- Vitamin D supplementation has not been proven to induce stone formation.
- Treat hypercalciuria with thiazides on an acute basis only.
- Treat hypocitraturia with potassium citrate and high-citrate juices (e.g., orange, lemon).
- Treat enteric hyperoxaluria with oral calcium/magnesium, cholestyramine, and potassium citrate.

**SURGERY/OTHER PROCEDURES**
- Immediate relief of obstruction is required for patients with the following conditions:
  - Sepsis
  - Renal failure (obstructed solitary kidney, bilateral obstruction)
  - Uncontrolled pain, despite adequate analgesia
- Emergency surgery for obstruction
  - Placement of a retrograde stent (i.e., endoscopic surgery, usually requires an anesthetic)
  - Radiologic placement of a percutaneous nephrostomy tube
- Elective surgery for stone treatment
– Extracorporeal shock wave lithotripsy
– Ureteroscopy with basket extraction/lithotripsy (laser/pneumatic)
– Percutaneous nephrolithotomy
• Open surgery is uncommon.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Analgesia
  – Combination of NSAIDs (ketorolac 30 to 60 mg) and oral opiate
  – Parenteral opioid if vomiting or if preceding fails to control pain (morphine 5 to 10 mg IV or IM q4h)
  – Antiemetic if required or prophylactically with parenteral narcotics
• Septic patients with urosepsis or pyonephrosis may require IV antibiotics (once blood and urine cultures are taken), IV fluids, and, in severe cases, cardiorespiratory support in intensive care during recovery.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
• Patients with ureteric stones who are being treated conservatively should be followed until imaging is clear or stone is visibly passed.
  – Strain urine and send stone for composition.
  – Tamsulosin and nifedipine in selected patients to speed passage
  – Present to the hospital if pain worsens/signs of infection.
  – If pain management is suboptimal or stone does not progress or pass within 2 to 4 weeks, patient should be referred to a urologist and imaging should be repeated.
• Patients with recurrent stone formation should have follow-up with a urologist for metabolic workup: 24-hour urine for volume, pH, creatinine, calcium, cystine, phosphate, oxalate, uric acid, and magnesium.

DIET

ALERT
• Increased fluid intake for life cannot be overemphasized for decreasing recurrence. Encourage intake of 2 to 3 L/day; advise patient to have clear urine rather than yellow.
- Decrease or eliminate carbonated drinks.
- Patients who form calcium stones should minimize high-oxalate foods such as green leafy vegetables, rhubarb, peanuts, chocolates, and beer.
- Decrease protein and salt intake.
- Lowering calcium intake is inadvisable and may even increase urine calcium excretion.
- Increase phytate-rich foods such as natural dietary bran, legumes and beans, whole cereal.
- Avoid excessive vitamin C and/or vitamin D.

**PROGNOSIS**

- Spontaneous stone passage depends on stone location (proximal vs. distal) and stone size (<5 mm, 90% pass; >8 mm, 10% pass).
- Stone recurrence: 50% of patients at 10 years

**REFERENCES**

**ADDITIONAL READING**

SEE ALSO

CODES

**ICD10**
- N20.9 Urinary calculus, unspecified
- N20.0 Calculus of kidney
- N20.1 Calculus of ureter

**CLINICAL PEARLS**
- Incidence in industrialized countries seems to be increasing, probably due to improved diagnostics as well as to increasingly rich diets.
- Vesical calculosis (bladder stones) due to malnutrition during early life is frequent in Middle East and Asian countries.
- Medical expulsive therapy: $\alpha_1$-Antagonists (e.g., terazosin) and calcium channel blockers (e.g., nifedipine) improve likelihood of spontaneous stone passage with NNT of $\sim$5.
- Increased fluid intake for life cannot be overemphasized for decreasing recurrence. Encourage 2 to 3 L/day intake; advise patient to have clear urine rather than yellow.
- Patients who form calcium stones should minimize high-oxalate foods such as green leafy vegetables, rhubarb, peanuts, chocolates, and beer.
- Decrease protein and salt intake.
- Lowering calcium intake is inadvisable and may even increase urine calcium excretion.
URTICARIA

Todd A. Wical, DO • Katie L. Westerfield, DO, IBCLC, FAAFP

BASICS

DESCRIPTION

- A cutaneous lesion or lesions involving edema of the epidermis and/or dermis presenting with rapid onset and pruritus, returning to normal skin appearance within 24 hours
- Pathophysiology is primarily mast cell degranulation and subsequent histamine release.
- Angioedema may occur with urticaria which is characterized by sudden pronounced erythematous nonpitting edema of the lower dermis and subcutis; may take up to 72 hours to remit.
- Pruritus and burning are more commonly associated with urticaria; pain more often with angioedema
- Lesions can occur on any part of the body.

Urticaria can be classified as acute or chronic.
- Acute: if lesions recur within <6 weeks
- Chronic: recurring lesions that persist for >6 weeks

Three main causal categories of urticarial lesions
- Immunoglobulin E (IgE) mediated
- Non-IgE immunologically mediated
- Nonimmunologically mediated

Underlying etiology may be difficult to pinpoint, although in some cases possible.
For those with chronic urticaria, 40% have concurrent angioedema.
Etiology of urticaria is either spontaneous or induced.
System(s) affected: integumentary
Synonym(s): hives; wheals

EPIDEMIOLOGY

Incidence

- Equally distributed across all ages: female > male (2:1 in chronic urticaria)
In 20% of patients, chronic urticaria lasts >10 years.

**Prevalence**
- 5–25% of the population
- Of people with urticaria, 40% have no angioedema, 40% have urticaria and angioedema, and 20% have angioedema with no urticaria.
- Up to 3% of the population has chronic idiopathic urticaria.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Mast cell degranulation with release of inflammatory reactants, which leads to vascular leakage, inflammatory cell extravasation, and dermal (angioedema) and/or epidermal (wheals/hives) edema
- Histamine, cytokines, leukotrienes, and proteases are main active substances released.
- If release of histamine and other mediators occurs in the dermis, urticaria lesions result. If release occurs deep in the dermis, then angioedema develops.
- Acute spontaneous urticaria (ASU)
  - Bacterial infections: strep throat, sinusitis, otitis, urinary tract
  - Viral infections: rhinovirus, rotavirus, hepatitis B, mononucleosis, herpes
  - Foods: peanuts, tree nuts, seafood, milk, soy, fish, wheat, and eggs; tend to be IgE-mediated; pseudoallergenic foods such as strawberries, tomatoes, preservatives, and coloring agents contain histamine.
  - Drugs: IgE-mediated (e.g., penicillin and other antibiotics), direct mast cell stimulation (e.g., aspirin, NSAIDs, opiates)
  - Inhalant, contact, ingestion, or occupational exposure (e.g., latex, cosmetics)
  - Parasitic infection; insect bite/sting
  - Transfusion reaction
- Chronic spontaneous urticaria (CSU)
  - Chronic subclinical allergic rhinitis, eczema, and other atopic disorders
  - Chronic indolent infections: *Helicobacter pylori*, fungal, parasitic (*Anisakis simplex*, strongyloidiasis), and chronic viral infections (hepatitis)
  - Collagen vascular disease (cutaneous vasculitis, serum sickness, lupus)
  - Thyroid autoimmunity, especially Hashimoto
  - Hormonal: pregnancy and progesterone
  - Autoimmune antibodies to the IgE receptor α chain on mast cells and to the IgE antibody
  - Chronic medications (e.g., NSAIDs, hormones, ACE inhibitors). NSAID sensitivity demonstrated almost in half of adults with chronic urticaria and
presents with a worsening of symptoms 4 hours after ingestion.
- Malignancy
- Physical stimuli (cold, heat, vibration, pressure) in physical urticaria

- Chronic inducible urticaria (CIU)
  - Dermatographism: “skin writing” or the appearance of linear wheals at the site of any type of irritation. This is the most common physical induced urticaria.
  - Cold urticaria: Wheals occur within minutes of rewarming after cold exposure; 95% idiopathic but can be due to infections (mononucleosis, HIV), neoplasia, or autoimmune diseases.
  - Delayed pressure urticaria: Urticaria occurs 0.5 to 12 hours after pressure to skin (e.g., from elastic or shoes), may be pruritic and/or painful, and may not subside for several days.
  - Solar urticaria: from sunlight exposure, usually UV; onset in minutes; subsides within 2 hours
  - Heat urticaria: from direct contact with warm objects or air; rare
  - Vibratory urticaria/angioedema: very rare; secondary to vibrations (e.g., motorcycle)
  - Cholinergic urticaria: due to brief increase of core body temperature from exercise, baths, or emotional stress. This is the second most common induced urticaria.
  - Adrenergic urticaria: caused by stress; extremely rare; vasoconstricted, blanched skin around pink wheals as opposed to cholinergic’s erythematous surrounding
  - Contact urticaria: wheals at sites where chemical substances contact the skin, may be either IgE-dependent (e.g., latex) or IgE-independent (e.g., stinging nettle)
  - Aquagenic and solar urticaria: small wheals after contact with water of any temperature or UV light, respectively; rare

**Genetics**
No consistent pattern known: Chronic urticaria has increased frequency of HLA-DR4 and HLA-D8Q MHC II alleles.

**COMMONLY ASSOCIATED CONDITIONS**
- Angioedema (common)
- Anaphylaxis (somewhat common)
DIAGNOSIS

HISTORY
Rapid onset; individual lesions resolve in <24 hours, pruritus

alert
Important to rule out underlying anaphylaxis in those patients presenting with acute onset of urticaria (1,2)[C]

physical exam
- Single/multiple raised, polymorphic indurated plaques with central pallor and edema with an erythematos flare
- Evaluate for underlying conditions including thyroid abnormalities (nodules), bacterial, viral, or fungal infection (e.g., fever)

Differential diagnosis
- Anaphylaxis (may present with urticaria)
- Morbilliform or fixed drug eruptions
- Erythema multiforme
- Systemic lupus erythematosus (SLE), vasculitis, and polyarteritis
- Angioedema without urticaria
- Urticaria pigmentosa/systemic mastocytosis
- Bullous pemphigoid (urticarial stage)
- Arthropod bite
- Atopic/contact dermatitis
- Viral exanthem

Diagnostic tests & interpretation
- Diagnosis is usually clinical (1,2)[A].
- In general, only if the history or physical are suggestive of a specific underlying disease should targeted laboratory studies be utilized.
- Directed by clinical suspicion of underlying cause:
  - Allergy skin tests and radioallergosorbent test (RAST) for inhaled allergens, insects, drugs, or foods
  - Infection: Consider pharyngeal culture, LFTs, mononucleosis test, urinalysis in appropriate setting.
- Chronic urticaria (CIU/CSU): Extensive lab testing is not indicated and has not proven to improve outcome nor is it cost-effective. Limit lab testing
according to clinical history and indication. Skin or IgE testing should be limited to specific history of provoking allergen (3)[C].
- CBC, ESR, and CRP are recommended by most guidelines.
- Thyroid function tests, LFTs, and urinalysis are recommended by several guidelines.
- Consider allergy skin tests and RAST for inhaled allergens, insects, drugs, or foods; total IgE level.
- Autoimmune: ESR, ANA, RF, complement (e.g., CH50, C3, C4), cryoglobulins in urticarial vasculitis
- Tests for *H. pylori* (e.g., antibodies) in dyspeptic patients. Consider stool for ova and parasites in at-risk individuals.
- Autologous serum skin testing: injection of serum under skin to test for presence of IgE receptor–activating antibodies
- Consider malignancy workup, including serum protein electrophoresis and immunofixation in the proper setting.

- Use the urticaria activity score (UAS7) for assessing CSU.
- Recently was developed urticaria control test (UCT)
  - The tool to assess disease control in patients with chronic urticaria (spontaneous and inducible) (4)[A]

**Diagnostic Procedures/Other**

- Food and drug reactions: elimination of (or challenges with) suspected agents
- Physical and special forms of urticaria: challenge tests:
  - Dermatographism: Stroke skin lightly with rounded object and observe for surrounding urticaria.
  - Cold urticaria: ice cube test: Place ice cube on skin for 5 minutes; observe for 10 to 15 minutes.
  - Cholinergic: Exercise to the point of sweating/partial immersion in 42°C bath for 10 minutes.
  - Solar: exposure to different wavelengths of light
  - Delayed pressure: Apply 5-lb sandbag to back for 20 minutes; observe 6 hours later.
  - Aquagenic: Apply water at various temperatures.
  - Vibratory: Apply vibration 4 to 5 minutes with a lab mixing device; observe.

- Skin biopsy with lesions lasting >24 hours or if concern for underlying vasculitis (1,2)[A]
TREATMENT

ISSUES FOR REFERRAL
Referral to an allergist, immunologist, or dermatologist for recalcitrant cases, especially if lesions consistently remain present for >24 hours

GENERAL MEASURES
The mainstay of therapy for urticaria is the avoidance of identified trigger(s).

MEDICATION

First Line
2nd-generation antihistamine (H₁) blockers are the first-line treatment of any urticaria in which avoidance of stimulus is impossible or not feasible (1,2)[A]:
- Fexofenadine (Allegra): 180 mg/day
- Loratadine (Claritin): 10 mg/day, increasing to 30 mg/day if needed; only medication studied for safe use in pregnancy
- Desloratadine (Clarinex): 5 mg/day (5)[A]
- Cetirizine (Zyrtec): 10 mg/day, increasing to 30 mg per day if needed
- Levocetirizine (Xyzal): 5 mg/day; requires weight-based dosing in children (5)[A]
- Rupatadine: novel H₁ antagonist with antiplatelet-activating factor activity

Second Line
Doubling the typical 2nd-generation H₁ blocker dosages should be attempted before adding 1st-generation H₁ or H₂ blockers (1,2,5)[A].
- H₂-specific antihistamines (beneficial as adjuvants): cimetidine, ranitidine, nizatidine, famotidine
- 1st-generation antihistamines (H₁; for patients with sleep disturbed by itching):
  - Older children and adults: hydroxyzine or diphenhydramine 25 to 50 mg q6h
  - Children <6 years of age: diphenhydramine 12.5 mg q6–8h (5 mg/kg/day) or hydroxyzine (10 mg/5 mL) 2 mg/kg/day divided q6–8h

Geriatric Considerations
1st-generation H₁ blockers may cause excessive drowsiness as well as dry mouth and eyes.

**Third Line**
- Corticosteroids: prednisolone 20 to 50 mg/day for max of 10 days; best used only for exacerbations; avoid chronic use (1,2)[C].
- Doxepin: tricyclic antidepressant with strong H₁- and H₂-blocking properties; 10 to 30 mg at bedtime; sedation limits usefulness (1)[C].
- Leukotriene antagonists (montelukast, zileuton, and zafirlukast): safe and worth trying in chronic, unresponsive cases; useful alone but best used in addition to antihistamines; limited data on use in treating acute urticaria.
- Refractory symptoms
  - Omalizumab: anti-IgE; effective, expensive. 150 to 300 mg SQ q2–4wk. Restricted to allergists and those who can manage acute anaphylaxis (1,6) [A], significantly reduce the urticarial symptoms of CIU/CSU at 12 weeks. The best effect is reached with omalizumab dose 300 mg (6)[A]. Omalizumab is currently the only licensed treatment for H₁-antihistamine-refractory CSU, has a favorable risk/benefit ratio, and was well tolerated in clinical studies.
  - Cyclosporine: well-studied, effective (2.5 to 5 mg/kg/day); best used in combination with antihistamines; significant renal side effects (1)[B],(2)[C]
  - Methotrexate: antifolate; proven useful in recalcitrant cases; GI upset most common complaint; long-term requires LFT monitoring.
  - UV therapy decreases number of mast cells; has shown promise in the treatment of mastocytosis-induced urticaria (2)[C]
- Adding Vitamin D 4,000 U/day for 12 weeks may decrease the symptoms and USS score.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Educating patient on use of EpiPen as pathophysiology is similar to anaphylaxis; if the airway is threatened, immediate consultation to evaluate for laryngeal edema and need for definitive airway management

**ONGOING CARE**
PROGNOSIS

- Resolution of acute symptoms: 70% <72 hours
- Chronic urticaria: 35% symptom-free in a year; another 30% will see symptom reduction

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**
- L50.9 Urticaria, unspecified
- L50.1 Idiopathic urticaria
- L50.8 Other urticaria

**CLINICAL PEARLS**
- Urticaria occurs rapidly and individual lesions resolve within 24 hours, although multiple crops of lesions can occur in stages.
- Mainstay of therapy is to avoid identified triggers.
- Antihistamines are the best studied and most efficacious therapy but may require higher-than-normal doses for efficacy.
- If individual lesions last >24 hours, patient should be evaluated for urticarial vasculitis and other more serious diagnoses.
UTERINE AND PELVIC ORGAN PROLAPSE

Maryse A. Pedoussaut, MD • John Delzell Jr., MD, MSPH • Suzanne Minor, MD, FAAFP

BASICS
DESCRIPTION
- Symptomatic descent of one or more of (1,2)
  - The anterior vaginal wall (bladder or cystocele)
  - The posterior vaginal wall (rectum or rectocele)
  - The apex of the vagina (uterine cervix descent and prolapse)
  - The vault (cuff) after hysterectomy (vault prolapse)
- Prolapses above or to the hymen are not symptomatic (2).
- Associated symptoms (2)
  - Feeling of vaginal or pelvic pressure
  - Heaviness
  - Bulging
  - Bowel or bladder symptoms
- Cost associated with treatment is >$1 billion annually (~200,000 surgeries/year) (2).

EPIDEMIOLOGY
Incidence
Pelvic organ prolapse (POP) is common but not always symptomatic. It does not always progress with time. In a 3-year prospective cohort study of 249 women, prolapse increased by at least 2 cm in 11% and regressed by 2 cm in 3% (2).

Prevalence
- A national survey of 7,924 women (>20 years of age) found a prevalence of 25% for one or more pelvic floor disorders (including urinary incontinence, fecal incontinence, and POP). Prevalence of POP was 2.9%.
- The prevalence of lower urinary tract symptoms is as high as 50% in parous women. 11% of all women have surgery for POP or lower urinary tract symptoms by 80 years old.
● 3–6% of women who present for gynecologic care have a prolapse beyond hymen (2).

ETIOLOGY AND PATHOPHYSIOLOGY
● Insidious process begins long before symptoms develop.
● There is a complex interaction between the pelvic floor musculature, connective tissue, and the vaginal wall, which provides support from the perineum to the sacrum (2). Integrity of levator ani is essential to this support system by providing a platform on which the pelvic organs rest (2).
● Symptomatic women typically have multiple defects, including laxity of supporting tissue and damage to the levator ani (2).
● Half of anterior prolapse can be attributed to apical descent of the vagina (2).

RISK FACTORS
● Vaginal childbirth (2): Women who have delivered two children vaginally have a relative risk of 8.4 and every additional child (up to five deliveries) increases the risk of prolapse by 10–20% (2).
● Age: Every 10 years of age increases the risk of prolapse by 40% (2). POP will become more prevalent, as the elderly population is expected to double by 2030 (3).
● Obesity: BMI >25 may increase the risk of developing prolapse (2).
● Constipation: independent risk factor in a survey of >2,000 women (2)
● Race: White and Hispanic women may be at higher risk than black or Asian women (2).
● Occupation (heavy lifting): variable support in the literature (2)
● Hysterectomy: variable support in the literature (2)
● Obstetric factors (operative delivery, infant weight, length of pushing in second stage of labor): variable support in the literature (2)

GENERAL PREVENTION
There is some evidence that pelvic floor muscle training (“Kegel exercises”) may decrease the risk of symptomatic POP (4)[B]. Weight loss and proper management of conditions that cause increase in intra-abdominal pressure may help prevent the problem.

COMMONLY ASSOCIATED CONDITIONS
● Urinary incontinence
● Other urinary symptoms
– Urgency
– Frequency

**DIAGNOSIS**

**HISTORY**

- Less than half of women discuss symptoms with PCP. Only 10–12% seek medical attention. Barriers include embarrassment, social stigma, ability to cope, belief that POP is part of the aging process, belief that treatment options are limited, and fear of surgery.
- Common symptoms include the following:
  - Feeling a bulge in vagina
  - Something “falling out” of vagina
  - Pelvic pressure
  - Difficulty with voiding or defecation
  - Urgency
  - Frequency
  - Incontinence (urinary or fecal)
  - Constipation
- Document the presence, duration, and severity of urinary, bowel, or prolapse symptom. Assess impact on sexual function and quality of life with validated questionnaires (PISQ 9 OR 12) (1,5).
- Assess past medical history.
  - Gravity and parity/obstetric history
  - History of ascites
  - Chronic constipation
  - Document physical impairment (mobility, dexterity, or visual acuity), as this may affect management (1).
  - Document the patient’s desire, goals, and expectation (1).

**PHYSICAL EXAM**

- Abdominal examination to document any distention or masses
- Complete pelvic and rectal examination. Have patient cough or strain, particularly in an upright (standing) position while examining the distal vagina.
- The gold standard is to measure vaginal descent using the Pelvic Organ Prolapse Quantification (POPQ) scale, which is a scale that describes the
prolapse in relationship to the vaginal hymen \(^2\). The validated simplified version has four measurements with classification in four stages. Patient is supine with the head of the bed at 45 degrees, performing Valsalva.

- **Stage 1**: prolapse in which the distal point is superior or equal to 1 cm above hymen
- **Stage 2**: prolapse in which the distal point is between 1 cm above and 1 cm below hymen
- **Stage 3**: prolapse in which the distal point is superior or equal to 1 cm below the hymen, but some vaginal mucosa is not everted
- **Stage 4**: complete vaginal vault eversion (“procidentia”); entire vaginal mucosa everted \(^2\)

- A split speculum can be used to observe anterior, posterior, and apical parts of the vagina successively.
- Patient should be standing for maximum descent \(^2\).

**DIFFERENTIAL DIAGNOSIS**

- Rectal prolapse
- Hemorrhoids
- Bartholin cyst
- Cervical elongation

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Urinalysis if symptomatic POP \(^1\)
- Renal function (serum creatinine) if urinary incontinence and probability of renal impairment \(^1\)
- Imaging: not routinely recommended \(^1\)

**Follow-Up Tests & Special Considerations**

- Postvoid residual if patient has urinary incontinence
- Urodynamic testing prior to invasive treatment or after treatment failure to plan further therapy \(^1\)
- Imaging of upper urinary tract if hematuria or back pain \(^1\)
- Cystoscopy recommended if patient has hematuria, pain, or discomfort suggesting bladder lesion \(^1\)
- Colonoscopy or sigmoidoscopy if patient has fecal incontinence \(^1\)
- Colonoscopy, air contrast barium enema, and/or computed tomography if change in bowel habits or rectal bleeding \(^1\)
TREATMENT

GENERAL MEASURES

- Treatment should take into account type and severity of symptoms, patient’s age, other comorbid conditions, sexual function, infertility, and risk of recurrence.
- Treatment for asymptomatic patients:
  - Stage 1 or 2: clinical observation (2)
  - Stage 3 or 4: regular follow-up and evaluation (every 6 to 12 months) (2)
- Treatment is indicated when there is urinary/bowel obstruction or hydronephrosis regardless of the degree of prolapse (2).
- A vaginal pessary should be considered in all women presenting with symptomatic prolapse.
  - There are >13 types of silicone devices that may be inserted into the vagina to support the pelvic organs.
  - The most commonly used pessaries are the ring pessary and Gellhorn.
  - They may prevent prolapse progression and may prove to be an appropriate prevention strategy in the future because the surgical failure rate is around 30% (2).
  - Most women can be successfully fitted with a pessary.
  - Satisfaction rate for patients using pessaries is very high.
- Complications may be seen with neglected pessaries, such as erosions, abrasions, ulcerations, and vaginal bleeding. Minor complications such as vaginal discharge and odor can be treated without discontinuing pessary use. Vaginal erosion can be treated by removal of pessary and optional vaginal estrogen supplementation.

MEDICATION

First Line

- Treatment of vaginal atrophy with topical estrogens may be beneficial for symptomatic POP (6)[B] if there are no contraindications; suggested to use in conjunction with pelvic floor muscle training (6)

Vaginal creams
  - Estradiol cream 0.01% (Estrace)
  - Conjugated estrogens 0.625 mg/day (Premarin)

Vaginal tablet
  - Estradiol 10 μg (Vagifem)
- Vaginal ring
  - Estradiol 2 mg (Estring)

**ISSUES FOR REFERRAL**
Referral when pessary or surgery is necessary

**ADDITIONAL THERAPIES**
Pelvic floor muscle training: may reduce the symptoms of POP (1). Pelvic floor muscle training does not affect the degree of prolapse, only the symptoms (1).

**SURGERY/OTHER PROCEDURES**
- Reconstructive procedures are done with the goal of restoration of vaginal anatomy.
- Reconstructive surgery is associated with a high rate of failure (1 in 3 lifetime risk of repeat surgery). New procedures, using surgical mesh and graft material, have higher success rates but limited follow-up or comparative data (2).

> Abdominal procedures such as sacral colpopexy using graft material have a higher success rate but a longer operating time, longer time to return to normal activity levels, and an increased cost (7)[B]. There may be resulting problems with sexual function and bladder/bowel complaints (2).

**ONGOING CARE**

**PATIENT EDUCATION**
- Patients should be educated about pessary complications and possible symptoms of POP if they are still asymptomatic.
- Limit caffeine product and bladder irritants if urinary symptoms.
- Using insoluble fibers may help patients with bowel complaints such as constipation.

**COMPLICATIONS**
- There is a risk of vaginal mesh extrusion, erosions, dyspareunia, and pelvic pain after surgical repair (8).
- Delays in diagnosis
  - 61% reported POP symptoms to a physician.
  - 65.9% blamed themselves for the delay (fear of surgery, embarrassment).
– 1/3 of women blame their physician for the delay in diagnosis.

REFERENCES

CODES

ICD10

- N81.9 Female genital prolapse, unspecified
- N81.10 Cystocele, unspecified
- N99.3 Prolapse of vaginal vault after hysterectomy

CLINICAL PEARLS

- Many women do not discuss POP with their doctor—ask routinely.
- Vaginal pessary should be considered in all patients with symptomatic prolapse.
- Traditional surgical treatment has a high long-term failure rate (1 in 3).
UTERINE MYOMAS

Christina N. Kufel, DO, MS • Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION

- Uterine leiomyomas are well-circumscribed, pseudoencapsulated, benign monoclonal tumors composed mainly of smooth muscle with varying amounts of fibrous connective tissue (1).
- Three major subtypes
  - Subserous: common; external; may become pedunculated
  - Intramural: common; within myometrium; may cause marked uterine enlargement
  - Submucous: ~5% of all cases; internal, evoking abnormal uterine bleeding and infection; occasionally protruding from cervix
- Rare locations: broad, round, and uterosacral ligaments
- System affected: reproductive
- Synonym(s): fibroids; myoma; fibromyoma; myofibroma; fibroleiomyoma

EPIDEMIOLOGY

Incidence

- Cumulative incidence up to 80%
  - 60% in African American women by age 35 years; 80% by age 50 years
  - 40% in Caucasian women by age 35 years; 70% by age 50 years (1–3)
- Incidence increases with each decade during reproductive years.
- Rarely seen in premenarchal females
- Predominant sex: females only

ETIOLOGY AND PATHOPHYSIOLOGY

- Enlargement of benign smooth muscle tumors that may lead to symptoms affecting the reproductive, GI, or genitourinary system
- Complex multifactorial process involving transition from normal myocyte to abnormal cells and then to visibly evident tumor (monoclonal expansion)
  - Hormones (1): Increases in estrogen and progesterone are correlated with
myoma formation (i.e., rarely seen before menarche). Estrogen receptors in myomas bind more estradiol than normal myometrium.

- **Growth factors (1)**
  - Increased smooth muscle proliferation (transforming growth factor β [TGF-β], basic fibroblast growth factor [bFGF])
  - Increase DNA synthesis (epidermal growth factor [EGF], platelet-derived growth factor [PDGF], activin, myostatin)
  - Stimulate synthesis of extracellular matrix (TGF-β)
  - Promote mitogenesis (TGF-β, EGF, insulin-like growth factor [IGF], prolactin)
  - Promote angiogenesis (bFGF, vascular endothelial growth factor [VEGF])

- Vasoconstrictive hypoxia (1): proposed, but not confirmed, mechanism of myometrial injury during menstruation

**Genetics**
- A variety of somatic chromosomal rearrangements have been described in 40% of uterine myomas.
  - Mutations in the gene encoding mediator complex subunit 12 (MED12) on the X chromosome were found in 70% of myomas in one study (2).
- Higher levels of aromatase and therefore estrogen have been found in myomas in African American women (2).

**RISK FACTORS**
- African American heritage
  - 2.9 times greater risk than Caucasian women; occur at a younger age, are more numerous, larger, and more symptomatic (1,3)
- Early menarche (<10 years)
- Oral contraceptive use before 16 years old (3)
- Nulliparous
- Hypertension
- Familial predisposition
  - 2.5 times more likely in women with a first-degree relative with myomas (1)
- Obesity
  - Risk increases by 21% with each 10 kg of weight gain (1).
- Alcohol
- Risk decreased by parity, progesterone-only contraceptives, diet (fruits, veggies, low fat dairy) (3)
COMMONLY ASSOCIATED CONDITIONS
Endometrial and breast cancer also associated with high, unopposed estrogen stimulation

DIAGNOSIS

HISTORY
- Usually asymptomatic; 30% present with abnormal symptoms—usually enlarged uterus or heavy bleeding.
- Symptoms include the following:
  - Abnormal uterine bleeding: usually heavy/prolonged menses
  - Pain: infrequent; usually associated with torsion of pedunculated myoma, degeneration, or cervical dilation by submucous myoma near cervical os
  - Pressure on bladder: suprapubic discomfort, urinary frequency/obstruction
  - Pressure on rectosigmoid: may cause low back pain, constipation
  - Infertility: rare, estimated 1–2.5%; usually from submucous myoma distorting the uterine cavity or interference with implantation

ALERT
Rapid growth, particularly in perimenopausal/postmenopausal patients; may indicate sarcoma; extremely rare, 0.1–0.3% of cases

PHYSICAL EXAM
- Usually incidental finding on abdominal and pelvic exam
- Firm, smooth nodules/masses arising from uterus
- Masses are mobile without tenderness.

DIFFERENTIAL DIAGNOSIS
- Intrauterine pregnancy
- Cancer, including ovarian, uterine, or leiomyosarcoma
- Cecal/sigmoid tumor
- Appendiceal abscess
- Diverticulitis
- Pelvic kidney
- Urachal cyst

DIAGNOSTIC TESTS & INTERPRETATION
**Initial Tests (lab, imaging)**
- Pregnancy test
- Hemoglobin
- Pelvic ultrasound: standard confirmatory test; shows characteristic hypoechoic appearance (3,4)
- Saline infusion hysterosonography: helps to distinguish submucosal myomas
- Hysterosalpingogram: evaluates the contour of the endometrial cavity (4)
- CT scan or MRI: provides info on degeneration and special relationships (3); may help to differentiate complex cases or used when uterine artery embolization is planned (4)[B]

**Follow-Up Tests & Special Considerations**
Consider cancer antigen 125 (CA-125): may be slightly elevated in some cases of uterine myoma but generally more useful in differentiating myomas from various gynecologic adenocarcinomas
- IV pyelogram: if suspect ureteral distortion (4)
- Barium enema

**Diagnostic Procedures/Other**
- Fractional dilation and curettage: aids in ruling out cervical/uterine carcinomas when clinically suspicious
- Hysteroscopy: helps to diagnose submucosal/intracavitary myomas
- Laparoscopy: useful in complex cases and to rule out other pelvic diseases/disorders

**Test Interpretation**
- Myomas are usually multiple and vary in size and location; have been reported up to 100 lb
- Gross pathology: firm tumors with characteristic whorl-like trabeculated appearance; a thin pseudocapsular layer is present.
- Microscopic: bundles of smooth muscle mixed with varying amounts of connective tissue elements running in different directions
- Cellular variant has a preponderance of muscle cells. Mitoses are rare.
- May undergo various types of degeneration
  - Hyaline degeneration: very common
  - Calcification: late result of circulatory impairment to myomas
  - Infection and suppuration: most common with submucosal myomas
  - Necrosis: most common with pedunculated myomas secondary to torsion
**TREATMENT**

- Treatment must be individualized and based on symptoms, fertility desires, and time until menopause.
- Medical therapy may be of benefit.
- Patients with minimal symptoms may be treated with iron preparations and analgesics.
- Conservative management of asymptomatic myomas
  - Pelvic exams and ultrasounds at ≥3-month intervals if size remains stable
  - Substantial regression usually occurs after menopause.
- Surgical options should be considered if symptomatic or worrisome myomas are unresponsive to conservative/medical management.

**GENERAL MEASURES**

Patients not desiring pharmacologic therapy or surgery may consider the following:

- Uterine artery embolization: averages 50% shrinkage of myomas (5)[A]; painful and may cause ovarian failure (1–2%), amenorrhea, postembolization syndrome, or other complications; shorter hospital stay and quicker recovery but no difference in satisfaction compared with hysterectomy (3)[B]; high reintervention rate (15–32% by 2 years) compared to hysterectomy/myomectomy (7% by 2 years) (5)
- MR-guided focused ultrasound (MRgFUS): noninvasive, ultrasound transducer passes through abdominal wall and causes coagulative necrosis of fibroid; up to 98% reduction in myoma volume and symptoms. Not appropriate for some types of myomas. Efficacy may be comparable with other hysterectomy-sparing procedures. Fertility has been shown to be preserved (3)[A] although risks and outcomes data are limited (3).

**MEDICATION**

- Progestins may reduce overall uterine size (4)[B].
  - Norethindrone 10 mg/day
  - Medroxyprogesterone 200 mg IM monthly
  - Levonorgestrel intrauterine device
- Combination oral contraceptives: may help prevent development of new fibroids and control bleeding
  - Contraindications: history of thromboembolic events
- Gonadotropin-releasing hormone agonists
- Nafarelin (nasal spray), goserelin acetate, and leuprolide
- Induces abrupt artificial menopause; may reduce myoma symptoms dramatically; induces atrophy of myomas by up to 40% in 2 to 3 months (4)[B]
- May be valuable as preoperative adjunct to myomectomy/hysterectomy by allowing recovery of anemia, donation of autologous blood, and possibly converting abdominal to vaginal hysterectomy (3,4,6)[B]
- Not recommended for use >6 months because of osteoporosis risk
- Following discontinuation, myomas return within 60 days to pretherapy size.

- Antiprogesterones
  - Mifepristone
    - Shown to have similar reduction in myoma size as gonadotropin-releasing hormone agonists
  - Decreases heavy bleeding and increases quality of life (7)[A]
  - Selective progesterone receptor modulator (SPRM)
    - Ulipristal acetate: may be as effective as gonadotropin-releasing hormones with fewer side effects (3)[B]

**ISSUES FOR REFERRAL**
- Medical therapy may be initiated by a primary care physician/gynecologist after adequate pelvic examination.
- Surgical considerations may be pursued with gynecologic consultation.
- Uterine embolization may be discussed with an interventional radiologist.

**SURGERY/OTHER PROCEDURES**
- Surgical management is indicated in the following situations (4)[B]:
  - Excessive uterine size or excessive rate of growth (except during pregnancy)
  - Submucosal myomas when associated with hypermenorrhea
  - Pedunculated myomas that are painful or undergo torsion, necrosis, and hemorrhage
  - If a myoma causes symptoms from pressure on bladder/rectum
  - If differentiation from ovarian mass is not possible
  - If associated pelvic disease is present (endometriosis, pelvic inflammatory disease)
  - If infertility/habitual abortion is likely due to the anatomic location of the myoma
- Surgical procedures
  - Preliminary pelvic examination, Pap smear, and endometrial biopsy should be performed to rule out malignant/premalignant conditions.
  - Hysterectomy: may be performed vaginally, laparoscopically, robotically, or by laparotomy
    - Effective in relieving symptoms and improving quality of life (3)[B]
    - Similar fertility and live birth rates between laparoscopic and abdominal myomectomy
    - FDA discourages the use of laparoscopic power morcellation during hysterectomy or myomectomy for uterine fibroids given the risk of spreading an occult malignancy and all patients should be counseled preoperatively of risk (3).
    - Abdominal, laparoscopic, robotic, or hysteroscopic myomectomy may be performed in younger women who want to maintain fertility (4,8)[B].
    - Hysteroscopic/laparoscopic cautery/laser myoma resection can be performed in selected patients.
    - Endometrial ablation: for small submucosal myomas

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Usually outpatient
- Inpatient for some surgical procedures

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Pelvic examination and ultrasound: every 2 to 3 months for newly diagnosed symptomatic/excessively large myomas
- Hemoglobin and hematocrit: if uterine bleeding is excessive
- Once uterine size and symptoms stabilize, monitor every 6 to 12 months although no high-quality evidence exists (3).

**DIET**
No restrictions
PATIENT EDUCATION

- Society of Interventional Radiology: http://sirweb.org/patients/uterine-fibroids/
- American Congress of Obstetricians and Gynecologists: http://www.acog.org

PROGNOSIS

- Resection of submucosal fibroids has been associated with increased fertility.
- At least 10% of myomas recur after myomectomy; however, only 25% require further treatment (3)[B].

COMPLICATIONS

- May mask other gynecologic malignancies (e.g., uterine sarcoma, ovarian cancer)
- Degenerating fibroids may cause pain and bleeding.
- May rarely prolapse through the cervix

Pregnancy Considerations

- Rapid growth of fibroids is common.
- Pregnant women may need additional fetal testing if placenta is located over or near fibroid.
- Complications during pregnancy: abortion, premature labor, 2nd-trimester rapid growth leading to degeneration/pain, 3rd-trimester fetal malpresentation, and dystocia during labor and delivery
- Cesarean section is recommended if the endometrial cavity was entered during myomectomy due to increased risk of uterine rupture.

Geriatric Considerations

Postmenopausal patients with newly diagnosed uterine myoma/enlarging uterine myomas have a high suspicion of uterine sarcoma/other gynecologic malignancy.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**
- D25.9 Leiomyoma of uterus, unspecified
- D25.2 Subserosal leiomyoma of uterus
- D25.1 Intramural leiomyoma of uterus

**CLINICAL PEARLS**
- Uterine myomas are benign smooth muscle tumors composed mainly of fibrous connective tissue.
- Usually incidental finding on pelvic exam or ultrasound but may cause pelvic pain and pressure, abnormal uterine bleeding, and/or infertility
- Management ranges from conservative to medical to surgical.
UVEITIS

Shailendra K. Saxena, MD, PhD • Mikayla L. Spangler, PharmD • Laura K. Klug, PharmD

BASICS
DESCRIPTION
- A nonspecific term used to describe any intraocular inflammatory disorder
- Symptoms vary depending on depth of involvement and associated conditions.
- The uvea is the middle layer of the eye between the sclera and retina. The anterior part of the uvea includes the iris and ciliary body. The posterior part of the uvea is the choroid.
  - Anterior uveitis: refers to ocular inflammation limited to the iris (iritis) alone or iris and ciliary body (iritidocyclitis)
  - Intermediate uveitis: refers to inflammation of the structures just posterior to the lens (pars planitis or peripheral uveitis)
  - Posterior uveitis: refers to inflammation of the choroid (choroiditis), retina (retinitis), or vitreous near the optic nerve and macula
- System(s) affected: nervous
- Synonym(s): iritis; iridocyclitis; choroiditis; retinochoroiditis; chorioretinitis; anterior uveitis; posterior uveitis; pars planitis; panuveitis. Synonyms are anatomic descriptions of the focus of the uveal inflammation.

Geriatric Considerations
The inflammatory response to systemic disease may be suppressed.

Pediatric Considerations
- Infection should be the primary consideration.
- Allergies and psychological factors (depression, stress) may serve as a trigger.
- Trauma is also a common cause in this population.

