**Follow-Up Tests & Special Considerations**
- Hospitalize nonimmune individuals with suspected or confirmed *P. falciparum*.
- Submit clinical specimens from suspected or confirmed malaria cases in the United States to the CDC for diagnostic confirmation, speciation, and drug resistance surveillance.

**Test Interpretation**
Interpretation of microscopy: Spread blood on a microscope slide as a thick/thin prep and stain with Giemsa (most commonly). View slide under 100X oil immersion to examine for ring, gametocyte, trophozoite, and schizont forms. The thick film is better for detecting parasites. The thin film is used to determine species and calculating the percentage of RBCs infected. Both should always be performed.

**TREATMENT**

**MEDICATION**

**First Line**
- For uncomplicated chloroquine-resistant *P. falciparum* (most *P. falciparum*), chloroquine-resistant *P. vivax*, or when species is unknown, the following regimens are recommended:
  - Atovaquone-proguanil (Malarone): adult tablet: 250 mg atovaquone and 100 mg proguanil. Pediatric tablet: 62.5 mg atovaquone and 25 mg proguanil. Adults: 4 adult tablets once per day for 3 days. Children 5 to 8 kg: 2 pediatric tablets once per day for 3 days; children 9 to 10 kg: 3 pediatric tablets once per day for 3 days; children 11 to 20 kg: 1 adult tablet once per day for 3 days; children 21 to 30 kg: 2 adult tablets once per day for 3 days; children 31 to 40 kg: 3 adult tablets once per day for 3 days; children >40 kg: 4 adult tablets once per day for 3 days
- Artemether-lumefantrine (Coartem): Tablet contains 20 mg artemether and 120 mg lumefantrine. Persons 5 to <15 kg: 1 tablet BID for 3 days; persons 15 to <25 kg: 2 tablets BID for 3 days; persons 25 to <35 kg: 3 tablets BID for 3 days; persons ≥35 kg: 4 tablets BID for 3 days.
- Quinine sulfate plus doxycycline or clindamycin: adults: quinine sulfate 650 mg (salt) TID for 3 days (should be extended to 7 days for infections acquired in Southeast Asia). Doxycycline 100 mg BID for 7 days. Clindamycin 20 mg (base)/kg/day divided TID for 7 days; children: quinine sulfate 10 mg (salt)/kg TID for 3 days (should be extended to 7 days for infections acquired in Southeast Asia) plus clindamycin dosed as above.
- Mefloquine: adults: 750 mg followed by 500 mg 8 hours later; children: 15 mg/kg followed by 10 mg/kg 8 hours later (maximum total dose: 1,250 mg)
- PO therapy for *P. ovale*, *P. malariae*, chloroquine-sensitive *P. falciparum* (rare), and chloroquine-sensitive *P. vivax* (New Guinea has highest rates of chloroquine-resistant *P. vivax*); in addition to the treatment regimens listed above, other options are as follows:
  - Chloroquine: adults: 1 g (600-mg base) followed by 500 mg (300-mg base) at 6, 24, and 48 hours after first dose; children: 16.6 mg/kg (10-mg base/kg) on day 1 (max 1,000 mg [600-mg base]) and then 8.3 mg/kg (5-mg/kg base) at 6, 24, and 48 hours after first dose.
  - Primaquine (should be added to the acute treatment regimen for cure of dormant forms of *P. vivax* and *P. ovale*): adults: 30-mg base (52.6 mg) daily for 2 weeks; children: 0.6-mg base/kg/day for 2 weeks.
- Therapy for severe malaria:
  - Clinical features defining severe malaria:
    - Impaired level of consciousness (LOC)
    - Respiratory distress, jaundice
    - Repeated convulsions, shock
    - Renal failure
  - Laboratory features:
    - Parasitemia >5%
    - Hypoglycemia
    - Acidosis (usually lactic acidosis)
- Parenteral therapy:
  - Quinidine gluconate 10 mg/kg in normal saline over 1 to 2 hours followed by 0.02 mg/kg/min continuous infusion
  - Intensive care monitoring is necessary, especially when initiating quinidine therapy.
- In severe malaria, contact the CDC for assistance; CDC Malaria Branch: 770-
In 2007, the CDC made artesunate available in the United States for severe malaria in special circumstances under an investigational protocol. Contact the CDC for assistance.