Pregnancy Considerations
May be of importance in the selection of medications

EPIDEMIOLOGY
- Predominant age: all ages
• Predominant sex: male = female, except for human leukocyte antigen B27 (HLA-B27) anterior uveitis: male > female, autoimmune etiology: female > male

**Incidence**
• Overall prevalence is 38 to 714 cases/100,000 annual incidence.
• Anterior uveitis is the most common.

**Prevalence**
Iritis is 4 times more prevalent than posterior uveitis.

**ETIOLOGY AND PATHOPHYSIOLOGY**
• Infectious: may result from viral, bacterial, parasitic, or fungal etiologies
• Suspected immune-mediated: possible autoimmune or immune-complex-mediated mechanism postulated in association with systemic (especially rheumatologic) disorders
  – Autoimmune uveitis (AIU) patients should be referred to an ophthalmologist for local treatment.
• Isolated eye disease
• Idiopathic (~25%)
• Some medications may cause uveitis. The most causative medications include rifabutin, bisphosphonates, sulfonamides, metipranolol, topical corticosteroids, brimonidine, prostaglandin analogs, anti-vascular endothelial growth factor (VEGF) agents, bacillus Calmette-Guérin (BCG) vaccination, and systemic and intraocular cidofovir.
• Masquerade syndromes: diseases such as malignancies that may be mistaken for primary inflammation of the eye

**Genetics**
• No specific pattern for uveitis in general
• Iritis: 50–70% are HLA-B27–positive.
• Predisposing gene for posterior uveitis associated with Behçet disease may include HLA-B51.

**RISK FACTORS**
• No specific risk factors
• Higher incidence is seen with specific associated conditions.
COMMONLY ASSOCIATED CONDITIONS

- Viral infections: herpes simplex, herpes zoster, HIV, cytomegalovirus, congenital Zika virus
- Bacterial infections: brucellosis, leprosy, leptospirosis, Lyme disease, propionibacterium infection, syphilis, tuberculosis (TB), Whipple disease
- Parasitic infections: acanthamebiasis, cysticercosis, onchocerciasis, toxocariasis, toxoplasmosis
- Fungal infections: aspergillosis, blastomycosis, candidiasis, coccidiodomycosis, cryptococcosis, histoplasmosis, sporotrichosis
- Suspected immune-mediated: ankylosing spondylitis, Behçet disease, Crohn disease, drug or hypersensitivity reaction, interstitial nephritis, juvenile rheumatoid arthritis, Kawasaki disease, multiple sclerosis, psoriatic arthritis, Reiter syndrome, relapsing polychondritis, sarcoidosis, Sjögren syndrome, systemic lupus erythematosus, ulcerative colitis, vasculitis, vitiligo, Vogt-Koyanagi (Harada) syndrome
- Isolated eye disease: acute multifocal placoid pigmentary epitheliopathy, acute retinal necrosis, birdshot choroidopathy, Fuchs heterochromic cyclitis, glaucomatocyclitic crisis, lens-induced uveitis, multifocal choroiditis, pars planitis, serpiginous choroiditis, sympathetic ophthalmia, trauma
- Masquerade syndromes: leukemia, lymphoma, retinitis pigmentosa, retinoblastoma

DIAGNOSIS

HISTORY

- Decreased visual acuity
- Pain, photophobia, blurring of vision (1)[C]
  - Usually acute
- Anterior uveitis (~80% of patients with uveitis) (1)[C]
  - Generally acute in onset
  - Deep eye pain
  - Photophobia (consensual)
- Intermediate and posterior uveitis (2)
  - Unresolving floaters
  - Generally insidious in onset
  - More commonly bilateral
PHYSICAL EXAM
Slit-lamp exam and indirect ophthalmoscopy are necessary for precise diagnosis (1)[C].

- Anterior uveitis (~80% of patients with uveitis)
  - Conjunctival vessel dilation
  - Perilimbal (circumcorneal) dilation of episcleral and scleral vessels (ciliary flush)
  - Small pupillary size of affected eye
  - Hypopyon or hyphema (WBCs or RBCs pooled in the anterior chamber)
  - Frequently unilateral (95% of HLA-B27–associated cases); if first occurrence and otherwise asymptomatic, no further diagnostic testing is needed (1)[C].
  - Bilateral involvement and systemic symptoms (fever, fatigue, abdominal pain) may be associated with interstitial nephritis (1)[C].
  - Systemic disease is most likely to be associated with anterior uveitis (in one study, 53% of patients were found to have systemic disease) (1)[C].

- Intermediate and posterior uveitis
  - More commonly bilateral
  - Posterior inflammation will generally cause minimal pain or redness unless associated with an iritis.

DIFFERENTIAL DIAGNOSIS
- Acute angle-closure glaucoma
- Conjunctivitis
- Episcleritis
- Keratitis
- Scleritis

DIAGNOSTIC TESTS & INTERPRETATION
No specific test for the diagnosis of uveitis. Tests for etiologic factors or associated conditions should be based on history and physical exam (1)[C].

Initial Tests (lab, imaging)
- CBC, BUN, creatinine (interstitial nephritis) (1)[C]
- HLA-B27 typing (ankylosing spondylitis, Reiter syndrome) (1)[C]
- Antinuclear antibody, ESR (systemic lupus erythematosus, Sjögren syndrome) (1)[C]
- Venereal disease research laboratory (VDRL) test, fluorescent titer antibody
(syphilis) (1)[C]
- Fluorescent treponemal antibody absorption (FTA-ABS) or microhemagglutination assay for antibodies to *Treponema pallidum* (MHA-TP) (1)[C]
- Purified protein derivative (PPD) tuberculin skin test (TB) (1)[C]
- Lyme serology (Lyme disease) (1)[C]
- Disorders that may alter lab results: immunodeficiency
- Chest x-ray (sarcoidosis, histoplasmosis, TB, lymphoma) (1)[C]
- Sacroiliac radiograph (ankylosing spondylitis) (1)[C]

**Diagnostic Procedures/Other**
Slit-lamp exam (1)[C]

**Test Interpretation**
- Keratic precipitates
- Inflammatory cells in anterior chamber or vitreous
- Synechiae (fibrous tissue scarring between iris and lens)
- Macular edema
- Perivasculitis of retinal vessels

**TREATMENT**

**GENERAL MEASURES**
- Outpatient care with urgent ophthalmologic consultation
- Medical therapy is best initiated following full ophthalmologic evaluation.
- Treatment of underlying cause, if identified
- Anti-inflammatory therapy

**MEDICATION**

**First Line**
- The treatment depends on the etiology, location, and severity of the inflammation.
- Prednisolone acetate 1% ophthalmic suspension: 2 drops to the affected eye q1h initially, tapering to once a day with improvement
  - Contraindications
    - Hypersensitivity to the medication or component of the preparation
    - Topical corticosteroid therapy is contraindicated in uveitis secondary to
infectious etiologies, unless used in conjunction with appropriate anti-infectious agents.

– Precautions
  o Topical corticosteroids may increase intraocular pressure, increase susceptibility to infections, impair corneal or scleral wound healing, or cause corneal epithelial toxicity or crystalline keratopathy. Prolonged use may cause cataract formation and exacerbate existing herpetic keratitis, which may masquerade as iritis.

– Significant possible interactions

  * Systemic corticosteroids are useful for maintenance therapy for patients with noninfectious uveitis. These should always be used with other immunosuppressive medications for steroid-sparing effects; prednisone 5 to 10 mg daily \(3,4\)[B]

  * Cycloplegic agents may be used to dilate the eye and relieve pain. Agents include scopolamine hydrobromide 0.25% (Isopto Hyoscine) or atropine 1% 1 to 2 drops up to QID or homatropine hydrobromide (Isopto) 2% or 5% 1 to 2 drops BID or as often as q3h if necessary \(1\)[C].

  – Contraindications
    o Cycloplegia is contraindicated in patients known to have, or be predisposed to, glaucoma.

  – Precautions
    o Use extreme caution in infants, young children, and elderly because of increased susceptibility to systemic effects.

**Second Line**

* Anti-inflammatory: prednisolone sodium phosphate 1%, dexamethasone sodium phosphate 0.1%, dexamethasone suspension, rimexolone 1% (Vexol), and loteprednol etabonate 0.5% (Lotemax), difluprednate (Durezol) 0.05\% \(1,4\)[C]
  – Rimexolone 1% (Vexol) may be equally effective as prednisolone acetate 1% for short-term treatment of anterior uveitis \(1\)[C].
  – Loteprednol etabonate (Lotemax) may not be as effective as prednisolone acetate 1% but may be less likely to increase intraocular pressure in cases of acute anterior uveitis.

* Periocular corticosteroids may be injected with triamcinolone acetonide being most commonly used; 40 mg/1 mL \(5\)[C]

* Intravitreous corticosteroid deposits may also be used for long-term maintenance; fluocinolone acetonide (Retisert) 590 \(\mu\)g released >30 months, dexamethasone (Ozurdex) 0.7 mg released slowly >3 to 6 months \(4,5\)[B]
– Retisert has caused all patients to develop cataracts and significant increases in intraocular pressure in about 2/3 of patients, whereas Ozurdex had only 1/4 of patients require medication for increased intraocular pressure and 15% develop cataracts (5)[C].

● Intravitreal corticosteroid injections are used only in severe cases of recurrence; triamcinolone acetonide 4 to 20 mg/0.1 mL, dexamethasone phosphate 0.4 mg/0.1 mL, dexamethasone implant (Ozurdex)
  – Ozurdex has a longer effect than triamcinolone acetonide.

● Immunosuppressive agents including antimetabolites (methotrexate, azathioprine, and mycophenolate mofetil), T-cell inhibitors (cyclosporine, tacrolimus, and sirolimus), and alkylating agents (cyclophosphamide, chlorambucil) may be employed in cases resistant to initial treatment but close monitoring is required (4,5)[C].

● Advancing research suggests benefit of the biologic agents in refractory uveitis. Adalimumab has gained FDA approval for this indication. Some expert panels recommend adalimumab and infliximab as second-line therapy options. Other biologic agents including etanercept, golimumab, secukinumab, and tocilizumab have also been studied.
  – Benefits of biologic therapy include glucocorticoid sparing effects but limitations may include high cost and adverse effect potential (3,4)[C].

● Systemic and ophthalmic preparations of NSAIDs may provide some symptom relief (1)[C].

ISSUES FOR REFERRAL
Caution should be used when using empiric treatment; referral to an ophthalmologist is recommended in most cases.

SURGERY/OTHER PROCEDURES
Various surgical procedures may be used therapeutically for visual rehabilitation, diagnostically, or to manage complications associated with uveitis (6).

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
● Complete history and physical to evaluate for associated systemic disease
Ophthalmologic follow-up as recommended by consultant

PATIENT EDUCATION
- Instruct on proper method for instilling eye drops.
- Wear dark glasses if photophobia is a problem.

PROGNOSIS
- Depends on the presence of causal diseases or associated conditions
- Uveitis resulting from infections (systemic or local) tends to resolve with eradication of the underlying infection.
- Uveitis associated with seronegative arthropathies tends to be acute (lasting <3 months) and frequently recurrent.

COMPLICATIONS
- Cycloplegia: paralysis of the ciliary muscle of the eye, resulting in a loss of accommodation
- Loss of vision as a result of the following:
  - Keratic precipitate deposition on the corneal or lens surfaces (1)
  - Increased intraocular pressure, acute angle-closure glaucoma (1)
  - Formation of synechiae
  - Cataract formation (1)
  - Vasculitis with vascular occlusion, retinal infarction
  - Macular edema (1)
  - Optic nerve damage

CODES

ICD10

- H20.9 Unspecified iridocyclitis
- H30.90 Unspecified chorioretinal inflammation, unspecified eye
- H20.019 Primary iridocyclitis, unspecified eye

CLINICAL PEARLS

- Symptoms vary depending on depth of involvement and associated conditions but should be suspected when eye pain is associated with visual changes.
- Severe or unresponsive uveitis may require therapy, including periocular injection of corticosteroids, sustained-release corticosteroid implants, systemic corticosteroids, cytotoxic agents, immunosuppressive agents, immunomodulatory agents, or tumor necrosis factor inhibitors.
BASICS

DESCRIPTION

- The normal vagina is lined with squamous epithelium. Adenosis is characterized by the presence of columnar epithelium or glandular tissue in the wall of the vagina.
- Around week 15 of embryologic development, the müllerian system, which forms the upper 2/3 of the vagina, fuses with the invaginating cloaca or urogenital sinus to form the lower 1/3 of the vagina. Squamous metaplasia from the cloacal region then produces squamous epithelium within the vagina (1).
- Adenosis occurs when this squamous epithelium fails to epithelialize the vagina completely.
- Three main types of adenosis epithelium:
  - Endocervical
  - Endometrial
  - Tubal
- System(s) affected: reproductive

Geriatric Considerations

- Adenosis is a disorder of the young female. By menopause, the vagina and cervix should be completely epithelialized.
- In a postmenopausal patient, the presence of glandular epithelium is an indication for excision and evaluation, given the risk of well-differentiated adenocarcinoma.

Pregnancy Considerations

Pregnancy produces a wide eversion of the transformation zone of the cervix. This can become so widely everted that it will extend onto the vaginal fornices, leading to the impression of adenosis. This will resolve after pregnancy.

EPIDEMIOLOGY
**Incidence**
- Although the cumulative incidence of vaginal adenosis is unknown, the incidence of cloacal malformations is 1/20,000 to 1/25,000 live births.
- Although spontaneous vaginal adenosis appears to be fairly common (10% of adult women), it is mostly an insignificant coincidental finding. Widespread symptomatic involvement is rare (2).

**Prevalence**
- In the United States, adenosis is common in young women, affecting 10–20%. As maturation progresses with puberty, epithelialization occurs.
- Predominant age
  - Age <1 month: 15%
  - Prepubertal: typically absent
  - Age 13 to 25 years: 13%
  - Age >25 years: decreasing prevalence, uncommon beyond age 30 years (2)

**ETIOLOGY AND PATHOPHYSIOLOGY**
- In most young females, the etiology is incomplete squamous metaplasia or epithelialization. This occurs as a natural phenomenon and resolves with age.
- Described as congenital or acquired:
  - Congenital: proliferation of the remnant müllerian epithelium in the vagina due to exposure to diethylstilbestrol (DES) in utero (“DES daughters”). DES is a synthetic, nonsteroidal estrogen used to prevent miscarriage or premature deliveries from 1938 to 1971 (3). An estimated 5 million women were prescribed DES during this period (4).
  - Transformation-related protein 63 (TRP63/p63) marks the cell fate of müllerian duct epithelium to become squamous epithelium in the cervix and vagina. DES disrupts the TRP63 expression and induces adenosis lesions (4). It has also been suggested that DES induces vaginal adenosis by inhibiting the BMP4/Activin A-regulated vaginal cell fate through a downregulation of RUNX1 (5).
  - Acquired: trauma and inflammation causing spontaneous de novo changes or changes in an acquired lesion in the vaginal epithelium
  - Additional reports documented adenosis subsequent to sulfonamide-induced Stevens–Johnson syndrome and after treatment of vaginal condylomas with 5-fluorouracil (6).

**RISK FACTORS**
Adenosis of the vagina/cervix may arise in up to 90% of DES daughters and has a 40-fold increased risk of developing into clear cell adenocarcinoma (3).

GENERAL PREVENTION
None: Last DES exposure was in the 1970s.

COMMONLY ASSOCIATED CONDITIONS
DES exposure
- Adenosis from DES exposure should lead to an evaluation of other DES-related abnormalities.
- Müllarian tract anomalies associated with DES exposure include cervical hood, cervical ridge, shortened cervix, incompetent cervix, and T-shaped uterine cavity.
- Patients with known DES exposure should have their reproductive tract evaluated prior to conception.
- Most patients with adenosis have not been DES-exposed and do not require evaluation of the reproductive system.
- The FDA issued a drug bulletin in 1971 advising physicians to stop prescribing DES to pregnant women because of its link to vaginal clear cell adenocarcinoma in DES daughters (3).

DIAGNOSIS

HISTORY
- Maternal DES exposure
- Complaints of
  - Profuse mucoid vaginal discharge from the glandular epithelium
  - Pruritus
  - Pain/soreness of the vaginal introitus
  - Postcoital bleeding
  - Dyspareunia

PHYSICAL EXAM
On pelvic exam, adenosis appearance is varied: patchy or diffuse red stippling, granularity or nodularity, single or multiple cysts, erosions, ulcers, or warty protuberances that may even extend to the vulva.
DIFFERENTIAL DIAGNOSIS

- Erosive lichen planus
- Fixed drug eruption
- Erythema multiforme
- Bullous skin disease
- Adenocarcinoma

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

Four-quadrant Pap smear should be used liberally to isolate quadrants of the vagina that may contain abnormalities. No imaging is indicated, unless diagnosed with underlying malignancy.

Follow-Up Tests & Special Considerations

Pap smear can be followed by colposcopy and biopsy.

Diagnostic Procedures/Other

- Colposcopy should be used to outline areas of adenosis to ensure that no malignancy is present.
- A thorough evaluation for adenocarcinoma of the vagina arising in adenosis should be done.
- A biopsy may be necessary to ensure that the process represents only benign adenosis.

Test Interpretation

- Biopsy will show benign glandular epithelium.
- Biopsies may show areas of ongoing squamous metaplasia.

TREATMENT

GENERAL MEASURES

- Unless malignancy is present, treatment is conservative.
- In most young females with this condition, it will resolve with expectant management.
- Treatment is warranted in women with severe subjective symptoms that impair the quality of life.
First-line treatment: If indicated in patients with focal lesions and no history of DES exposure, simple excision is an effective treatment. 

ISSUES FOR REFERRAL
Malignancy found on biopsy warrants referral to gynecologic oncology specialist.

SURGERY/OTHER PROCEDURES
- Aggressive therapy, such as laser or surgical excision, is necessary if premalignant or malignant changes arise.
- Symptomatic treatment has been performed with carbon dioxide laser coagulation, unipolar coagulation, or vaginal resection.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Outpatient management

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
If the initial colposcopy is normal, a yearly four-quadrant Pap smear of the vagina and of the cervix should be performed.

DIET
No special diet is recommended.

PATIENT EDUCATION
- No limitations
- It is not necessary to avoid intercourse or placing objects in the vagina.
- The patient should be educated to keep normal guideline-recommended pelvic and Pap smear appointments. In most situations, this is benign, and expectant management is all that is necessary.
- http://www.acog.org/

PROGNOSIS

mebooksfree.com
Most patients will have squamous metaplasia and epithelialization with complete resolution of the adenosis.

The rare patient, 1/1,000 to 1/10,000, may develop adenocarcinoma in the adenosis and will require definitive therapy as for vaginal cancer.

– Cumulative incidence of progression of adenosis to adenocarcinoma is 1.5/1,000 for DES daughters (3).

COMPLICATIONS

- Infertility with DES association
- Adverse pregnancy outcome with DES association
- Adenocarcinoma of vagina
- Clear cell adenocarcinoma with DES association

**SEE ALSO**

Vaginal Malignancy

**CODES**

**ICD10**
- Q52.4 Other congenital malformations of vagina
- N89.8 Other specified noninflammatory disorders of vagina
- T38.5X5A Adverse effect of other estrogens and progestogens, initial encounter

**CLINICAL PEARLS**

- Adenosis is characterized by the presence of columnar epithelium or glandular tissue in the wall of the vagina.
- Adenosis is common among the daughters of women exposed to DES.
- Rarely, adenosis can be associated with an underlying vaginal malignancy.
BASICS
DESCRIPTION
- Vaginal bleeding during pregnancy has many causes and ranges in severity from benign with normal pregnancy outcome to life-threatening for both infant and mother.
- Etiology can be from the vagina, cervix, uterus, fetus, or placenta. The differential diagnosis is guided by the gestational age of the fetus.

EPIDEMIOLOGY
Prevalence
- In early pregnancy: 7–25% of patients
- In late pregnancy: 0.3–2% of patients

ETIOLOGY AND PATHOPHYSIOLOGY
- Many times the cause is unknown.
- Anytime in pregnancy:
  - Cervicitis (infectious or noninfectious)
  - Vaginal or cervical trauma (including postcoital)
  - Cervical lesion or neoplasia
  - Hyperemia of cervix (increased blood flow from pregnancy)
- Early pregnancy:
  - For up to 50% of early pregnancy bleeding, no cause is ever found.
  - Ectopic pregnancy: leading cause of 1st-trimester maternal death in the United States. Risk factors: previous ectopic, trauma to fallopian tubes (tubal surgery, infection, tumor), congenital anomaly of tubes, in utero diethylstilbestrol (DES) exposure, current use of IUD, history of infertility, tobacco use
  - Spontaneous abortion: risk factors: advanced maternal age (AMA), alcohol use, tobacco use, anesthetic gas, heavy caffeine use, cocaine use, chronic maternal diseases (poorly controlled diabetes mellitus [DM], celiac disease,
autoimmune diseases such as antiphospholipid syndrome), short interconception time (3 to 6 months), current use of IUD, maternal infection (e.g., herpes simplex virus [HSV], gonorrhea, chlamydia, toxoplasmosis, listeriosis, HIV, syphilis, malaria), medications (e.g., retinoids, methotrexate, NSAIDs), multiple previous therapeutic abortions, previous spontaneous abortion, toxins (arsenic, lead, polyurethane), uterine abnormalities (congenital, adhesions, fibroids)

- Implantation bleeding: benign, about 6 days after fertilization
- Uterine fibroids
- Subchorionic bleed: in late 1st trimester
- Low-lying placenta
- Gestational trophoblastic disease: hydatidiform mole (most common), choriocarcinoma, or placental-site trophoblastic tumors

- Late pregnancy:
  - Bloody show of labor (mucus plug)
  - Placenta previa: painless bleeding; occurs in 0.4% deliveries in the United States. Risk factors: previous history of placenta previa, previous uterine surgery (cesarean section, D&C), chronic hypertension, multiparity, multiple gestation, tobacco use, AMA
  - Placental abruption: (typically) painful bleeding; occurs in 1–2% deliveries in the United States. Risk factors: previous placental abruption, 1st-trimester bleeding, hypertension, preeclampsia, multiple gestation, tobacco, cocaine or methamphetamine use, unexplained elevated maternal α-fetoprotein, poly- or oligohydramnios, AMA, trauma to abdomen, premature rupture of membranes, thrombophilia, short umbilical cord, male fetus, chorioamnionitis, nutritional deficiency
  - Vasa previa: minimal bleeding with fetal distress; rare (1:2,500 deliveries). Risk factors: in vitro fertilization, multiple gestations, placental abnormalities (low-lying position, bilobate, succenturiate lobe, velamentous insertion of umbilical cord)
  - Placenta accreta, increta, percreta: risk factors: uterine scar (e.g., from cesarean section, endometrial ablation, or D&C), current placenta previa, AMA, tobacco use, multiparity, uterine anomalies, uterine fibroids, hypertension
  - Uterine rupture: vaginal bleeding, abnormal fetal heart rate, and disordered or hypertonic uterine contractions with or without pain. Risk factors: previous cesarean section (most common), trauma, use of oxytocin or prostaglandins, multiparity, external cephalic version, placental abruption, shoulder dystocia, placenta percreta, müllerian duct anomalies, history of
pelvic radiation

**RISK FACTORS**

See specific etiologies in earlier discussion.

**GENERAL PREVENTION**

- Address modifiable risk factors such as domestic violence and tobacco and drug use.
- If placenta or vasa previa, nothing per vagina

**DIAGNOSIS**

**HISTORY**

- Anytime in pregnancy: quality of pregnancy dating, context (e.g., following bowel movement, during voiding, after intercourse, drug use, or trauma including domestic violence), amount of bleeding, obstetrical history, personal or family history of inherited bleeding disorders
- Early pregnancy: severe nausea/vomiting (can be associated with molar pregnancy); amount of bleeding, pelvic pain, or suprapubic cramping (e.g., spontaneous abortion, ectopic) complications in previous pregnancies (e.g., spontaneous abortion, abruption, 1st-trimester vaginal bleeding)
- Late pregnancy: contractions (labor), abdominal pain especially between contractions (abruption, uterine rupture), presence or absence of fetal movement, rupture of membranes
- See “**Etiology and Pathophysiology**” for additional pertinent history.

**PHYSICAL EXAM**

- Vital signs: When present, signs of hemodynamic instability are first tachycardia and tachypnea and then hypotension and thready pulse.
- Abdomen: uterine tenderness, fundal height (increasing fundal height may be associated with placental abruption)
- Speculum: Visualize cervix and identify source of bleeding (from cervical os or from within vagina).
- Cervix: Assess for dilation; required to assess for labor but should not be performed until placenta previa ruled out via ultrasound
- Fetal monitoring: Doppler heart tones in early pregnancy; external fetal monitoring for gestational age >26 weeks
DIFFERENTIAL DIAGNOSIS

- Hematuria (UTI, kidney stones)
- Rectal bleeding

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- CBC
- Blood type and screen; if significant hemorrhage, type and cross-match
- Quantitative β-human chorionic gonadotropin (β-hCG):
  - Prior to 12 weeks, levels can be followed serially every 2 days with following trends:
    - Doubles or at least 66% rise in 48 hours in normal pregnancy
    - Falls in spontaneous abortion
    - Extremely high in molar pregnancy
    - Rises gradually (<50% in 48 hours) or plateaus in ectopic pregnancy
- Transvaginal ultrasound should be used to confirm an intrauterine pregnancy (IUP) when the quantitative β-hCG >2,000 (1)[A].

- Other lab tests based on clinical scenario:
  - Wet mount, gonorrhea/chlamydia, Pap smear
  - Progesterone level occasionally used to determine viability in threatened abortion (<5 indicates not viable, >25 indicates viability, 5 to 25 is equivocal).
  - Bleeding time, fibrinogen, and fibrin split products: if suspect coagulopathy or abruption
  - Kleihauer-Betke: low sensitivity and specificity for abruption; helpful for dosing Rho(d) immune globulin (RhoGAM)
- Ultrasound is the preferred imaging modality.
  - Early pregnancy:
    - Gestational sac seen at 5 to 6 weeks; fetal heartbeat observed by 8 to 9 weeks
    - Diagnostic of ectopic with nearly 100% sensitivity when β-hCG level 1,500 to 2,000 mIU/mL. If no IUP is present and ultrasound does not confirm ectopic pregnancy, serial quantitative β-hCG values should be followed (2)[C].
  - Late pregnancy:
    - Proceed to rule out placenta previa with ultrasound, labor with serial cervical exams, and abruption with external fetal monitoring.
ALERT
Confirm fetal presentation and placental position prior to cervical exam.

TREATMENT

MEDICATION

First Line
- Treat underlying cause of bleeding, if identified.
- If mother is Rh-negative, give RhoGAM to prevent autoimmunization. In late pregnancy, dose according to the amount of estimated fetomaternal hemorrhage.
- If cause of bleeding is preterm labor, consider betamethasone for fetal lung maturity if <36 weeks’ gestation. Tocolytics may be used to prolong pregnancy to allow for course of steroids.
- If threatened abortion: Consider progesterone (relative risk 0.53) (3)[A].
- If mother has an inherited bleeding disorder or if bleeding is severe, consider recombinant or donor blood products.

SURGERY/OTHER PROCEDURES
- Cesarean section may be indicated for recurrent or uncontrolled bleeding with placenta or vasa previa.
- If ectopic is diagnosed, immediate surgical treatment may be needed. Some early ectopic pregnancies can be treated medically if certain criteria are met (2)[C].
- Surgical uterine evacuation is necessary for molar pregnancy due to malignant potential (4)[C].
- Incomplete or inevitable spontaneous abortion: Management is patient centered. In the absence of infection, patient may elect expectant, medical, or surgical management. If expectant management, typically wait 2 weeks for patient to complete abortion; most complete by 9 days. If at 2 weeks abortion is not completed or medical management has failed, surgical intervention (D&C or aspiration) is generally indicated (5)[A]; may send tissue to pathology to confirm

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• In early pregnancy: based on quantity of bleeding, need for surgical treatment for ectopic pregnancy, or presence of infection in case of spontaneous abortion
• In late pregnancy, if significant bleeding and/or presence of maternal or fetal compromise
• In late pregnancy with trauma, if ≥2 contractions/10 minutes
• In late pregnancy, may discharge when bleeding has stopped; labor, previa, and abruption have been ruled out; and fetal heart tracing is normal.
• After trauma in late pregnancy, may discharge home if normal fetal heart tracing for ≥4 hours with <2 contractions/10 minutes

ONGOING CARE

PATIENT MONITORING
• Patient should be instructed to report any increase in the amount or frequency of bleeding and to seek immediate care if experiencing fever, abdominal pain, or sudden increased bleeding. Patient should save any tissue passed vaginally for examination.
• Frequency of outpatient follow-up as indicated based on etiology of bleeding

PATIENT EDUCATION
• American Academy of Family Physicians (AAFP): http://www.familydoctor.org
• American College of Obstetricians & Gynecologists (ACOG): www.acog.org

PROGNOSIS
• Prognosis depends on the etiology of vaginal bleeding, severity of bleeding, and rapidity of diagnosis.
• Maternal mortality is 31.9 deaths/100,000 ectopic pregnancies.
• 1/2 of patients with early pregnancy bleeding miscarry; if fetal heart activity (ultrasound) present in 1st-trimester bleed, <10% chance of pregnancy loss
• Heavy bleeding in early pregnancy, particularly when accompanied by pain, is associated with higher risk of spontaneous abortion. Spotting and light episodes are not, especially if lasting only 1 to 2 days.
• Subchorionic hemorrhage has about 2- to 3-fold increased risk of spontaneous abortion. Smaller hemorrhage and presence of viable fetal heart rate confer lower risk of loss; most resolve spontaneously
Women with early pregnancy bleeding have an increased risk of preterm delivery, premature rupture of membranes, manual removal of placenta, placental abruption, elective cesarean delivery, and term labor induction later in the same pregnancy. These women also have an increased risk of adverse pregnancy outcomes, including hyperbilirubinemia, congenital anomalies, NICU admission, and reduced neonatal birth weight. Finally, there is an increased risk in subsequent pregnancies of recurrence of early pregnancy bleeding.

Bed rest has not been shown to affect the outcome of bleeding in early pregnancy but may be indicated for bleeding in late pregnancy with placenta or vasa previa or with maternal hypertension.

**CODES**

**ICD10**

- O20.9 Hemorrhage in early pregnancy, unspecified
- O46.90 Antepartum hemorrhage, unspecified, unspecified trimester
- O20.0 Threatened abortion
CLINICAL PEARLS

- Obtain blood type and screen all women presenting with vaginal bleeding in pregnancy and administer RhoGAM to all Rh-negative patients.
- For up to 50% of early pregnancy bleeding, no cause is ever found.
- Always consider ectopic pregnancy in 1st-trimester bleeding.
- Do not perform digital exam in late pregnancy bleeding until placenta has been located on ultrasound.
VAGINAL MALIGNANCY

Christina N. Kufel, DO, MS • Michael P. Hopkins, MD, MEd

BASICS

DESCRIPTION

- Carcinomas of the vagina are uncommon: 2–3% of gynecologic malignancies, 2,300 new cases annually.
- Vaginal intraepithelial neoplasia (VAIN), defined by squamous cell atypia, is classified by the depth of epithelial involvement:
  - VAIN 1: 1/3 thickness
  - VAIN 2: 2/3 thickness
  - VAIN 3 and carcinoma in situ (CIS): >2/3
  - CIS, designating full-thickness neoplastic changes without invasion through the basement membrane
- Invasive malignancies: Vaginal malignancies include squamous cell carcinoma (85–90%), adenocarcinoma (5–10%), sarcoma (2–3%), and melanoma (2–3%). Clear cell carcinoma is a subtype of adenocarcinoma. Invasive squamous cell carcinoma has the potential for metastasis to the lungs and liver.
- To be classified as a vaginal malignancy, only the vagina can be involved. If the cervix or vulva is involved, then the tumor is classified as a primary cancer arising from the cervix or the vulva.
- Most vaginal malignancies are metastatic (e.g., cervix, vulva, endometrium, breast, ovary).
- Most common sites of metastases: lung, liver, bone

Pregnancy Considerations

This malignancy is not associated with pregnancy.

EPIDEMIOLOGY

Incidence

Predominant age

- CIS: mid-40 to 60 years
- Invasive squamous cell malignancy: mid-60 to 70 years
- Adenocarcinoma: any age; 50 years is the mean age. Peak incidence is between 17 and 21 years of age.
- Clear cell adenocarcinoma occurs most often in females <30 years with a history of exposure to diethylstilbestrol (DES) in utero.
- Mixed müllerian sarcomas and leiomyosarcomas in the adult population: mean age 60 years

**Pediatric Considerations**
Vaginal tumors are extremely rare. Rhabdomyosarcoma (botryoid and embryonal subtype) is the most common malignant neoplasm of the vagina. Less common entities are germ cell tumor and clear cell adenocarcinoma.

**Prevalence**
In the United States, it is one of the rarest of all gynecologic malignancies (3%).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Women with a history of cervical malignancy have a higher probability of developing squamous cell malignancy in the vagina even after hysterectomy.
- Human papillomavirus (HPV) is found in 80–93% of patients with vaginal CIS and 50–65% of the patients with invasive vaginal carcinoma.
- HPV-16 is the most common, found in 66% of CIS and 55% of invasive vaginal cancers.
- Smokers have a higher incidence.
- Clear cell adenocarcinoma of the vagina in young women has been associated with DES exposure. The incidence, however, is exceedingly rare, estimated at 1/1,000 to 1/10,000 exposed females.
- Metastatic lesions can involve the vagina, spreading from the other gynecologic organs.
- Although rare, renal cell carcinoma, lung adenocarcinoma, GI cancer, pancreatic adenocarcinoma, ovarian germ cell cancer, trophoblastic neoplasm, and breast cancer can all metastasize to the vagina.

**Genetics**
No known genetic pattern

**RISK FACTORS**
- Similar risk factors as cervical cancer
• Age
• African American
• Smoking
• Multiple sex partners, early age of first sexual intercourse
• History of squamous cell cancer of the cervix or vulva
• HPV infection
• Vaginal adenosis
• Vaginal irritation
• DES exposure in utero
• Immunocompromised, HIV
• Prior pelvic radiation

**COMMONLY ASSOCIATED CONDITIONS**
Due to the field effect, patients with vaginal cancer are more likely to develop malignancy in the cervix or vulva and should be followed closely.

**DIAGNOSIS**

**HISTORY**
- Abnormal bleeding is the most common symptom.
- Postcoital bleeding can result from direct trauma to the tumor.
- Vaginal discharge
- Dyspareunia
- Urinary symptoms, including hematuria and increased frequency
- Constipation
- Pain along with symptoms and signs of hydroureter are late findings when the tumor has spread into the paravaginal tissues and extends to the pelvic sidewall.

**Pediatric Considerations**
In children, sarcomas can present either as a mass protruding from the vagina or as abnormal genital bleeding.

**PHYSICAL EXAM**
Pelvic examination
- The vagina, uterus, adnexa (fallopian tubes and ovaries), bladder, and rectum should be evaluated for unusual changes.
• Vaginal malignancies are found most commonly on the posterior wall in the upper 1/3 of the vagina.

DIFFERENTIAL DIAGNOSIS
• Premalignant changes: VAIN 1, 2, 3, and CIS
• Adequate biopsies ensure that invasive lesions are not overlooked. Invasive lesions penetrate the basement membrane and cannot be treated conservatively.
• Other malignancies, such as endometrial, cervix, bladder, or colon cancer, can invade directly into the vagina or metastasize to the vagina.
• In the childbearing years, trophoblastic disease should be considered.
  – The vagina is a common site of metastases; however, biopsy should typically be avoided because the implants are very vascular and may hemorrhage if sampled.
  – The clinical presentation is typically obvious so histopathologic confirmation before treatment is not required.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Pap smear may incidentally detect asymptomatic lesions.
• Biopsy suspicious lesions
• Chest x-ray (CXR): to evaluate for metastatic disease
• CT scan and MRI: to evaluate the liver and retroperitoneum, especially the lymph nodes in the pelvic and periaortic area
• PET scan detects primary and secondary metastatic lesions more often than CT scan.

ALERT
PET scan correlation with CT scan lesions strongly suggests malignancy.

Follow-Up Tests & Special Considerations
• Lymphoscintigraphy (sentinel lymph node mapping) as part of the pretreatment evaluation can result in a change in the radiation fields and improve comprehensive treatment planning in women with vaginal cancer.
• HPV vaccination: Implementation of prophylactic HPV vaccination could prevent ~2/3 of the intraepithelial lesions in the lower genital tract but is yet proven.
**Diagnostic Procedures/Other**
- Colposcopy with directed biopsies for small lesions
- Wide excision under anesthesia of superficial disease may be necessary to ensure that invasive cancer is not present.
- Cystoscopy to rule out bladder invasion
- Proctosigmoidoscopy to rule out rectal invasion

**Test Interpretation**
Tumors are staged clinically:
- Stage 0: VAIN and CIS
- Stage I: carcinoma limited to the vaginal wall (26%)
- Stage II: involves the subvaginal tissues but has not extended to the pelvic wall (37%)
- Stage III: extends to the pelvic wall (24%)
- Stage IV: extends beyond the true pelvis (13%)
  - IVa: Tumor invades bladder and/or rectal mucosa and/or direct extension beyond the true pelvis.
  - IVb: spread to distant organs

---

**TREATMENT**

**GENERAL MEASURES**
Treatment methods for VAIN and CIS include the following:
- Wide local excision
- Partial or total vaginectomy
- Intravaginal chemotherapy with 5% fluorouracil cream
- Laser therapy
- Intracavitary radiation therapy

**MEDICATION**
- Imiquimod
  - In a review of the effectiveness of 5% imiquimod cream in the treatment of VAIN, the following results were reported (1)[C]:
    - 26–100% of patients had complete regression.
    - 0–60% of patients had partial regression.
    - 0–37% experienced recurrence.
Contraindications
- The diagnosis must be established with certainty prior to treatment.
- If there is any doubt that a process beyond in situ disease exists, vaginectomy must be performed. These patients are often elderly, and aggressive therapy is limited by the patient’s performance status and ability to tolerate radical surgery, chemotherapy, or radiation.

ISSUES FOR REFERRAL
Patients should be treated by a gynecologic oncologist and/or a radiation oncologist.

ADDITIONAL THERAPIES
- Treatment with radiotherapy depends on the stage of disease. This treatment option should be discussed with physicians experienced with this malignancy.
- It is common to use radiotherapy and chemotherapy (chemoradiation) for better cancer control.
- Early-stage primary squamous cell carcinoma treated with radiation alone has shown good results.
- Stage III vaginal cancer may benefit from combined radiation and hyperthermia (2)[C].
- Patients with advanced squamous cell carcinoma or adenocarcinoma receive concurrent irradiation and cisplatin-based chemotherapy.
- Neoadjuvant chemotherapy followed by radical surgery may benefit selected patients (3)[C].
- In most tumor types, metastatic disease from the vagina to other sites is only minimally responsive to chemotherapy.
- With one exception, no chemotherapeutic agents have shown a survival advantage. The exception is childhood sarcomas, which have been treated with combinations of the following:
  - Vincristine
  - Dactinomycin (actinomycin-D)
  - Cyclophosphamide (Cytoxan)
  - Cisplatin
  - Etoposide (VP-16)

SURGERY/OTHER PROCEDURES
- Whenever there is a doubt as to the presence or absence of invasive disease, vaginectomy must be performed.
Invasive lesions usually are treated by radiation therapy, but stage I lesions can be treated with radical hysterectomy or radical vaginectomy with pelvic lymph node dissection.

If the lesion involves the lower vagina, inguinal node dissection also must be done because cancer involving the lower vagina can metastasize to the groin region (inguinal-femoral nodes).

Premenopausal women who desire to retain ovarian function are better candidates for radical surgery for early-stage disease, with vaginal reconstruction possible afterward.

Patients who have not completed their family can occasionally be treated with limited resection and localized radiation to the area.

Sarcomas are treated by radiation therapy followed by pelvic exenteration if persistent disease is present.

**Pediatric Considerations**
The treatment of vaginal tumors today mainly consists of neoadjuvant chemotherapy followed by local control with surgery or radiotherapy.

**Geriatric Considerations**
Older patients, many with a long history of smoking, are at a higher risk for malignancies requiring surgical treatments.