**ISSUES FOR REFERRAL**
Infectious disease or tropical medicine consultation. Malaria is reportable (http://www.cdc.gov/malaria/features/new_report_form.html).

**ADDITIONAL THERAPIES**
None

**Pediatric Considerations**
- Children particularly susceptible to severe disease
- All children, even infants, should receive chemoprophylaxis if traveling to an endemic area.
- Malaria can resemble acute gastroenteritis in children.
- Children with severe disease are prone to hypoglycemia. Use IV fluids with glucose for maintenance and monitor blood glucose frequently.

**Pregnancy Considerations**
- Chloroquine is safe in the doses recommended for prevention and treatment of malaria; FDA pregnancy Category C
- Mefloquine is safe in the doses recommended for prevention and treatment of malaria; FDA pregnancy Category B
- Atovaquone-proguanil (Malarone) has not been studied in pregnant women; it has not been shown to cause birth defects or other problems in animal studies; FDA pregnancy Category C
- No primaquine (FDA class undetermined) or tetracyclines (FDA pregnancy Category D) in pregnancy
- Quinine/quinidine (FDA pregnancy Category C, respectively) should be used during pregnancy because benefit outweighs risk.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
None. Deaths have resulted from using unapproved alternatives to recommended medications.
SURGERY/OTHER PROCEDURES
Rarely, splenectomy must be performed in patients with splenic rupture.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Inpatient care for all cases of *P. falciparum* malaria. Hospitalize patients with signs of severe illness, regardless of species; outpatient care for others
- Nonimmune patients with *P. falciparum* may progress from mild symptoms to death within 12 hours.
- All patients treated as an outpatient should have clinical follow-up within 24 hours.
- Add glucose to maintenance IV fluids because of risk of hypoglycemia if unable to tolerate fluids by mouth. Excess fluids may promote iatrogenic pulmonary edema.
- Observe for fluid excess, renal insufficiency (urine output), and hypoglycemia.
- Discharge criteria: clinical improvement and ability to tolerate oral medications and fluids, with documented decreasing parasitemia levels.

ONGOING CARE

PATIENT EDUCATION
- Malarial chemoprophylaxis prior to travel
- Travel information may be obtained at the CDC travel Web site: [http://www.cdc.gov/travel](http://www.cdc.gov/travel).

PROGNOSIS
Malaria infection (particularly *P. falciparum*) can carry a high mortality if untreated. If diagnosed early and treated appropriately, the prognosis is excellent.

COMPLICATIONS
- If not treated early: cerebral malaria, acute renal failure, acute gastroenteritis, respiratory distress syndrome, and massive hemolysis
- Other complications: seizures, anuria, delirium, coma, dysentery, algid malaria, blackwater fever, hyperpyrexia
- *P. malariae*: Nephrotic syndrome may develop in patients with chronic infection.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- B54 Unspecified malaria
- B50.9 *Plasmodium falciparum* malaria, unspecified
- B51.9 *Plasmodium vivax* malaria without complication

**CLINICAL PEARLS**

- Consider malaria in travelers returning from endemic areas presenting with fever or flulike illness.
- Early identification (sometimes requiring a high index of suspicion) and aggressive treatment, particularly of nonimmune persons with suspected or confirmed *P. falciparum* malaria, is essential.
- Patients who develop clinical malaria despite chemoprophylaxis should be treated with a medication different than their chemoprophylaxis agent.
- *P. falciparum* malaria can be rapidly fatal and should be cared for in the
inpatient setting.
MARIJUANA (CANNABIS) USE DISORDER

Jason E. Lambrecht, MD, PharmD • Jai D. Parekh, MBBS

BASICS

DESCRIPTION

Marijuana or cannabis use disorder is classified into different categories (mild, moderate, or severe) depending on how many symptoms are present. Mild: 2 to 3; moderate: 4 to 5; severe: 6+ (1). The definition is used when use leads to clinically significant impairment or distress, manifested by two or more of the following symptoms within a 12-month period:

- Taken in larger amounts and over a longer period of time than intended
- Persistent desire or unsuccessful efforts to cut down or control amount used
- A great deal of time spent in activities is necessary to obtain, use, or recover from use.
- Presence of craving for the substance
- Recurrent use resulting in failure to fulfill major role obligations at work, school, or home
- Continued use despite having persistent or recurrent social or interpersonal problems due to cannabis use
- Important social, occupational, or recreational activities are given up or reduced.
- Recurrent use in physically hazardous situations
- Use is continued despite knowledge of having a persistent physical or psychological problem caused or exacerbated by cannabis.
- Tolerance defined by using increased amounts of cannabis to achieve the desired effect or intoxication or diminished effect with continued use of the same amount
- Withdrawal

EPIDEMIOLOGY

- The United States is ranked first among 17 European and North American countries by the World Health Organization for prevalence of marijuana use.
Cannabis is the most widely used illicit psychoactive substance in the United States (2).
In 2014, an estimated 22 million Americans, 12 years old and older, self-identified as current marijuana users.
45% of 12th graders have tried marijuana.
Approximately 30% of students have used marijuana at the time of college entry (3).
In the United States, 10% of marijuana users become daily users, 20–30% become weekly users.
Younger users have a higher rate of addiction; 1 in 6 adolescents become addicted with repeated use.
Marijuana use is increasing in pregnant women. In 2002, 2% reported using in the last month.
In 2014, 7% of 18- to 25-year-old women reported use.
In the United States, the legal landscape is changing rapidly. Multiple states have approved recreational marijuana use.
Even more states have legalized medical marijuana.

ETIOLOGY AND PATHOPHYSIOLOGY
- Currently, there are two well-known therapeutically active cannabinoids in marijuana, delta-9-tetrahydrocannabinol (THC) and cannabidiol (CBD).
- THC is responsible for marijuana’s analgesic, anti-emetic, and intoxicating properties.
- Cannabidiol is the nonpsychoactive component responsible for marijuana’s antianxiety, antidepressant, antipsychotic, antispastic, anticonvulsant, and antineoplastic properties.
- In terms of bioavailability, smoking marijuana results in 25–50% absorption of THC, which rapidly passes into the circulation. When ingested, the oral bioavailability of THC is significantly less (only 3–10%).
- Effects of smoked marijuana occur within minutes and last several hours.
- Effects from marijuana consumed in foods or beverages appear after 30 minutes to 1 hour and can last up to 4 hours.
- Cannabinoid receptors (CBRs) are associated with memory, thinking, concentration, sensory/time perception, pleasure, movement, and coordination.
- THC artificially stimulates the CBRs, disrupting the function of endogenous cannabinoids. A marijuana “high” results from overstimulation of these receptors.
- With time, overstimulation alters the function of CBRs, leading to addiction.
and withdrawal.

**RISK FACTORS**
- Age (highest use among those 18 to 25 years)
- Male sex
- Comorbid psychiatric disorders (i.e., bipolar disorder, posttraumatic stress disorder [PTSD])
- Other substance use (i.e., alcohol, cocaine)
- Lower educational achievement (rates of dependence are lowest among college graduates)
- Employment status and income

**DIAGNOSIS**
- Screen for marijuana in a similar way to tobacco and alcohol.
- Ask for frequency and amount used (e.g., “How often do you use marijuana? Daily? Weekly?”; “How long does a typical ‘nickel bag’ last?”).
- Unexplained deterioration in school or work performance is a red flag for abuse.
- Problems with, or changes in, social relationships (e.g., spending more time alone or with persons suspected of using drugs) and recreational activities (e.g., giving up activities that were once pleasurable) may also indicate abuse.
- If possible, obtain information from concerned parents or significant others.