---

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Patients are usually ambulatory and able to resume full activity by 6 weeks after surgery.
- Most patients are fully active while receiving chemotherapy and radiation therapy.

**Patient Monitoring**

- Pelvic examination and Pap smear every 3 months for 2 years, then every 6 months for the next 3 years and then yearly thereafter
- Annual CXR

**PATIENT EDUCATION**

- Printed patient information available from American College of Obstetricians
PROGNOSIS
Stage and 5-year survival (4)
- I: 77.6%
- II: 52.2%
- III: 42.5%
- IVA: 20.5%
- IVB: 12.9%
- Stage is the most important determinant of survival (5).
- Tumor size >2 cm, correlated with worse survival outcome

COMPLICATIONS
- Those typically associated with major abdominal surgery or radiation therapy
- Common complications of treatment include rectovaginal or vesicovaginal fistulas, rectal/vaginal strictures, radiation cystitis, and/or proctitis.
- Most recurrences occur within the first 2 years after initial diagnosis

REFERENCES
ADDITIONAL READING

ICD10
- C52 Malignant neoplasm of vagina
- D07.2 Carcinoma in situ of vagina
- N89.3 Dysplasia of vagina, unspecified

CLINICAL PEARLS
- Vaginal cancer is rare; 85–90% of vaginal cancers are squamous cell.
- Vaginal malignancies are found most commonly on the posterior wall in the upper 1/3 of the vagina.
- Most vaginal malignancies are metastatic (from cervix, vulva, endometrium, breast, or ovary).
BASICS

DESCRIPTION

- “Vaginosis” and “Vaginitis” are broad terms indicating any disease process of the vagina caused by or leading to infection, inflammation, or changes in the normal vaginal flora.
- The difference between vaginitis and vaginosis is the presence (vaginitis) or absence (vaginosis) of inflammation.
- The most common symptoms of vaginitis/vaginosis are vaginal discharge, odor, itching, burning, or pain.
- The most common causes of vaginitis/vaginosis are bacterial vaginosis (BV), vulvovaginal candidiasis (VVC), and trichomoniasis.
- Other causes of vaginitis can be stratified by age and are generally associated with postmenopausal vaginal atrophy or foreign bodies in the pediatric population.
- Lichen planus, lichen sclerosus, psoriasis, and contact/allergic dermatitis may also cause vaginitis.
- Diagnosis of vaginitis relies on thorough history, physical exam, and clinical assessment. Microscopy, cultures, DNA probes, and tissue biopsy can be helpful in confirming diagnosis.
- BV is the most common cause of vaginal discharge in reproductive-aged women. It is caused by a disturbance in the normal vaginal flora. The normally dominant hydrogen peroxide–producing lactobacilli are overwhelmed by an overgrowth of gram-negative species causing an increase in the vaginal pH, discharge, and odor.
- VVC is the second most common cause of vaginitis in reproductive-aged women. It is caused by invasion of the *Candida* organism into the superficial epithelial cells of the vagina causing mild to severe vaginal inflammation, pruritus, and discharge.

EPIDEMIOLOGY

- Vaginal symptoms are typical and common in the general population and are one of the most frequent reasons women present to their medical care.
providers accounting for approximately 10 million office visits each year.

- About 30% of women with complaint of vaginal discharge or irritation remain undiagnosed despite extensive testing.
- In the United States, BV continues to be the leading cause of vaginal complaints. The frequency of VVC is highest among women in their reproductive years.
- Neither vaginal candidiasis nor BV is considered to be sexually transmitted diseases.
- Vaginal trichomoniasis is a common sexually transmitted disease with 7.4 million cases diagnosed yearly in the United States, and is the most common curable, nonviral sexually transmitted infection worldwide.

**ETIOLOGY AND PATHOPHYSIOLOGY**

- **BV**
  - BV is caused by a change in the normal vaginal flora. Dominant lactobacilli responsible for maintaining the acidic vaginal pH are overcome by an increase of the gram-negative organisms.
  - Change in the vaginal environment leads to an increase in the pH and an overgrowth of vaginal anaerobes, causing a malodorous, clear, white, or gray discharge and a fishy odor.
  - BV is highly prevalent and associated with multiple adverse outcomes, including enhanced HIV transmission.
  - The organisms generally implicated in BV infections include:
    - *Gardnerella vaginalis*
    - *Prevotella* species
    - *Porphyromonas* species
    - *Bacteroides* species
    - *Peptostreptococcus* species
    - *Mycoplasma hominis*
    - *Ureaplasma urealyticum*
    - *Mobiluncus* species
    - *Fusobacterium* species
    - *Atopobium vaginae*

- **VVC**
  - VVC is caused by *Candida albicans* (80–92%) and *Candida glabrata* (<10%).
  - *Candida* organisms can be identified in the lower genital tract in healthy women, and it is thought to gain access via rectal and perianal colonization and migration.
– Symptoms occur when candidal organisms overwhelm the normal vaginal flora and invade the superficial vaginal epithelial cells, causing inflammation, pruritus, and thick vaginal discharge.
– Complicated VVC should be considered in pregnant patients, patients with diabetes, or immunocompromising conditions. Patients who experience four or more episodes of VVC in a year or who have only budding yeast on wet mount may also be considered to have complicated VVC.

• Trichomoniasis
  – Caused by an infection via *Trichomonas vaginalis*, a flagellate protozoan. The organism infects the squamous epithelium of the vagina, as well as the urethra and paraurethral glands. This infection is primarily transmitted during sexual intercourse.

• Desquamative inflammatory vaginitis (DIV)
  – A chronic, purulent vaginitis occurring most commonly in the perimenopause
  – Etiology and pathogenesis uncertain
  – Diagnosis of exclusion. Estrogen deficiency should be considered and addressed.

• Other sources of vaginitis/vaginosis are usually mediated by disruption of the vaginal squamous epithelium. This disruption can lead to inflammation, pain, and discharge.
  – Other than the three most common causes of vaginitis/vaginosis, menses, sexual activity, contraception, pregnancy, foreign bodies, estrogen levels, STDs, and use of vaginal hygiene products, topical creams, or antibiotics can contribute to vaginal symptoms.

**RISK FACTORS**

• **BV**
  – Sexual activity; although BV is not considered an STD, studies show increased rates of BV in women with multiple sex partners.
  – Women who have sex with women
  – Smoking
  – Vaginal douching
  – The presence of STDs such as HSV-2 (1)

• **VVC**
  – Diabetes
  – Diet high in refined sugars
  – Use of broad-spectrum antibiotics
  – Immunosuppression
- Higher estrogen levels have been associated with increased vaginal yeast infection, explaining why it is more commonly diagnosed in reproductive-aged women and in pregnancy.

- Trichomoniasis
  - Inconsistent use of barrier contraception
  - Multiple sex partners
  - African Americans
  - Limited education and low socioeconomic status
  - Illicit drug use
  - Smoking

- Other risk factors associated with vaginitis/vaginosis:
  - Decreased estrogen
  - Smoking
  - Use of vaginal douches and creams
  - Tight-fitting clothing
  - Poor hygienic practice
  - Changes in diet

**GENERAL PREVENTION**

- Vulvar hygiene
- Except in cases of trichomoniasis, treatment of sexual partners generally is not recommended but may be considered in recurrent cases.
- Advise patients not to douche.

**COMMONLY ASSOCIATED CONDITIONS**

- STDs such as gonorrhea, chlamydia, or HSV
- Vaginal intraepithelial neoplasia and cancer can present with symptoms of vaginitis.
- DIV presents with similar symptoms but most commonly occurs in postmenopausal women.

**DIAGNOSIS**

**HISTORY**

- General principles:
  - The key to diagnosis is clarification of the presenting symptoms.
  - Onset, timing, and character of the vaginal symptoms are important
questions to ask.
– Many patients will be asymptomatic, and diagnosis is made on routine physical exam and lab testing.
– Pap smears should not be used as diagnostic tools due to low sensitivity and specificity.
– Symptomatic patients generally complain of itching, burning, irritation, and abnormal discharge.

**BV**
– Symptomatic patients complain of abnormal vaginal discharge and a fishy odor.
– Pain and pruritus are uncommon.

**VVC**
– Symptomatic women report itching, burning, irritation, dyspareunia, burning with urination, and a white thick discharge.
– Odor is uncommon.

**Trichomoniasis**
– Symptomatic patients will complain of abnormal discharge, itching, burning, or postcoital bleeding.

**PHYSICAL EXAM**

**BV**
– Thin watery, sometimes foamy discharge. Can appear beige- or tan-colored. An amine or “fishy” smell may be present on exam.
– The vaginal epithelium should appear normal and noninflamed.

**VVC**
– Erythema and swelling of the vulva and vaginal mucosa
– Some patients may have vulvar excoriation and fissures.
– If discharge is present, it is usually white, thick, and can have a cottage cheese appearance. Some women may have thin white dilute discharge. No odor is present.

**DIV**
– Purulent discharge
– Wet mount shows WBC and parabasal (immature) squamous epithelial cells, with pH >4.5.

**Trichomoniasis**
– Significant erythema of the vulva and vaginal mucosa
– Greenish discharge with an amine or fishy odor
– Discharge can also appear purulent in some patients.
– Occasionally punctate hemorrhages can be seen on the vaginal walls and on
the cervix ("strawberry cervix").

DIFFERENTIAL DIAGNOSIS
- Physiologic discharge
- Leukorrhea of pregnancy
- STDs
- Foreign body
- Contact dermatitis
- Cervicitis
- DIV
- Urinary tract infection (UTI)
- Atrophic vaginitis
- Dermatoses: lichen sclerosus, lichen planus, seborrheic dermatitis, psoriasis

DIAGNOSTIC TESTS & INTERPRETATION
- **BV**
  - Symptomatic patients complain of an abnormal vaginal discharge and a fishy odor.
  - Clinical diagnosis is established with Amsel criteria. A positive diagnosis can be made if 3 out of 4 of the following criteria are present.
    - Thin, homogenous discharge
    - Vaginal pH >4.5
    - A positive amine or “Whiff” test with use of KOH solution added to discharge
    - >20% of the epithelial cells identified as “clue cells”

- **VVC**
  - Visualization of blastospores or pseudohyphae on saline or 10% KOH microscopy
  - A positive culture in a symptomatic patient

- **Trichomoniasis**
  - Visualization of motile trichomonads on saline microscopy
  - Several POC identification tests, including patient performed, are available with increased sensitivity compared to microscopy but are expensive.

TREATMENT

GENERAL MEASURES
Avoid douching and tight-fitting clothing.
Regular use of condoms may help to prevent BV.
Asymptomatic, pregnant women generally do not require treatment for BV.

MEDICATION
Medication recommendations based on CDC treatment guidelines (2)[A]

- **BV**
  - Metronidazole 500 mg orally BID for 7 days, vaginally 0.75% gel 1 applicator daily for 5 days, or clindamycin given vaginally (1 applicator = 100 mg) for 5 days. Recurrent infection may require repeated treatment (e.g., 1 week monthly for 6 months). Advise patients to avoid alcohol during treatment with oral metronidazole and for 3 days following.

- **VVC**
  - Uncomplicated infections can be treated with a one-time dose of fluconazole 150 mg tab. Topical/vaginal suppository antifungal regimens such as butoconazole, clotrimazole, miconazole, terconazole, or nystatin creams. Treatment can range from 3 to 7 days.
  - Recurrent or complicated infections may require additional oral dosing of fluconazole 150 mg tab for extended treatment and/or prophylaxis.
  - Non-albican candidiasis may require longer duration of treatment with topical or oral azoles.
  - Avoid oral azoles in pregnant women.
  - Advise patients that topical medications may weaken rubber or latex condoms.

- **Trichomoniasis**
  - A one-time 2-g oral dose of either tinidazole or metronidazole; alternatively, 500-mg dose of metronidazole twice daily for 7 days
  - The patient’s partner should be treated as well and counseled to abstain from sex until both patients have completed treatment and are asymptomatic.
  - Test of cure is not necessary.

- **DIV**
  - Clindamycin cream vaginally or
  - Hydrocortisone vaginal suppository 300 to 500 mg nightly for 3 weeks; may need additional maintenance

ISSUES FOR REFERRAL
Treating male partners does not reduce symptoms or prevent recurrence but can
be considered in patients with recurrent infection.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

A Cochrane analysis reviewed the use of probiotics for BV and found inconclusive evidence to recommend probiotics as primary treatment or as a preventive strategy (3)[A]. Further study was recommended.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Delay sexual relations until symptoms clear/discomfort resolves.
- Use of condoms may reduce recurrence of BV.
- Consider suppressive therapy for recurrent infection.
- Monthly presumptive treatment may help reduce colonization of bacteria associated with BV (4)[C].

**Patient Monitoring**

No specific follow-up needed; if symptoms persist or recur within 2 months, repeat pelvic exam and culture.

**PATIENT EDUCATION**

American College of Obstetricians and Gynecologists (ACOG), 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG: www.acog.org

**PROGNOSIS**

VVC: 80–90% of uncomplicated cases cured with appropriate treatment; 30–50% of recurrent infections return after discontinuation of maintenance therapy; there is a relatively high spontaneous remission rate of untreated symptoms as well.

**COMPLICATIONS**

- VVC may occur following treatment of BV.
- BV has been associated with an increased risk of acquisition and transmission of HIV.
- BV has been associated with increased risk of preterm birth, chorioamnionitis,
postpartum and postabortal endometritis, and pelvic inflammatory disease.

SEE ALSO
Algorithm: Discharge, Vaginal

CODES
ICD10

- N76.0 Acute vaginitis
- B37.3 Candidiasis of vulva and vagina
- N95.2 Postmenopausal atrophic vaginitis

CLINICAL PEARLS

Clinical symptoms, signs, and microscopy have relatively poor performance compared with so-called gold standards such as culture and DNA probe assays, but these more sensitive assays can detect organisms that may not be causing symptoms.

- Most women experience relief of symptoms with therapy chosen without such gold standard tests, even when the treatment does not correspond with the underlying infection.
- Vaginal pH is underused as a diagnostic tool for evaluation of vaginitis.
VARICOSE VEINS

Joseph A. Florence, MD • Fereshteh Gerayli, MD, FAAFP

BASICS

DESCRIPTION

- Superficial venous disease causing a permanent dilatation and tortuosity of superficial veins ≥3 mm in diameter usually occurring in the legs and feet; caused by systemic weakness in the vein wall and may result from congenitally incomplete valves or valves that have become incompetent
- Affects legs where reverse flow occurs when dependent
- Truncal varices involve the great and small saphenous veins; branch varicosities involve the saphenous vein tributaries.
- Categorized as the following:
  - Uncomplicated (cosmetic)
  - With local symptoms (pain confined to the varices, not diffuse)
  - With local complications (superficial thrombophlebitis, may rupture causing bleeding)
  - Complex varicose disease (diffuse limb pain, swelling, skin changes/ulcer)
- System(s) affected: cardiovascular; skin

ALERT

Ulceration of varicose veins has a high rate of infection, which can lead to sepsis.

Geriatric Considerations

- Common; usually valvular degeneration but may be secondary to chronic venous insufficiency
- Elastic support hose and frequent rests with legs elevated rather than ligation and stripping

Pregnancy Considerations

- Frequent problem
- Elastic stockings are recommended for those with a history of varicosities or if prolonged standing is involved.
EPIDEMIOLOGY

Incidence
- Predominant age: middle age
- Predominant gender: female > male (2:1)
- National Women’s Health Information Center estimates that 50% of women have varicose veins.

ETIOLOGY AND PATHOPHYSIOLOGY
- Varicose veins are caused by venous insufficiency from faulty valves in ≥1 perforator veins in the lower leg, causing secondary incompetence at the saphenofemoral junction (valvular reflux).
- Valvular dysfunction causing venous reflux and subsequently venous hypertension (HTN)
- Failed valves allow blood to flow in the reverse direction (away from the heart), from deep to superficial and from proximal to distal veins.
- Deep thrombophlebitis
- Increased venous pressure from any cause
- Congenital valvular incompetence
- Trauma (consider arteriovenous fistula; listen for bruit)
- Presumed to be due to a loss in vein wall elasticity with failure of the valve leaflets
- An increase in venous filling pressure is sufficient to promote varicose remodeling of veins by augmenting wall stress and activating venous endothelial and smooth muscle cells.

Genetics
Autosomal dominant with incomplete penetrance

RISK FACTORS
- Increasing age
- Pregnancy, especially multiple pregnancies
- Prolonged standing
- Obesity
- History of phlebitis (postthrombotic syndrome)
- Family history
- Female sex
- Increased height
• Congenital valvular dysfunction

COMMONLY ASSOCIATED CONDITIONS
• Stasis dermatitis
• Large varicose veins may lead to skin changes and eventual stasis ulceration.

DIAGNOSIS

HISTORY
• Symptoms range from minor annoyance/cosmetic problem to a lifestyle-limiting problem (1).
• Localized symptoms: pain, burning, itching
• Generalized symptoms
  – Leg muscular cramp, aching
  – Leg fatigue/swelling
• Pain if varicose ulcer develops
• Symptoms often worse at the end of the day, especially after prolonged standing.
• Women are more prone to symptoms due to hormonal influences: worse during menses.
• No direct correlation with the severity of varicose veins and the severity of symptoms

PHYSICAL EXAM
• Inspect lower extremities while the patient is standing. Varicose veins in the proximal femoral ring and distal portion of the legs may not be visible when the patient is supine (1).
• Varicose veins are the following:
  – Dilated, tortuous, superficial veins, ≥3 mm, chiefly in the lower extremities
  – Dark purple/blue in color, raised above the surface of the skin
  – Often twisted, bulging, and can look like cords
  – Most commonly found on the posterior/medial lower extremity
• Edema of the affected limb may be present.
• Skin changes may include the following:
  – Eczema
  – Hyperpigmentation
  – Lipodermatosclerosis
Spider veins (idiopathic telangiectases)
  – Fine intracutaneous angiectasis
  – May be extensive/unsightly

Neurologic sensory and motor exam
Peripheral arterial vasculature; pulses
Musculoskeletal exam for associated rheumatologic/orthopedic issues

DIFFERENTIAL DIAGNOSIS

- Nerve root compression
- Arthritis
- Peripheral neuritis
- Telangiectasia: smaller, visible blood vessels that are permanently dilated
- Deep vein thrombosis
- Inflammatory liposclerosis

DIAGNOSTIC TESTS & INTERPRETATION

Duplex ultrasound: Noninvasive imaging duplex ultrasound will confirm the etiology, anatomy, and pathophysiology of segmental venous reflux. The severity of both symptoms and signs tends to correlate with the degree of venous reflux, which is identified by duplex ultrasound as retrograde or reversed flow of >0.5 seconds duration (1)[A].

Diagnostic Procedures/Other

Duplex scanning, venous Doppler study, photoplethysmography, light-reflection rheography, air plethysmography, and other vascular testing should be reserved for patients who have venous symptoms and/or large (>4 mm in diameter) vessels or large numbers of spider telangiectasia indicating venous HTN.

Test Interpretation

The clinical, etiologic, anatomic, and pathologic (CEAP) classification is considered the gold standard of classification of chronic venous disorders. Clinical classification illustrating the current physical state is useful in clinical practice (1)[A].

- 0: no visible or palpable signs of venous disease
- 1: spider veins or telangiectasias
- 2: varicose veins
- 3: edema
- 4: skin changes (pigmentation, eczema, lipodermatosclerosis, atrophie
5: healed ulcer
6: active ulcer

**TREATMENT**

- Indications for treatment include pain, aching, soreness, heaviness, fatigue, burning, edema, stasis dermatitis, recurrent superficial phlebitis or ulceration.
- Conventional wisdom suggests conservative therapy (e.g., elevation, external compression, weight loss) as being helpful.
- Compression stockings improve subjective symptoms, but have no real effect on progression or recurrence (1,2)[A]; significant failure rate due to nonadherence (3)[A]; typical compression levels
  - 20 to 30 mm Hg: Uncomplicated varicose veins for pain and edema control
  - 30 to 40 mm Hg: venous stasis ulcers
- The most important part of the stocking is below the knee, where the standing venous pressure is the highest.

**Sclerotherapy:** indicated for spider veins and small varicose veins (1)[A]

**CHIVA:** Ambulatory conservative hemodynamic management of varicose veins is a less-invasive approach based on venous hemodynamics with deliberate preservation of the superficial venous system. The CHIVA method reduces recurrence of varicose veins and produces fewer side effects than vein stripping (1)[A].

**Injection of sclerosant into a vein and then apply compression resulting in occlusive fibrosis without clot formation; chemical irritants (chromated glycerin), osmotic (hypertonic saline), detergent (sodium tetradecyl sulphate [STS] and polidocanol [POL])

**Poor long-term results with liquid sclerotherapy (LS), however, foam sclerotherapy (FS) is an option for treatment of the incompetent saphenous vein. Ultrasound-guided FS is recommended as a second-line treatment under current NICE guidelines (4)[A].

**Radiofrequency ablation (RFA) thermal energy (85–120°C) is used to seal the incompetent vein via heat damage. Endovenous laser ablation (EVLA) uses laser and fiber-optic catheter technology to generate thermal energy (up to 800°C) (1,3)[A].
  - RFA and EVLA have been demonstrated to be superior to open surgical techniques for the treatment of varicose veins with similar improvement in quality of life. NICE recommends using them as first-line treatment of
truncal vein incompetence (4)[A].
– EVLA and RFA have similar safety and efficacy (including vein ablated length, pain scores, quality of life, occlusion, thrombophlebitis, hematoma, and recanalization) (5)[A].
– RFA has overall lower complication risk (5)[A].
• Nonthermal, Nontumescent ablation: (1)[A] Mechanochemical endovenous ablation (MOCA) is a hybrid system composed of a rotating tip with simultaneous injection of liquid sclerosant and does not use heat energy. It is less painful with similar occlusion rates to standard endovenous ablation.

GENERAL MEASURES
Patients with unsightly varicose veins often seek treatment for cosmetic reasons.

MEDICATION
Superficial thrombophlebitis is not an infective condition and does not require antibiotic treatment.

 ISSUES FOR REFERRAL
• National Institute for Health and Care Excellence (NICE) (4)[A] recommends referral of patients with:
  – Symptomatic primary (or recurrent) varicose veins
  – Skin changes
  – Superficial venous thrombosis
  – Venous leg ulcers
  – Healed ulcers

ADDITIONAL THERAPIES
• Apply elastic stockings before lowering legs from the bed.
• Activity
  – Frequent rest periods with legs elevated
  – If standing is necessary, frequently shift weight from side to side.
  – Appropriate exercise routine as part of conservative treatment
  – Walking regimen after sclerotherapy is important to help promote healing.
  – Never sit with legs hanging down.
• Physical therapy

SURGERY/OTHER PROCEDURES
Surgery
Once considered the gold-standard treatment, now minimally invasive outpatient procedures are preferred.

Surgery for varicose veins can be performed under general, local, or regional anesthesia and is performed as a day-case procedure in all but special cases.

The basic principle is disconnection of the refluxing superficial venous system from the deep system.

Saphenofemoral junction ligation (SJL) and saphenopopliteal junction ligation (SPJ): SPJ ligation is less successful than SFJ ligation, with high recurrence and complication rates, particularly regarding common peroneal nerve damage resulting in foot drop, which is a cause of litigation.

ONGOING CARE

DIET

- No special diet
- Weight-loss diet is recommended if obesity is a problem.

PATIENT EDUCATION

- Avoid long periods of standing and crossing legs when sitting.
- Exercise (walking, running) regularly to improve leg strength and circulation.
- Maintain an appropriate weight.
- Wear elastic support stockings.
- Avoid clothing that constricts legs.

PROGNOSIS

- Usual course: chronic
- Favorable with appropriate treatment

COMPLICATIONS

- Complications with sclerotherapy include hyperpigmentation, matting, local urticaria, cutaneous necrosis, microthrombi, accidental intra-arterial injection, phlebitis, deep vein thrombosis, thromboembolism, scintillating scotomas, nerve damage, and allergic reactions.
- Petechial hemorrhages
- Chronic edema
Superimposed infection
Varicose ulcers
Pigmentation
Eczema
Recurrence after surgical treatment
Scarring/nerve damage from stripping technique
Neurologic complications after sclerotherapy are rare.

REFERENCES

CODES

**ICD10**

- I83.90 Asymptomatic varicose veins of unspecified lower extremity
- I83.009 Varicose veins of unsp lower extremity w ulcer of unsp site
- I83.10 Varicose veins of unsp lower extremity with inflammation

**CLINICAL PEARLS**

- Once considered the gold-standard treatment, now minimally invasive outpatient procedures are preferred.
- RFA and EVLA have been demonstrated to be superior to open surgical techniques for the treatment of varicose veins with similar improvement in quality of life. NICE recommends using them as first-line treatment of truncal
vein incompetence.
BASICS

DESCRIPTION

An inflammatory blood vessel disorder

- Clinical features result from the destruction of blood vessel walls with subsequent thrombosis, ischemia, bleeding, and/or aneurysm formation.
- Vasculitis is a large, heterogeneous group of diseases classified by the predominant size, type, and location of involved blood vessels (1).
  - Small-vessel vasculitis
    o Microscopic polyangiitis (MPA)
    o Granulomatosis with polyangiitis (GPA, formerly Wegener granulomatosis)
    o Eosinophilic granulomatosis with polyangiitis (EGPA; formerly Churg-Strauss syndrome)
    o Antiglomerular basement membrane disease (anti-GBM)
    o Cryoglobulinic vasculitis
    o IgA vasculitis (formerly Henoch-Schönlein purpura)
    o Hypocomplementemic urticarial vasculitis
  - Medium-vessel vasculitis
    o Polyarteritis nodosa (PAN)
    o Kawasaki disease (KD)
  - Large-vessel vasculitis
    o Takayasu arteritis (TAK)
    o Giant cell arteritis (GCA)
- Vasculitis occurs as a primary disorder or secondary to infection, a drug reaction, malignancy, or connective tissue disease.
  - Variable vessel vasculitis
    o Behçet disease
    o Cogan syndrome
  - Single-organ vasculitis
    o Cutaneous leukocytoclastic angiitis
    o Cutaneous arteritis
    o Primary CNS vasculitis
- Vasculitis associated with systemic disease
  - Lupus vasculitis
  - Rheumatoid vasculitis
  - Sarcoid vasculitis
- Vasculitis associated with other etiology
  - Hepatitis C–associated cryoglobulinemic vasculitis
  - Hepatitis B–associated vasculitis
  - Syphilis-associated aortitis
  - Drug-induced immune complex vasculitis
  - Drug-associated antineutrophil cytoplasmic antibodies (ANCA)–associated vasculitis
  - Cancer-associated vasculitis
- Protean features often delay definitive diagnosis.

**EPIDEMIOLOGY**
Highly variable, depending on the particular syndrome
- Hypersensitivity vasculitis is most commonly encountered in clinical practice.
- KD, IgA vasculitis, and dermatomyositis are more common in children.
- TAK is most prevalent in young Asian women. GPA, MPA, and EGPA are more common in middle-aged males.
- GCA occurs exclusively in those >50 years of age and is rare in the African American population.

**Incidence**
Annual incidence in adults (unless otherwise specified)
- IgA vasculitis: 200 to 700/1 million in children <17 years of age
- GCA: 100 to 170/1 million in Caucasians age >50 years
- KD: depends on race/age; ~200/1 million
- PAN: 2 to 33/1 million
- GPA: 4 to 15/1 million
- MPA: 1 to 24/1 million
- EGPA: 1 to 3/1 million
- TAK: 2/1 million
- Primary CNS vasculitis: 2/1 million in adults
- Hypersensitivity vasculitis: depends on drug exposure
- Viral-/retroviral-associated vasculitis: unknown; >90% of cases of cryoglobulinemic vasculitis are associated with hepatitis C.
- Connective tissue disorder–associated vasculitis: variable
ETIOLOGY AND PATHOPHYSIOLOGY

- Three major immunopathogenic mechanisms
  - Immune-complex formation: systemic lupus erythematosus (SLE), IgA vasculitis (HSP), and cryoglobulinemic vasculitis
  - ANCA: GPA, MPA, and EGPA
  - Pathogenic T-lymphocyte response: GCA and TAK

Pathophysiology best understood where known drug triggers have been identified (e.g., antibiotics, sulfonamides, and hydralazine)

Genetics

- Several vasculitides linked to candidate genes.
- No single gene has been found to cause vasculitis.
- Angiotensin-converting enzyme insertion/deletion polymorphism is associated with susceptibility to vasculitis, especially in Behçet disease and IgA vasculitis.

RISK FACTORS

A combination of genetic susceptibility and environmental exposure likely triggers onset.

GENERAL PREVENTION

Early identification is the key to prevent irreversible organ damage in severe forms of systemic vasculitis.

COMMONLY ASSOCIATED CONDITIONS

Hepatitis C (cryoglobulinemic vasculitis), hepatitis B (PAN), cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV (viral-/retroviral-associated vasculitis), SLE, rheumatoid arthritis (RA), Sjögren syndrome, mixed connective tissue disease (MCTD), dermatomyositis, ankylosing spondylitis, Behçet disease, relapsing polychondritis (CTD-associated vasculitis), respiratory tract methicillin-resistant Staphylococcus aureus (MRSA) in GPA, levamisole-adulterated cocaine, medications: propylthiouracil, methimazole, hydralazine, minocycline, levamisole-tainted cocaine

DIAGNOSIS

HISTORY
- Consider age, gender, and ethnicity.
- Comprehensive medication history
- Family history of vasculitis
- Constitutional symptoms: fever, weight loss, malaise, fatigue, diminished appetite, sweats
- CNS/PNS: mononeuritis multiplex, polyneuropathy, headaches, visual loss, tinnitus, stroke, seizure, encephalopathy
- Heart/lung: myocardial infarction, cardiomyopathy, pericarditis, cough, chest pain, hemoptysis, dyspnea
- Renal: hematuria
- GI: abdominal pain, hematochezia, perforation
- Musculoskeletal: arthralgia, myalgia
- Miscellaneous: unexplained ischemic or hemorrhagic events, chronic sinusitis, and recurrent epistaxis
- Note the organs affected and estimate the size of blood vessels involved.
- Demographics, clinical features, and the predominant vessel size/organ involvement help identify specific type of vasculitis.

**PHYSICAL EXAM**
- Vital signs: blood pressure (hypertension) and pulse (regularity and rate)
- Skin: palpable purpura, livedo reticularis, nodules, ulcers, gangrene, nail bed capillary changes
- Neurologic: cranial nerve exam, sensorimotor exam
- Ocular exam: visual fields, scleritis, episcleritis
- Cardiopulmonary exam: rubs, murmurs, arrhythmias
- Abdominal exam: tenderness, organomegaly

**DIFFERENTIAL DIAGNOSIS**
- Fibromuscular dysplasia
- Embolic disease (atheroma, cholesterol emboli, atrial myxoma, mycotic aneurysm with embolization)
- Drug-induced vasospasm (cocaine, amphetamines, ergots)
- Thrombotic thrombocytopenic disorders (disseminated intravascular coagulation [DIC], thrombotic thrombocytopenic purpura [TTP], antiphospholipid syndrome, heparin- or warfarin-induced thrombosis), thromboangiitis obliterans
- Systemic infection (infective endocarditis, fungal infections, disseminated gonococcal infection, Lyme disease, syphilis, Rocky Mountain spotted fever [RMSF], bacteremia, ehrlichiosis, babesiosis)
Malignancy (lymphomatoid granulomatosis, angioimmunoblastic T-cell lymphoma, intravascular lymphoma)

Miscellaneous (Goodpasture syndrome, sarcoidosis, amyloidosis, Whipple disease, congenital coarctation of aorta)

DIAGNOSTIC TESTS & INTERPRETATION

**ALERT**
Renal involvement is often clinically silent. Routine serum creatinine and urinalysis with microscopy are needed to identify underlying glomerulonephritis.

- Initial tests exclude alternate diagnoses and guide therapy
- Routine tests
  - CBC
  - Liver enzymes
  - Serum creatinine
  - Urinalysis with microscopy
- Specific serology
  - Antinuclear antibodies (ANA)
  - Rheumatoid factor (RF)
  - Rapid plasma reagin/venereal disease reaction level (RPR/VDRL)
  - RMSF titers; Lyme titers
  - Complement levels C3, C4
  - ANCA
  - Antiproteinase 3 antibodies (anti-PR3)
  - Antimyeloperoxidase antibodies (anti-MPO)
  - Hepatitis screen for B and C
  - Cryoglobulin
  - Anti-GBM titer
  - HIV
  - Serum and urine protein electrophoresis
- Miscellaneous
  - Drug screen
  - ESR
  - C-reactive protein
  - Creatine kinase (CK)
  - Blood culture
  - ECG
CXR, CT scan, MRI, and arteriography may be required to delineate extent of organs involved.

**Diagnostic Procedures/Other**
- Electromyography with nerve conduction can document neuropathy and target nerve for biopsy.
- Biopsy of affected site confirms diagnosis (e.g., temporal artery, sural nerve, renal biopsy).
- If biopsy is not practical, angiography may be diagnostic for large- and medium-vessel vasculitides.
- Bronchoscopy may be required to differentiate pulmonary infection from potentially life-threatening hemorrhagic vasculitis in patients with hemoptysis.

**Test Interpretation**
Blood vessel biopsy shows immune cell infiltration into vessel wall layers with varying degrees of necrosis and granuloma formation, depending on the type.

**TREATMENT**

**GENERAL MEASURES**
- Discontinue offending drug (hypersensitivity vasculitis).
- Simple observation for mild cases of IgA vasculitis.
- ANCA-associated vasculitis has two-phase treatment: initial induction followed by maintenance (steady tapering of corticosteroids with immunosuppressants or immunomodulators).

**MEDICATION**

**First Line**
Corticosteroids are initial anti-inflammatory of choice.

**Second Line**
Cytotoxic medications, immunomodulatory, or biologic agents (e.g., cyclophosphamide (2)[B],(3)[A] methotrexate (4)[A], azathioprine (4)[A], leflunomide (4)[A], mycophenolate mofetil (2)[B], and rituximab (3)[A]) are often required in combination with corticosteroids for rapidly progressive vasculitis with significant organ involvement or inadequate response to
corticosteroids. Rituximab (3)[A] is the first FDA-approved treatment for GPA and MPA. Tocilizumab (5)[A] is the first FDA-approved treatment for GCA.

**ISSUES FOR REFERRAL**
- Rheumatology referral for complicated cases where newer or more toxic treatments are required
- Nephrology referral for persistent hematuria or proteinuria, rising creatinine, or a positive ANCA titer
- Pulmonary referral for persistent pulmonary infiltrate unresponsive to antibiotic therapy or if gross hemoptysis

**ADDITIONAL THERAPIES**
- IVIG and aspirin for KD, where corticosteroids are contraindicated
- Plasma exchange appears to improve recovery of patients with severe acute renal failure secondary to vasculitis and pulmonary hemorrhage (4)[A].

**SURGERY/OTHER PROCEDURES**
Rarely, corrective surgery is required to repair tissue damage as a result of aggressive vasculitis.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Hemoptysis, acute renal failure, intestinal ischemia, any organ-threatening symptoms or signs, and/or need for biopsy
- Initial therapy is guided by the organ system involved.
  - If pulmonary hemorrhage is present, life-saving measures may include mechanical ventilation, plasmapheresis, and immunosuppression.
  - If acute renal failure is present, attend to electrolyte and fluid balance and consider plasma exchange and immunosuppression.
  - If signs of intestinal ischemia are present, make NPO and consider plasmapheresis, immunosuppression, and parenteral nutrition.
- Discharge criteria: stabilization or resolution of potential life-threatening symptoms

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS
If significant coronary artery disease is involved in KD, moderate activity restriction may be of benefit.

Patient Monitoring
Frequent clinical follow-up supported by patient self-monitoring to identify disease relapse

DIET
Alter diets for patients with renal involvement or hyperglycemia/dyslipidemia.

PROGNOSIS
Prognosis is good for patients with vasculitis and limited organ involvement. Relapsing courses, renal, intestinal, or extensive lung involvement have a poorer prognosis.

COMPLICATIONS
- Persistent organ dysfunction may be the result of the disease, medications, or inflammation/scarring in the more serious forms of vasculitis.
- Early morbidity/mortality is due to active vasculitic disease; delayed morbidity/mortality may also be secondary to complications of chronic therapy with cytotoxic medications.

5. Villiger PM, Adler S, Kuchen S, et al. Tocilizumab for induction and

**ADDITIONAL READING**

- Vasculitis Foundation: [www.vasculitisfoundation.org/](http://www.vasculitisfoundation.org/)

**CODES**

**ICD10**

- I77.6 Arteritis, unspecified
- M31.30 Wegener’s granulomatosis without renal involvement
- M30.0 Polyarteritis nodosa

**CLINICAL PEARLS**

- Suspect vasculitis in patients with a petechial rash, palpable purpura, glomerulonephritis, pulmonary-renal syndrome, intestinal ischemia, or mononeuritis multiplex.
- Exclude silent renal involvement by routinely obtaining serum creatinine and urinalysis with microscopy.
- Vasculitis has “skip” lesions, which may complicate diagnostic biopsy.
- In patients with vasculitis, look for a primary underlying process such as medication, infection, thrombosis, or malignancy.
VENOUS INSUFFICIENCY ULCERS

Barbara J. Provo, MSN, FNP-BC, CWON • Theodore MacKinney, MD, MPH, CWSP

BASICS

- Venous insufficiency disorders include simple spider veins, varicose veins, and leg edema.
- In the United States, 23% of adults have varicose veins, an estimated 22 million women and 11 million men.
- Venous leg ulcers are the most serious consequence of venous insufficiency.
- Venous leg ulcers are a type of chronic wound affecting up to 1% of adults in developed countries at some point during their lives.
- 500,000 people in the United States have chronic venous ulcers, with an estimated treatment cost of >$3 billion per year.

DESCRIPTION

- Full-thickness skin defect with surrounding pigmentation and dermatitis
- Most frequently located in ankle region of lower leg (“gaiter region”)
- Present for >30 days and fails to heal spontaneously
- May only have mild pain unless infected
- Other signs of chronic venous insufficiency include edema/brawny edema and chronic skin changes (i.e., hyperpigmentation and/or fibrosis).

EPIDEMIOLOGY

Up to 80% of leg ulcers are caused by venous disease; arterial disease accounts for 10–25%, which may coexist with venous disease.

Incidence

- Overall incidence of venous ulcers is 18/100,000 persons.
- Prevalent sex: women > men (20.4 vs. 14.6 per 100,000 for venous ulcer); increased with age for both sexes

Prevalence

- Seen in ~1% of adult population in industrialized countries; increased to 5% in patients ≥80 years old
Prevalence studies only available for Western countries
Point prevalence underestimates the extent of the disease because ulcers often recur.
70% of ulcers recur within 5 years of closure.

ETIOLOGY AND PATHOPHYSIOLOGY
In a diseased venous system, venous pressure in the deep system fails to fall with ambulation, causing venous hypertension.
Venous hypertension comes from the following:
– Venous obstruction
– Incompetent venous valves in the deep or superficial system
– Inadequate muscle contraction (e.g., arthritis, myopathies, neuropathies) so that the calf pump is ineffective
Venous pressure transmitted to capillaries leading to venous hypertensive microangiopathy and extravasation of RBCs and proteins (especially fibrinogen)
Increased RBC aggregation leads to reduced oxygen transport, slowed arteriolar circulation, and ischemia at the skin level, contributing to ulcers.
Leukocytes aggregate to hypoxic areas and increase local inflammation.
Factors promoting persistence of venous ulcers
– Prolonged chronic inflammation
– Bacterial infection, critical colonization

RISK FACTORS
History of leg injury
Obesity
Congestive heart failure (CHF)
History of deep venous thrombosis (DVT)
Failure of calf muscle pump (e.g., ankle fusion, inactivity) is a strong independent predictor of poorly healing wounds.
Previous varicose vein surgery
Family history

GENERAL PREVENTION
Primary prevention after symptomatic DVT: Prescribe compression hose to be used as soon as feasible for at least 2 years (≥20 to 30 mm Hg compression).
Secondary prevention of recurrent ulceration includes compression, correction of the underlying problem, and surveillance. Circumstantial evidence from
two RCTs showed those who stopped wearing compression hose were more likely to recur.

- Compression hose reduces rates of recurrence compared with no compression.
- Because most ulcers develop following some type of trauma, avoiding lower leg trauma may help to prevent ulceration.

COMMONLY ASSOCIATED CONDITIONS

Up to 50% of patients have allergic reactions to topical agents commonly used for treatment.

- Contact sensitivity was more common in patients with stasis dermatitis (62% vs. 38%).

Avoid neomycin sulfate in particular (including triple antibiotic ointment) \(^{(1)}\) [A].

DIAGNOSIS

A diagnosis of venous reflux or obstruction must be established by an objective test beyond the routine clinical examination of the extremity.

HISTORY

- Family history of venous insufficiency and ulcers
- Recent trauma
- Nature of pain: achy (better with leg elevation)
- Wound drainage
- Duration of wound and over-the-counter (OTC) treatments already attempted
- History of DVTs (especially factor V Leiden mutation; strongly associated with ulceration)
- History of leg edema that improves overnight
- Edema that does not improve overnight is more likely lymphedema.

PHYSICAL EXAM

- Look for evidence of venous insufficiency:
  - Pitting edema
  - Hemosiderin staining (red and brown spotty or diffuse pigment changes)
  - Stasis dermatitis
  - White, nondraining skin lesions (atrophie blanche)
  - Lipodermatosclerosis (“bottle neck” narrowing in the lower leg from
fibrosis and scarring)
- Look for evidence of significant lymphedema (i.e., dorsal foot or toe edema, edema that does not resolve overnight or with elevation). This may require referral for special comprehensive lymph therapy.
- Examine for palpable pulses.

**ALERT**
- Examine wound for the following:
  - Length, width, depth, to monitor wound healing rate
  - Presence of necrotic tissue
  - Presence of biofilms or infection: purulent material in the wound, increased amount odorous exudate, spreading cellulitis, fever, and chills
- Get initial and interim girth measurements (at ankle and midcalf) to monitor edema.
- Important to rule out poor arterial circulation:
  - Compression dressings cannot be used in patients with ankle brachial index (ABI) <0.8.

**DIFFERENTIAL DIAGNOSIS**
- Arterial insufficiency ulcer
- Neuropathic ulcer
- Malignancy
- Sickle cell ulcer
- Vasculitic ulcer
- Calciphylaxis
- Cryoglobulinemia
- Pyoderma gangrenosum
- Collagen vascular disease
- Leishmaniasis
- Cutaneous tuberculosis

**DIAGNOSTIC TESTS & INTERPRETATION**
- Consider prothrombin time (PT)/international normalization ratio (INR) and partial thromboplastin time (PTT) if patient is anticoagulated.
- Consider biopsy of leg ulcers that fail to heal or have atypical features.
- Consider factor V Leiden mutation; strongly associated with venous ulcers
- Test for diabetes as necessary with fasting glucose.
- Use duplex imaging to diagnose anatomic and hemodynamic abnormalities with venous insufficiency. It will also identify any DVT present.
**Diagnostic Procedures/Other**
- Check ABI for evidence of arterial disease.
- An ABI <0.8 is a relative contraindication to compression therapy.
- Duplex imaging for evaluation of superficial and deep venous reflux and incompetent perforator veins
- With concomitant severe arterial insufficiency, refer to a vascular surgeon for revascularization.

**Test Interpretation**
Strongly consider biopsy on wounds with atypical locations, failure to heal, or any suspicion of malignancy.

---

**TREATMENT**

**GENERAL MEASURES**

Dressings: All wounds need some kind of a dressing underneath the compression system.
- Wound dressings: No single type of dressing has data indicating greater efficacy.
- Maintain semimoist wound environment: not excessively wet or dry.
- Wounds are often exudative until edema is decreased: Use absorptive dressings (calcium alginate or absorptive pads) \(^{(2)}[B]\). Both superabsorbent diapers and female protection pads are cost-effective alternatives.
- Consider using barrier ointment/cream to prevent maceration of surrounding skin.
- If wound tends to be dry, use a hydrogel.
- A hydrocolloid dressing may be used with minimal exudate, if skin adhesive is tolerated.

**MEDICATION**

- Effective compression management is the cornerstone of therapy.
- Diuretics may help to reduce edema, but compression is the mainstay.
- Routine use of antibiotics for all venous ulcers is not recommended \(^{(1)}[A],(2)\).
  Do not use antibiotics on noninfected wounds \(^{(2)}[A]\).
- Levamisole, not widely available, was the only systemic antibiotic with some evidence of benefit in terms of ulcer healing versus treatment of infection \(^{(2)}[B]\).
Evidence is insufficient for use of silver-based preparations and honey for healing wounds.

Pentoxifylline 400 mg PO TID, in addition to local care and compression, improves cure rates. There is some response even without compression. GI side effects are common (3)[A].

Aspirin 300 mg PO daily; effective when used with compression therapy

ISSUES FOR REFERRAL

With prominent toe or foot edema, consider lymphedema. Refer to a certified lymphedema therapist (CLT).

Refer to a wound clinic for complex or poorly healing ulcers.

Refer to a vein clinic or vascular specialist for recurrent ulcers.

Use home health nurses to help with immobile patients needing frequent wrapping/dressing changes.

ADDITIONAL THERAPIES

Edema management: Reduce venous hypertension and improve venous return to reduce inflammation, pain, and improve healing (4)[A].

- Compression therapy for edema management is the cornerstone of treatment for venous insufficiency with or without ulcers.
- Short-stretch multilayer bandages are ideal for acute phase, until edema is stable, and the patient can be fitted for compression hose.
- Long-term compression hose (fit once edema is reduced). Aim for a minimum pressure 20 to 30 mm Hg, preferably 30 to 40 mm Hg, if able to don.
- Elevation of legs to heart level for 30 minutes 3 to 4 times per day
- Exercise to strengthen calf muscle pump is also effective.

Infection control
- Débride necrotic tissue.
- Treat cellulitis (usually gram-positive bacteria) with bactericidal systemic antibiotics. Suspect local infection when there is pain or no improvement in the wound after 2 weeks of compression. Consider deep quantitative swab, after thorough cleansing, or tissue biopsy for culture.
- Treat critical colonization with topical antimicrobials, such as cadexomer iodine (silver dressings and honey are widely used, but definitive data are lacking) (2)[B].

For venous ulcers resistant to healing with wound care and compression,
consider adding an intermittent compression pump 1 to 4 hr/day.
- Encourage exercise (e.g., activation of calf muscle pump with ankle flexion and extension) in conjunction with leg compression and elevation.
- Negative pressure wound therapy (NPWT) (i.e., vacuum-assisted closure [VAC] dressings may be beneficial but no clear benefit over optimal traditional wound care).

**SURGERY/OTHER PROCEDURES**
- Necrotic tissue impedes healing.
  - Consider sharp débridement.
  - Other methods include enzymatic ointments (collagenase), low-frequency ultrasound, and wet-to-dry dressings.
  - Avoid using collagenase with silver dressings because silver inactivates the enzyme.
- In addition to standard skin grafts, there is a role for engineered grafts. Allografts made of synthetic bilayered skin with living keratinocytes and fibroblasts are the only cellular tissue product (CTP) to improve healing at 6 months; there is insufficient evidence to support use of autografts, xenografts (5)[A].
- In patients with ulcers refractory to conservative therapy, a variety of endovenous and surgical options exist. Vascular surgery consultation is recommended.
- Endovenous ablation of incompetent superficial and perforator veins shown to reduce size and recurrence of ulcers in those failing conventional compression therapy (6)[A].
- A subset of nonhealing ulcer patients have stenosis and obstruction of the deep venous system. Venous angioplasty and stenting is emerging as an important adjunct to compression and other therapies (6)[A].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Chestnut seed extract (50 mg BID) is effective for venous insufficiency but not ulceration.
- Topical medicinal honey used on wounds shows no evidence of improved healing.
- Oral zinc has not been shown to be beneficial.

**ADMISSION, INPATIENT, AND NURSING**
CONSIDERATIONS

- For those with acute significant cellulitis
- Infected wounds requiring IV antibiotics, especially in diabetics

ONGOING CARE

- Venous insufficiency is a lifelong issue.
- After resolution of an ulcer, edema management must be maintained lifelong.

FOLLOW-UP RECOMMENDATIONS

When ulcers are nearly healed and edema is controlled, switch from compression bandages to compression hose.

- Insurance may not reimburse for compression hose unless an ulcer is present.
- Referral for hose fitting must be done just prior to the ulcer being healed for some insurances to reimburse.

Patient Monitoring

Monitor the ulcer for healing by measuring its area. Expect at least 10% reduction every 2 weeks.

DIET

- Obese patients may benefit from weight loss.
- Low-salt diets help fluid retention.

PATIENT EDUCATION

Patient education for understanding of underlying mechanism is important for long-term management.

- Develop long-term plan for edema management and instruction on compression therapy.
- Instruct the patient on topical wound therapy.
- Teach early recognition and treatment of new ulcers or cellulitis.

PROGNOSIS

- Ulcers recur frequently. Early identification and immediate treatment are essential.
- Ongoing diligence, with edema control, avoiding infections, and avoiding
trauma, are important.

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- I87.2 Venous insufficiency (chronic) (peripheral)
I83.009 Varicose veins of unsp lower extremity w ulcer of unsp site
I89.0 Lymphedema, not elsewhere classified

CLINICAL PEARLS

- Initial diagnostic workup should include venous duplex scan and arterial evaluation.
- Refer patients with ABI <0.8 to vascular surgery specialist.
- Refer patients with recurrent or venous ulcers failing to heal with moist wound care and compression after 4 to 6 weeks, to venous specialist or wound specialist.
- Compression is essential for edema management with or without wounds.
- Treat critical colonization with topical antimicrobials (avoid neomycin).
- Make sure that the diagnosis is correct and biopsy when in doubt.
VENTRICULAR SEPTAL DEFECT

Luay Sarsam, MD • Cherry Onaiwu, MD, MS • Carrie Valenta, MD, FACP

BASICS

DESCRIPTION

- Congenital or acquired defect of the interventricular septum that allows communication of blood between the left and the right ventricles
- Second most common congenital heart malformation reported in infants and children. It can also occur as a complication of acute myocardial infarction (MI).
- Severity of the defect is correlated with its size, with large defects being the most severe.
- Blood flow across the defect typically is left to right, depending on defect size and pulmonary vascular resistance (PVR).
- Prolonged left to right shunting of blood can lead to pulmonary hypertension (HTN). This may eventually lead to a reversal of flow across the defect and cyanosis (Eisenmenger complex).

Geriatric Considerations
Almost entirely associated with MI

Pediatric Considerations
Congenital defect

ALERT

- Pregnancy may exacerbate symptoms and signs of a ventricular septal defect (VSD).
- Can be tolerated during pregnancy if VSD is small
- May be associated with an increased risk of preeclampsia in women with an unrepaired VSD

EPIDEMIOLOGY

Incidence
• Congenital defect: no gender predilection, occurs in ~2/1,000 live births and accounts for 30% of all congenital cardiac malformations
• Post-MI: Some studies suggest that gender may play a role.

Prevalence
In the United States:
• Occurs in ~ 50% of all children with congenital heart disease
• Low prevalence in adults (~0.3 per 1,000) due to spontaneous closure
• Post-MI complication in ~0.2–3% of cases

ETIOLOGY AND PATHOPHYSIOLOGY
• Congenital
• In adults, complication of MI
• Some reports of iatrogenic causes

Genetics
Multifactorial etiology; autosomal dominant and recessive transmissions have been reported.

RISK FACTORS
• Congenital VSD:
  – Risk of sibling being affected: 4.2%
  – Risk of offspring being affected: 4%
  – Prematurity
• Post-MI VSD:
  – Advanced age
  – Arterial HTN
  – First MI
  – Most frequent within 1st week after MI
  – Most commonly after anterior wall acute MI

GENERAL PREVENTION
Avoid prenatal exposure to known risk factors (ibuprofen, marijuana, organic solvents, febrile illness). For adults, avoid risk factors for MI and obtain evaluation before pregnancy.

COMMONLY ASSOCIATED CONDITIONS
• Congenital:
- Tetralogy of Fallot
- Aortic valvular deformities, especially aortic insufficiency and bicuspid aortic valve
- Down syndrome (trisomy 21), endocardial cushion defect
- Transposition of great arteries
- Coarctation of aorta
- Tricuspid atresia
- Truncus arteriosus
- Patent ductus arteriosus
- Atrial septal defect
- Pulmonic stenosis
- Subaortic stenosis

- Adult: coronary artery disease

**DIAGNOSIS**

**HISTORY**

- Presentation depends on degree of shunting across the defect; may be completely asymptomatic with small defects
- Respiratory distress, tachypnea, tachycardia
- Diaphoresis with feeds, poor weight gain in infants

**PHYSICAL EXAM**

- Small defect:
  - Harsh holosystolic murmur loudest at left lower sternal border
  - Detected after PVR drops at 4 to 8 weeks of life
- Moderate defect:
  - Harsh holosystolic murmur at left lower sternal border associated with a thrill
  - Forceful apical impulse with lateral displacement
  - Increased intensity of P2
  - Diastolic rumble at apex due to increased flow across the mitral valve
- Large defect:
  - Holosystolic murmur heard throughout the precordium with diastolic rumble at apex with precordial bulge and hyperactivity, although large defects may have little or no murmur initially
  - If congestive heart failure (CHF) exists: tachycardia, tachypnea, and...
hepatomegaly
- If pulmonary HTN exists: cyanosis with exertion
- If Eisenmenger complex is present: cyanosis and clubbing

**DIFFERENTIAL DIAGNOSIS**
- Patent ductus arteriosus, atrial septal defect
- Children: tetralogy of Fallot
- Adults: mitral regurgitation

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- A 12-lead ECG may show left ventricular hypertrophy and left atrial enlargement initially. As pulmonary HTN develops, right ventricular hypertrophy and right atrial enlargement may be seen.
- A chest x-ray (CXR) may demonstrate increased pulmonary vascularity and/or cardiomegaly.
- A 2D echocardiogram for visualization of location and size of defect
- Color flow Doppler for direction and velocity of VSD jet; may be used to estimate right ventricular pressure
- Ventriculography in conjunction with above imaging modalities can aid in characterization of VSD but is invasive.

**Follow-Up Tests & Special Considerations**
- Weight and hematocrit check
- Cardiac catheterization performed occasionally for perioperative planning or to assess need for closure of defect

**Diagnostic Procedures/Other**
- Cardiac catheterization (left and right sides of heart) can confirm the diagnosis, document number of defects, quantify ratio of pulmonary blood flow to systemic blood flow (Qp/Qs), and determine PVR.
- Demonstration of an oxygen saturation step up from the right atrium to the distal pulmonary artery

**Test Interpretation**
- Congenital VSD (four major anatomic types)
  - Membranous (70%)
  - Muscular (20%)
– Atrioventricular canal type (5%)
– Supracristal (5%; higher in Asians)

● Post-MI VSD predominantly involves muscular septum.
● Right bundle branch block is common after surgical repair.

**TREATMENT**

● Start diuretic therapy if signs of fluid overload (1)[A].
● Minimize IV fluids.
● Consider ACE inhibitor and/or digoxin.
● Nasogastric feeds for neonates
● Correct anemia via iron supplementation or a possible RBC transfusion.

**GENERAL MEASURES**

● Appropriate health care maintenance
● Outpatient, until surgical repair is indicated
● Inpatient management in setting of acute MI
● Inpatient for treatment of severe CHF

**MEDICATION**

*First Line*

● Per the 2007 American Heart Association guidelines, endocarditis antibiotic prophylaxis is not recommended for most VSDs. It is recommended for VSDs associated with complex cyanotic heart disease, during the first 6 months after surgical repair, or for residual VSDs located near the patch following surgery (2)[A].

● Pediatric: Medications aim to control pulmonary edema, decrease work of breathing, and allow for growth:
  – Furosemide 1 to 2 mg/kg PO/IV once to twice a day
  – Spironolactone 1 to 2 mg/kg/day divided BID
  – Captopril
    o Infants: oral: 0.3 to 2.5 mg/kg/day divided every 8 to 12 hours; max 2 mg/kg/day
    o Children and adolescents: oral: 0.3 to 6.0 mg/kg/day divided every 8 to 12 hours; maximum daily dose: 150 mg/day
  – Digoxin: infants <2 years of age, 10 μg/kg/day PO divided BID; children, 2 to 10 years of age, 5 to 10 μg/kg/day PO divided BID; children >10 years of
age, 2 to 5 μg/kg/day PO divided BID
- Adults: Digoxin and diuretics may be beneficial in some circumstances (1)[A].
- Side effects:
  - Drugs that increase systemic vascular resistance may increase left-to-right shunting and cause signs and symptoms of pulmonary overcirculation.
  - HTN

**Second Line**
- Surgical closure is indicated if the pulmonic-to-systemic flow is >2:1 or with poorly controlled pulmonary overcirculation despite maximal medical and dietary interventions.
- If an infant with a VSD has persistent pulmonary HTN or failure to grow, surgical repair is recommended prior to 6 months of age even if patient is otherwise asymptomatic.
- For post-MI VSDs, afterload reduction, inotropic support, intra-aortic balloon pump, and left ventricular assist device may be used to stabilize the patient prior to surgery. Surgical repair includes septal débridement and patch placement.

**ISSUES FOR REFERRAL**
Close follow-up of a congenital VSD is necessary until primary intracardiac repair is performed to ensure that significant pulmonary HTN does not develop.

**ADDITIONAL THERAPIES**
- Infant caloric requirements up to 150 kcal/kg/day or more for adequate weight gain
- Treatment of iron deficiency anemia to increase oxygen-carrying capacity

**SURGERY/OTHER PROCEDURES**
- Surgical correction with either a VSD patch or repair is commonly used. Postsurgical outcomes for isolated VSD are excellent. Complications are rare and include reoperation for residual VSD, extended hospital stay, arrhythmias, valve injury, depressed ventricular function, and heart block (3)[B].
- Percutaneous transcatheter device closure has become a safe and effective option for some children with small to moderate VSDs. Complications include valvular regurgitation, residual defects, and heart block. There is a greater risk of conduction abnormality with this technique compared to
surgical closure. Recent studies have shown steroids may decrease this risk (4)[A].

- Perventricular device closure (hybrid technique) of some subtypes of isolated VSDs without cardiopulmonary bypass is feasible under transesophageal echocardiographic (TEE) guidance. Complications are similar to percutaneous closure (5)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Failure to thrive
- Pulmonary overcirculation/CHF
- Stabilize airway.
- Reduce temperature stress.
- Frequent vital sign monitoring; daily weight and calorie counts
- Discharge criteria: CHF stabilization, weight gain, or successful repair

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Small VSDs without evidence of CHF or pulmonary HTN generally can be followed every 1 to 5 years after the neonatal period.
- Moderate to large VSDs require more frequent follow-up.
- Potential complications of VSDs include right ventricular outflow obstruction and aortic valve prolapse.

Patient Monitoring

- Physical growth and development monitoring
- Influenza vaccine for children >6 months of age
- Palivizumab to children <12 months of age with hemodynamically significant lesions. Children with small VSDs do not need RSV prophylaxis (6)[A].

DIET

- Low sodium in heart failure
- High calorie in failure to thrive

PATIENT EDUCATION
• No activity restriction in absence of pulmonary HTN
• Parents need support and instructions for prevention of complications until the child is ready for surgery.

PROGNOSIS
• Congenital:
  – Course is variable depending on the size of the VSD.
  – Small VSD: Many will close spontaneously by age 3 years. Muscular defects are more likely to close spontaneously.
  – Large VSD: CHF or failure to thrive in infancy necessitating surgical repair
  – 20-year cumulative survival rate after surgery for isolated VSD is 87%; 40 years is 78% (7).
  – Progressive pulmonary vascular disease and pulmonary HTN are the most feared complications of VSD caused by left-to-right shunting and may eventually lead to reversal of the shunt (Eisenmenger complex). Death usually occurs in the 4th decade of life if untreated.
• Post-MI:
  – With medical management alone, 80–90% mortality in the first 2 weeks
  – Prognosis worse with inferior MI compared with anterior MI

COMPLICATIONS
• CHF
• Aortic insufficiency
• Sudden death
• Hemoptysis
• Cerebral abscess
• Paradoxical emboli
• Cardiogenic shock
• Heart block rarely may accompany surgical closure.
• Pulmonary HTN

SEE ALSO

Acute Coronary Syndromes: NSTE-ACS (Unstable Angina and NSTEMI); Down Syndrome; Tetralogy of Fallot

CODES

ICD10

- Q21.0 Ventricular septal defect
- I23.2 Ventricular septal defect as current comp following AMI
- Q21.3 Tetralogy of Fallot
CLINICAL PEARLS

- A loud 2/6 to 3/6 low-pitched harsh holosystolic murmur at the left lower sternal border is typical.
- A diastolic rumble at the apex indicates moderate to large VSD or ratio of pulmonary to systemic blood flow (Qp/Qs) >2:1, which likely will require surgical or percutaneous closure.
- Disappearance of the murmur could be secondary to spontaneous closure of the defect or the development of pulmonary HTN.
- Development of a new murmur of semilunar valve insufficiency should be further evaluated. Pulmonary regurgitation may occur as PVR increases, and the development of aortic regurgitation usually will require early surgery.
VERTIGO
Jeremy Raab, MD • James J. Arnold, DO, FAAFP

BASICS
DESCRIPTION
- A symptom, not a disease process. Causes can be peripheral or central, benign or life-threatening. Cause determines treatment.
- May be described as a sensation of movement (“room spinning”) when no movement is actually occurring
- However, do not rely on symptom quality—often unreliable. Focus on timing and triggers (1).
- System(s) affected: nervous, cardiovascular, psych
- Synonym(s): dizziness

EPIDEMIOLOGY
Incidence
- Vertigo accounts for half of cases of dizziness reported in primary care; >90% of these patients are diagnosed with peripheral causes (2).
- Predominant sex: female = male; women are 3x more likely to experience vertiginous migraine (1).

Geriatric Considerations
- Keep a higher index of suspicion for CVD, arrhythmias, orthostatic hypotension.
- BPPV is most common among the elderly, is often undiagnosed, and is an important risk factor for falls.

Prevalence
- Ranges from 5% to 10% within the general population
- Lifetime prevalence for BPPV is 2.4%.

ETIOLOGY AND PATHOPHYSIOLOGY
- Dysfunction of the rotational velocity sensors of the inner ear results in asymmetric central processing; combination of sensory disturbance of motion and malfunction of the central vestibular apparatus
Peripheral causes: acute vestibular neuritis, BPPV (posterior canal 85–95%, lateral canal 5–15%), Ménière disease, otosclerosis, acute labyrinthitis, cholesteatoma, perilymphatic fistula, superior canal dehiscence syndrome, motion sickness (1,2). BPPV, vestibular neuritis, and Ménière disease account for 93% of all peripheral causes (2).

Central causes: cerebellar tumor, stroke, migraine, vestibular ischemia (1,2)

Drug causes: psychotropic agents, anticonvulsants, aspirin, aminoglycosides, furosemide (diuretics), amiodarone, α-/β-blockers, nitrates, urologic medications, muscle relaxants, phosphodiesterase inhibitors (sildenafil), excessive insulin, ethanol, quinine, cocaine

Other causes: orthostasis, arrhythmia, psychological

Genetics
Family history of CVD/migraines may indicate higher risk of central causes.

RISK FACTORS
- History of migraines
- History of CVD/risk factors for CVD
- Use of ototoxic medications
- Trauma/barotrauma
- Perilymphatic fistula
- Heavy weight bearing
- Psychosocial stress/depression
- Exposure to toxins

GENERAL PREVENTION
If due to motion sickness, consider pretreatment with anticholinergics, such as scopolamine.

DIAGNOSIS

HISTORY
- Avoid over-reliance on patient description of how symptoms feel; focus on triggers and timing (1).
- TiTRATE is a clinically useful evaluation tool: **Timing, Triggers, And a Targeted Evaluation** (1).
- **Timing**: episodic or continuous. Episodic may last seconds to a few days.
Continuous lasts days to weeks.
- If continuous, assess for trauma or toxins (including prescribed and recreational).
- To further evaluate continuous, spontaneous vertigo, perform HINTS exam (1,3) (see “Physical Exam”).
- If episodic, assess for triggers.

**Triggers:** present or absent
- If triggers, perform Dix-Hallpike maneuver.
- Do not confuse *worsening* of symptoms with motion to be the same as triggering. Many central vertigos are worse with movement (1).
- If no triggers, assess for hearing loss, migraines, or psych symptoms. Cardiovascular causes may also fall into this category.

**And a Targeted Evaluation:** See “Physical Exam” for more details.
- Include assessment for orthostasis, assessment for nystagmus, and Dix-Hallpike maneuver (1)[C].

**Specific history items that suggest a diagnosis:**
- Unilateral hearing loss suggests Ménière disease (1)[C]. Further assess to determine if sensorineural versus conductive, as the latter suggests otosclerosis.
- Symptoms triggered by sudden change in head position suggest BPPV.
- Symptoms triggered when going from sitting to standing suggests orthostatic hypotension.
- History of migraines suggests vestibular migraine. Differentiate from non-migrainous headaches, which can also be present with CNS tumors.
- Depressed mood/anxiety with episodic vertigo that has since become continuous suggests psychiatric causes.
- History of unilateral sensory or motor symptoms indicates a central cause such as TIA or CVA until proven otherwise.
- Onset after decompression (diving, flying) suggests decompression sickness or barotrauma and warrants emergency evaluation.

**PHYSICAL EXAM**
- Cardiovascular: orthostatic blood pressure assessment on all patients (1)[C]
- HEENT: may identify barotrauma, otosclerosis, cholesteatoma. Also check Rinne and Weber tests if hearing loss.
- Neurologic: Assess for nystagmus in all patients (1)[C].
  - Vertical nystagmus is almost always of central origin.
  - Peripheral nystagmus may be horizontal or rotational.
- Dix-Hallpike maneuver: for episodic, triggered vertigo (1,4)[C]: Rapidly
move the patient from seated to supine position with the head turned 45 degrees to the right. Observe for nystagmus and patient report of vertigo. Nystagmus/vertigo may not appear immediately. Wait until symptoms resolve and then return the patient to the sitting position. Repeat on the left.

– The presence of extinguishing horizontal nystagmus is a positive test. If induced nystagmus does not subside however, consider central causes and perform HINTS.
– Vertical nystagmus always indicates a central cause even if triggered by Dix-Hallpike.
– In primary care, PPV of 83% for BPPV and NPV of 52%
– If Dix-Hallpike negative, check for lateral canal BPPV with a log roll test (5)[C].
– If duration and trigger of symptoms is not consistent with BPPV, do not perform Dix-Hallpike to avoid overlooking a central cause.

• HINTS exam: Perform for continuous, spontaneous vertigo with spontaneous nystagmus (1,3)[C].
  – Horizontal Head Impulse: Rapidly and repeatedly bring patient’s head to midline from 20 degrees. Patients with vestibular neuritis will show rapid saccades to refocus on a target. With normal peripheral nervous function, eyes stay on target, raising concern for central causes.
  – Direction changing Nystagmus: Having already assessed for presence and direction of nystagmus, now check for changing direction. Nystagmus that changes direction with eye motion indicates a central lesion.
  – Test of Skew: Vertical eye movement during cover-uncover test indicates a central lesion. A normal test has no movement.
  – A combination of these findings is 96.8% sensitive, 98.5% specific for CVA/other central cause (HINTS positive) (3)[C].
  – If a patient meets criteria for HINTS exam, do not perform Dix-Hallpike.
• Perform a full neuro exam if diagnosis not already clear, paying attention to sensation, gait, and Romberg testing.

DIFFERENTIAL DIAGNOSIS
Causes (1):
• BPPV (episodic, triggered, positive Dix-Hallpike)
• Orthostatic hypotension (episodic, triggered, positive orthostatic blood pressure drop)
• Ménière disease (episodic, spontaneous, associated with unilateral sensorineural hearing loss)
- Otosclerosis (spontaneous, duration varies, unilateral conductive hearing loss)
- Vestibular migraine (episodic, associated with migraine HA)
- CVD (continuous, spontaneous. HINTS exam shows normal horizontal head impulse, direction-changing nystagmus, or vertical skew on cover-uncover)
- Posterior fossa tumor (continuous, spontaneous)
- Psychiatric (associated psych symptoms)
- Medication/toxin (continuous, medication/substance history, evaluation otherwise negative)
- Other cardiovascular such as arrhythmia (episodic, often no triggers or triggered by exertion)
- Hypoglycemia (episodic, associated medications or comorbidities)
- Perilymphatic fistula, canal dehiscence (trauma including suspicion of barotrauma from history)
- Decompression sickness (acute, recent dive or flight)
- Degenerative neurologic disease (often progressive by hx, associated neurologic findings)
- Peripheral neuropathy

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- Labs not routinely necessary unless abnormal neuro exam, and identify a cause in <1% of patients (1,4)[C].
- Start MRI if a central cause is suspected to rule out stroke. CT cannot reliably see the posterior fossa and will not show changes in the early stages of an infarct. Vertigo may be the only symptom of acute stroke (3,4)[C].
- ENT/audiology referral if Ménière disease suspected for electronystagmography (1),(4)[C]
- If acoustic neuroma is suspected, either CT or MRI to evaluate internal auditory canal (1),(4)[C]

*Diagnostic Procedures/Other*

Audiometry if acoustic neuroma or Ménière disease is suspected

**TREATMENT**

**GENERAL MEASURES**

Treatments depend on cause.
BPPV: Epley maneuver \([1,2,5]\)[A] and modified Epley maneuver \([2]\)[B] (Epley maneuver–YouTube)

Vestibular neuritis and labyrinthitis
- Vestibular-suppressant medications \([1][C],(2]\)
- Vestibular rehabilitation exercises \([1),(4][B]\)
- No evidence to support improvement of symptoms with corticosteroid use \((6)[B]\)

Ménière disease (see separate topic) \((1,2)[B]\):
- Low-salt diet (<1 to 2 g/day)
- Diuretics such as hydrochlorothiazide

Vascular ischemia: prevention of future events through BP reduction, lipid lowering, smoking cessation, antiplatelet therapy, and anticoagulation, if necessary \((1),(2,3)[C]\); MRI or CT if suspected

Vertiginous migraines: dietary and lifestyle modifications, vestibular rehab, prophylactic and abortive medications \((2)[B]\)

Psychological: SSRIs are better than benzodiazepines for anxiety-related vertigo. Use slow titration to avoid worsening symptoms \((2)[B]\).

MEDICATION
Avoid use of medication in mild cases. Use for a few days only, as longer use may impair adaptation/compensation by the brain \((1,2);\) medications not recommended for BPPV \((1),(2,5)[C]\)

- Meclizine: 12.5 to 50.0 mg PO q4–8h \((1,2]\)
- Dimenhydinate: 50 mg PO q6hr \((1]\)
  - Precautions: prostatic hyperplasia, glaucoma
  - Adverse effects: sedation, xerostomia
  - Interactions: CNS depressants
- Prochlorperazine: 5 to 10 mg PO or IM q6–8h; 25 mg rectally q12h; 5 to 10 mg by slow IV over 2 minutes \((1,2]\)
  - Contraindications: blood dyscrasias, age <2 years, hypotension
  - Precautions: acutely ill children, glaucoma, breast cancer history, impaired cardiac function, prostatic hyperplasia
  - Adverse effects: sedation, extrapyramidal effects
  - Interactions: phenothiazines, tricyclics antidepressants
- Metoclopramide: 5 to 10 mg PO q6h, 5 to 10 mg slow IV q6h \((1,2]\)
  - Contraindications: concomitant use of drugs with extrapyramidal effects, seizure disorders
  - Precautions: history of depression, Parkinson disease, hypertension
– Adverse effects: sedation, fluid retention, constipation
– Interactions: linezolid, cyclosporine, digoxin, levodopa

Psychiatric causes (1)
– SSRIs for depression/anxiety (1)[B]
– Lorazepam (Ativan) 0.5 to 2.0 mg orally, IM, or IV q4–8h for short-term relief of more severe anxiety
– Diazepam (Valium) 2 to 10 mg orally or IV q4–8h for short-term relief of more severe anxiety

Geriatric Considerations
Use vestibular-suppressant medications with caution due to increased risk of falls and urinary retention.

Pregnancy Considerations
Meclizine and dimenhydrinate are pregnancy Category B.

ISSUES FOR REFERRAL
Consider referral to otolaryngologist, ENT specialist, vestibular rehabilitation therapist, or neurologist if patient requires further care.

ADDITIONAL THERAPIES
– Epley maneuver/modified Epley maneuver for BPPV to displace calcium deposits in the semicircular canals (1,2,5)[A]
  – Effective for short-term symptomatic improvement and for converting patient from positive to negative Dix-Hallpike maneuver. Some studies suggest long-term relief (2)[C].
– Lateral canal BPPV may respond to barbecue roll maneuvers (5)[C].
– Vestibular rehabilitation exercises: ball toss, lying-to-standing, target-change, thumb-tracking, tightrope, walking turns (2)[B]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Balance exercises should be adhered to for symptom reduction and return to normal activities of daily living (ADLs).

Patient Monitoring
After 1 to 2 weeks, assess for the following:
- Recurrence of symptoms
- New-onset symptoms
- Medication-related adverse effects
- Relief from vestibular rehabilitation exercises

**DIET**
- Restricted salt intake for Ménière disease
- Dietary modifications for vertiginous migraine
- Heart healthy diet for CVD

**PATIENT EDUCATION**
- Reduce sodium intake (Ménière disease).
- Avoid triggers such as caffeine/alcohol (vertiginous migraine).

**PROGNOSIS**
Depends on diagnosis and response to treatment

**COMPLICATIONS**
- Anxiety
- Depression
- Disability
- Injuries from falls

**REFERENCES**

**CODES**

**ICD10**

- R42 Dizziness and giddiness
- H81.10 Benign paroxysmal vertigo, unspecified ear
- H81.49 Vertigo of central origin, unspecified ear

**CLINICAL PEARLS**

- TiTrATE your assessment.
- Acute, spontaneous, continuous vertigo with a normal horizontal head impulse, direction-changing nystagmus, and skew deviation (HINTS positive) is highly sensitive and specific for CVA.
- Episodic, triggered vertigo with positive Dix-Hallpike test is consistent with BPPV.
- If patient warrants a HINTS exam, do not perform Dix-Hallpike, as central cause can also produce a positive Dix-Hallpike.
- The Epley maneuver is recommended for the treatment of BPPV.
Medications are not recommended for BPPV.
VERTIGO, BENIGN PAROXYSMAL POSITIONAL (BPPV)

Chirag N. Shah, MD, FACEP • Kyung In Yoon, MD

BASICS

DESCRIPTION
- Benign paroxysmal positional vertigo (BPPV) is a mechanical disorder of the inner ear characterized by a brief period of vertigo experienced when the position of the patient’s head is changed relative to gravity.
- Vertigo results from the mismatch of the perception of movement by the visual, vestibular, and proprioceptive symptoms when none exist.
- The brief period of vertigo is caused by abnormal stimulation of ≥1 of the 3 semicircular canals of the inner ear, with the posterior canal most commonly affected.
- BPPV is the single most common cause of vertigo.

EPIDEMIOLOGY
- Lifetime prevalence is 2.4% and 1-year incidence 0.6%.
- Age of onset is most commonly between the 5th and 7th decades of life.
- Incidence of increases with each decade of life
- Prevalent sex: female > male
- BPPV affects the quality of life of elderly patients and is associated with reduced activities of daily living scores, falls, and depression.

Prevalence
- Common
- Lifetime prevalence 2.4% with 1-year incidence 0.6%

ETIOLOGY AND PATHOPHYSIOLOGY
- In BPPV, calcite particles (otoconia) that normally weight the sensory membrane of the maculae become dislodged and settle into the semicircular canal, changing the dynamics of the canal. Reorientation of the canal relative to gravity causes the otoconia to move to the lowest part of the canal, causing displacement of the endolymph, deflection of the cupula, and activation of the
primary afferent. This results in the generation of nystagmus and the associated sensation of vertigo.

- BPPV may be idiopathic, posttraumatic, or associated with viral neurolabyrinthitis.

**DIAGNOSIS**

- The diagnosis is established based on history and findings on positional testing, clarified by Dix and Hallpike in 1952 (1,2)[A].
- Positional tests place the plane of the canal being tested into the plane parallel with gravity.

**HISTORY**

- Brief episodes of vertigo (sensation that the room is spinning) associated with
  - Rolling over in bed
  - Getting out of bed
  - Looking up (referred to as “top-shelf syndrome”)
  - Bending forward
  - Quick head movements
- Patients may also complain of light-headedness or feeling “off balance.”
- Frequently, patients complain of nausea and, if severe enough, vomiting.

**PHYSICAL EXAM**

- The Dix-Hallpike test (DHT) is used to diagnose BPPV (1)[A]. The test provokes the characteristic nystagmus associated with the symptoms of vertigo. For the DHT, the estimated sensitivity is 79% (95% CI 65–94) and specificity is 75% (95% CI 33–100) (3)[B].
- To perform the DHT, the patient is positioned in long-sitting on the exam table with the knees extended. The head is then rotated 45 degrees toward the side to be tested. The patient is then lowered quickly to supine with the head 30 to 40 degrees below the horizontal, over the edge of the exam table. The position is maintained for a minimum of 45 to 60 seconds.
- For each position, the clinician notes the direction of the fast phase of the nystagmus and the latency and duration of the nystagmus.
- Supportive for BPPV: latency period of <30 seconds between head movement and onset of nystagmus, nystagmus peaks then slowly resolves, duration of nystagmus is 5 to 40 seconds, nystagmus reverses direction with head positioning from the down direction to the sitting position, and repeated head
positioning causes the vertiginous symptoms with nystagmus to fatigue

- **Posterior canal BPPV:**
  - In the head-hanging position, the otoconia move away from the ampullary organ resulting in upward ipsitorsional nystagmus.
  - The superior poles of the eyes beat up toward the forehead and rotate toward the lower most ear, the involved ear.
  - On return to the seated position, the otoconia move toward the ampullary organ resulting in the nystagmus reversing direction.
  - The latency of onset of nystagmus is 1 to 45 seconds, and the duration is usually <1 minute.
  - The nystagmus fatigues (reduction in the severity of symptoms) with repeated positioning.

- **Horizontal canal BPPV**
  - Directional-changing positional nystagmus is observed in the test positions; the eyes will beat linear-horizontal toward the ground (geotropic nystagmus) or beat toward the sky (apogeotropic nystagmus).
  - One position may illicit a stronger nystagmus response. The side with great intensity indicates the side involved with geotropic lateral canal BPPV and the uninvolved side with apogeotropic lateral canal BPPV.

- **Anterior canal BPPV**
  - In the head-hanging position, the nystagmus is downbeating and torsional, with the top of the eye torting away from the lower ear.
  - Usually caused by “canal switching” from canalith repositioning procedure (CRP) maneuvers.
  - No further testing is indicated unless the diagnosis is uncertain, or there are additional symptoms and signs unrelated to BPPV that warrant testing.