**HISTORY**
- Clinical presentation of acute intoxication:
  - Euphoria, elation, laughter, heightened sensory perception, altered perception of time, increased appetite
  - Poor short-term memory, concentration
  - Fatigue, depression
  - Occasionally, distrust, fear, anxiety, panic
  - With large doses, acute psychosis: delusions, hallucinations, loss of sense of identity (4)
- Withdrawal symptoms include:
  - Nausea
  - Weight loss
  - Decreased appetite
  - Insomnia
– Depressed mood

**PHYSICAL EXAM**

- Evaluate for:
  - Conjunctival injection
  - Xerostomia
  - Nystagmus
  - Increased heart rate
  - Altered pulmonary status
  - Altered body temperature
  - Reduced muscle strength
  - Decreased coordination

- Withdrawal findings include:
  - Restlessness/agitation
  - Irritability
  - Tremor
  - Diaphoresis
  - Increased body temperature

**DIAGNOSTIC TESTS & INTERPRETATION**

Positive urine drug screen; cannabinoids can be detected in urine weeks to months after marijuana use. Blood testing is preferred for interpreting acute effects and levels. In the United States, there is no consensus for acceptable legal limits for marijuana levels while driving. Hair testing can be unreliable and may reflect second-hand exposure. In general, testing can identify cannabis use but not necessarily cannabis use disorder.

**TREATMENT**

- Several methods of behavioral-based interventions:
  - Cognitive-behavioral therapy
  - Motivational interviewing
  - Counseling
  - Contingency management
  - Social network behavior therapy
  - 12-step approach
  - Family-oriented therapy
  - Brief intervention
– Relapse prevention
– Community reinforcement approach

No intervention has proved consistently effective for marijuana abuse. Users often have a hard time quitting.

Despite this, trials on cognitive-behavioral therapy and contingency management show better outcomes for reducing use and maintaining abstinence (5).

The addition of a comprehensive parenting training curriculum does not further enhance efficacy (5).

Among patients suffering from comorbid psychiatric disorders, treating the mental health disorder may help reduce use, particularly among heavy users.

Advice to help manage withdrawal:
– Reduce amount used before quitting entirely.
– Delay first use of marijuana until later in the day.
– Consider nicotine replacement therapy if planning to stop; separate tobacco use at the same time.
– Relaxation, distraction
– Avoid cues and triggers associated with use.

Prescribe short-term analgesia and sedation for withdrawal symptoms, if required.

With marked irritability and restlessness, consider very-low-dose diazepam for 3 to 4 days.

Provide user and family members with information regarding abuse and withdrawal to increase understanding of abuse and reduce likelihood of relapse.

Withdrawal symptoms peak on day 2 or 3, and generally subside by day 7. Vivid dreams can continue for 2 to 3 weeks.

MEDICATION

– No effective medication currently exists to treat marijuana abuse.
– Oral THC may help abate marijuana withdrawal in individuals who are trying to quit.
– Medications used to treat other drug use disorders, such as buspirone, lithium, and fluoxetine, may have therapeutic benefit.
FOLLOW-UP RECOMMENDATIONS
- Monitor cessation by testing urine over several weeks for the inactive cannabis metabolites (carboxy-THC).
- Heavy smokers may “pop” positive for marijuana up to 6 weeks after last use.

PATIENT EDUCATION
National Institute on Drug Abuse (NIDA):
- [http://www.drugabuse.gov](http://www.drugabuse.gov)
- [https://drugpubs.drugabuse.gov/promotions/back-to-school](https://drugpubs.drugabuse.gov/promotions/back-to-school)
- [http://www.drugabuse.gov/drugs-abuse/marijuana](http://www.drugabuse.gov/drugs-abuse/marijuana)
- [https://teens.drugabuse.gov/](https://teens.drugabuse.gov/)