- **Peripheral versus central vertigo**
  - Onset: sudden versus sudden or slow
  - Severity: intense spinning versus less intense
  - Pattern: paroxysmal versus constant
  - Aggravated by movement: yes versus variable
  - Nausea or diaphoresis: frequent versus variable
  - Nystagmus: rotatory-vertical, horizontal versus vertical
  - Fatigue of symptoms: yes versus no
  - Hearing loss or tinnitus: may occur versus no
  - Abnormal TM: may occur versus no
  - CNS symptoms: No versus usually present

- **Red flags in vertigo**
  - Neurologic deficit, ipsilateral hearing loss, gait abnormality, direction-
changing nystagmus

- **Head Impulse Nystagmus Test of Skew (HINTS)**
  - Head impulse test of vestibulo-ocular reflex function
    - Normally, eye movement will correct with rapid head movement so that the center of the vision remains on a target. This reflex fails in peripheral causes of vertigo.
    - Have patient fix their eyes on your nose, and move their head in the horizontal plane to the left and then to the right.
    - When the head is turned toward the normal side, the vestibulo-ocular reflex remains intact and eyes are fixated on the examiner’s nose.
    - When the head is turned toward the affected side, the vestibulo-ocular reflex fails and the eyes make a corrective saccade to refixate on the examiner’s nose.
    - It is reassuring if the reflex is abnormal (due to dysfunction of the peripheral nerve).
  - Nystagmus in primary, right, and left gaze
  - Test for skew deviation “vertical dysconjugate gaze.”
    - Skew deviation is a fairly specific predictor of central lesion in patients with acute vestibular syndrome.
    - The presence of skew may help identify stroke when a positive head impulse test falsely suggests a peripheral lesion.
    - Have patient look at your nose with their eyes and start by covering one eye and then rapidly move to cover the other eye, do this rapidly back and forth.
    - When each eye is uncovered, quickly look to see if the eye has movement or refixation. Horizontal is normal, vertical is not.
  - In the setting of dizziness and vertigo, HINTS substantially outperforms ABCD² for stroke diagnosis and outperforms MRI obtained within the first 2 days after symptom onset (4)[B].

**DIFFERENTIAL DIAGNOSIS**

- Orthostatic hypotension and other disorders that cause low BP; symptoms usually occur when the patient stands up.
- Damage to the brainstem or cerebellum can cause positional vertigo but is accompanied by other neurologic signs and usually has a different pattern of nystagmus.
- Low spinal fluid pressure may cause positional symptoms that are better when the patient lies down.
- Migraine-associated vertigo
- Traumatic brain injury
- Brain tumors
- Brain hemorrhage or infarction
- Vestibular neuronitis

**TREATMENT**

The CRP or Epley maneuver is effective in the treatment of posterior canal BPPV (1)[A]. Using a particle repositioning maneuver, the clinician moves the patient through a series of positions. With each position, the otoconia settles to the lowest part of the canal. The debris is moved around the arc of the canal into the vestibule. In randomized controlled trials, the average short-term success rate of the CRP following one treatment session is 80 ± 9% (1)[A].

The clinician moves the patient through a series of four provoking positions:
- Placement of the right posterior canal (involved canal) in the right head-hanging position of the DHT
- The head is then rotated a total of 90 degrees toward the left (uninvolved side) into 45 degrees of left head rotation.
- Maintaining 45 degrees of left head rotation, the patient is rolled onto the left side (uninvolved side) with the head slightly elevated from the supporting surface.
- The patient then sits up and flexes the neck 36 degrees. Each position is maintained for a minimum of 45 seconds or as long as the nystagmus lasts. The procedure is repeated 3 times.

CRP is the best maneuver for posterior BPPV and should be offered to all age groups (5)[A].

Semont maneuver is also another maneuver, less superior when performed alone (5)[A].

Contraindications are carotid stenosis, unstable cardiac disease, and severe neck disease. If the CRP is ineffective, self-administered CRP is performed at home (1)[A]. The patient performs the CRP on the bed with the head extended over the edge of a pillow. Better outcomes are achieved with a combination of CRP with self-administered CRP (1)[A].

CRP and Semont are ineffective for horizontal BPPV; variations of the Lempert maneuver, barbecue roll, or Gufoni maneuver are widely used treatment methods for horizontal BPPV.
Postmaneuver activity restrictions were previously advocated, but in controlled trials, it did not differ in clinical outcomes (2,5)[A].

MEDICATION
- Vestibular suppressant medications are not recommended for treatment of BPPV, other than for the short-term management of vegetative symptoms (3)[A].
- Antiemetics such as ondansetron (Zofran) may be considered for prophylaxis for patients who have had severe nausea or vomiting with the DHT.
- Vestibular suppressants such as benzodiazepines and antihistamine anticholinergics such as meclizine should be avoided because they may suppress nystagmus during the DHT and treatment.

ISSUES FOR REFERRAL
Consider a referral to a specialist if BPPV is unresponsive to treatment or if the patient is diagnosed with atypical BPPV involving the anterior or lateral canal. Consider referring to a physical therapist, neurologist, or an otolaryngologist.

ADDITIONAL THERAPIES
- Brandt-Daroff exercises and habituation exercises are not as effective as self-administered CRP. At 1 week, the average success rate for the Brandt-Daroff exercise is 23–24% compared with 90% for self-administered CRP (1)[A].
- Surgical intervention is rarely indicated, except for refractory BPPV, and includes posterior canal occlusion and singular neurectomy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
The patient should follow up within a week after treatment to ensure resolution.

PATIENT EDUCATION
A number of illustrative videos are available at www.youtube.com for education and self CRP maneuvers.

PROGNOSIS
80% cure rate with CRP maneuvers, with a 30% recurrence rate at 1 year, and 44% redevelop BPPV within 2 years
COMPLICATIONS
During the maneuvers, a canal conversion may occur. The debris from the canal being treated may reflux into another canal.

ADDITIONAL READING
ICD10
- H81.10 Benign paroxysmal vertigo, unspecified ear
- H81.12 Benign paroxysmal vertigo, left ear
- H81.11 Benign paroxysmal vertigo, right ear

CLINICAL PEARLS
- The diagnosis of BPPV is based on history and findings on positional testing.
- The typical presentation is a report of transient episodes of vertigo (sensation that the room is spinning) associated with a change in position of the head relative to gravity.
- BPPV may be treated effectively with particle-repositioning maneuvers in the office and at home.
- Vestibular suppressant medications and antiemetics are not recommended for treatment of BPPV, other than for the short-term management of symptoms.
- Patients should always be ambulated in to verify normal gait prior to discharge.
VINCENT STOMATITIS

Elisa R. Wing, MD • Daniel V. Girzadas Jr., MD

BASICS

DESCRIPTION

- Inflammatory oral infection of the gingiva, characterized by pain, ulcerations, and necrotizing damage to interdental papillae
- Caused by an imbalance of oral flora resulting in a predominance of invasive anaerobic bacteria: *Fusobacterium, Prevotella intermedia*, and spirochetes
- Concomitant infection with Epstein-Barr virus, herpes simplex virus, and type 1 human cytomegalovirus is common.
- Organisms invade gingiva and interdental papillae with the formation of a gray pseudomembranous exudate.
- Clinical presentation includes pain, fetid breath, gingival ulcerations, bleeding, and interdental papillary necrosis. It is differentiated from other periodontal diseases by rapid onset, pain, ulcerated gingival mucosa, and “punched out” interdental papillary necrosis.
- Synonym(s): Vincent angina; trench mouth; acute necrotizing ulcerative gingivitis

EPIDEMIOLOGY

Incidence

- Predominant age: 18 to 30 years in developed countries
- Affects both genders with similar frequency
- Malnourished children ages 3 to 14 years

Prevalence

- Prevalence is low in healthy children up to age 18 years.
- Prevalence is more common in persons aged 18 to 30 years. Prevalence increases with malnutrition, immunocompromised, poor oral hygiene, and smoking, or those from underdeveloped countries.

ETIOLOGY AND PATHOPHYSIOLOGY

- Impaired host immunologic response due to immunocompromised or malnutrition
Disruption of normal oral flora with predominance of invasive anaerobic bacteria
Loss of integrity and necrosis of the gingival mucosa and interdental papillae
Increased bacterial attachment with herpesvirus active infection

RISK FACTORS
- Malnutrition
- Immunosuppression (cancer, HIV infection)
- Tobacco use
- Poor oral hygiene
- Infrequent or absent dental care
- Orthodontics
- Herpesvirus infection
- Psychological stress

GENERAL PREVENTION
- Appropriate nutrition
- Proper oral hygiene
- Regular dental care
- Prompt recognition and institution of therapy
- Management of medical problems such as cancer and HIV infection
- Stress management

COMMONLY ASSOCIATED CONDITIONS
- Seen most commonly in malnourished patients, patients undergoing cancer treatment, or those from underdeveloped countries
- HIV infection
- Vitamin deficiencies
- Bacteremia
- Osteomyelitis
- Tooth loss
- Dehydration
- Noma/cancrum oris, which can be life threatening
- Aspiration pneumonia

DIAGNOSIS
HISTORY
- Acute onset of oral pain
- Gingival ulcerations
- Fetid odor of breath
- Bleeding and necrosis of interdental papillae
- Cervical adenopathy
- Fever
- Malaise
- History of immunosuppression, chemotherapy, HIV infection
- History of herpesvirus infection

PHYSICAL EXAM
- Fetid odor of breath
- Ulceration of gingival mucosa
- Inflamed, erythematous gingiva
- Necrosis of interdental papillae
- Gingival bleeding
- Formation of gray, pseudomembranous exudate
- Cervical lymphadenopathy
- Fever and malaise may be present.

DIFFERENTIAL DIAGNOSIS
- Herpes simplex virus
- Periodontitis
- Recurrent aphthous stomatitis
- Medication side effects
- Oral malignancy
- Xerostomia
- Diphtheria
- Lymphoma/leukemia
- Primary syphilis
- Ascorbic acid deficiency
- Gingivitis
- Behçet disease
- Granulomatosis with polyangiitis
- Oral mucositis
- Erosive lichen planus
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Diagnosis is primarily based on clinical exam, but if systemic illness or invasive spread to deeper tissue or bone is suspected, the following studies should be considered:
- Aerobic and anaerobic cultures of inflamed or débrided tissue
- Group A strep rapid antigen detection assay
- Group A strep throat culture
- Blood cultures if systemic involvement
- Dental radiographs
- CT imaging of the face and neck if infection has progressed

TREATMENT

GENERAL MEASURES
Elimination of tobacco, improved nutritional status, and improved immunologic status will increase rate of healing and reduce risk of future gingival disease.

MEDICATION
Most cases are treatable on outpatient basis. Severe disease with systemic effects and/or neck involvement requires inpatient treatment.

First Line
- Chlorhexidine gluconate 0.12% 15 mL 30 seconds rinse/spit QID (1)[C] plus
- Penicillin V potassium 250 to 500 mg QID PO for 10 days; pediatric dosing: 25 to 50 mg/kg/day divided q6–8h or
- Metronidazole 500 mg q8h for 7 to 10 days (2)[C]; pediatric dosing: 30 mg/kg/day divided q6h or
- Amoxicillin 500 mg TID PO for 7 days (2)[C]; pediatric dosing: 25 to 45 mg/kg/day divided q12h or
- Amoxicillin-clavulanate 875 mg q12h for 7 to 10 days (2)[C]; pediatric dosing: 25 to 45 mg/kg/day divided q12h (based on amoxicillin component)

Second Line
- Tetracycline 250 to 500 mg QID PO for 10 days (do not use for children <8 years of age); pediatric dosing: 25 to 50 mg/kg/day divided q6h or
Erythromycin 250 to 500 mg QID PO for 10 days; pediatric dosing: 30 to 50 mg/kg/day divided q6–8h or
Clindamycin 450 mg q8h for 7 to 10 days; pediatric dosing: 10 to 25 mg/kg/day divided q6–8h

**Pediatric Considerations**
- Chlorhexidine and alcohol mouth rinses are generally avoided due to risk of ingestion, but chlorhexidine may be prescribed in gel format for topical application.
- Metronidazole is first-line oral therapy (refer to dosing above) (3).

**ISSUES FOR REFERRAL**
Severe disease requires débridement by consultant dentist, oral surgeon, or ENT specialist.

**ADDITIONAL THERAPIES**
- Warm saline rinses q2h
- Sodium bicarbonate toothpaste, brush q2h
- Viscous lidocaine 2% 1 tbsp rinse/spit q6–8h
- NSAID medications q4–12h
- Opioid analgesics q4–6h (severe pain)
- Treatment of underlying immunodeficiency (if present)

**SURGERY/OTHER PROCEDURES**
- Débridement of inflamed/necrotic gingival tissue
- Dental extraction
- Gingival restoration

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Multivitamins

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Severe disease, failure of oral antibiotics, or ongoing comorbidities
- Parenteral antibiotics and/or analgesia requirement
- Inability to tolerate PO
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Close dental follow-up
- Primary care follow-up
- Specialty follow-up (if underlying immunodeficiency)

DIET
- Soft diet until healed
- Balanced nutritional diet
- Multivitamin supplementation

PATIENT EDUCATION
- Proper nutrition
- Oral hygiene
- Tobacco cessation

COMPLICATIONS
- Pain
- Malnutrition
- Gingival/tooth loss
- Deep infection of neck
- Systemic infection

REFERENCES

ADDITIONAL READING
1051.

**CODES**

**ICD10**

A69.1 Other Vincent’s infections

**CLINICAL PEARLS**

- Immunosuppression, malnourishment, smoking, and poor oral hygiene are key risk factors for necrotizing ulcerative gingivitis.
- Diagnosis is largely clinical based on symptoms of oral pain, fetid breath, gingival ulcerations, interdental papillary necrosis, and grayish exudate on the gingival surface.
- Most patients experience rapid improvement following appropriate treatment with chlorhexidine rinses, improved oral hygiene, and oral antibiotics.
- Smoking cessation and treatment of malnutrition or underlying illness are additional important treatment considerations.
- Severe disease requires débridement of necrotic gingival tissue.
VITAMIN B₁₂ DEFICIENCY

Justin D. Chaltry, DO • Katie L. Westerfield, DO, IBCLC, FAAFP

**BASICS**

- Vitamin deficiency related to inadequate intake or absorption of cobalamin (vitamin B₁₂)
- Cobalamin is critical for CNS myelination and normal functioning.
- Deficiency can cause a multitude of symptoms and disorders including megaloblastic anemia, bone marrow dysfunction, and diverse and potentially irreversible neuropsychiatric changes.
- Neuropsychiatric disorders are due to demyelination of cervical, thoracic dorsal, and lateral spinal cords; demyelination of white matter; and demyelination of cranial and peripheral nerves (1)[C].
- Low vitamin B₁₂ level can lead to elevated methylmalonic acid (MMA) and homocysteine levels (2)[C].
- Elevated MMA causes abnormality in fatty acid synthesis affecting neuronal membrane.
- Elevated homocysteine is neurotoxic through overstimulation of the N-methyl-d-aspartate (NMDA) receptor and toxic to vasculature through activation of coagulation system and effects on endothelium.

**DESCRIPTION**

Normal B₁₂ absorption

- B₁₂ present in animal-source foods (meat, fish, eggs, milk) and foods fortified with B₁₂
- Dietary vitamin B₁₂ (cobalamin) bound to food is cleaved by acids in stomach and bound to haptocorrin (commonly known as R-factor).
- Duodenal proteases cleave B₁₂ from haptocorrin.
- In duodenum, B₁₂ uptake depends on binding to intrinsic factor (IF) secreted by gastric parietal cells.
- B₁₂-IF complex is absorbed by terminal ileum into portal circulation.
- Body’s B₁₂ stored in liver = 50–90%
– $B_{12}$ secreted into bile from liver recycled via enterohepatic circulation
– Delay 5 to 10 years from onset of $B_{12}$ deficiency to clinical symptoms due to hepatic stores and enterohepatic circulation

• Typical Western diet: 5 to 30 $\mu$g/day; however, only 1 to 5 $\mu$g/day is effectively absorbed.
  – Recommend 2.4 $\mu$g/day for adults and 2.6 $\mu$g/day during pregnancy and 2.8 $\mu$g/day during lactation (most prenatal vitamins contain $B_{12}$).

**EPIDEMIOLOGY**

**Prevalence**

• Endemic area: Northern Europe, including Scandinavia; more common in those of African ancestry
• Increasing recognition in breastfed-only infant populations with vitamin $B_{12}$–deficient mothers
• Prevalence 5–20% in developed countries
  – 12% in elderly living in community
  – 30–40% in elderly in institutions, sick, or malnourished
  – 5% patients in tertiary reference hospitals
• Prevalence by age group
  – 20 to 39 years old: prevalence 3%
  – 40 to 59 years old: prevalence 4%
  – >70 years old: prevalence 6%

**ETIOLOGY AND PATHOPHYSIOLOGY**

• Decreased oral intake
  – Vegetarians and vegans: $B_{12}$ is found in animal source foods; however, strict vegetarians uncommonly develop deficiency because only 1 mg/day is needed, with adequate amounts present in legumes.
• Decreased IF
  – Pernicious anemia (PA): can be associated with autoantibodies directed against gastric parietal cells and/or IF
  – Chronic atrophic gastritis: autoimmune attack on gastric parietal cells causing autoimmune gastritis and leading to decreased IF production
  – Gastrectomy: Removal of entire or part of stomach decreases number of parietal cells.
• Decreased ileal absorption
  – Crohn disease: Terminal ileal inflammation decreases body’s ability to
absorb B₁₂.
– Chronic alcoholism: decreases body’s ability to absorb B₁₂
– Ileal resection
– Pancreatic insufficiency: Pancreatic proteases are required to cleave the vitamin B₁₂–haptocorrin bond to allow vitamin B₁₂ to bind to IF.
– *Helicobacter pylori* infection: impairs release of B₁₂ from bound proteins

Medications: Proton pump inhibitors (PPIs), H₂ antagonists, and antacids decrease gastric acidity, inhibiting B₁₂ release from dietary protein; metformin
– Metformin usage
  o Chronic metformin usage leads to vitamin B₁₂ deficiency. Caused by calcium-dependent membrane inhibition, interfering with vitamin B₁₂–IF absorption. Years on metformin is the only predictive factor for B₁₂ deficiency.

Hereditary (rare)
– Imerslünd-Grasbeck disease (juvenile megaloblastic anemia)
– Congenital deficiency of transcobalamin
– Severe methylene tetrahydrofolate reductase deficiency
– Abnormalities of methionine synthesis

Causes:
– Food-cobalamin malabsorption syndrome
  o As many as 60–70% of cases
  o Primary cause in elderly
  o Pathophysiology: inability to release cobalamin from food or binding protein, especially if in the setting of hypochlorhydria
  o Seen in atrophic gastritis, long-term ingestion of antacids and biguanides, possible relationship to *H. pylori* infection

PA
  o 15–30% of all cases; most frequent cause of severe disease. Neurologic disorders are common presenting complaints.
  o Common in elderly, as high as 20%, with mild atrophic gastritis, hypochlorhydria, and impaired release of dietary vitamin B₁₂
  o Autoimmune disease with destruction of gastric fundal mucosa cells via a cell-mediated process
  o Anti-gastric parietal cell antibodies: sensitivity >90%, specificity 50%; use for screening test
  o Anti-IF antibodies: sensitivity 50%
  o Associated with other autoimmune diseases
– Insufficient dietary intake: 2% of cases; vegans or long-standing vegetarians
– Infants born to vitamin B$_{12}$-deficient mothers may have deficiency or develop it if breastfed exclusively.
– Intestinal causes:
  o 1% of cases; prevalence depends on risk factors, such as surgical conditions.
  o Gastrectomy: due to decreased production of IF
  o Gastric bypass: appears 1 to 9 years after surgery, prevalence 12–33%
  o Ileal resection or disease
  o Fish tapeworm
  o Severe pancreatic insufficiency
– Undetermined etiology
  o 1/10 of cases

**Genetics**
Imerslünd-Grasbeck disease (juvenile megaloblastic anemia) caused by mutations in the amnionless (AMN) or cubilin (CUBN) genes with autosomal recessive pattern of inheritance; inadequate ileal uptake of B$_{12}$-IF complex and B$_{12}$ renal protein reabsorption

**GENERAL PREVENTION**
Risk factors: vegan diet, age >65 years, female, chronic atrophic gastritis, Crohn disease or other ileal disorders, chronic medication use including PPI, metformin, H$_2$ antagonists

**DIAGNOSIS**
Symptoms and physical exam findings:
- Asymptomatic patients may be diagnosed by the incidental finding of anemia or an elevated mean corpuscular volume (MCV) during routine testing or evaluation of unassociated disorders.
- Hematologic
  – Frequent: macrocytosis, neutrophil hypersegmentation, spinal cord medullar megaloblastosis (blue spinal cord)
  – Rare: isolated thrombocytopenia and neutropenia, pancytopenia
  – Very rare: hemolytic anemia, thrombotic microangiopathy with schistocytes
Neuropsychiatric
- Frequent: sensory polyneuritis, paresthesias, positive Babinski sign, weakness, gait unsteadiness, loss of proprioception (impaired vibratory sensation, positive Romberg, ataxia, hyperreflexia)
- Classic but uncommon: subacute combined degeneration of spinal cord associated with PA; myelin degeneration in the lateral and posterior columns; ataxia, proprioception and vibration loss, bowel and bladder incontinence, orthostatic hypotension, decreased memory, mania, delirium, psychosis, depression

Digestive
- Classic: Hunter glossitis, jaundice, and high lactate dehydrogenase and bilirubin
- Possible: abdominal pain, dyspepsia, nausea, vomiting, diarrhea
- Rare: mucocutaneous ulcers

Other
- Frequent: pallor, edema, jaundice
- Under investigation: chronic vaginal and urinary infections, atrophy of vaginal mucosa, hypofertility, venous thromboembolism, angina, miscarriages
- Commonly insidious and nonspecific; thus, delay in diagnosis is common.

HISTORY
- Underlying disease associated with vitamin B₁₂ deficiency
- Fatigue, anorexia
- Depression
- Falls (due to diminished proprioception)
- Loss of sensation in “stocking-glove” distribution
- Glossitis/loss of sense of taste and other subtle, nonspecific neurologic symptoms

DIAGNOSTIC TESTS & INTERPRETATION
- Measurement of vitamin B₁₂, CBC (MCV)
- Measurement of B₁₂ may be low or low normal depending on institution’s cutoff value.
  - 65–95% sensitivity levels <200 pg/mL
  - May need additional tests such as MMA and homocysteine if vitamin B₁₂ level is low normal (<350 pg/mL) and no evidence of anemia depending on clinical suspicion
If high suspicion on normal B₁₂ with high/normal MCV, consider testing MMA and homocysteine levels.

- MCV often increased
- Measurement of MMA
  - More sensitive and specific than homocysteine
  - Levels increased in renal failure and volume depletion.
- Measurement of homocysteine
  - Levels increased in folate deficiency, renal failure, and homocystinuria.
- MMA and homocysteine levels only reliable in an untreated patient, as levels fall with supplementation
- Other tests: folate and other markers of anemia (iron studies)
- MCV may be normal, decreased, or increased if vitamin B₁₂ deficiency coexists with other forms of anemia, such as iron deficiency or hemolysis. Thus, RBCs may be normochromic, normocytic, or hypochromic microcytic.

**ALERT**

- Low levels of vitamin B₁₂ are seen in folate deficiency, HIV, and multiple myeloma.
- Elevated levels of vitamin B₁₂ are seen in renal disease, occult malignancy, and alcoholic liver disease and as a result of technical error.
- Macrocytosis may be due to folate deficiency, reticulocytosis, medications, bone marrow dysplasia, and hypothyroidism or be masked by concomitant microcytic anemia.
- Serum homocysteine and MMA
  - Elevated in B₁₂ deficiency secondary to decreased metabolism
  - If both are normal, B₁₂ deficiency is effectively ruled out.
  - If MMA is normal and homocysteine is increased, think folate deficiency.
- PA
  - Check antibody to IF; positive test is confirmatory for PA, but sensitivity is only 50–70%.
  - Antiparietal cell antibody positivity indicates PA.
  - For patients who are antibody positive, consider screening for autoimmune thyroid disease.

**Pregnancy Considerations**

- Because B₁₂ crosses the placenta, pregnant women with low levels of B₁₂ are at higher risk of having children with neural tube defects, congenital heart
defects, developmental delay, and failure to thrive.

- Exclusively breastfed infants of mothers who are B₁₂ deficient are at risk of developing B₁₂ deficiency. Infants breastfed from B₁₂-deficient mothers might not show signs or symptoms until 4 to 6 months of age, which may include developmental regression, feeding difficulties, lethargy, or hypotonia.

**Diagnostic Procedures/Other**

- Bone marrow exam is usually unnecessary in the evaluation of B₁₂ deficiency because of the inability to differentiate from folate deficiency.
- Spinal cord imaging is not standard; MRI in selected cases, especially with severe myelopathy

**TREATMENT**

**MEDICATION**

- Parenteral cyanocobalamin replacement recommended in patients with severe neurologic symptoms: IM cyanocobalamin (2)[C]
  - 1,000 μg/day for 7 days, then
  - 1,000 μg weekly for 4 weeks, then
  - 1,000 μg monthly for life

- High-dose, daily oral cyanocobalamin at doses of 1,000 to 2,000 μg are as effective as monthly intramuscular injection and is the preferred route of initial therapy in most circumstances because it is cost-effective and convenient (3)[A]. Requires greater patient compliance. Transnasal and buccal preparations of cyanocobalamin are also available; however, further study is needed.

**ALERT**

Folic acid without vitamin B₁₂ in patients with PA is contraindicated; it will not correct neurologic abnormalities.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Consider blood transfusion for severe anemia.
- Draw blood for hematologic parameters before transfusing.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Hematologic
  - Reticulocytosis in 1 week
  - Rise in hemoglobin beginning at 10 days; usually will return to normal in 6 to 8 weeks
  - Monitor potassium in profoundly anemic patients (hypokalemia due to potassium use).
  - Serum MMA decreases with replacement therapy.
- Neurologic: can note improvement within 3 months of treatment; however, maximum improvement noticed at 6 to 12 months. Some symptoms may be irreversible.

Diet

Meat, animal protein, and legumes unless contraindicated

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**

- E53.8 Deficiency of other specified B group vitamins
- D51.0 Vitamin B₁₂ defic anemia due to intrinsic factor deficiency
- D51.3 Other dietary vitamin B₁₂ deficiency anemia

**CLINICAL PEARLS**

- Consider screening for B₁₂ deficiency in high-risk patients including the elderly and monitoring B₁₂ levels annually if on metformin or on chronic PPIs.
- Correcting folate deficiency without treating with cyanocobalamin in megaloblastic anemia may correct hematologic but not neurologic disorders.
- Vitamin B₁₂ deficiency can coexist with other causes of anemia, including iron deficiency or hemolysis; thus, MCV can be normal, decreased, or increased.
- For patients with PA, cyanocobalamin replacement must be lifelong.
- Patients with PA are at increased risk for other autoimmune conditions as well as gastric malignancy.
VITAMIN D DEFICIENCY

Frank J. Domino, MD • Samir Malkani, MD, MRCP—UK

BASICS
This topic covers the commonly acquired vitamin D deficiency and not type II vitamin D–resistant rickets/type I pseudovitamin D–resistant rickets (both rare autosomal recessive disorders).

DESCRIPTION
- Vitamin D is a hormone and a vitamin.
- Cholecalciferol (D₃) is synthesized in the skin by exposure to ultraviolet B (UV-B) radiation. Ergocalciferol (D₂) and D₃ are present in foods.
- D₂ and D₃ are hydroxylated in the liver to 25 vitamin D (calcidiol), the major circulating form.
- Calcidiol is further hydroxylated in the kidney to the active metabolite 1,25 vitamin D (calcitriol).
- Hypocalcemia stimulates parathyroid hormone (PTH) to be secreted, which prompts the increased conversion of 25 vitamin D to 1,25 vitamin D.
  - 1,25 vitamin D decreases renal calcium and phosphorus excretion, increases intestinal calcium and phosphorus absorption, and increases osteoclast activity. The net result is an increase in serum calcium.

EPIDEMIOLOGY
- A community cohort study of asymptomatic adolescents in Boston found 24% were deficient, with 5% severely deficient.
- A study of hospitalized patients in Massachusetts found 57% vitamin D–deficient (VDD).
- Women with history of osteoporosis/osteoporotic fracture have high prevalence of vitamin D deficiency.
- A cohort study in Arizona found >25% of adults were VDD; highest rates among African Americans and Hispanics
- A study of about 56,000 individuals across Europe found 13% to have vitamin D deficiency.
Pediatric Considerations
NHANES data suggest 70% of children do not have sufficient 25-OH vitamin D serum levels (9% deficient and 61% insufficient); associated with an increase in BP and decrease in high-density lipoprotein (HDL) cholesterol

ETIOLOGY AND PATHOPHYSIOLOGY
- Insufficient dietary intake of vitamin D and/or lack of UV-B exposure (in sunlight) results in low levels of vitamin D.
  - This limits calcium absorption, causing excess PTH release.
- PTH stimulates osteoclast activity, which helps to normalize calcium and phosphorous, but results in osteomalacia.
- Dietary deficiency
  - Inadequate vitamin D intake
- Inadequate sunlight exposure
  - Institutionalized/hospitalized patients
- Chronic illness: liver/kidney disease
- Malabsorptive states

Genetics
Vitamin D–dependant rickets type 1 occurs due to inactivating mutation of the 1α hydroxylase gene; as a result, calcidiol is not hydroxylated to calcitriol.

RISK FACTORS
- Inadequate sun exposure
- Female
- Dark skin
- Immigrant populations
- Low socioeconomic status
- Latitudes higher than 38 degrees
- Elderly
- Institutionalized
- Depression
- Medications (phenobarbital, phenytoin)
- Gastric bypass surgery/malabsorption syndromes
- Obesity

GENERAL PREVENTION
- Adequate exposure to sunlight and dietary sources of vitamin D (plants, fish);
many foods are fortified with vitamin D$_2$ and D$_3$.  

- Recommended minimum daily requirement is 600 IU/day from age 1 to 70 years and 800 IU/day for those >70 years. Up to 4,000 IU/day is safe in healthy adults without risk of toxicity.
- For ages 51 to 70 years, minimally recommended supplementation is 800 IU/day to prevent nonvertebral fractures.

**Pediatric Considerations**  
- The American Academy of Pediatrics recommends all breastfed babies receive 400 IU/day of vitamin D beginning “within the first few days of life.”
- 2016 Global Consensus Recommendations suggest all infants, regardless of feeding method, begin vitamin D 400 IU within a few days of birth (1).

**Pregnancy Considerations**  
Insufficient data to recommend routine screening of all pregnancies; only “at risk” should be screened; it is safe to take 1,000 to 2,000 IU/day during pregnancy (2)[B].

**Geriatric Considerations**  
U.S. Preventive Services Task Force recommends at least 800 IU/day vitamin D plus exercise or physical therapy to reduce risk of falls in community-dwelling older adults (3)[A].

**COMMONLY ASSOCIATED CONDITIONS**  
- Osteomalacia, osteoporosis
- Premenstrual syndrome
- Rickets
- Celiac disease
- Gastric bypass
- Chronic renal disease
- Bacterial vaginosis in pregnant women
- Hypertension

**ALERT**  
Vitamin D deficiency is associated with risk of myocardial infarction (MI) and all-cause mortality (4)[A].
DIAGNOSIS

- Nonspecific musculoskeletal complaints
- Weak antigravity muscles
- Fracture with minimal trauma

HISTORY

- Senior citizens at risk of falling
- Renal disease
- GI (malabsorption) disorders
- Liver dysfunction
- Immigration from tropical to colder climates
- Dark-skinned/veiled individuals
- Housebound patients
- Women at perimenopause

PHYSICAL EXAM

- Vague neurologic signs: numbness, proximal myopathy, paresthesias, muscle cramps, laryngospasm
- Chvostek sign: contraction of the facial muscles by tapping along the facial nerve
- Trousseau phenomenon: carpal spasms and paresthesia produced by pressure on nerves and vessels of the upper arm, by inflation of a BP cuff
- Tetany, seizures

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- 25-OH vitamin D (most sensitive measure of vitamin D status)
- Vitamin D deficiency
  - <20 ng/mL
- PTH elevation: not routinely obtained unless severe deficiency
- Low-normal/low calcium and phosphorous
- Elevated alkaline phosphatase (in later disease)
- Plain radiographs: If atypical fracture, radiographs may show osteomalacia (pseudofractures/looser zones) in pelvis, femur, and fibula.
- Osteoporosis screen
  - Women ≥65 years with no risk factors
  - Women ≥60 years at risk: body weight <70 kg (best predictor)
– Less evidence: smoking, low body mass index, family history, decreased activity, alcohol or caffeine use
– African American women have higher bone density than Caucasians.

**TREATMENT**

- Treatment goals remain unclear, but current “normal” 25-OH vitamin D levels are based on suppression of PTH.
- Obesity: Treatment of VDD in obesity, especially those who are obese and depressed, improves depressive symptoms and may improve weight loss.
- Systematic review level data showing vitamin D supplementation lowers URI risk in adults, improves outcomes in asthma, depression, breast cancer

**ALERT**

All-cause mortality: Cochrane Systematic Review found vitamin D supplementation lowers all-cause mortality (5)[A].

*Geriatric Considerations*

In senior citizens, serum 25-OH vitamin D of 20 ng/mL resulted in improved physical performance scores; recent data suggests supplementation may not improve fracture risk and remains unclear about a true benefit.

**MEDICATION**

- Vitamin D sufficient (25-OH vitamin D ≥20 ng/mL)
  - Vitamin D 800 to 4,000 IU/day D$_2$/D$_3$
  - D$_3$ (animal derived) may be slightly more effective than D$_2$ (plant derived), but clinical significance is uncertain.
  - Calcium supplementation: unclear benefit and may increase some CHD risk in patients; no supplementation currently required (see below)
- Vitamin D deficiency (25-OH vitamin D <20 ng/mL)
  - D$_2$ 50,000 IU/week for 8 to 12 weeks, followed by 800 to 2,000 IU/day of vitamin D$_3$
- Calcium: meta-analysis data support
  - Dietary intake of ~700 mg/day leads to best outcomes; higher doses did NOT decrease risk of osteoporotic fractures.
  - Dietary calcium may be more beneficial than calcium supplementation.
  - Supplementary calcium associated with an increased risk of MI, especially
in women, but this data remains controversial.

ISSUES FOR REFERRAL
Endocrinology if no response to treatment

ADDITIONAL THERAPIES
Aggressive calcium in ICU patients with ionized calcium <3.2 mg/dL or if symptomatic (tetany, seizures, QT prolongation, bradycardia, or hypotension or ventilated patient with decreased diaphragmatic function)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Symptoms of severe hypocalcemia
- Malabsorption syndromes

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Follow-up of abnormal 25-OH vitamin D not required

DIET
- Cod liver oil is most potent source of vitamin D and has ~1,300 IU vitamin D/tablet/tables
- Fatty fish (tuna, salmon)
- Fortified milk (100 IU/8 oz), cereal, and foods

PROGNOSIS
- Systematic review of 63 observational studies found adequate 25-OH vitamin D levels correlate with lower rates of colon, breast, and prostate cancer.
- Cohort study found that vitamin D deficiency is correlated with increased risk of all-cause mortality.

ALERT
Meta-analysis data support supplementation of >500 IU/day lowered the risk of all-cause mortality (5,6)[A] but remains controversial.
REFERENCES

CODES

ICD10
- E55.9 Vitamin D deficiency, unspecified
- M83.8 Other adult osteomalacia

CLINICAL PEARLS

- Risk factors for vitamin D deficiency include age >65 years, renal disease, GI (malabsorption) disorders, liver dysfunction, immigration from tropical to colder climates, dark-skinned/veiled individuals, housebound patients, perimenopause.
- 25-OH vitamin D (most sensitive measure of vitamin D status) is the most sensitive laboratory test for diagnosis.
- Vitamin D deficiency is defined by serum levels <20 ng/mL.
- Up to 4,000 IU/day of supplemental vitamin D is safe in healthy adults.
without risk of toxicity.

- For those aged 51 to 70 years, a minimum 800 IU/day plus exercise is recommended to prevent fractures.
- The American Academy of Pediatrics recommends all breast-fed babies receive 400 IU/day of vitamin D beginning within a few days of birth.
VITAMIN DEFICIENCY
Michelle E. Szczepanik, MD • Christopher D. Meyering, DO

BASICS
DESCRIPTION
- Vitamins are essential micronutrients required for normal metabolism, growth, and development.
- Deficiencies are less common in the Western world, but certain populations are at increased risk.
- Regulations mandating vitamin supplementation in food products, adequate food security, and availability of vitamin supplements make vitamin deficiencies less common in developed countries.
- Toxicity is rare for water-soluble vitamins; toxicity is possible with fat-soluble vitamins (A, D, E, K).

EPIDEMIOLOGY

Incidence
- Predominant age
  - Geriatric patients, pregnant women, exclusively breastfed infants, and individuals with certain chronic disease states
- Individuals from Africa and Southeast Asia are at increased risk.
- True incidence is unknown as most vitamin deficiencies are asymptomatic.

Prevalence
- Varies by age groups, comorbid conditions, geography, and setting (i.e., urban, rural)
- The prevalence of vitamin B_{12} deficiency is \sim 6\% in patients <60 years of age and increases to around 20\% after age 60 years (1).
- Vitamin D deficiency has become increasingly recognized and its prevalence is increased in individuals with darker skin pigmentation, obesity, low dietary intake of vitamin D, or low sunlight exposure.

ETIOLOGY AND PATHOPHYSIOLOGY
Disease-related deficiency can develop under healthy conditions, generally due to 1 of 5 mechanisms:
- Reduced intake
- Diminished absorption
- Increased use
- Increased demand
- Increased excretion

Chronic disease states: HIV, malabsorption (such as celiac sprue and short bowel syndrome), chronic liver and kidney disease, alcoholism, malignancies, pernicious anemia, and rare inborn errors of metabolism

Bariatric surgeries: gastric bypass, gastrectomy, small or large bowel resection

Related to certain drugs: prednisone, phenytoin, isoniazid, protease inhibitors, methotrexate, phenobarbital, alcohol, nitrous oxide, H₂ receptor antagonists, metformin, colchicine, cholestryramine, 5-fluorouracil, 6-mercaptopurine, azathioprine, chloramphenicol, proton pump inhibitors, chronically used antibiotics, penicillamine, and hydralazine

Malnutrition, imbalanced nutrition, obesity, fad diets, extreme vegetarianism, total parenteral nutrition, bulimia/anorexia, and other eating disorders

Dialysis

Parasitic infestation

Genetics
- Cystic fibrosis
- Hartnup disease
- Rare genetic predisposition
  - Autoimmune disease (e.g., pernicious anemia)
  - Congenital enzyme deficiencies (e.g., biotinidase or holocarboxylase synthetase deficiency)
  - Transcobalamin II deficiency
  - Ataxia with vitamin E deficiency (AVED)
- A-β-lipoproteinemia

RISK FACTORS
Poverty, malnutrition, chronic disease states, advanced age, dietary restrictions, bariatric surgery, and exclusively breastfed infants

GENERAL PREVENTION
- Ingesting large and varied amounts of vitamins increases risk of toxicity and
drug–drug interactions.

- Antioxidant supplement use has not been shown to impact cancer incidence and has increased mortality risk in some studies (2).
- Avoiding restrictive diets decreases the likelihood of vitamin deficiency.
- In particular age groups or with certain risk factors, vitamin supplementation may be recommended.

U.S. Preventive Services Task Force (USPSTF) recommends vitamin D supplementation in community-dwelling adults aged 65 years or older who are at increased risk for falls (3)[B].

USPSTF recommends against low-dose supplementation with vitamin D (<400 IU) and calcium (<1,000 mg) to reduce fracture risk in noninstitutionalized populations, concluding that data on the effects of higher doses were insufficient (3).

USPSTF recommends that all women planning or capable of pregnancy take a daily supplement containing 0.4 to 0.8 mg of folic acid (4)[A].

USPSTF recommends against the use of beta carotene or vitamin E supplements for the prevention of cardiovascular disease or cancer (2).

- All infants should receive 400 IU/day of vitamin D soon after birth whether breast- or formula-fed (5).

**COMMONLY ASSOCIATED CONDITIONS**

Anemia, neuropathies, dermatitis, visual disturbances

**DIAGNOSIS**

**HISTORY**

- Review dietary intake.
- Decreased visual acuity or night blindness
- Poor wound healing or easy bruising
- Skin changes or new rash
- Neuropathy
- Abnormal food cravings (pica)
- Osteomalacia or history of low-energy fracture
- Previous birth of a child with spina bifida
- Previous GI or bariatric surgery (1)
- Recurrent or persistent vomiting or diarrhea
- Prior or current medical conditions
– Tuberculosis (TB), HIV infection, hepatitis, cancer
– Hypermetabolic state
  o Thyrotoxicosis
  o 2nd- or 3rd-degree burns
  o Extensive or chronic wound
  o Any systemic infection
• Chronic disease requiring steroids, disease-modifying antirheumatic drugs (DMARDs), or immunosuppressants
• Malabsorptive or chronic GI disorder: celiac disease, sprue, Crohn disease, ulcerative colitis, GERD
• Parenteral or enteral nutrition via tube feeding
• Pregnancy
• Amenorrhea or infertility issues
• Medications, supplements
• Food allergies or intolerances, fad or restrictive diet

PHYSICAL EXAM
• Neurologic exam: gait, memory/cognitive impairment, reflexes, sensory or motor impairment, peripheral neuropathy (1)
• Oropharyngeal exam to look for glossitis, bleeding gums, hyperemic pharynx, stomatitis, cheilitis (1)
• Skin exam to look for maculosquamous dermatitis, photosensitive pigmented dermatitis, ecchymosis and/or petechiae
• Visual assessment

DIFFERENTIAL DIAGNOSIS
Many conditions may mimic signs and symptoms of vitamin deficiencies.
• Diabetes mellitus (DM), thyroid disorders, hyperparathyroidism, heart failure, Alzheimer disease, multiple sclerosis, substance abuse, toxic ingestions, and hematologic disorders/malignancies

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• No routine screening indicated
• Test if symptomatic or history indicates high risk. If clinical characteristics are present, consider:
  – 25-OH vitamin D (5)
  – Prothrombin time (PT)/partial thromboplastin time (PTT)
- Vitamin $B_{12}$ and folate levels (1)
- Serum homocysteine and methylmalonic acid levels if high suspicion of vitamin $B_{12}$ deficiency with normal serum $B_{12}$ level
- Retinol serum level, retinol-binding protein

* Ancillary tests include the following:
  - BUN, calcium, phosphorus, magnesium
  - Albumin, liver function tests
  - CBC
  - Parathyroid hormone

* Bone densitometry indicated in the following:
  - Women 65 years of age or older without previous known fractures or risk factors
  - Women <65 years old whose 10-year fracture risk is equal to that of a 65-year-old white woman without additional risk factors
  - According to the fracture risk assessment tool (FRAX), the 10-year fracture risk for a 65-year-old white woman without risk factors is 9.3%.

* Bariatric surgery patients are at risk for deficiencies. Laparoscopic gastric banding is less frequently associated with vitamin deficiencies.

* Cyanocobalamin, thiamine, vitamin A

* Disease states from vitamin deficiency
  - Vitamin A (retinol): night blindness, complete blindness, xerophthalmia
  - Vitamin $B_1$ (thiamine)
    - Wernicke encephalopathy: acute syndrome with memory disturbance, truncal ataxia, nystagmus, ophthalmoplegia
    - Korsakoff syndrome: anterograde and retrograde amnesia, confabulation
    - Dry beriberi: symmetric motor and sensory peripheral neuropathy, paresthesias, loss of reflexes
    - Wet beriberi: neuropathy with cardiovascular symptoms of peripheral vasodilation, high-output failure, dyspnea, and tachycardia
    - Infantile beriberi: loud piercing cry, cyanosis, tachycardia, cardiomegaly, dyspnea, vomiting, seizures
  - Vitamin $B_2$ (riboflavin): glossitis, stomatitis, cheilitis, hyperemia of the pharyngeal mucosal membranes, normocytic-normochromic anemia
  - Vitamin $B_3$ (niacin): pellagra: photosensitive pigmented dermatitis, dementia, and diarrhea
  - Vitamin $B_5$ (pantothenic acid): paresthesias and dysthesias, anemia
  - Vitamin $B_6$ (pyridoxine): dermatitis, cheilosis, atrophic glossitis, stomatitis,
neuropathy
- Vitamin B\textsubscript{9} (folate): megaloblastic anemia, rarely manifest neurologic symptoms
- Vitamin B\textsubscript{12} (cobalamin): pernicious anemia, shuffling broad-based gait, atrophic glossitis, loss of vibration and position sense, cognitive impairment
- Vitamin C (ascorbic acid): scurvy: ecchymoses, bleeding gums, petechiae, hyperkeratosis, arthralgias, impaired wound healing
- Vitamin D (calciferol): rickets, osteomalacia
- Vitamin E: neuromuscular disorders and hemolysis
- Vitamin K: easy bruising, mucosal bleeding, melena, hematuria
- Biotin: changes in mental status, dysesthesias, nausea, maculosquamous dermatitis of the extremities

**TREATMENT**

Vitamin D deficiency is linked with worse cardiovascular morbidity and mortality, and is associated with vascular dysfunction; arterial stiffening; left ventricular hypertrophy; and worsened metrics of diabetes, hypertension, and hyperlipidemia. A causal effect between deficiency and cardiovascular disease has not been shown. Trials have failed to show improvements in blood pressure, insulin sensitivity, or lipids (6).

**MEDICATION**
- Ask patients about herbal or dietary supplement use; encourage patients to bring in vitamin and supplement bottles for review.
- Assess for potential adverse drug effects/reactions. Patients with alcohol use disorders should receive thiamine, folic acid, and MVI.
- Give patients with suspected thiamine deficiency 100 mg thiamine prior to IV fluids containing glucose to prevent precipitating Korsakoff psychosis.
- If there is concomitant B\textsubscript{12} and folate deficiency, start B\textsubscript{12} first to avoid precipitating subacute combined degeneration of the spinal cord (1).
- Consider obtaining prealbumin/albumin levels and a dietary consult for malnourished patients.
- Bariatric surgery patients will need lifelong vitamin supplementation; there are no consensus practice guidelines for supplement dosing regimens.

**Geriatric Considerations**
Vitamin B₁₂ deficiency exists in around 20% of those >60 years. Treat symptomatic or severe deficiency with an IM injection of cyanocobalamin 1,000 μg/day 3 times a week for 2 weeks. If there are neurologic symptoms, give the same dose of cyanocobalamin every other day for 3 weeks or until symptoms have resolved. To prevent recurrence or treat mild deficiency, use a regimen of oral vitamin B₁₂ 1,000 μg/day or an IM injection of vitamin B₁₂ 1,000 μg every month. Low-dose oral therapy with 50 to 150 μg/day may be considered for mild cases (1). High-dose (1,000 to 2,000 μg/day) oral treatment is as effective as monthly IM injections, but use caution in patients with malabsorption or compliance issues (1)[C].

>40% of elderly Americans are vitamin D deficient. Deficiency is defined as a serum 25-OH vitamin D level of <20 ng/mL.

Treat vitamin D deficiency with weekly 50,000 IU of oral ergocalciferol for 8 weeks (3).

**Pediatric Considerations**

- Vitamin K deficiency increases bleeding risk.
  - Neonates may exhibit signs of vitamin K deficiency because they require 1 week of life to establish intestinal flora which manufactures vitamin K.
  - Condition peaks 2 to 10 days after birth: bleeding from the umbilical stump and/or circumcision site, generalized bruising, and GI hemorrhage
  - Infrequent in developed countries due to routine injection of newborns with vitamin K (1 mg)

- Vitamin D deficiency: Vitamin D supplementation (400 IU/day) is recommended for all infants starting in the first few days of life (5)[A].
- 600 IU/day of vitamin D are recommended for children >12 months and adults either through diet or supplementation (5).
- Morbidly obese and minority children are at increased risk for vitamin D deficiency.
- In children age >6 months in developing countries, vitamin A supplementation has been shown to decrease mortality.
- Vitamin deficiency associated with developmental delay

**Pregnancy Considerations**

All pregnant women and women of childbearing age considering pregnancy are strongly encouraged to take a multivitamin containing at least 0.4 mg folic acid daily to prevent neural tube defects (4)[A].
ONGOING CARE

DIET
Vitamins are best utilized by the body from food intake. Supplements should be used where it is not feasible to ingest the recommended amount of a particular vitamin.

PATIENT EDUCATION
- In healthy adults, multivitamins have no value if dietary intake is adequate and may increase risk of some cancers.
- Drug–drug interactions may occur between vitamins and medications. Patients should report all supplements and medications to their health care provider.
- Risk of vitamin toxicity is most common with fat-soluble vitamins (A, D, E, K).

PROGNOSIS
Most vitamin deficiencies are fully reversible if treated without undue delay.

COMPLICATIONS
- Vitamin toxicities
- Liver failure (vitamins A, D, E, K)
- Desquamation of skin (vitamin A)
- Neuropathy (vitamin B₆)
- Kidney stones (vitamin C, vitamin D)
- Hypercoagulability (vitamin K)
- Pseudohyperparathyroidism (vitamin D)
- Masking of pernicious anemia (folic acid)

REFERENCES
3. LeBlanc ES, Zakher B, Daeges M, et al. Screening for vitamin D deficiency:

**ADDITIONAL READING**

**CODES**

**ICD10**

- E56.9 Vitamin deficiency, unspecified
- E56.0 Deficiency of vitamin E
- E55.9 Vitamin D deficiency, unspecified

**CLINICAL PEARLS**

- Obtain a thorough dietary history when assessing for potential vitamin deficiencies.
- Specifically ask patients about dietary supplement use.
- Vitamin D supplementation is recommended in community-dwelling adults aged 65 years or older who are at increased risk for falls.
- All women planning or capable of pregnancy should take a daily supplement containing 0.4 to 0.8 mg of folic acid.
- All infants and children, including adolescents, should have a minimum daily intake of 400 IU of vitamin D beginning soon after birth.
BASICS

DESCRIPTION

- An acquired depigmentation of the skin, which correlates with a loss of epidermal melanocytes. There are three clinical variants, each with subtypes.
- Localized: often in childhood, rapid onset then stabilizes. Involvement of hair is common early in the course; lacks associated autoimmune diseases
  - Focal: few lesions, random distribution
  - Segmental: Lesions occur within a dermatome (mostly trigeminal) or may follow Blaschko lines. Lesions usually stop abruptly at the midline.
  - Mucosal: only mucosal surfaces involved
- Generalized/nonsegmental (most common variant): progressive, with flares, commonly associated with autoimmunity. Common locations are acral, periorificial, and in sites sensitive to pressure/friction (Koebner phenomenon).
  - Vulgaris: most common subtype; scattered macules; often symmetric, wide distribution; mostly hands, axillae, and groin
  - Acrofacial: on distal extremities and face
  - Mixed: coexistence of above
- Universal: involves >80% of the body surface area (BSA). Most likely to have family history; comorbidities are common and associated with poorest quality-of-life (QOL) scores.
- Other rare variants
  - Ponctué: discrete confetti-like macules
  - Inflammatory: peripheral erythematous rim
  - Trichrome: Tan zone is present between normal and depigmented skin.
  - Quadrichrome: as above but with marginal/perifollicular hyperpigmentation
  - Blue: Dermal melanophages give blue hue, in areas affected by prior postinflammatory hyperpigmentation.
- System(s) affected: skin, mucous membranes
- Synonym(s): leukoderma

EPIDEMIOLOGY
• 50% begin before age 20 years, peak in females: 1st decade; males: 5th decade. Onset earlier with positive family history; can appear as early as 6 weeks
• Predominance: male = female; however, females are more likely to seek treatment.
• No race or socioeconomic predilection

Prevalence
~1% in the United States and Europe (1); 0.1–8% in the world; highest in Gujarat, India, at 8.8% (1,2)

ETIOLOGY AND PATHOPHYSIOLOGY
Most likely a spectrum of disorders with a common phenotype and multiple mechanisms contribute to the pathology (convergence theory).
• Genetic: See “Genetics.”
• Autoimmune: humoral autoantibodies and skin-homing T cells
• Neural: local or systemic dysregulation leading to excess neurotransmitters
• Viral: direct melanocyte toxicity, cytomegalovirus (CMV), hepatitis C, and Epstein-Barr virus (EBV) found in lesional biopsies
• Oxidative stress from elevated H₂O₂ and NO and decreased catalase and erythrocyte glutathione

Genetics
• Polygenic/multifactorial inheritance
• 20% of patients report affected relative, but monozygotic twins have only 23% concordance.
• HLA haplotypes, small nucleotide polymorphisms, and specific genes are all possible contributors.

RISK FACTORS
• Family history of vitiligo/autoimmune disorders
• Personal history of associated conditions

COMMONLY ASSOCIATED CONDITIONS
• Most common
  – Endocrine: thyroid disease (hypo-/hyperthyroidism), hypoparathyroidism, Addison disease, insulin-dependent diabetes
  – Dermatologic: psoriasis, atopic dermatitis, alopecia areata, chronic
urticaria, halo nevi, ichthyosis
- Pernicious anemia
- Hypoacusis, rheumatoid arthritis
- Ocular abnormalities in up to 40%
- Elevated antinuclear antibodies in up to 40%
- Elevated thyroperoxidase antibodies in 50%

- Less common
  - Systemic lupus erythematosus
  - Inflammatory bowel disease
  - Melanoma (may be a sign of positive outcome of melanoma) and other skin cancers
  - Syndromes: Alezzandrini; mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes (MELAS); Schmidt; and autoimmune polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED)

- Age >50 years at onset should prompt investigation for associated conditions.

**Pediatric Considerations**
Associated with Hashimoto thyroiditis in a significant portion of children. Screening at onset and possibly annually may be beneficial.

**DIAGNOSIS**

**HISTORY**
- Inquire about recent history of sunburns, pregnancy, skin trauma, or emotional stress.
- Family history of premature graying, vitiligo, and autoimmune disorders
- Review of systems for related associated conditions
- Ascertain psychological impact on QOL, Dermatology Life Quality Index (DLQI).

**PHYSICAL EXAM**
- Full-body skin exam with Wood lamp to accentuate lesions and distinguish depigmentation from hypopigmentation
- Lesions are well-demarcated, uniform white macules and patches.
- Look for evidence of repigmentation (most commonly around hair follicles).

**DIFFERENTIAL DIAGNOSIS**
- Infectious: tinea versicolor, leprosy, leishmaniasis, onchocerciasis, treponematoses (pinta/syphilis)
- Postinflammatory hypopigmentation: psoriasis, atopic dermatitis, pityriasis alba, systemic lupus erythematosus, scleroderma
- Inherited hypomelanoses: piebaldism, tuberous sclerosis, Waardenburg, hypomelanosis of Ito, Vogt-Koyanagi-Harada
- Malformations: nevus anemicus, nevus depigmentosus
- Paraneoplastic: mycosis fungoides, melanoma-associated leukoderma
- Occupational and chemical induced
  - Occupational: phenolic/catechol derivatives and arsenic-containing compounds
  - Chemical: numerous, including cosmetics, cleansers, insecticides, and even medications (imatinib, potent topical corticosteroids [TCS])
- Melasma: Normal skin may be confused as vitiligo in the setting of surrounding hyperpigmentation.
- Halo nevi
- Lichen sclerosus et atrophicus
- Idiopathic guttate hypomelanosis
- Progressive-acquired macular hypomelanosis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- TSH, CBC, ANA
- Consider antithyroid peroxidase, antithyroglobulin antibodies, hemoglobin, vitamin B₁₂ levels if family/patient history of autoimmune disease.

**Follow-Up Tests & Special Considerations**
- Monitor for disease progression/flares.
- Monitor for symptoms of related conditions.

**Diagnostic Procedures/Other**
- Skin biopsy is rarely needed. Highest yield is with comparison of lesional/perilesional biopsies.
- Consider ophthalmologic and audiologic evaluation.

**Test Interpretation**
Few or no epidermal melanocytes. At margins, melanocytes may be larger, vacuolated, and dendritic. Early lesions show inflammation and later,
degeneration, including of adnexa and nerves.

**TREATMENT**

The variant of vitiligo may affect response.

- If untreated, progression is the natural course for those with mucosal involvement, family history, koebnerization, and nonsegmental variants.
- Lesions that respond best are on the face, of recent onset, in darker skin type, and in younger patients.

**GENERAL MEASURES**

- Sunscreen to decrease sunburn and prevent accentuation of uninvolved skin
- Corrective camouflage as cover-up (Cover FX, Dermablend)

**MEDICATION**

- Individualize therapy depending on age, extent, distribution, and rate of progression.
- Many therapies are considered “off-label” and not FDA-approved for vitiligo, although they are often considered first-line therapy.

- **Corticosteroids**: Midpotency TCS (mometasone furoate, fluticasone propionate) applied daily as monotherapy are considered first-line treatments. Do not use on face/axilla/groin; do not occlude except under close monitoring. Pediatric: as above, for children >12 years of age. Consider decreased potency. Local side effects including atrophy, telangiectasia, hypertrichosis, acneiform eruptions, and striae limit treatment; regular steroid holidays are recommended (1). The combination of light therapy and TCS is the most effective treatment overall (2). Most efficacious on sun-exposed areas: face/neck, dark-skinned patients, newer lesion (1). Addition of tretinoin 0.025–0.05% BID is effective and can decrease potential skin atrophy (2,3). Systemic corticosteroids can be helpful, but dosage and safety parameters have not been fully evaluated for long term treatment (2,4)[A].

- **Topical calcineurin inhibitors**: slightly inferior to TCS as monotherapy but better side effect profile (2,5,6)[B]; can be used as adjunctive to light therapy; carries a controversial black box warning for a theoretical risk of lymphoma or skin cancer. Extensive safety profiling has not revealed any evidence for this in children or adults using topical calcineurin inhibitors. Local reactions include burning sensation, pruritus, erythema, and rare transient
hyperpigmentation (4).
- Tacrolimus 0.03% or 0.1% ointment BID (2); pediatric: 0.03% ointment BID, for children >2 years of age (6)
- Pimecrolimus 1% cream BID (2); pediatric: as adults, for children >2 years of age (6)

**Topical vitamin D₃ analogs:** less effective than TCS alone, but in combination with TCS or phototherapy can shorten time until, and improve stability of, repigmentation (4,5)[B]
- Calcipotriene ointment 1 to 2 times per day; pediatric: not defined
- Available as a combination formulation, betamethasone dipropionate 0.064%/calcipotriene 0.005% ointment daily, max dose of 100 g/week for 4 weeks, not for >30% BSA, and not for face/axilla/groin; pediatric: not defined

**Oral vitamin D₃:** reported to induce repigmentation. Oral vitamin D₃ 35,000 IU once daily plus low-calcium diet for 6 months; pediatric: not defined

**Phototherapy:** Narrow band UVB (NBUVB) is superior to UVA and indicated for lesions involving > 15–20% BSA (3,5,6)[A]. Psoralen and khellin enhance the effect of light. Psoralen plus UVA (PUVA) may increase the incidence of skin cancers. Khellin may have reduced cross-linking of DNA and may be less carcinogenic; however, it is associated with increased liver toxicity (6). L-phenylalanine can be used topically and orally as a photosensitizer for natural or artificial light. Pediatric: Oral PUVA is contraindicated.

**Laser therapy:** Excimer laser (308 nm) is superior to other light therapy. Helium–neon laser works for segmental vitiligo (5)[A].

**Antioxidants:** may have protective role in preventing melanocyte degradation from reactive oxygen species. Options include vitamin C, vitamin E, Vitix, *Polypodium leucotomos* extracts, and *Ginkgo biloba* (5)[B].

**Surgical therapy:** See later discussion.

**New concepts:** Tumor necrosis factor-α inhibitors, cyclosporine, cyclophosphamide, azathioprine, minocycline, and immunosuppressants are currently being evaluated (6).

**First Line**
- Recommended: avoidance of triggering factors plus TCS alone or in combination with NBUVB
- Alternatively
  - Topical calcineurin inhibitors (preferred for face, neck, axilla, and groin)
  - NBUVB
– PUVA in adults
– Camouflage and psychotherapy should be offered to all patients at any stage (6).

**Second Line**
- Recommended: photochemotherapy with psoralens or vitamin D analogues
- Alternatively
  - Topical vitamin D analogues
  - Targeted phototherapy
  - 308-nm laser in combination with topical steroids, topical calcineurin inhibitors, or vitamin D analogues
  - Oral corticosteroids (pulse therapy)
  - Surgical treatments indicated for stable 2- to 3-cm lesions, refractory to other treatments
    - Mini-punch graft (pretreat with cryotherapy/dermabrasion or posttreat with phototherapy) (6)[B]
    - Suction blister graft (6)[B]
    - Autologous melanocyte suspension transplant (5)[B]

**ISSUES FOR REFERRAL**
- Dermatologist: for facial/widespread vitiligo or when advanced therapy is necessary
- Ophthalmologist: for ocular symptoms or monitoring of TCS near eyes
- Endocrinologist: evaluation/management of associated conditions
- Psychologist: for severe distress
- Medical geneticist for associated conditions

**ADDITIONAL THERAPIES**
- Depigmentation therapy with monobenzone, hydroquinone, or Q-switched ruby laser: for extensive vitiligo recalcitrant to therapy (6)
  - Pseudocatalase with addition of NBUVB (1)[B]
  - Prostaglandin E for short-duration disease and localization to face and scalp (2)[B]
- Cosmetic tattooing for localized stable vitiligo

**SURGERY/OTHER PROCEDURES**
- Goal is to transport melanocytes from other areas of the skin. Methods include punch, blister, or split-thickness skin grafting, or transplantation of autologous
melanocytes.

- Dermabrasion and curettage alone or in combination with 5-fluorouracil may induce follicular melanocyte reservoirs (5)[A].
- Patients who koebnerize or form keloids may be worse, and permanent scarring is a risk for all patients.

### COMPLEMENTARY & ALTERNATIVE MEDICINE

*Ginkgo biloba* 60 mg PO daily may significantly improve extension and spreading of lesions (4)[B].

- *Polypodium leucotomos* may help with repigmentation with NB UVB and aid in reducing phototoxic reactions (5)[B].

### ONGOING CARE

#### FOLLOW-UP RECOMMENDATIONS

- Monitor for symptoms of related conditions.
- With topical steroids, follow at regular intervals to avoid steroid atrophy, telangiectasia, and striae distensae.

### DIET

No restrictions

### PATIENT EDUCATION

- Discussion of disease course, progression, and cosmesis
- Education regarding trauma/friction and Koebner phenomenon

### PROGNOSIS

- Vitiligo may remain stable or slowly or rapidly progress.
- Spontaneous repigmentation is uncommon.
- Generalized vitiligo is often progressive, with flares. Focal vitiligo often has rapid onset and then stabilizes.

### COMPLICATIONS

- Adverse effects of each treatment modality
- Psychiatric morbidity: depression, adjustment disorder, low self-esteem,
sexual dysfunction, and embarrassment in relationships (1,2)
– Different cultures may have different perceptions/social stigmas about vitiligo. Some believe it to be contagious or related to infection. Women with vitiligo may have difficulty finding a marriage partner and have low self-esteem.

REFERENCES

ADDITIONAL READING

CODES

ICD10
L80 Vitiligo
CLINICAL PEARLS

- Vitiligo can be a psychologically devastating skin disease.
- Screen for associated diseases, particularly if onset occurs later in life.
- Treatment should be individualized based on BSA, skin type, and patient goals.
- Dermatology consultation when extensive disease, facial involvement, and when advanced treatments are considered.
VON WILLEBRAND DISEASE

Chang Liu, DO • Jarrett Sell, MD, AAHIVS • Stacey L. Milunic, MD

BASICS

DESCRIPTION

- von Willebrand disease (vWD) is a bleeding disorder caused by deficiency or a defect of von Willebrand factor (vWF) protein.
- vWF is critical to the initial stages of blood clotting, acting as a bridge for platelet adhesion; it also acts as a carrier for factor VIII (FVIII).
- vWD most common subtypes manifest as mucocutaneous, perioperative bleeding, or menorrhagia, whereas more serious subtypes may result in joint and soft tissue bleeding.
- vWD is an inherited condition but rarely can be acquired (AvWD).

EPIDEMIOLOGY

Prevalence

- Prevalence of the inherited forms of vWD is 1 in 100 to 10,000 of the general population with more females being diagnosed than males (1).
- Exact prevalence of the acquired forms of vWD (AvWD) is unknown but is estimated to be up to 0.1% of the general population.

ETIOLOGY AND PATHOPHYSIOLOGY

- vWF is a large, multimeric protein that is released from endothelial cells and is also carried within platelets in α-granules.
- vWF binds to collagen at sites of vascular injury and creates a surface for platelet adhesion through GP1b receptor. This results in platelet plug formation.
- vWF is also a carrier for FVIII and stabilizes this factor from degradation. A deficiency in vWF may result in lower levels of FVIII.
- When vWF is deficient or dysfunctional, primary hemostasis is compromised, resulting in increased mucocutaneous and postprocedural bleeding.
- Three major inherited types of vWD exist
  - Type 1, the most common and mildest form, represents 60–80% of cases.
Mild to moderate quantitative deficiency of vWF and concordant deficiency of FVIII
- Generally, a mild bleeding disorder
  - Type 2, caused by qualitative defect in vWF, accounts for 10–30% of cases and is divided into the following multiple subtypes:
    - Type 2A is noted for loss of hemostatically active large multimers with low ristocetin cofactor/vWF activity.
    - Type 2B, noted for increased binding affinity for platelets, is associated with thrombocytopenia, low ristocetin cofactor/vWF activity, abnormal ristocetin-induced platelet aggregation (RIPA), and loss of large multimers.
    - Type 2M is noted for defective platelet or collagen binding without loss of large multimers.
    - Type 2N demonstrates defective binding to FVIII, which results in increased clearance of FVIII and hemophilia A–like picture.
  - Type 3 represents 1–5% of cases.
    - Most severe form with markedly decreased-to-undetectable levels of vWF and FVIII
    - Manifests as hemophilia A with hemorrhages (1–3)
- AvWD may be due to cardiovascular, hematologic, or autoimmune conditions as well as tumors and medications. The pathophysiology of AvWD is related to the underlying cause and may result from shear-induced cleaving of vWF in cardiovascular conditions, increased adsorption of vWF by certain tumor cells or activated platelets, or presence of anti-vWF autoantibodies detected in hematologic disorders.
- Individuals with type O blood have accelerated clearance of vWF leading to vWF levels that are 25–30% lower than other those with blood types A, B, or AB. Type 1 disease is diagnosed more frequently in individuals with type O blood.
- Platelet-type vWD (PLT-vWD)—also pseudo vWD, caused by platelet GP1 alpha receptor mutation

**Genetics**
- The 175-kb gene for vWF is located on short arm of chromosome 12.
- Type 1 follows an autosomal dominant inheritance pattern, with variable expressivity.
- Type 2 varies but primarily follows an autosomal dominant inheritance pattern.
- Type 3 follows an autosomal recessive inheritance pattern (2).
COMMONLY ASSOCIATED CONDITIONS
AvWD may be found in patients with hematologic disorders such as MGUS and myeloproliferative neoplasms. Commonly associated cardiovascular conditions include aortic stenosis and left ventricular assist device (LVAD) placement. AvWD is associated with gastrointestinal bleeding from arteriovenous malformations.

DIAGNOSIS

HISTORY
- Most patients with vWD have a positive family history of bleeding disorder; however, patients with mild forms of vWD and their families may be unaware of their disease. Those with AvWD usually have no family history of this disorder.
- Common symptoms are those of mucocutaneous (recurrent epistaxis, menorrhagia, ecchymosis) or postprocedural bleeding. Hemarthrosis is a rare presentation, mostly associated with types 2N and 3.
- The most important component of diagnosis is the hemostatic history often aided by specifically designed bleeding questionnaires, such as the ISTH-BAT found at isth.org (International Society on Thrombosis and Haemostasis).

PHYSICAL EXAM
- Physical exam may be entirely normal, although there may be some ecchymoses.
- Findings suggestive of other causes of increased bleeding should be sought (liver disease, skin laxity, or telangiectasias).

DIFFERENTIAL DIAGNOSIS
- Primary hemostatic disorders: congenital thrombocytopenia or qualitative platelet defects, coagulation factor deficiencies
- Secondary hemostatic disorders: liver disease, uremia, connective tissue disorders, coagulation factor inhibitors

DIAGNOSTIC TESTS & INTERPRETATION
- Abnormal bleeding initial screening tests
  - Complete blood count: decreased platelets in type 2B
  - PT/INR: normal or prolonged in liver disease or warfarin use
- aPTT: normal or isolated prolonged aPTT that corrects in 1:1 mixing study
- May consider bleeding time or platelet function analyzer (PFA-100): normal or prolonged

- **Diagnostic vWD tests**
  - vWF antigen (vWF:Ag): reduced
  - vWF ristocetin cofactor (vWF:RCo): reduced, except type 2N
  - vWF collagen binding (vWF:CB): reduced in most vWD types
  - Factor VIII (FVIII:C): reduced in types 2N and 3

- **Classifying tests**
  - Ratios of vWF:RCo/vWF:Ag: <0.5 to 0.7 differentiates type 1 from type 2.
  - vWF multimer assay: differentiates type 2
  - RIPA: diagnose type 2B
  - vWF propeptide (vWFpp): Identify accelerated clearance variants.
  - FVIII binding assay: low in Type 2N
  - Gene sequencing
  - Assays for vWF antibodies
  - Platelet-binding studies

- Interpretation of tests should always be preceded by significant bleeding history; best assessed with ISTH-BAT score and family history for bleeding and/or diagnosed with vWD (1–3).  

---

**Follow-Up Tests & Special Considerations**

- Unless patients have severe forms of vWD or are undergoing treatment, follow-up laboratory studies are not usually obtained.
- vWF is an acute-phase reactant, so elevations may be seen in inflammatory conditions, liver disease, pregnancy (which may correct mild deficits), or with estrogen use. Levels also increase with age; however, it is unclear if this decreases bleeding risk (2).

---

**TREATMENT**

**GENERAL MEASURES**

- Most patients with type 1 vWD do not require activity restrictions.
- Patients with type 3 vWD should avoid contact sports.
- An emergency ID bracelet may be useful.

**MEDICATION**
**First Line**

- Desmopressin (DDAVP)
  - Enhances release of vWF from endothelial cells
  - Primarily effective for type 1 vWD; not to be used in type 2B. Trial of DDAVP should initially be measured in nonbleeding state to determine response.
  - Not effective in severe deficiencies, in types of vWD with defective vWF, or for prophylaxis prior to major procedures
  - Dosed 0.3 μg/kg (max 20 mg) IV/SC; intranasal (high concentration) spray: <50 kg: 150 μg/day; >50 kg: 300 μg/day (Stimate)
  - Common side effects: flushing, tachycardia, water retention, hyponatremia. Tachyphylaxis may develop with prolonged dosing; limit use to administering DDAVP once every 24 to 48 hours for 3 to 5 days.
  - Test therapeutic responsiveness by testing vWF:Ag, vWF:RCo, and FVIII:C at baseline, 1 hour and 4 hours postinfusion. An increase in levels at least 2- to 3-fold, >30 IU/dL and preferably >50 IU/dL for invasive procedures is adequate response; vWF and FVIII concentrates

- Plasma-derived vWF and FVIII concentrates of various purity such as Humate-P, Alphanate, Wilate, or Fandhi (not available in United States) are commercial concentrates of vWF and FVIII that are given in doses of 25 to 60 IU/kg/day based on clinical situation (4,5).
  - Administration of 1 IU/kg vWF:RCo concentrate raises the plasma RCo activity by approximately 2%.
  - Dose of vWF concentrate may be adjusted for FVIII levels and ristocetin cofactor activity.
  - FVIII levels should be monitored to avoid supranormal levels and possible venous thromboembolism (VTE).
  - Contraindicated if patient develops alloantibodies to vWF
  - Recombinant vWF concentrate (Vonvendi) is approved for use in adults for on-demand treatment of bleeding episodes. It requires rFVIII with the first infusion if baseline levels are <40% or unknown.
  - In patients with severe bleeding phenotype, prophylactic treatment is used.

- Cryoprecipitate
  - Cryoprecipitate contains FVIII, fibrinogen, vWF, factor XIII, and fibronectin.
  - Not considered as safe as the recombinant and virus-inactivated plasma concentrates listed above and should not be used unless those are unavailable
Antifibrinolytics
- Useful for mucosal bleeding
- Contraindicated in patients with hematuria due to risk of retention of large blood clots in the renal collecting system
- Given as adjunct to DDAVP
- Aminocaproic acid may be given at 50 to 70 mg/kg (max: 5 g; lower doses may be effective) q4–6h IV or PO.
- Tranexamic acid may be given at 10 to 15 mg/kg IV or 25 mg/kg (1,300 mg) PO q8–12h.

Recombinant FVIIa/NovoSeven
- Used for patients who develop alloantibodies to vWF
- Given as IV bolus of 90 μg/kg q2h or 20 μg/kg every hour until hemostasis is achieved

Second Line
- Combined oral contraceptives or the levonorgestrel-releasing intrauterine system raise vWF/FVIII levels and have a role in the treatment of chronic menorrhagia (6)[B].
- Platelets may be given as an adjunct to factor concentrates if hemostasis has not been achieved.
- IVIG has been useful in some patients with AvWD associated with monoclonal gammopathy (7)[C].
- Recombinant FVIIa has been used effectively in patients with type 3 vWD.

SURGICAL CONSIDERATIONS
- For patients undergoing minor surgeries, maintain FVIII levels >50 IU/dL for 5 to 7 days.
- For patients undergoing major surgeries, maintain vWF:RCo and FVIII levels >100 U/dL preoperatively and >50 units/dL postoperatively.
- Valve replacement or correction may be curative for patients with AvWD associated with underlying cardiovascular conditions.

Pediatric Considerations
Many cases of vWD are diagnosed in childhood, often during initial years of menstruation. vWD may be difficult to diagnose before 6 months of age.

Pregnancy Considerations
- Women with vWD are more likely to experience an increased incidence of
obstetric complications that manifest with bleeding.
- Type 1 vWD may spontaneously improve, whereas type 2B may be exacerbated by pregnancies.
- FVIII or vWF:Ag should be checked during the 3rd trimester with treatment goal to maintain at levels >50 IU/dL.
- Consider treating with vWF concentrates during pregnancy and desmopressin or tranexamic postpartum period to achieve treatment goals.
- Women with preeclampsia should not be treated with desmopressin.
- Regional anesthesia not recommended in patients with type 2 and 3 or type 1 with <50 U/dL of vWF:RCo
- Fetal scalp electrodes should be avoided due to the 50% risk of fetus inheritance of vWD and circumcisions should be postponed (2,6).

**ISSUES FOR REFERRAL**
The diagnosis and management of vWD is not always straightforward; consider consultation with a hematologist.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Patients should be seen by a hematologist prior to invasive procedures for determination of perioperative management or advice regarding delivery.

*Patient Monitoring*
Patients with mild disease do not require monitoring.

**DIET**
No dietary restrictions are recommended. However, aspirin and other NSAIDs should be avoided due to their antiplatelet effects, which can exacerbate the bleeding phenotype.

**PATIENT EDUCATION**
National Hemophilia Foundation:  
www.hemophilia.org/NHFWeb/MainPgs/MainNHF.aspx?menuid=182&contentid=47&rptname=bleeding

**PROGNOSIS**
Most patients with vWD have a normal life expectancy.

COMPlications

- Significant perioperative bleeding may occur.
- Patients with type 3 vWD and type 2N can have bleeding complications similar to patients with hemophilia A such as hemarthrosis and intracranial hemorrhage.
- Patients with aortic stenosis and AvWD are known to have higher rates of GI bleeding.
- Multiple transfusions may result in alloantibodies against vWF.
- VTE may result from supranormal levels of FVIII.

CODES

ICD10

D68.0 Von Willebrand’s disease

CLINICAL PEARLS

- vWD varies from a minor to severe bleeding disorder; affects up to 1% of the U.S. population
- It is important to determine the exact type of vWD (type 1, 2, or 3) to guide treatment.
- Treatment should be administered for recurrent bleeding episodes in all types of vWD, but prophylaxis is rarely required because most cases are mild.
- AvWD should be considered in patients with acquired bleeding disorder if they have underlying predisposing conditions.
BASICS

DESCRIPTION

- Premalignant lesions of the vulva are collectively known as vulvar intraepithelial neoplasia (VIN). Exposure to human papillomavirus (HPV) has been linked to >70% of VIN.
- Invasive squamous cell carcinoma is the most common malignancy involving the vulva (90% of patients); can be well, moderately, or poorly differentiated and derives from keratinized skin covering the vulva and perineum.
- Melanoma is the second most common type of vulvar malignancy (8%) and sarcoma is the third.
- Other invasive cell types include basal cell carcinoma, Paget disease, adenocarcinoma arising from Bartholin gland or apocrine sweat glands, adenoid cystic carcinoma, small cell carcinoma, verrucous carcinoma, and sarcomas.
- Sarcomas are usually leiomyosarcoma and probably arise at the insertion of the round ligament in the labium major; however, sarcoma can arise from any structure of the vulva, including blood vessels, skeletal muscle, and fat.
- Rarely, breast carcinoma has been reported in the vulva and is thought to arise from ectopic breast tissue.
- System(s) affected: reproductive

Geriatric Considerations

- Older patients with associated medical problems are at high risk from radical surgery. The surgery, however, is usually well tolerated.
- Patients who are not surgical candidates can be treated with combination chemotherapy and/or radiation.
- In the very elderly, palliative vulvectomy provides relief of symptoms for ulcerating symptomatic advanced disease.

EPIDEMIOLOGY
Incidence
- In 2015, 5,150 women were diagnosed with vulvar cancer and 1,080 women died from vulvar cancer in the United States (1); accounting for approximately 4% of all gynecologic malignancies (2)
- Estimated 6,020 new cases and 1,150 deaths in 2017
- Surveillance, epidemiology, and end result (SEER) data showed that the incidence of in situ vulvar carcinoma increased by >400% between 1973 and 2000.
- Mean age at diagnosis 65 years; in situ disease: mean age 40 years; invasive malignancy: mean age 60 years
- Ethnic distribution: more common in Caucasian women than in any other race

ETIOLOGY AND PATHOPHYSIOLOGY
- Patients with cervical cancer are more likely to develop vulvar cancer later in life, secondary to “field effect” phenomenon with a carcinogen involving the lower genital tract.
- HPV has been associated with squamous cell abnormalities of the cervix, vagina, and vulva; 55% of vulvar cancers are attributable to oncogenic HPV, predominantly HPV 16 and 33; 92% of VIN 2/3, vaginal intraepithelial neoplasia (VAIN) 2/3, and anal intraepithelial neoplasia (AIN) are attributable to HPV.
- Squamous cell carcinoma
  - The warty basaloid type, also known as bowenoid type, is related to HPV infection and occurs in younger women. Although traditionally graded in a three-level system, the International Society for the Study of Vulvovaginal Disease voted not to use a grading system for VIN in 2004. This system eliminated VIN 1 and combined VIN 2 and VIN 3. This is based on the fact that VIN 1 is not reproducible. VIN 2 and VIN 3 were combined because VIN 2 is rare and carries the same risk of progression to malignancy as VIN 3.
  - The more common variant is simplex or differentiated and does not appear to be related to HPV, occurs in older age groups, and associated with lichen sclerosus and chronic venereal diseases. It is thought to carry a higher risk of progression to malignancy.
  - Melanoma, second most common histology, often identified in postmenopausal women; often pigmented but can be amelanotic, arising de novo, often found on clitoris or labia minora
- Cases not associated with HPV infection are typically associated with vulvar
dystrophies causing chronic inflammation, such as lichen sclerosus or squamous cell hyperplasia.

- Smoking is associated with squamous cell disease of the vulva, possibly from direct irritation of the vulva by the transfer of tars and nicotine on the patient’s hands or from systemic absorption of carcinogen.