COMPLICATIONS
- Acute adverse effects
  - Acute panic or paranoid reactions can occur, especially in drug naïve individuals or those with a history of psychosis or other behavioral health conditions.
  - Psychotic symptoms can present with high doses.
  - Driving while intoxicated on marijuana likely increases the risk of motor vehicle accidents.
  - Chronic adverse effects: abnormal brain development; diminished lifetime achievement
  - Chronic bronchitis and impaired respiratory function in regular smokers
  - Smoking marijuana is likely harmful in transplant patients and other immunosuppressed individuals with an increased risk of inhaled aspergillosis or and other infections.
  - Marijuana use has been associated with an increased risk of fibrosis in hepatitis C patients.
  - Psychotic symptoms in heavy users, especially those with a personal or family history of schizophrenia
  - Addiction to other substances
  - An increased risk of overall mortality has been suggested in heavy cannabis users.
  - Higher mortality rates due to hypertension have been shown in marijuana users.
  - Cannabinoid hyperemesis syndrome is characterized by episodes of cyclic nausea and vomiting in association with chronic cannabis use.
REFERENCES

ADDITIONAL READING

CODES

ICD10
- F12.10 Cannabis abuse, uncomplicated
- F12.20 Cannabis dependence, uncomplicated
- F12.288 Cannabis dependence with other cannabis-induced disorder

CLINICAL PEARLS
- Marijuana abuse may result in poor performance in school or work, legal problems, and family dysfunction.
- Patients with schizophrenia use marijuana more frequently, often hindering their treatment.
- Effects of smoked marijuana have an almost immediate onset and can last 1 to 3 hours. Effects from foods or beverages containing marijuana appear later, usually in 30 minutes to 1 hour but can last up to 4 hours.
- Smoking marijuana delivers significantly more THC into the bloodstream than eating or drinking the drug.
- Acute marijuana intoxication is manifested by conjunctival injection, increased heart rate, euphoria, heightened sensory perception, altered perception of time, increased appetite, poor short-term memory and concentration, and fatigue. Large doses may result in acute psychosis, panic or paranoid reactions, delusions, or hallucinations.
- Withdrawal symptoms include nausea, weight loss, decreased appetite, insomnia, and depressed mood. These symptoms peak on day 2 or 3 and resolve by day 7.
- Cognitive-behavioral therapy, motivational interviewing, motivational enhancement therapy, and contingency management are four methods of behavioral-based interventions used to treat marijuana abuse.
MASTITIS
Anne C. Adams, MD • Montiel T. Rosenthal, MD

BASICS
DESCRIPTION
- Mastitis is an inflammation of the breast parenchyma and possibly associated tissues (areola, nipple, subcutaneous [SC] fat).
- Usually associated with bacterial infection (and milk stasis in the postpartum mother)
- Usually an acute condition but can become chronic cystic mastitis

EPIDEMIOLOGY
- Predominantly affects females
- Mostly in the puerperium; epidemic form rare in the age of reduced hospital stays for mothers and newborns
- Neonatal form
- Posttraumatic: ornamental nipple piercing increases risk of transmission of bacteria to deeper breast structures: *Staphylococcus aureus* is the predominant organism.

Incidence
- 3–20% of breastfeeding mothers develop nonepidemic mastitis.
- Greatest incidence among breastfeeding mothers 2 to 6 weeks postpartum
- Neonatal form occurs at 1 to 5 weeks of age, with equal gender risk and unilateral presentation.
- Pediatric form
- Around or after puberty
- 82% of cases in girls

ETIOLOGY AND PATHOPHYSIOLOGY
- Microabscesses along milk ducts and surrounding tissues
- Inflammatory cell infiltration of breast parenchyma and surrounding tissues
- Nonpuerperal (infectious)
  - *S. aureus, Bacteroides* sp., *Peptostreptococcus, Staphylococcus* (coagulase neg.), *Enterococcus faecalis*
– *Histoplasma capsulatum*
– *Salmonella enterica*
– Rare case of *Actinomyces europaeus*

- **Puerperal (infectious)**
  - *Staphylococcus aureus, Streptococcus pyogenes* (group A or B),
    *Corynebacterium* sp., *Bacteroides* sp., *Staphylococcus* (coagulase neg.),
    *Escherichia coli*, *Salmonella* sp.
  - Methicillin-resistant *S. aureus* (MRSA)

- Rare secondary site for tuberculosis in endemic areas (1% of mastitis cases in these areas): single breast nodule with mastalgia