**Genetics**
No known genetic pattern

**RISK FACTORS**
- VIN or cervical intraepithelial neoplasia (CIN)
- Smoking
- Lichen sclerosus (vulvar dystrophy)
- HPV infection, condylomata or sexually transmitted diseases (STD) in the past
- Low economic status
- Autoimmune processes
- Immunodeficiency syndromes or immunosuppression
- Northern European ancestry

**GENERAL PREVENTION**
- HPV vaccination has the potential to decrease vulvar cancer by 60% (3).
- Abstinence from smoking/smoking cessation counseling

**COMMONLY ASSOCIATED CONDITIONS**
- Patients with invasive vulvar cancer are often elderly and have associated medical conditions.
- High rate of other gynecologic malignancies

**DIAGNOSIS**

**HISTORY**
Complaints of pruritus or raised lesion in the vaginal area, vaginal bleeding, discharge

**PHYSICAL EXAM**
- In situ disease: a small raised area associated with pruritus, single vulvar
plaque, ulcer, or mass on labia majora, perineum, clitoris; most commonly found on labia majora

- Vulvar bleeding, dysuria, enlarged lymph nodes less common symptomatology
- Invasive malignancy: an ulcerated, nonhealing area; as lesions become large, bleeding occurs with associated pain and foul-smelling discharge; enlarged inguinal lymph nodes indicative of advanced disease

DIFFERENTIAL DIAGNOSIS

- Infectious processes can present as ulcerative lesions and include syphilis, lymphogranuloma venereum, and granuloma inguinale.
- Disorder of Bartholin gland, seborrheic keratosis, hidradenomas, lichen sclerosus, epidermal inclusion cysts
- Crohn disease can present as an ulcerative area on the vulva.
- Rarely, lesions can metastasize to the vulva.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Hypercalcemia can occur when metastatic disease is present.
- Squamous cell antigen can be elevated with invasive disease.

Follow-Up Tests & Special Considerations

- Upon examination, any suspicious lesions should be biopsied.
- Diagnosis based on histologic findings following vulvar biopsy (4)
- The vulva can be washed with 3% acetic acid to highlight areas and visualized with a colposcope, allows for visualization of acetowhite lesions and vascular lesions (4).
- For patients with new onset of pruritus, the area of pruritus should be biopsied.
- Liberal biopsies must be used to diagnose in situ disease prior to invasion and to diagnose early invasive disease.
- The patient should not be treated for presumed benign conditions of the vulva without full exam and biopsy, including Pap smear and colposcopy of cervix, vagina, and vulva.
- When symptoms persist, reexamine and rebiopsy.
- Treatment of benign condyloma of the vulva has not been shown to decrease the eventual incidence of in situ or invasive disease of the vulva.
- CT scan to evaluate pelvic and periaortic lymph node status if tumor >2 cm or
if suspicion of metastatic disease (4)[A]

**Diagnostic Procedures/Other**
Office vulvar biopsy is done to establish the diagnosis.

**Test Interpretation**
A surgical staging system is used for vulvar cancer (International Federation of Obstetrics and Gynecology Classification).

- **Stage I:** tumor confined to the vulva
  - Stage IA: lesions ≤2 cm in size, confined to the vulva or perineum and with stromal invasion ≤1 mm, no node metastasis
  - Stage IB: lesions >2 cm in size or with stromal invasion >1 mm, confined to the vulva or perineum, with negative nodes
- **Stage II:** tumor of any size with extension to adjacent perineal structures (lower 1/3 urethra, lower 1/3 vagina, anus) with negative nodes
- **Stage III:** tumor of any size with or without extension to adjacent perineal structures (lower 1/3 urethra, lower 1/3 vagina, anus) with positive inguinofemoral lymph nodes
  - Stage IIIA
    - With 1 lymph node metastasis (≥5 mm), or
    - 1 to 2 lymph node metastases (<5 mm)
  - Stage IIIB
    - With ≥2 lymph node metastases (≥5 mm), or
    - ≥3 lymph node metastases (<5 mm)
  - Stage IIICC: with positive nodes with extracapsular spread
- **Stage IV:** Tumor invades other regional (upper 2/3 urethra, upper 2/3 vagina) or distant structures.
  - Stage IVA: Tumor invades any of the following:
    - Upper urethral and/or vaginal mucosa, bladder mucosa, rectal mucosa, or fixed to pelvic bone
    - Fixed or ulcerated inguinofemoral lymph nodes
  - Stage IVB: any distant metastasis, including pelvic lymph nodes

**TREATMENT**

**GENERAL MEASURES**
- Wide excision can be performed for carcinoma in situ, and any suspicious
lesion should be excised for definitive diagnosis.

- Cystoscopy and sigmoidoscopy should be performed if there is a question of invasion into the urethra, bladder, or rectum.

MEDICATION

- As an adjuvant therapy, fluorouracil (Efudex) cream for in situ disease can produce occasional results but is not well tolerated because of irritation of the vulva (5)[A].
- Chemoradiotherapy with cisplatin and 5-fluorouracil (5-FU) has been successful in advanced or recurrent disease, although local morbidity is increased (5)[A].
- Contraindications: elderly patients: If chemotherapeutic agents are used, pay close attention to the patient’s performance status and ability to tolerate aggressive chemotherapy.

ISSUES FOR REFERRAL

Patients may need care from a gynecologic oncologist and/or a radiation oncologist.

ADDITIONAL THERAPIES

- Preoperative radiation therapy can be used in those with advanced vulvar cancer (4)[B].
- Adjuvant radiation should be considered with tumor size >4 cm, evidence of lymphovascular invasion, positive surgical margins, or lymph node involvement.
- Preoperative chemoradiation allows for a less radical surgical procedure in patients who are not surgical candidates (5)[A].
- Postoperative radiation decreases recurrence frequency and may improve survival (5)[A].
- Radiation is contraindicated with verrucous carcinoma because it induces anaplastic transformation and increases metastases.

SURGERY/OTHER PROCEDURES

- In situ disease can be treated with wide excision or laser vaporization of the affected area. Laser vaporization is preferable in the younger patient, whereas wide excision is preferable in the elderly patient, in whom the risk of invasive disease is also higher (4)[A].
- If tumor extension within <1 cm from structures that will not be removed,
preoperative radiation to prevent inadequate surgical margins prior to excision
- Inguinofemoral lymphadenectomy: removal of superficial inguinal and deep femoral lymph nodes
- 1-cm tumor-free margin is required because smaller margin would increase risk of recurrence (5)[A].
- Stage IA: radical local excision without lymph node dissection
- Stage IB: radical local excision with either sentinel lymph node biopsy (SLNB) or ipsilateral inguinofemoral lymph node dissection because the risk of metastases is >8%
- Stage II: modified radical vulvectomy and/or chemoradiation and groin node dissection
- Stages III and IV: neoadjuvant chemoradiation and less radical surgery
- Pelvic exenteration after radiation provides effective therapy for advanced or recurrent malignancies involving the bladder or rectum.
- More limited surgery
  - Has been undertaken for early invasive lesions, especially in young patients, to preserve the clitoris and sexual function
  - SLNB also has been advocated for early invasive lesion (stage IB or higher). It has shown to accurately diagnose groin metastases in women with early vulval cancer and unknown groin node status. This will limit the surgical morbidity associated with inguinofemoral lymphadenectomy in those with early stage disease (6)[A].
  - Radical vulvectomy with bilateral groin node dissection through separate incisions provides better cosmetic results than en bloc technique.
  - Unilateral lymphadenectomy should be considered when lesion <2 cm, lateral lesion >2 cm from vulvar midline, or no palpable groin nodes.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Typically inpatient for treatment
- In advanced malignancy involving the urethra and rectum, concomitant cisplatin/5-FU chemotherapy with radiation produces a significant decrease in size of the primary tumor, usually obviating the need for pelvic exenteration.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
**Patient Monitoring**

- Early stage, treated with surgery alone: clinical exam of the groin nodes and vulvar area every 6 months for 2 years; then annually
- Following chemoradiation, assessment for further treatment within 6 to 12 weeks of therapy completion
- Advance stage, clinical exam of the groin nodes and vulvar area every 3 months for 2 years, then every 6 months for 3 years, and then annually
- Cervical and/or vaginal cytology annually
- Majority of relapses occur within 1st year.

**DIET**

As tolerated and according to comorbid conditions

**PATIENT EDUCATION**

- American College of Obstetricians and Gynecologists (ACOG), 409 12th St. SW, Washington, DC 20024-2188; (800) 762-ACOG; [http://www.acog.org/](http://www.acog.org/)

**PROGNOSIS**

The 5-year survival is based on stage:

- Stage I: 78.5%
- Stage II: 58.8%
- Stage III: 43.2%
- Stage IV: 13.0%

**Inguinal and/or femoral node involvement is the most important determinant of survival (7)[A].**

**COMPLICATIONS**

- The major complications from radical vulvectomy and groin node dissection are wound breakdown, lymphedema, urinary stress incontinence, and psychosexual consequences.
- Two common complications with radical vulvectomy and bilateral groin node dissection
  - In the immediate postoperative period, ~50% of patients experience breakdown of the wound. This requires aggressive wound care by visiting nurses as often as twice a day. The wounds usually granulate and heal over a period of 6 to 10 weeks.
  - ~15–20% of patients experience some form of mild to moderate
lymphedema after the groin node dissection. These patients should be instructed in the use of leg elevation and support hose. <1% of patients experience severe, debilitating lymphedema.

REFERENCES

CODES

**ICD10**
- C51.9 Malignant neoplasm of vulva, unspecified
- D07.1 Carcinoma in situ of vulva
- C51.0 Malignant neoplasm of labium majus

**CLINICAL PEARLS**
- 55% of vulvar cancers are attributable to oncogenic HPV and 92% of all VIN 2/3, VAIN 2/3, and AIN are attributable to HPV. Therefore, HPV vaccination has the potential to decrease vulvar cancer by 1/3.
- Biopsy all suspicious or nonhealing vulvar lesions.
VULVODYNIA

Jessica Johnson, MD, MPH • Amy L. Wiser, MD

BASICS

DESCRIPTION

- Vulvar pain lasting 3 months or more; occurs in the absence of relevant visible findings, relevant lab abnormalities, or a clinically identifiable neurologic disorder
- 2015 ISSVD classification is based on whether vulvar pain is caused by a specific disorder or has no clear identifiable cause (1).
- Specific disorders (differential diagnosis) include infectious, inflammatory, neoplastic, neurologic, trauma, iatrogenic, or hormonal deficiency.
- Descriptors for unclear etiology include localized versus generalized versus mixed, provoked versus spontaneous versus mixed, primary versus secondary onset, and temporal.

EPIDEMIOLOGY

- Most women diagnosed between age 20 and 80 years
- Nearly half of women opt not to seek treatment (2).
- Patients are psychologically comparable with asymptomatic controls and have similar marital satisfaction.

Incidence

- Recent retrospective study estimates annual rate of new onset vulvodynia to be 1.8%.
- Evidence indicates lifetime cumulative incidence approaches 15%, suggesting nearly 14 million U.S. women will experience persistent vulvar discomfort at some point in their lives (3).

Prevalence

- Reports between 8.3% and 16%; non–clinical-based studies approximate a prevalence of 7% with validation by exam (2).
- Studies show Hispanics are 80% more likely to present with vulvar pain compared with Caucasians and African Americans.
ETIOLOGY AND PATHOPHYSIOLOGY

- Vulvodynia is likely to be neuropathically mediated:
  - Hypothesized that neurogenic inflammation sensitizes afferent nerves, and transmits impulses to the CNS, where reinforcing signals sustain pain loop
  - In recent investigations of vulvar biopsy specimens, increased neuronal proliferation and branching in vulvar tissue are evident when compared with tissue of asymptomatic women.
- Pelvic floor pathology also should be considered: In one study, the vulvodynia group showed an increase in pelvic floor hypertonicity at the superficial muscle layer, less vaginal muscle strength with contraction, and decreased relaxation of pelvic floor muscles after contraction (3).
- No cause of vulvodynia has been established. It is most likely a neuropathic pain caused by a combination of the following:
  - Recurrent vulvovaginal candidiasis or other infections
  - Immune-mediated chronic neuroinflammatory process within vulvar tissues
  - Chemical exposure (trichloroacetic acid) or physical trauma
  - Reduced estrogen receptor expression/changes in estrogen concentration
  - CNS etiology, similar to other regional pain syndromes

RISK FACTORS

- Vulvovaginal infections, specifically candidiasis. Unclear if infection, treatment, or underlying hypersensitivity is the cause (2). Multiple infections compound this risk.
- Hormonal factors: Controversial evidence proposes increased risk with use of oral contraceptive pills (OCPs); pain onset or increased severity may be associated with menopause. Symptoms may flare before menses.
- Pelvic floor dysfunction: Increased instability of pelvic floor muscles may perpetuate vulvar tissue inflammation, leading to vascular changes and histamine release.
- Comorbid interstitial cystitis and painful bladder syndrome; potentially related to common embryologic origin of structures
- Abuse: increased risk of vulvodynia if childhood had physical or sexual abuse by a primary family member; causal relationship remains unclear (3).
- Depression and anxiety (2)
- Other neuropathic disorders, including regional pain syndrome

Genetics

Proposed genetic deficiency impairing one’s ability to stop the inflammatory
response triggered by infection or chemicals; homozygosity of the two alleles of the IL-1 receptor antagonist occurs in 25–50% of vestibulodynia patients, compared with <10% in controls.

**GENERAL PREVENTION**
- Wear 100% cotton underwear in the daytime and no underwear to sleep.
- Avoid douching and other vulvar irritants such as perfumes, dyes, and detergents.
- Avoid abrasive activities and tight, synthetic clothing.
- Avoid panty liners.
- Clean the vulva with water only and pat area dry after bathing.
- Avoid use of hair dryers in the vulvar area.

**COMMONLY ASSOCIATED CONDITIONS**
Higher incidence of chronic pain syndromes associated with vulvodynia, including chronic cystitis, irritable bowel syndrome, fibromyalgia, migraines, depression, endometriosis, low back pain. Women with vulvodynia have a higher incidence of depression and anxiety both preceding and resulting from their symptoms (2).

**DIAGNOSIS**
- Vulvodynia is a clinical diagnosis and it should be suspected in any women with chronic pain at the introitus and vulva.
- Pain should be characterized using a standard measure such as the McGill Pain Questionnaire; duration and nature of the pain should be established. Use physical exam to rule out other causes of vulvovaginal pain. Negative fungal culture, along with relevant history and positive cotton swab test, confirms diagnosis.

**HISTORY**
Adequate sexual, social, and pain history should be taken to assess degree of symptoms. Visual pain scales and pain diaries may be helpful (4)[B]:
- Onset of vulvodynia often sudden and without precedents
- Pain often described as generalized, unprovoked
- Quality of pain is burning, stinging, irritating, or rawness (2).
- Specifically ask about bowel and bladder habits, history of trauma or abuse,
history of infections including herpes and personal hygiene.

- Specific skin complaints may suggest alternate diagnosis; a history of allergies may suggest vulvar dermatitis.
- Assess for precipitants of vulvar pain: tight garments, bicycle riding, tampon use, prolonged sitting, perfumed or deodorant soaps, douching (2).
- Assess for complaints of dyspareunia:
  - Presence of vaginismus (involuntary vaginal muscle spasm), adequate lubrication, anorgasmia, partner problems, abuse
  - Psychosexual morbidity significantly higher in patients with vulvodynia; counseling may complement medical interventions.

**PHYSICAL EXAM**

- Ask patient to show where pain is localized or most painful.
- Mouth and skin exams to assess for lesions suggestive of lichen planus or lichen sclerosus
- Vaginal exam should be done to exclude other causes of vulvovaginal pain, including external inspection; palpation; and single digit, speculum, and bimanual exams:
  - The vulva may be erythematous, especially at the vestibule. Discomfort with separation of the labia minora is common.
  - Spontaneous or elicited pain at the lower 1/2 of anterior vaginal wall suggests bladder etiology.
- Bulbocavernosus and anal wink reflexes should be checked to assess for peripheral neuropathy.

**DIFFERENTIAL DIAGNOSIS**

- Infections: candidiasis, herpes, human papillomavirus (HPV), bacterial vaginosis, trichomoniasis, dermatophytes
- Inflammation: lichen planus, immunobullous disorder, allergic vulvitis, lichen sclerosus, atrophic vaginitis
- Neoplasia: Paget disease, vulvar or vaginal intraepithelial neoplasia, squamous cell carcinoma
- Neurologic/muscular: herpes neuralgia, spinal nerve compression, vaginismus

**DIAGNOSTIC TESTS & INTERPRETATION**

- Tampon test: reproduces pain in real-life settings
- Cotton swab or Q-tip test: Vulva tested for localized areas of pain, beginning at thighs and continuing medially toward vestibule, using the soft end and
broken sharp end of the cotton swab. Five distinct positions (2, 4, 6, 8, and 10 o’clock) surveyed using light palpation. Pain rated on a scale from 0 (none) to 10 (most severe); posterior introitus and posterior hymenal remnants most common sites of increased sensitivity

- Test for concurrent vaginismus: Apply pressure with a gloved finger to levator ani and obturator internus muscles to assess for tenderness, pain, or contracture.

**Initial Tests (lab, imaging)**

- Vaginal pH, wet mount, and yeast culture are recommended to rule out vaginitis.
- Gonorrhea and chlamydia testing done at physician’s discretion
- HPV screening is unnecessary; association is controversial between HPV and vulvodynia.

**Follow-Up Tests & Special Considerations**

- Varicella-zoster and herpes simplex virus should be considered if ulcers or vesicular eruptions are present.
- Consider biopsy if concerned for neoplasm or dermatophyte infection or if the patient is resistant to treatment.

**Diagnostic Procedures/Other**

Colposcopy can be helpful if epidermal abnormalities are present. This should be done with caution because acetic acid worsens vulvar pain.

**Test Interpretation**

No specific histologic features are associated with vulvodynia, although reactive squamous atypia has been observed. Biopsies are unnecessary for diagnosis. Presence of rash/altered mucosa is not consistent with vulvodynia; this requires further evaluation (4)[C].

**TREATMENT**

A trial of several medications for at least 3 months is usually needed.

**GENERAL MEASURES**

Combining treatments should be encouraged when treating women with
vulvodynia (4)[C]: Various reports on use of a combination of medical treatments, psychotherapy, and dietary intervention reveal women on these combinations do significantly better compared with those who receive medication only.

**MEDICATION**

- **Oral therapies**
  - Tricyclic antidepressants (TCAs): first-line treatment for unprovoked vulvodynia (4)[B]; do not stop use abruptly; contraindicated in patients with cardiac abnormalities and those taking MAOIs; fatigue, constipation, sweating, palpitations, and weight gain are most common side effects.
    - Amitriptyline, nortriptyline: most widely studied; start at 10 mg daily; dose titrated to pain control. Average effective dose is 60 mg daily. In one study, a 47% complete response rate was recorded (5)[B]. Nortriptyline may be preferred due to less anticholinergic adverse effects.
  - Anticonvulsant therapies:
    - Gabapentin: started at 300 mg daily at HS and increased by 300 mg every 3 days. Maximum recommended dose is 3,600 mg daily divided into 3 doses.
    - Topiramate and lamotrigine have been recommended if other therapies are not effective.
  - SSNRIs: not commonly used; however, have been helpful in those who cannot tolerate TCAs
    - Venlafaxine or duloxetine have also been used; evidence is limited.
  - Opioids/NSAIDs: not consistently helpful in relieving vulvar pain; not appropriate for maintenance

- **Topical therapies**
  - A trial of local anesthetics may be recommended for all patients who present with vulvodynia. Use judiciously to avoid increased irritation (4)[C].
  - Lidocaine 5% ointment: for provoked vestibulodynia; application advised 15 to 20 minutes prior to intercourse. Penile numbness and possible toxicity with ingestion can occur.
    - In one study, lidocaine 5% ointment was left in vestibule overnight (average of 8 hours) for a period of 6 to 8 weeks; at follow-up, up to 76% of women reported no discomfort with intercourse (3)[C].
  - Cromolyn 4% cream: decreases mast cell degranulation in vulvar tissue; recommended application TID (2)[C]
  - Capsaicin 0.025%: decreases in discomfort and increases in frequency of
intercourse with 20-minute daily application (3)[B]

- Topical amitriptyline 2% combined with baclofen 2% is helpful in patients with comorbid vaginismus.
- Topical corticosteroids and testosterone creams have not been shown to alleviate symptoms of vulvodynia.
- Gabapentin 3–6% ointment (must be compounded)
- Topical nitroglycerin may be helpful but may cause headaches.
- Topical estrogen

Injectable therapies
- Triamcinolone acetonide: no >40 mg should be injected monthly; is best when combined with 0.25–0.50% bupivacaine
- Submucosal methylprednisone and lidocaine: reports of up to 68% response rate with weekly injections (4)[B]
- Interferon-α: useful in treatment of vestibulodynia. Side effects (myalgias, fever, malaise) limit its use.
- Botulinum toxin A injectable is being studied.

ISSUES FOR REFERRAL

A team approach is recommended for most effective management. Referral to psychosexual medicine, psychology, partner therapy, and pain management teams should be strongly considered (4)[B].

ADDITIONAL THERAPIES

- Cognitive-behavioral therapy (CBT): One randomized trial revealed that CBT is associated with a 30% decrease in vulvar discomfort with sexual intercourse. CBT is the recommended treatment for patients who present with dyspareunia as a main complaint (6)[B].
- Biofeedback/physical therapy: useful with concomitant vaginismus. Treats both generalized and localized vulvar pain; treatment value for unprovoked pain remains unclear. Most studies report an average of 12- to 16-week treatment time.
- Vaginal dilators
- Surface electromyography (sEMG): efficacious for pelvic floor rehabilitation. Patients are more likely to experience pain-free sexual intercourse after sEMG; significant reductions seen on pain measures at long-term follow-up

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture: Small studies of women with unprovoked vulvodynia who did not respond to conventional treatment reported significant decreases in pain severity with acupuncture; treatment value with provoked pain is unknown (4)[C].

SURGERY/OTHER PROCEDURES
- Surgery may be considered for patients with localized symptoms who have failed to respond to other measures; not recommended for generalized vulvodynia (4)[B]
- 60–80% of women who undergo surgery report a significant reduction in pain symptoms; however, when surveyed, patients prefer behavioral therapies than surgical intervention.
- All patients who are considering surgical intervention should be tested and treated for vaginismus. Vestibulectomy is less successful in this subgroup.
- Surgical approaches
  - Local excision: precise localization of painful areas; tissue closed in elliptical fashion
  - Total vestibulectomy: Tissue is removed from Skene ducts to perineum. The vagina is then brought down to cover defect.
  - Perineoplasty: vestibulectomy plus removal of perineal tissue; incision usually terminated above the anal orifice; reserved for severe cases (2)[B]

ONGOING CARE

PATIENT EDUCATION
Patients should be reassured that this condition is neither infectious, nor does it predispose to cancer (4)[C]. Counsel that condition is manageable, but likely not curable, and may require multiple therapeutic trials before remission is achieved. Emphasize self-hygiene. Encourage treatment with home remedies, including ice packs, sitz baths with baking soda, olive oil, and barrier cream to preserve moisture after bathing.

PROGNOSIS
Traditionally viewed as a chronic pain disorder, new evidence of remission has been documented; recent 2-year follow-up study revealed 1 in 10 vulvodynia patients reported remission regardless of treatment.

REFERENCES

CODES

ICD10
- N94.819 Vulvodynia, unspecified
- N94.818 Other vulvodynia
- N94.810 Vulvar vestibulitis

CLINICAL PEARLS
- Vulvodynia is a clinical diagnosis; it should be suspected in any woman with chronic pain at the introitus and vulva.
- A decrease in pain may take weeks to months and may not be complete.
- No single treatment is proven in all women; improvement over time is common even without treatment.
VULVOVAGINITIS, ESTROGEN DEFICIENT

Karla M. Alba, MD • Michelle Rodriguez, MD • Mark T. Nadeau, MD, MBA

BASICS

DESCRIPTION
- Estrogen-deficient vulvovaginitis is a hypoestrogenic state with external genital, urologic, and sexual sequelae.
- Estrogen deficiency affects all tissues in the female body; however, the genital tissues are especially hormone responsive and are most affected.
- Decreased estrogen leads to decreased blood flow to vaginal tissues and thinning of vaginal tissues, dryness, and atrophy. Patients with estrogen-deficient vulvovaginitis may present with urinary incontinence, vaginal burning and itching, dyspareunia, increased urinary frequency, recurrent UTIs, or various other symptoms.
- This condition is also referred to as genitourinary syndrome of menopause.
- System(s) affected: reproductive

EPIDEMOLOGY

Incidence
Predominant age: postmenopausal females. The average age of menopause in the United States is 51.3 years but ranges from 45 to 55 years old.

Prevalence
- Approximately 40–54% of postmenopausal women are affected.
- Approximately 15% of premenopausal women are also affected.
- This condition is likely underdiagnosed as patients may be reluctant to report symptoms because of embarrassment or the misconception that symptoms should be accepted as a natural part of aging (1)[C].

ETIOLOGY AND PATHOPHYSIOLOGY
- Estrogen is vasoactive, increasing blood flow to target tissues, lubrication, and
Decreased estrogen levels in the vagina and vulva result in decreased blood flow and decreased lubrication and elasticity of vaginal and vulvar tissues as well as thinning of these tissues. Decreased cellular maturation results in decreased glycogen stores, which affects the normal vaginal flora and consequently the pH. The resulting increased pH impairs the viability of the normal flora, permitting the proliferation of fecal and other flora, resulting in UTIs and vaginal infections (1)[C].

Estrogen deficiency is caused by the following:
- Menopause (surgical or natural)
- Premature ovarian failure (chemotherapy, radiation, autoimmune, anorexia, genetic)
- Postpartum estrogen deficiency in lactating women
- Medications that alter hormonal concentration, such as gonadotropin-releasing hormone agonists, selective estrogen receptor modulator (tamoxifen), danazol, medroxyprogesterone, and aromatase inhibitors
- Elevated prolactin from hypothalamic–pituitary disorders

**Genetics**
No known pattern

**RISK FACTORS**
- Estrogen-deficient states
- Smoking
- Alcohol abuse
- Sexual abstinence or decreased frequency of coital activity
- Lack of exercise
- Absence of vaginal childbirth
- Chemotherapy
- Radiation therapy

**COMMONLY ASSOCIATED CONDITIONS**
- Urge and stress urinary incontinence
- Pelvic organ prolapse
- Frequent UTIs
- Bacterial vaginosis or yeast infections
- Vaginal stenosis
• Loss of libido
• Dyspareunia

DIAGNOSIS

HISTORY
• All female patients should be asked about symptoms because many women are embarrassed to discuss these issues with their health care providers (1)[C].
  – Vaginal dryness
  – Dyspareunia
  – Pruritus
  – Burning
  – Pressure
  – Tenderness
  – Malodorous discharge
  – Urinary symptoms: dysuria, hematuria, frequency, infections, stress, and urge urinary incontinence
• Ask about exposure to radiation therapy and medications.
• Ask about self-treatment and products used.
• Determine exposure to irritants (e.g., soaps, feminine sprays, lotions, lubricants, constant pad use).

PHYSICAL EXAM
Evidence for the diagnosis includes the following:
• Loss of pubic hair
• Decreased vulvar and vaginal fullness
• Fusion of labia minora
• Vulvar erythema or ecchymosis
• Decreased vulvar subcuticular fat and moisture
• Pale-appearing, shiny, smooth vaginal and urethral epithelium
• Vaginal shortening, intolerance to speculum exams
• Loss of vaginal rugation
• Pelvic organ prolapse
• Urethral atrophy
• Atrophy of Bartholin glands
• Cervical atrophy and stenosis of os
DIFFERENTIAL DIAGNOSIS

- Malignancy
- Sexual trauma
- Infection secondary to foreign bodies (e.g., piercings)
- Dermatologic conditions of vulva and vagina:
  - Dermatitis
  - Lichen sclerosis
  - Lichen planus
- Bacterial or yeast vulvovaginitis

DIAGNOSTIC TESTS & INTERPRETATION

Because vulvovaginitis is a clinical diagnosis, labs are not always necessary, but if suspect dermatologic or oncologic condition, biopsy is recommended (2)[A].

Initial Tests (lab, imaging)

Lab tests are generally unnecessary to make the diagnosis. However, the following labs and imaging may be obtained as corroborative of clinical impression:

- Follicle-stimulating hormone (FSH) and estrogen levels. FSH rises and estrogen drops with menopause.
- Evaluate for infections via wet preparation and vaginal pH (usually >5).
- Urinalysis if suspected concomitant UTI
- Cytology for maturation index: Higher proportion of parabasal cells and lower proportion of intermediate and superficial cells indicate decreased maturation index.
- Transvaginal ultrasound: Endometrial stripe <5 mm indicates loss of estrogen stimulation.

Follow-Up Tests & Special Considerations

Drugs that may alter lab results:

- Estrogen therapy will alter the maturation index, but may improve symptoms.
- Digoxin has estrogen-like properties.
- Tamoxifen may produce menopausal-type symptoms but also may act on genital tissues as a weak estrogen agonist.
- Progestins, danazol, and gonadotropin-releasing hormone agonists may produce a reversible pseudomenopausal state.
TREATMENT

GENERAL MEASURES
- Wear loose-fitting, undyed cotton underwear.
- Avoid prolonged pad use, especially scented pads.
- Avoid feminine deodorant sprays and douching.
- Use over-the-counter water-based lubricants, as needed.
- Symptomatic relief, if needed (e.g., cool baths or compresses)
- Increase coital activity.
- Smoking cessation

MEDICATION
- Estrogen therapy:
  - Systemic hormonal therapy is typically reserved for patients wanting treatment for vasomotor symptoms associated with estrogen deficiency in addition to atrophic vulvovaginitis. Transdermal preparations may be safer from a cardiovascular standpoint than oral preparations.
  - Local hormonal therapy (vaginal estrogen) is preferred first-line treatment and can reverse atrophic changes and alleviate symptoms (3)[A].
    - Vaginal cream 1 g (conjugated equine estrogens or estradiol cream): Insert via applicator each night for 14 days and then 2 to 3 times per week.
    - Vaginal estradiol 10-µg tablet: Insert via preloaded applicator each night for 14 days and then 2 to 3 times per week.
    - Estradiol-containing vaginal ring 2 mg: Insert into vagina, and replace every 3 months.
  - Estrogen therapy should be used in the lowest possible dose for the shortest duration of time (4)[B].
  - Long-term therapy may be necessary owing to the chronic nature of estrogen-deficient vulvovaginitis (5)[A].
  - Contraindications:
    - Breast or estrogen-dependent cancers
    - Undiagnosed vaginal bleeding
    - Thromboembolic disorders
    - Endometrial hyperplasia or cancer
    - Hypertension
    - Hyperlipidemia
    - Liver disease
- History of stroke
- Coronary heart disease
- Smoking in ages >35 years
- Migraines with neurologic symptoms
- Acute cholecystitis/cholangitis
- Pregnancy

**Nonestrogen therapy: selective estrogen receptor modulators** (1)[C], (6)[B]
- Ospemifene (Osphena) 60-mg tablet daily
- Contraindications:
  - Breast or estrogen-dependent carcinoma
  - Undiagnosed vaginal bleeding
  - Thromboembolic disorders
  - Thrombophlebitis
  - Hepatic impairment
- Precautions: Any abnormal vaginal bleeding must be evaluated. Monitor for DVT and stroke.

**ISSUES FOR REFERRAL**
- Refer to urogynecologist for evaluation if symptomatic due to pelvic organ prolapse and/or refractory stress and urge urinary incontinence.
- Recurrent UTIs should be further evaluated and may require a referral to urogynecology and/or urology.

**ADDITIONAL THERAPIES**
- Laser therapy with fractional CO₂ has demonstrated promise in initial studies; however, randomized controlled trial with long-term follow-up are still needed (1)[C].
- Lasofoxifene (Fablyn, Oporia) and oxytocin vaginal gel (Vagitocin) are under development but not yet approved (1)[C].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Management of this condition occurs primarily in the outpatient setting.

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS
Follow up as needed to determine response to treatment and for adjustment of treatment regimen.

Patient Monitoring
Instruct the patient that symptoms should improve within 30 to 60 days. If they do not, reevaluate and reexamine for other causes.

DIET
Increased consumption of cranberry juice or extract to prevent recurrent UTIs has been recommended, but not well-supported by evidence.

PATIENT EDUCATION
- American College of Obstetricians and Gynecologists (ACOG), 409 12th St., SW, Washington, DC 20024-2188; 800-762-ACOG: http://www.acog.org/
- Lactating postpartum women with high levels of prolactin are in a hypoestrogenic state. These women should be instructed to use lubrication for symptoms of dyspareunia and reassured that the symptoms will resolve when they are no longer breastfeeding.

PROGNOSIS
The prognosis is good. Most symptoms will be alleviated with vaginal estrogen replacement therapy.

COMPLICATIONS
- Recurrent UTIs may occur in women with vaginal atrophy.
- Vaginal atrophy predisposes patients to vaginal infections.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- N95.2 Postmenopausal atrophic vaginitis
- E28.39 Other primary ovarian failure

**CLINICAL PEARLS**

- Estrogen-deficient vulvovaginitis affects virtually all postmenopausal women to some degree as well as some premenopausal women.

- This disorder is associated with genital, urologic, and sexual symptoms including vaginal itching, vaginal dryness, urinary incontinence, increased urinary frequency, recurrent UTIs, and dyspareunia.

- Lab tests are generally unnecessary to make the diagnosis.

- Vaginal estrogen preparations, rather than systemic preparations, should be the first-line therapy in a woman whose primary complaint is associated with vaginal atrophy.
VULVOVAGINITIS, PREPUBESCENT
Sarah Parrott, DO

BASICS

DESCRIPTION
- Vulvitis is inflammation of the external genitals.
- Vaginitis, often associated with vaginal discharge, is inflammation involving the vaginal mucosa.
- In premenarchal girls, vulvitis is usually primary with secondary extension into the vagina.
- System(s) affected: reproductive, skin/exocrine
- Synonym(s): vaginitis; vulvitis

EPIDEMIOLOGY

Incidence
Unknown

Prevalence
Most common gynecologic problem in prepubertal girls

ETIOLOGY AND PATHOPHYSIOLOGY
- In the prepubertal child, the levels of estrogen are low.
- Due to the low levels of estrogen, the vaginal epithelium is thin, immature, and fragile.
- Absence of pubic hair and a well-developed labia as well as close proximity of the anus and vagina, make contamination more likely.
- The prepubertal child also has an absence of lactobacilli, creating a neutral to alkaline vaginal pH.
- Neutral pH, atrophic mucosa, and moist environment of the vagina increase the risk of infection.
- Most cases of pediatric vulvovaginitis are nonspecific inflammation.
- Specific infections that occur are typically respiratory, enteric, or sexually transmitted.
- Nonspecific vulvovaginitis
- Poor perineal hygiene (wiping back to front) (1)
Nonspecific chemical irritants (bubble baths, scented soaps, shampoos)

Tight-fitting clothing

Etiology
  – Bacterial: The most common bacteria are introduced from respiratory and GI tracts.
    o The most common respiratory pathogen is *Streptococcus pyogenes* (2) [B]. Vulvitis may occur in the absence of respiratory symptoms.
    o Urinary tract infections are common in children with vulvovaginitis (3) [B].
      o *Escherichia coli* is the most common fecal pathogen.
      o *Shigella* vaginitis is associated with mucopurulent bloody discharge and likewise, is not always accompanied by a history of diarrhea.

*Enterobius vermicularis* (pinworms)
  – Very common in young children and certain populations
  – Should be considered in children with vaginal itching and irritation
  – Most common symptom is nocturnal perineal itching.
  – Foreign body
    o Presents with foul-smelling, bloody, or brown discharge from the vagina
    o Should be considered with recurrent vulvovaginitis where other causes have been eliminated
  – Other
    o With chronic vulvovaginitis, anatomic abnormalities or systemic disease should be considered:
      ■ Anatomic abnormalities include double vagina with fistula, ectopic ureter, and urethral prolapse.
  – Systemic disease (inflammatory diseases)
  – Other conditions, such as lichen sclerosus, vitiligo, psoriasis, and atopic dermatitis, should be considered.

*Genetics*
Understudied

**RISK FACTORS**

– Prepubertal girls are particularly susceptible due to behavioral and anatomic reasons:
  – Inadequate hand washing or perineal cleansing after urination and defecation
  – Tight-fitting clothing
– Proximity of the vagina to the anus, lack of protective hair, and labial fat pads
– Trauma

Obese girls are also susceptible to nonspecific vulvovaginitis (4)[A].

GENERAL PREVENTION

● Good perineal hygiene (including wiping from front to back)
● Urination with legs spread apart and labia separated
● Avoidance of tight-fitting clothing and nonabsorbent underwear
● Avoidance of irritants such as harsh/perfumed soaps and bubble baths

ALERT
Cultures of sexually transmitted organisms in prepubertal children warrant investigations of sexual abuse.

DIAGNOSIS

HISTORY
Obtain careful history addressing any recent respiratory or enteric infections in the patient or a close family member. Symptoms may include:

● Vaginal discharge (44.4%)
● Vaginal itching (24.4%)
● Vulvar erythema (37.8%)
● Dysuria (33.3%)
● Perineal pain/burning during urination (6.3%)
● Enuresis (13.3%)
● Encopresis (2.1%)
● Anal itching (35.6%)

PHYSICAL EXAM
● Look for evidence of chronic illness or dermatologic disease.
● Look for trauma or other signs that may correlate with abuse.
● Inspect the genital area in the supine position:
  – Excoriation of the genital area
  – Inflammation (erythema, swelling) of the introitus
  – Inspect the vagina and cervix in the knee–chest position or frog leg position.
– Perform rectal exam if vaginal bleeding or abdominal pain.

DIFFERENTIAL DIAGNOSIS

- Contact dermatitis
- Eczema
- Psoriasis
- Lichen sclerosus

DIAGNOSTIC TESTS & INTERPRETATION

**Initial Tests (lab, imaging)**

- Culture for bacteria, fungi (yeast), or viruses (herpes)
- Urinalysis, urine culture, and urine for STI (via nucleic acid amplification test)—vulvovaginitis may cause UTIs by altering the perineal biome, increasing colonization of uropathogens (2)
- Tape exam for pinworms
- Potassium hydroxide and saline smears of vaginal discharge, if present
- If an anatomic abnormality is suspected, imaging may be necessary to confirm.
- Consider consultation with a pediatric or adult gynecologist to determine the most appropriate imaging study.

**Follow-Up Tests & Special Considerations**

Exploration of the vagina for a foreign body may be necessary in cases of persistent, recurrent vulvitis.

**Diagnostic Procedures/Other**

If blood or foul-smelling discharge is present, visualization is mandatory:

- Place the child in the knee–chest position for best results. Hold the buttocks apart and slightly upward.
- Visualization of the vagina may be necessary by using a nasal speculum or infant laryngoscope.
- If available, consider referral to a provider with specific training/experience in this specialized exam.

**TREATMENT**

- The definitive diagnosis of bacterial vulvitis requires a culture of vulva and
vaginal secretions.
- The typical colony count and bacterial mix are unknown in prepubescent girls. Antibiotic use should be directed against the species with the highest colony count.
- General hygiene should always be recommended, particularly in cases of a retained foreign body (e.g., toilet paper).
- When no cause is identified, treatment should focus on hygiene as well as minimizing soap exposure and tight-fitting clothes (2).

GENERAL MEASURES
- Appropriate health care: outpatient (except where systemic illness requires hospital care)
- Soak the vulva/perineum in a small amount of clear, warm water for 15 minutes BID.
- If smegma is present in the labial folds, clean the area gently with a mild soap.

MEDICATION

First Line
- To break the itching–scratching–infection cycle, use a low-dose topical hydrocortisone cream for a limited time.
- Estrogen deficiency with labial adhesion/agglutination: estrogen cream 0.625 mg to fused area nightly for 2 weeks
- Emollients or protective creams may offer symptomatic relief.
- Antibiotic use should be restricted to cases of bacterial infection only (5)[A].
- Specific organisms on culture
  - Group A Streptococcus, *Streptococcus pneumoniae*: penicillin V (Pen Vee K) 250 mg PO BID–TID for 10 days
  - *Haemophilus influenzae*: amoxicillin, 20 to 40 mg/kg/day PO divided TID for 7 days
  - *Staphylococcus aureus*: cephalexin, 25 to 50 mg/kg/day PO divided QID for 7 to 10 days or dicloxacillin, 25 mg/kg/day divided QID for 7 to 10 days or amoxicillin-clavulanate, 20 to 40 mg/kg/day PO divided BID for 7 to 10 days
  - *S. pyogenes*: amoxicillin, 50 mg/kg/day PO divided into 3 doses/day for 10 days
  - *Candida* sp.: topical nystatin (Mycostatin), miconazole, clotrimazole, or terconazole
  - *Shigella*: trimethoprim/sulfamethoxazole or ampicillin for 5 days
– Pinworms: mebendazole, 100 mg PO, repeated in 2 weeks
– *Chlamydia trachomatis*: ≤45 kg: erythromycin, 50 mg/kg/day QID for 14 days; ≥45 kg and <8 years old: azithromycin, 1 g PO single dose; ≥45 kg and ≥8 years old: azithromycin, 1 g PO single dose or doxycycline 100 mg BID for 7 days
– *Neisseria gonorrhoeae*: ≤45 kg: ceftriaxone, 125 mg IM plus medication for chlamydia; >45 kg: ceftriaxone, 250 mg IM × 1 plus medication for chlamydia
– *Trichomonas*: metronidazole, 15 mg/kg/day PO divided TID (max 250 mg TID) for 7 days

- Contraindications: allergy to proposed treatment
- Precautions: Avoid potential allergens and topical sensitizers if possible.

**ISSUES FOR REFERRAL**
- Suspected sexual abuse
- Suspected anatomic abnormality (except minor labial agglutination)
- Persistent, severe, or recurrent infections

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Monitor for fever, pruritus, and vaginal discharge.

**DIET**
- Healthy balanced diet, high in fiber to prevent constipation
- Adequate fluid intake

**PATIENT EDUCATION**

Hygiene
- Wipe front to back after elimination.
- Avoid bubble baths and other irritating products.
- Clean daily with mild soap and water and dry gently with soft towel or cool hair dryer.
- Apply bland ointments for skin protection, if necessary.
PROGNOSIS
Excellent

COMPLICATIONS
- If an STI is identified and not treated effectively, the patient is at risk for pelvic inflammatory disease (PID).
- Vaginismus

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- N76.0 Acute vaginitis
N77.1 Vaginitis, vulvitis and vulvovaginitis in dis classd elswhr

CLINICAL PEARLS

- Vulvovaginitis is the most common gynecologic problem in prepubescent girls.
- The hypoestrogenic state and prepubescent anatomy may increase susceptibility to vulvar and vaginal infection.
- Treatment is typically supportive (avoid scratching, warm soaks) but may require antibiotics if a bacterial infection is suspected.
- Isolating an infection with known sexual transmission should prompt further investigation.
- Recurrent or persistent vulvitis, especially with foul-smelling discharge, should prompt a skilled exam of the vagina for a retained foreign body (most common toilet paper).
- Good perineal hygiene will limit this condition.
WARTS

Mercedes E. Gonzalez, MD • Herbert P. Goodheart, MD

BASICS

- Warts (verrucae) are benign growths that are confined to the epidermis. All warts are caused by the human papillomavirus (HPV). Warts can appear on any area of the skin or mucous membranes. Common warts are predominantly seen in children and young adults.
- Clinically, warts are rather arbitrarily described as the following:
  - Common warts (verrucae vulgaris)
  - Plantar warts (verrucae plantaris)
  - Flat warts (verrucae plana)
  - Venereal warts (condyloma acuminatum)
  - Epidermodysplasia verruciformis is a rare, lifelong hereditary disorder characterized by chronic infection with HPV.
- System(s) affected: skin/exocrine

DESCRIPTION

- Common warts are most often found at sites subject to frequent trauma, such as the hands and feet. Because warts often vary widely in shape, size, and appearance, the various descriptive names for them generally reflect their clinical appearance, location, or both.
- For example, filiform (fingerlike) warts are threadlike, planar warts are flat, and plantar warts are located on the plantar surfaces (soles) of the feet.
- Genital warts, or condyloma acuminata, may be large and cauliflower-like, or they may consist of small papules.
- Warts on mucous membranes (mucosal papillomas), such as those in the mouth or vagina, tend to be white in color due to moisture retention.

EPIDEMIOLOGY

Incidence
- Predominant age: young adults and children
- Predominant sex: female = male

Prevalence
- ~7–10% of the U.S. population
- Common warts appear 2 times as frequently in whites as in blacks or Asians.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- HPV is a double-stranded, circular, supercoiled DNA virus.
- The virus infects epidermal keratinocytes, stimulating cell proliferation.
- Various strains of DNA HPV: To date, >150 different subtypes have been identified.
- Common warts: HPV types 2 and 4 (most common), followed by types 1, 3, 27, 29, and 57
- Palmoplantar warts: HPV type 1 (most common), followed by types 2, 3, 4, 27, 29, and 57
- Flat warts: HPV types 3, 10, and 28
- Butcher warts: HPV type 7
- The virus is passed primarily through skin-to-skin contact or from the recently shed virus kept intact in a moist, warm environment.

**RISK FACTORS**
- HIV/AIDS and other immunosuppressive diseases (e.g., lymphomas)
- Immunosuppressive drugs that decrease cell-mediated immunity (e.g., prednisone, cyclosporine, and chemotherapeutic agents)
- Pregnancy
- Handling raw meat, fish, or other types of animal matter in one’s occupation (e.g., butchers)
- Previous wart infection

**GENERAL PREVENTION**
There is no known way to prevent warts.

**DIAGNOSIS**
- Most often made on clinical appearance
- Skin biopsy, if necessary

**PHYSICAL EXAM**
- Distribution of warts is generally asymmetric, and lesions are often clustered or may appear in a linear configuration due to scratching (autoinoculation).
- Common wart: rough-surfaced, hyperkeratotic, papillomatous, raised, skin-
colored to tan papules, 5 to 10 mm in diameter; several may coalesce into a larger cluster (mosaic wart); most frequently seen on hands, knees, and elbows; usually asymptomatic but may cause cosmetic disfigurement or tenderness

- Filiform warts: These are long, slender, delicate, fingerlike growths, usually seen on the face around the lips, eyelids, or nares.
- Plantar warts often have a rough surface and appear on the plantar surface of the feet in children and young adults.
  - Can be tender and painful; extensive involvement on the sole of the foot may impair ambulation, particularly when present on a weight-bearing surface.
  - Most often seen on the metatarsal area, heels, and toes in an asymmetric distribution (pressure points)
  - Pathognomonic “black dots” (thrombosed dermal capillaries); punctate bleeding becomes more evident after paring with a no. 15 blade.
  - Both common and plantar warts generally demonstrate the following clinical findings:
    o A loss of normal skin markings (dermatoglyphics) such as finger, foot, and hand prints
    o Lesions may be solitary or multiple, or they may appear in clusters (mosaic warts).
- Flat warts: slightly elevated, flat-topped, skin-colored or tan papules, small (1 to 3 mm) in diameter
  - Commonly found on the face, arms, dorsa of hands, shins (women)
  - Sometimes exhibit a linear configuration caused by autoinoculation
  - In men, shaving spreads flat warts.
  - In women, they often occur on the shins, where leg shaving spreads lesions.
- Epidermodysplasia verruciformis (rare): Widespread flat, reddish brown pigmented papules and plaques that present in childhood with lifelong persistence on the trunk, hands, upper and lower extremities, and face are characteristics.

DIFFERENTIAL DIAGNOSIS

- Molluscum contagiosum
- Seborrheic keratosis
- Epidermal nevus
- Acrochordon (skin tag)
- Solar keratosis and cutaneous horn
- Acquired digital fibrokeratoma
- Squamous cell carcinoma (SCC)
- Keratoacanthoma
- Subungual SCC can easily be misdiagnosed as a subungual wart or onychomycosis.
- Corns/calluses
  - Corns (clavi) are sometimes difficult to distinguish from plantar warts. Like calluses, corns are thickened areas of the skin and most commonly develop at sites subjected to repeated friction and pressure, such as the tops and the tips of toes and along the sides of the feet.
  - Corns are usually hard and circular, with a polished or central translucent core, like the kernel of corn from which they take their name.
  - Corns do not have “black dots,” and skin markings are retained except for the area of the central core.

**ALERT**
- A melanoma on the plantar surface of the foot can mimic a plantar wart.
- Verrucous carcinoma, a slow-growing, locally invasive, well-differentiated SCC, also may be easily mistaken for a common or plantar wart.

### DIAGNOSTIC TESTS & INTERPRETATION

**Initial Tests (lab, imaging)**

**Diagnosis**
- HPV cannot be cultured, and lab testing is rarely necessary.
- Definitive HPV diagnosis can be achieved by the following:
  - Electron microscopy
  - Viral DNA identification employing Southern blot hybridization is used to identify the specific HPV type present in tissue.
  - Polymerase chain reaction may be used to amplify viral DNA for testing.

**Follow-Up Tests & Special Considerations**

Skin biopsy if unusual presentation or if diagnosis is unclear

**Test Interpretation**
- Histopathologic features of common warts include digitated epidermal hyperplasia, acanthosis, papillomatosis, compact orthokeratosis, hypergranulosis, dilated tortuous capillaries within the dermal papillae, and vertical tiers of parakeratotic cells with entrapped red blood cells above the tips of the digitations.
In the granular layer, HPV-infected cells may have coarse keratohyalin granules and vacuoles surrounding wrinkled-appearing nuclei. These koilocytic (vacuolated) cells are pathognomonic for warts.

**TREATMENT**

The abundance of therapeutic modalities described below is a reflection of the fact that none of them is uniformly or even clearly effective in trials. Placebo treatment response rate is significant and quality of evidence in general is poor. Beyond topical salicylates, there is no clear evidence-based rationale for choosing one method over another (1)[A].

The choice of method of treatment depends on the following:

- Age of the patient
- Cosmetic and psychological considerations
- Relief of symptoms
- Patient’s pain threshold
- Type of wart
- Location of the wart
- Experience of the physician

**GENERAL MEASURES**

- There is no ideal treatment.
- In children, most warts tend to regress spontaneously.
- In many adults and immunocompromised patients, warts are often difficult to eradicate.
- Painful, aggressive therapy should be avoided unless there is a need to eliminate the wart(s).
- For surgical procedures, especially in anxious children, pretreat with anesthetic cream such as EMLA (emulsion of lidocaine and prilocaine).

**MEDICATION**

**First Line**

- Self-administered topical therapy
  - Keratolytic (peeling) agents: The affected area(s) should be hydrated first by soaking in warm water for 5 minutes before application. Most over-the-counter agents contain salicylic acid and/or lactic acid: agents such as Duofilm, Occlusal-HP, Trans-Ver-Sal, and Mediplast.
Office-based
- Cantharidin 0.7%, an extract of the blister beetle that causes epidermal necrosis and blistering but may be difficult to obtain as a solution in the United States. It may be compounded in compounding pharmacies.
- Combination cantharidin 1%, salicylic acid 30%, and podophyllin resin 5% in flexible collodion; applied in a thin coat, occluded 4 to 6 hours and then washed off.

Second Line
Home-based
- Imiquimod 5% (Aldara) cream, a local inducer of interferon, is applied at home by the patient. It is approved for external genital and perianal warts and is used off-label and may be applied to warts under duct tape occlusion. It is applied at bedtime and washed off after 6 to 10 hours; applied to flat warts without occlusion.
- Topical retinoids (e.g., tretinoin 0.025–0.1% cream or gel) for flat warts.

Office-based
- Immunotherapy: induction of delayed type hypersensitivity with the following:
  - Diphenylcyclopropenone (DCP) (2)[B]
  - Dinitrochlorobenzene (DNCB)
  - Squaric acid dibutylester (SADBE): There is possible mutagenicity and side effects with this agent.
- Intralesional injections
  - Mumps or Candida antigen
  - Bleomycin: Intradermal injection is expensive and usually causes severe pain.
  - Interferon-α-2b
- Oral therapy
  - Oral high-dose cimetidine: possibly works better in children (40 mg/kg/day; max 1600 mg)
  - Acitretin (an oral retinoid)
- Other treatments (all have all been used with varying results)
  - Dichloroacetic acid, trichloroacetic acid, podophyllin, formic acid, aminolevulinic acid in combination with blue light, 5-fluorouracil, silver nitrate, formaldehyde, levamisole, topical cidofovir (3)[B] or IV cidofovir for recalcitrant warts in the setting of HIV, and glutaraldehyde
- The quadrivalent HPV vaccine has cleared recalcitrant, chronic oral, and cutaneous warts (4)[C].
COMPLEMENTARY & ALTERNATIVE MEDICINE

Duct tape: Cover wart with waterproof tape (e.g., duct tape). Leave the tape on for 6 days, and then soak, pare with emery board, and leave uncovered overnight; then reapply tape cyclically for eight cycles; 85% resolved compared with 60% efficacy with cryotherapy (5)[A]

- Hyperthermia: safe and inexpensive approach; immerse affected area into 45°C water bath for 30 minutes 3 times per week
- Hypnotherapy
- Raw garlic cloves have demonstrated some antiviral activity.
- Vaccines are currently in development.

Pregnancy Considerations
The use of some topical chemical approaches may be contraindicated during pregnancy or in women who are likely to become pregnant during the treatment period.

SURGERY/OTHER PROCEDURES

- Cryotherapy with liquid nitrogen (LN₂) may be applied with a cotton swab or with a cryotherapy gun (Cryogun). Aggressive cryotherapy may be more effective than salicylic acid (6)[A], but it is associated with increased adverse effects (blistering and scarring):
  - Best for warts on hands; also during pregnancy and breastfeeding
  - Fast; can treat many lesions per visit
  - Painful; not tolerated well by young children
  - Freezing periungual warts may result in nail deformation.
  - In darkly pigmented skin, treatment can result in hypo- or hyperpigmentation.
  - Uneven uptake of LN₂ can result in a larger ring wart.
- Light electrocautery with or without curettage
  - Best for warts on the knees, elbows, and dorsa of hands
  - Also good for filiform warts
  - Tolerable in most adults
  - Requires local anesthesia
  - May cause scarring
- Photodynamic therapy: Topical 5-aminolevulinic acid is applied to warts followed by photoactivation.
- CO₂ or pulse-dye laser ablation: expensive and requires local anesthesia
- For filiform warts: Dip hemostat into LN₂ for 10 seconds, then gently grasp the wart for 10 seconds and repeat. Wart sheds in 7 to 10 days.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*

1/3 of the warts of epidermodysplasia may become malignant.

**PROGNOSIS**

- More often than not (especially in children), warts tend to “cure” themselves over time.
- In many adults and immunocompromised patients, warts often prove difficult to eradicate.
- Rarely, certain types of lesions may transform into carcinomas.

**COMPLICATIONS**

- Autoinoculation (pseudo-Koebner reaction)
- Scar formation
- Chronic pain after plantar wart removal or scar formation
- Nail deformity after injury to nail matrix

**REFERENCES**

5. Wenner R, Askari SK, Cham PM, et al. Duct tape for the treatment of

## ADDITIONAL READING

## CODES

### ICD10

- B07.9 Viral wart, unspecified
- B07.0 Plantar wart
- A63.0 Anogenital (venereal) warts

## CLINICAL PEARLS

- No single therapy for warts is uniformly effective or superior; thus, treatment involves a certain amount of trial and error.
- Because most warts in children tend to regress spontaneously within 2 years, benign neglect is often a prudent option.
- Conservative, nonscarring, least painful, least expensive treatments are preferred.
- Freezing and other destructive treatment modalities do not kill the virus but merely destroy the cells that harbor HPV, triggering host immune repair response.
WILMS TUMOR
John K. Uffman, MD, MPH

BASICS

DESCRIPTION

- Most common renal tumor in children; fifth most common pediatric malignancy
- An embryonal renal neoplasm containing blastemal, stromal, or epithelial cell types, usually affecting children <5 years of age
- Staging: In the United States, National Wilms Tumor Study (NWTS) group staging is done pretreatment based on radiographic imaging and surgery, whereas in Europe/Asia, Société Internationale d’Oncologie Pédiatrique (SIOP) staging is done after neoadjuvant chemotherapy is administered (1):
  - I: tumor limited to kidney; completely excised
  - II: tumor extends beyond kidney; completely excised
  - III: residual nonhematogenous tumor confined to abdomen (lymph nodes positive, spillage of tumor, peritoneal implants, extension beyond resection region)
  - IV: hematogenous metastases
  - V: bilateral renal involvement
- System(s) affected: renal/urologic
- Synonym(s): nephroblastoma

Pediatric Considerations

- Occurs only in children
- Most common renal malignancy in childhood

EPIDEMIOLOGY

Incidence

- Frequency rare in East Asian populations than whites
- Frequency higher in black children than in whites
- Predominant age: median age of 36.5 months
- Predominant sex: female > male (1.1:1)
- Represents 6–7% of all childhood cancers
  - >80% are diagnosed before 5 years of age (median age is 3.5 years at
diagnosis).
– Wilms tumor makes up 95% of all renal cancers in children <15 years (2).

**Prevalence**
United States: 0.69/100,000; 7.6 cases/1 million children <15 years old

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Hereditary or sporadic forms of genetic mutation
- Familial form: autosomal dominant trait with incomplete penetrance (1%)
- Potential of parental occupational exposure (machinists, welders, motor vehicle mechanics, auto body repairmen)

**Genetics**
- Several congenital anomalies are known to be associated with Wilms tumor. A two-stage mutational model has been proposed: occurrence in either hereditary form or sporadic form. Patients with aniridia have a deletion of the short arm of chromosome 11 (11p13).
- Abnormalities of chromosome 11 at the 11p15 locus are associated with Beckwith-Wiedemann syndrome. Wilms tumor-suppressor gene (WT1) has been identified as well as additional candidates for another suppressor gene (WT2). Chromosome band 17q12–17q21 has been linked to two kindreds with Wilms tumor, and other kindred are associated with a Wilms tumor predisposition gene at 19q13.3–19q13.4. Loss of heterozygosity at chromosomes 16q and 1p is associated with adverse outcome (1).
- p53 is associated with anaplastic Wilms tumors (2).

**RISK FACTORS**
- Familial occurrence (5%) (2)
  – These patients tend to have earlier age of onset.
  – Familial patients have greater risk of bilateral disease.
- Parental occupation (machinists, welders, motor vehicle mechanics, auto body repairmen)
- Maternal exposure to pesticides prior to child’s birth (3)
- High birth weight or preterm birth (3)
- Compared with firstborn, being a second or later birth may be associated with significantly decreased risk of Wilms tumor (3).

**GENERAL PREVENTION**
Routine surveillance in patients with syndromes associated with Wilms tumor
Routine screening with serial renal US at 3- to 4-month intervals has been recommended in children who have syndromes associated with an incidence of Wilms tumor >5% (4)[C].
Routine screening with serial renal US is also recommended for infants born to kindreds with familial Wilms (every 3 to 4 months until age 7 years) (4)[C].

COMMONLY ASSOCIATED CONDITIONS
- Aniridia (partial or complete absence of iris) 600 times normal risk
- Hemihypertrophy (100 times normal risk)
- Cryptorchidism
- Hypospadias
- Duplicated renal collecting systems
- Denys-Drash syndrome (nephropathy, renal failure, male pseudohermaphroditism, Wilms tumor)
- Klippel-Trenaunay syndrome
- Wilms tumor, aniridia, genitourinary malformations, and mental retardation (WAGR) complex
- Beckwith-Wiedemann syndrome (visceromegaly, macroglossia, omphalocele, hyperinsulinemic hypoglycemia)

DIAGNOSIS
- Symptoms of pain, anorexia, vomiting, malaise in 30% (1)
- >90% present with asymptomatic abdominal mass (2)

HISTORY
- History of increasing abdominal size
- Usually asymptomatic; may have fever, abdominal pain

PHYSICAL EXAM
- Palpable upper abdominal mass
- Fever, hepatosplenomegaly
- Rarely, signs of acute abdomen with free intraperitoneal rupture
- Cardiac murmur
- Ascites, prominent abdominal wall veins, varicocele
- Gonadal metastases
- Aniridia (present in 1.1% of Wilms tumor patients)
Hypertension (20–65%) (1)

**DIFFERENTIAL DIAGNOSIS**

- Neuroblastoma
- Hepatic tumor
- Sarcoma
- Rhabdoid tumor
- Cystic nephroma
- Renal cell carcinoma (generally occurs in older children)
- Mesoblastic nephroma: distinguished only by histology. Age usually <6 months, essentially benign, although metastases have been reported; tend to be locally invasive
- Nephroblastomatosis: considered premalignant; may present as nodularity of one or both kidneys

**DIAGNOSTIC TESTS & INTERPRETATION**

- Urinalysis (occasional hematuria, proteinuria)
- CBC (anemia)
- Lactate dehydrogenase
- Plasma renin (rarely helpful)
- Urine catecholamines
- Serum creatinine and calcium
- Coagulation factors
- Chest radiograph
- Abdominal US (with Doppler imaging): best initial test; gives best information about tumor and extension into inferior vena cava
- CT scan (with IV and oral contrast material) of chest and abdomen; allows anatomic visualization and excludes synchronous bilateral disease with a high degree of sensitivity (2)
- CT may have high sensitivity and specificity for atrio caval thrombus and obviate the needs for US (2).
- Chest lesions only identified on CT have improved event-free survival with three-drug treatment regimens (5)[B].

**Diagnostic Procedures/Other**

Occasionally, bone marrow aspiration is necessary to distinguish from neuroblastoma.
**Test Interpretation**

- **Favorable findings** (mortality of 7%)
  - Local lesion, well encapsulated
  - Focal areas of hemorrhage and necrosis
  - Absence of anaplasia and sarcomatous cell types
  - Presence of blastemal, stromal, and epithelial elements (3)
    - Predominance of epithelial elements usually is less aggressive when diagnosed early but tend to be resistant to treatment when diagnosed late.
    - Predominance of blastemal elements indicate more aggressive tumors.

- **Unfavorable histology** (mortality rate of 57%)
  - Anaplasia: markedly enlarged and multipolar mitotic figures, 3-fold enlargement of nuclei in comparison with adjacent similar nuclei, hyperchromasia of enlarged nuclei; anaplasia may be diffuse or focal.
  - Sarcomatous changes: now considered to be separate from Wilms, not subtypes (mortality 64%)
  - Rhabdoid tumor of the kidney: now considered to be separate tumor from Wilms

- Nephroblastomatosis: considered premalignant
- Nephrogenic rests (3): These are precursor lesions found in 25–40% of Wilms; found in 1% of infants at autopsy, but most do not develop into malignancy

**TREATMENT**

**GENERAL MEASURES**

- Appropriate health care: inpatient workup and treatment until stable postoperatively and induction chemotherapy completed
- Chemotherapy; some recommend pretreatment with neoadjuvant chemotherapy (1)[B].
  - May decrease incidence of intraoperative tumor rupture (debatable)
  - May result in inappropriate treatment with chemotherapeutic agents of non-Wilms tumors (5%) or benign lesions (1.6%)
  - Results in the inability to directly compare treatment results worldwide
- Radiation therapy in stage II (unfavorable histology), stage III, and stage IV

**MEDICATION**
**First Line**
Children typically treated with protocols based on staging, histology, and other variables as part of a multimodal therapy approach (chemotherapy, radiation, surgery). The following medications may be used as part of a protocol:
- Dactinomycin (actinomycin-D)
- Vincristine
- Doxorubicin
- Cyclophosphamide (Cytoxan)
- Ifosfamide
- Etoposide
- Topotecan
- Irinotecan

**Second Line**
- Doxorubicin (Adriamycin)
- Cyclophosphamide

**SURGERY/OTHER PROCEDURES**
- Exploration of contralateral kidney no longer required if adequate CT done preoperatively
- Radical nephroureterectomy and lymph node sampling is needed to provide precise staging information.
- Renal-sparing resection
  - Tumors are usually too large, but 10–15% may be amenable to partial nephrectomy if given preoperative chemotherapy (4)[C].
  - May be recommended for patients with high risk of bilateral disease or renal failure (4)[C]
- Sampling of any enlarged lymph nodes (absence of any lymph nodes in the surgical specimen mandates treatment as stage III disease) (4)[C]
- Identification of any retained tumor with titanium clips
- Tumor should be given to pathologist fresh, not in formalin.
- Vertical midline incision if tumor extension to right atrium—increased morbidity (2)
- Bilateral Wilms tumors (represent 4–6% of Wilms) (2)[C]
  - Preoperative chemotherapy with reevaluation by CT or MRI after 6 weeks (some are biopsied prior to chemotherapy)
  - Renal-sparing operation at 6 weeks if good response to chemotherapy:
    o Partial nephrectomy or wedge excision of tumor is preferred but only if it
does not compromise tumor resection.
  o Kidney with lowest tumor burden is addressed first. If successful resection is accomplished, radical nephrectomy can be done on the contralateral kidney. Bilateral partial nephrectomy may be possible in some cases.
  
  • Preoperative treatment also generally is accepted in a solitary kidney, horseshoe kidneys, intravascular extension of tumor above the intrahepatic vena cava, and in the case of respiratory distress from extensive metastatic tumor.
  • Treatment of patients with relapsed Wilms (4)[C]: Current treatment is either with chemotherapy with or without radiation therapy alone or high-dose chemotherapy followed by autologous stem cell rescue.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
  • Multidrug chemotherapy every 3 to 4 weeks for 16 weeks to 15 months depending on stage
  • Every 4 months for 1 year, every 6 months for 2nd to 3rd year; yearly after that
  • CBC, CT of chest and abdomen with each visit
  • Patients at high risk for developing Wilms tumor should be monitored with renal US every 3 to 4 months until 5 years of age. Patients with Beckwith-Wiedemann syndrome or Simpson-Golabi-Behmel syndrome should have yearly US until 7 years of age (6)[C].

**PATIENT EDUCATION**
  • Possibility of second malignancy (up to 12% by age 50 years)
  • Side effects of chemotherapy, radiation therapy

**PROGNOSIS**
  • With favorable histology (1)
    – Children <2 years of age and stage I, favorable histology: 98% survival in NWTS-1 to NWTS-3 studies
    – Children with stage III, favorable histology tumor: overall survival of 89%
in NWTS-3 to NWTS-4 studies

- With diffuse anaplasia (1)
  - Children with stage I, diffuse or focal anaplasia: overall survival 82.6%
  - Stage II tumors with anaplasia: overall survival 81.5%
  - Stage III tumors with anaplasia: overall survival 66.7%
  - Stage IV tumors with anaplasia: overall survival 33.3%

- With bilateral involvement (stage V): 4-year survival 81.7% (1)

- With rhabdoid features: 19% 3-year survival

Survival of patients with relapsed Wilms tumor is 40–70% (6)\[B\]:

- Patients with pulmonary relapse only had higher 4-year survival rate (77.7%) compared to other sites (41.6%)

**COMPLICATIONS**

- Complication rate of 6–10%
- 1–2% will develop second malignant neoplasms (leukemia, lymphoma, hepatocellular carcinoma, soft tissue sarcoma): 12.2% by 50 years of age
- High risk of delivering low-birth-weight infants, perinatal mortality in offspring of female survivors of Wilms tumor
- Chest is usual site of recurrence.
- Occurrence of second malignant neoplasms in 2% of patients 7 to 34 years after treatment
  - Bone and soft tissue sarcomas, breast cancer, hepatocellular carcinoma, lymphoma, gastrointestinal tract tumors, melanoma, leukemias
- Surgical complications
  - Postoperative small bowel obstruction (5–7%)
  - Tumor rupture with spillage in 15.3% according to NWTS-5; this may be spontaneous or surgical and results in upstaging the tumor. Only 2.7% of spills are considered avoidable. Incidence of tumor spillage is reported at 2.2% by SIOP following preoperative neoadjuvant chemotherapy (4)\[B\].
- Local tumor recurrence
  - Abdominal tumor recurrence after tumor spillage is reduced by radiation therapy (10 or 20 Gy).
- Renal failure
- Cardiomyopathy (usually related to doxorubicin and radiation therapy)
- Impaired pulmonary function (radiation therapy)

**REFERENCES**

1. Sonn G, Shortliffe LM. Management of Wilms tumor: current standard of

CODES

ICD10
- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C64.1 Malignant neoplasm of right kidney, except renal pelvis
- C64.2 Malignant neoplasm of left kidney, except renal pelvis

CLINICAL PEARLS
- Wilms is the most common renal tumor in children; it is an embryonal renal neoplasm containing blastemal, stromal, or epithelial cell types, usually affecting children <5 years of age.
- Nephrectomy performed as soon as possible after completing radiographic evaluation is the major component in tumor staging.
- Sampling regional lymph nodes or specifically mentioning “No nodes present” in the operative report is necessary or the tumor will automatically be considered stage III.
ZOLLINGER-ELLISON SYNDROME
Douglas S. Parks, MD

BASICS

DESCRIPTION
- Zollinger-Ellison syndrome (ZES) triad
  - Markedly elevated gastric acid secretion
  - Peptic ulcer disease
  - A gastrinoma or non-β islet cell tumor of the pancreas or duodenal wall that produces gastrin
    - Gastrinomas (at the time of diagnosis) may be single or multiple (1/2 to 2/3), large or small, benign or malignant (2/3), sporadic (70–75%) or associated with multiple endocrine neoplasia type 1 (MEN1) (25–30%).
- System(s) affected: endocrine/metabolic, gastrointestinal
- Synonym(s): Z-E syndrome; pancreatic ulcerogenic tumor syndrome; multiple endocrine neoplasia, partial; ulcerogenic islet cell tumor

EPIDEMIOLOGY

Incidence
- 1 to 3 per million per year in the United States
- Predominant age: middle age (30 to 65 years). Mean age of onset is 43 years; presents a decade earlier in patients with ZES/MEN1
- Predominant sex: male > female (1.3:1)

Pediatric Considerations
Aggressive cases have been reported in teenagers.

Pregnancy Considerations
Rare, pregnancy alters medication choices and surgical timing.

ETIOLOGY AND PATHOPHYSIOLOGY
- Gastrinoma is equally distributed between the head of the pancreas and the first or second portion of the duodenum; if in the pancreas, the lesion is more likely to metastasize to the liver.
- Hypergastrinemia results in gastric mucosal hypertrophy and increased acid
production. Increased acid production causes mucosal ulceration. Diarrhea and malabsorption are also common in ZES.

- Increasing number found in stomach wall, up to 8%; may be due to increased surveillance and/or increased PPI use masking symptoms (1)[C]
- Also may be found rarely in the mesentery, peritoneum, spleen, skin, or mediastinum (possibly metastasis with primary not identified)

**Genetics**

~25–30% of cases occur in association with the MEN1 syndrome—tumors of pancreas, pituitary, and parathyroid.

**RISK FACTORS**

- MEN1
- Family history of ulcer disease

**GENERAL PREVENTION**

Screen first-degree relatives of patients with MEN1.

**COMMONLY ASSOCIATED CONDITIONS**

- MEN1
- Insulinoma
- Carcinoid tumors

**DIAGNOSIS**

**HISTORY**

Average of 5 years of symptoms (including recurrent ulcers) before diagnosis is made

- Abdominal pain is the most common symptom (80%).
- Diarrhea (postprandial and fasting) (70%)
- Heartburn (60%)
- Nausea (30%)
- Reflux esophagitis
- Vomiting that is unresponsive to standard therapy
- Weight loss

**PHYSICAL EXAM**
Hepatomegaly with metastasis
- Conjunctival pallor if anemic
- Jaundice (tumor compressing common bile duct)
- Epigastric tenderness
- Dental erosions
- Heme + stools on rectal exam
- Complications of severe peptic ulcer disease, including hemorrhage, perforation, and obstruction
- Signs of MEN1 are hypercalcemia, hyperparathyroidism, and Cushing syndrome.

**Geriatric Considerations**
Consider the diagnosis in a patient with persistent or recurring peptic ulcer disease; it is a less aggressive disease if it appears after 65 years.

**DIFFERENTIAL DIAGNOSIS**
- Elevated serum gastrin with hypochlorhydria/achlorhydria
  - Atrophic gastritis
  - Drug-induced (associated with proton pump inhibitors [PPIs])
  - Gastric cancer
  - Pernicious anemia
  - Postvagotomy
- Elevated serum gastrin with normal or increased gastric acid
  - Antral G-cell hyperfunction
  - Chronic renal failure
  - *Helicobacter pylori* infection
  - Gastric outlet obstruction
  - Retained gastric antrum
- Consider gastrinoma in all patients with:
  - Recurrent or refractory ulcer disease
  - Gastric hypertrophy and ulcers
  - Duodenal and jejunal ulcers
  - Ulcers and diarrhea
  - Ulcers and kidney stones
  - Hypercalcemia and ulcers
  - Pituitary disease
  - Family history of ulcer disease or endocrine tumors suggestive of MEN1
DIAGNOSTIC TESTS & INTERPRETATION

- Secretin stimulation test is preferred: gastrin level >100 pg/mL (>100 ng/L) (2,3)[A].
- Some gastrin assays undermeasure serum gastrin; if have strong index of suspicion but gastrin levels low, may need to repeat with a different lab (3)[B].
- Gastric secretory studies: basal acid output
- Alternative test is calcium infusion test: gastrin level >400 pg/mL (test is less specific and more dangerous because of IV calcium infusion).
- Elevated fasting serum gastrin: >1,000 pg/mL with ulcers diagnostic; >200 pg/mL with ulcers is suggestive.
- Elevated basal gastric acid output: >15 mEq/hr (>15 mmol/hr)
- Gastric pH <2 with elevated gastrin
- Check serum calcium, phosphorus, cortisol, and prolactin to rule out MEN1.
- Drugs may alter lab results:
  - Histamine (H₂) blockers and PPIs may increase gastric pH and serum gastrin.
  - Hold PPIs 7 days and H₂ blockers 2 days prior to drawing gastrin level.
- Endoscopic US: finds 24–38% of primary tumors
- Endoscopic findings include esophagitis, duodenal ulceration with multiple ulcers, and prominent gastric and duodenal folds.
- Used to localize tumor for possible resection
- Much more likely to find tumors >3 cm (95%) than <1 cm (<15%)
- Abdominal CT scan: most useful for pancreatic tumors and metastasis >3 cm
- Abdominal US, MRI, and angiography are not typically useful except in large tumors.
- Somatostatin receptor scintigraphy (SRS): more sensitive than radiologic studies, still only finds 30% of small tumors
- Portal venous sampling and selective venous sampling for gastrin can localize the area of tumor and metastasis (80–90% sensitivity).
- Brain imaging (MRI) and serum calcium are useful if MEN1 is suspected.
- Because pancreatic tumors are most likely to be large and to metastasize to the liver (worse prognosis), SRS and an abdominal CT scan are suggested to look for resectable tumors. Resection improves prognosis.

**Diagnostic Procedures/Other**

Endoscopy may reveal tumors in the duodenal or stomach wall; multiple ulcers, including jejunal ulcers; and prominent gastric and duodenal folds.
**Test Interpretation**

- 90% of gastrinomas are found in the gastric triangle (bordered by the bile duct, the junction of second and third portions of the duodenum, and the junction of the head and body of pancreas).
- ~50% of gastrinomas are in the head of the pancreas (more likely >3 cm, metastasis to liver).
- ~50% of gastrinomas are in the wall of the first or second portion of duodenum (more likely small and solitary).
- 2/3 of gastrinomas are malignant.
- 50% of gastrinomas stain positive for adrenocorticotropic hormone (ACTH), vasoactive intestinal polypeptide, insulin, or neurotensin.
- 1/3 of patients have metastasis on presentation: regional nodes > liver > bone, > peritoneum, spleen, skin, and mediastinum.
- Biopsy shows hyperplasia of antral gastrin-producing cells; histology appears similar to carcinoid.

**TREATMENT**

**GENERAL MEASURES**

- Goals are to control acid hypersecretion and resect the tumor.
- Advanced imaging initially to evaluate for resection
- Surgical removal when primary tumor can be identified and as adjunct to control symptoms
- Medical treatment for symptom control when primary tumor is not found or metastasis on initial diagnosis

**MEDICATION**

- PPIs are the first-line treatment; add H₂ blockers.
- Medications heal 80–85% of ulcers, most of which recur. Lifelong medication use should be anticipated.
- 4- to 8-fold higher PPI dose often necessary
  - Start at a lower dose, and titrate to symptoms (or maximum recommended dosage).
- If hyperparathyroidism is present (MEN1), correct hypercalcemia.

**First Line**

- PPIs
- Omeprazole 60 to 120 mg/day
- Lansoprazole 60 to 180 mg/day (doses >120 mg need to be divided BID)
- Rabeprazole 60 to 100 mg/day up to 60 mg BID
- Pantoprazole 40 to 240 mg/day PO; 80 to 120 mg q12h IV

- **H₂ blockers**
  - Cimetidine 300 mg q6h up to 2.4 g/day
  - Ranitidine 150 mg q12h up to 6 g/day
  - Famotidine 20 mg q6h; up to 640 mg/day

- **Contraindications**
  - Known hypersensitivity to the drug
  - H₂ blockers: antiandrogen effects, drug interactions due to cytochrome P450 inhibition
  - PPIs: none

- **Precautions**
  - Adjust doses for geriatric patients and patients with renal insufficiency.
  - Gynecomastia has been reported with high-dose cimetidine (>2.4 g/day).
  - PPIs may induce a profound and long-lasting effect on gastric acid secretion, thereby affecting the bioavailability of drugs depending on low gastric pH (e.g., ketoconazole, ampicillin, iron).

- Significant possible interactions: Consider drug–drug interactions and consult prescribing materials accordingly.

### Second Line
- Octreotide may slow growth of liver metastases, or (occasionally) promote regression. Octreotide LAR can be given every 28 days.
- Chemotherapy regimens using streptozocin, 5-fluorouracil, and doxorubicin shows limited response.
- Interferon shows a limited response but may be useful in combination with octreotide.

### SURGERY/OTHER PROCEDURES
- Laparotomy to search for resectable tumors unless patient has liver metastasis on presentation or MEN1; surgery improves outcomes.
- Definitive therapy: removal of identifiable gastrinomas (95% of tumors are found at the time of surgery; 5-year cure is 40% when all are removed.)
- Total gastrectomy is rarely indicated.
- In MEN1, parathyroidectomy, by lowering calcium, may also decrease acid production and decrease antisecretory drug use. Gastrinomas in MEN1 are
generally small, benign, and multiple, and surgery is not usually curative in this situation.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Titrate medication to symptom control.
- Appropriate surveillance postoperatively to look for metastasis

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Longitudinal follow-up to evaluate for metastases
- Titrate medical therapy to control symptoms.
- Advise patients of potential danger of stopping antisecretory treatment. Rare cases have been reported of severe adverse outcomes within 2 days of stopping PPIs (4)[B]. Gastric acid analysis can help guide medical therapy to maintain basal gastric acid output at <10 mEq/hr (<2 mEq/hr if patient has complications such as perforation or esophagitis).

**DIET**

Restrict foods that aggravate symptoms.

**PATIENT EDUCATION**

Inform patients as to the nature of disease and prognosis.

**PROGNOSIS**

- Overall survival rate: 5 to 10 years: 69–94%
- The prognosis improves with complete surgical removal of the tumor.
- If liver metastasis is present on initial surgery, 5-year survival is 30–40%; 10-year survival is 25%.
- Mortality is directly related to liver metastasis tumor size and presence of pancreatic tumors.

**COMPLICATIONS**

- Complications of peptic ulcer disease (bleeding, perforation, obstruction)
• 2/3 of gastrinomas are malignant with metastasis.
• Paraneoplastic phenomena (e.g., production of ACTH with resulting Cushing syndrome) is possible.
• Decrease in vitamin B₁₂ levels is possible with long-term PPI use (5)[A].

CODES

ICD10

mebooksfree.com
E16.4 Increased secretion of gastrin

CLINICAL PEARLS

- Consider ZES if peptic ulcers recur or if high doses of PPI are needed to control symptoms/ulcers.
- ~25–30% of cases of ZES occur in association with MEN1.
- Once ZES is diagnosed, search for gastrinomas in the head of the pancreas and the first or second portion of the duodenum.
- PPIs heal ZES ulcers. Patients should anticipate lifelong therapy.