- *Corynebacterium* sp. associated with greater risk for development of chronic cystic mastitis

- **Granulomatous mastitis**
  - Idiopathic
    - Predilection for Asian and Hispanic women
    - Association with α₁-antitrypsin deficiency, hyperprolactinemia with galactorrhea, oral contraceptive use, *Corynebacterium* sp. infection, and breast trauma
    - Most women have a history of lactation in previous 5 years.
  - Lupus; autoimmune

- **Puerperal**
  - Retrograde migration of surface bacteria up milk ducts
  - Bacterial migration from nipple fissures to breast lymphatics
  - Secondary monilial infection in the face of recurrent mastitis or diabetes
  - Seeding from mother to neonate in cyclical fashion

- **Nonpuerperal**
  - Ductal ectasia
  - Breast carcinoma
  - Inflammatory cysts
  - Chronic recurring SC or subareolar infections
  - Parasitic infections: *Echinococcus*; filariasis; Guinea worm in endemic areas
  - Herpes simplex
  - Cat-scratch disease

- **Lupus**

**RISK FACTORS**

- Breastfeeding
Milk stasis
- Inadequate emptying of breast
  - Scarring of breast due to prior mastitis
  - Scarring due to previous breast surgery (breast reduction, biopsy, or partial mastectomy)
- Breast engorgement: interruption of breastfeeding

Nipple trauma increases risk of transmission of bacteria to deeper breast structures: \( S.\ aureus \) predominant organism

Neonatal colonization with epidemic \( Staphylococcus \)

Neonatal
- Bottle-fed babies
- Manual expression of “witch’s milk”
- Can predispose to lethal necrotizing fasciitis

Maternal diabetes
Maternal HIV
Maternal vitamin A deficiency (in animal models)

GENERAL PREVENTION
Regular emptying of both breasts and nipple care to prevent fissures when breastfeeding; also good hygiene including hand washing and washing breast pumps after each use (1)[A]

COMMONLY ASSOCIATED CONDITIONS
Breast abscess

DIAGNOSIS
- Fever >38.5°C and malaise
- Nausea ± vomiting
- Localized breast tenderness, heat, swelling, and redness
- Possible breast mass

HISTORY
- Breast pain
- “Hot cords burning in chest wall”
- Consider yeast infection if nipple pain and burning and/or infant with thrush.

PHYSICAL EXAM
- Breast tenderness
- Localized breast induration, redness, and warmth
- Peau d’orange appearance to overlying skin

**DIFFERENTIAL DIAGNOSIS**
- Abscess (bacterial, idiopathic granulomatous mastitis, fungal, tuberculosis)
- Tumor
  - Idiopathic granulomatous mastitis
  - Inflammatory breast cancer
  - Wegener granulomatosis
  - Sarcoidosis
  - Foreign body granuloma
  - Vasospasm (may be presentation for Raynaud) (2)[B]
- Ductal cyst (ductal ectasia)
- Consider monilial infection in lactating mother, especially if mastitis is recurrent.

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
Mastitis is typically a clinical diagnosis. Labs rarely needed. In those ill enough to need hospitalization, consider the following:
- CBC
- Blood culture
- In epidemic puerperal mastitis
  - Milk leukocyte count
  - Milk culture
  - Neonatal nasal culture
- No imaging required for postpartum mastitis in a breastfeeding mother that responds to antibiotic therapy.
- Mammography for women with nonpuerperal mastitis
- Breast ultrasound to rule out abscess formation in women
  - Special consideration for this in women with breast implants who have mastitis

**Follow-Up Tests & Special Considerations**
Lactating mothers produce salty milk from affected side (higher Na and Cl concentrations) as compared with unaffected side. Consider breast milk culture if suspect MRSA. Also consider testing for tuberculosis as may be initial
presentation.

**Diagnostic Procedures/Other**
Options if further progression to abscess formation
- Needle aspiration
- Incision and drainage
- Excisional biopsy
- Ultrasound (US)-guided core needle biopsy is diagnostic method of choice for idiopathic granulomatous mastitis

**TREATMENT**
A Cochrane review found that insufficient evidence exists to confirm or refute the effectiveness of antibiotic therapy for the treatment of lactational mastitis (3) [A]. If present <24 hours and symptoms are mild, conservative management with milk removal and supportive measures is recommended.

**MEDICATION**
- Prioritized on the basis of likelihood of MRSA as etiologic factor and clinical severity of condition.
- Treat for 10 to 14 days.
- For idiopathic granulomatous mastitis and localized infection, usually resolves with antibiotics and drainage

**First Line**
- Outpatient
  - Effective milk removal is most important management step (4)[A]
  - Dicloxacillin 500 mg QID
  - Cephalexin 500 mg QID
  - Trimethoprim/sulfamethoxazole (TMP/SMX); DS BID (If mastitis not improving within 48 hours after starting first-line treatment, consider MRSA.)
  - *Lactobacillus fermentum* or *Lactobacillus salivarius* 9 log 10 CFU/day
- Inpatient
  - Nafcillin 2 g q4h
  - Oxacillin 2 g q4h
  - Vancomycin 1 g q12h (MRSA possible)
Breastfeeding beyond 1 month
- Penicillin, ampicillin, or erythromycin

If idiopathic granulomatous mastitis, consider corticosteroids ± methotrexate (5)[B]; surgical excision reserved for refractory cases (6)[C]

**Pediatric Considerations**
TMP/SMX given to breastfeeding mothers with mastitis can potentiate jaundice for neonates.

**Second Line**
- If mastitis is odoriferous and localized under areola, add metronidazole 500 mg TID IV or PO.
- If yeast is suspected in recurrent mastitis, add topical and oral nystatin.

**ISSUES FOR REFERRAL**
- Abscess formation
- Need for breast biopsy

**ADDITIONAL THERAPIES**
- Warm packs to improve blood flow and milk letdown and/or ice packs to reduce inflammation to affected breast for comfort
- The use of a breast pump may aid in breast emptying, especially if the infant is unable to assist in doing this.
- Wear supporting bra that is not too tight.

**SURGERY/OTHER PROCEDURES**
In cases of biopsy-proven idiopathic granulomatous mastitis, surgical removal can result in a 5–50% chance of recurrence, fistula formation, and poor wound healing.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- If a new mother is admitted to the hospital for treatment of her mastitis, rooming-in of the infant with the mother is mandatory so that breastfeeding can continue (4)[C]. In some hospitals, rooming-in may require hospital admission of the infant.
- Admission criteria/initial stabilization
  - Failure of outpatient/oral therapy
- Patient unable to tolerate oral therapy
- Patient noncompliant with oral therapy
- Severe illness without adequate supportive care at home
  - Neonatal mastitis
  - Antibiotics
  - Frequent emptying of breasts, if breastfeeding
  - Analgesics for pain
    - Ibuprofen
    - Acetaminophen
- Breastfeeding/pumping of breasts encouraged
- Start infant with feedings on affected side.
- Abscess drainage is not a contraindication for breastfeeding.
- Massage in direction from blocked area toward nipple.
- Positioning infant at breast with chin or nose pointing to blockage will help drain affected area.
- Discharge criteria
  - Afebrile
  - Tolerating oral antibiotics well

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Rest for lactating mothers, up to bathroom

**DIET**
- Encourage oral fluids.
- Multivitamin, including vitamin A

**PATIENT EDUCATION**
- Encourage oral fluids.
- Rest is essential.
- Regular emptying of both breasts with breastfeeding
- Nipple care to prevent fissures

**PROGNOSIS**
- Puerperal
  - Good with prompt (within 24 hours of symptom onset) antibiotic treatment
and breast emptying; 96% success rate
- 11% risk of abscess if left untreated with antibiotics
- Antibodies develop in breast glands within first few days of infection, which may provide protection against infection or reinfection.

- Rare risk of abscess formation beyond 6 weeks postpartum if no recurrent mastitis
- Idiopathic granulomatous mastitis recurrence rates high, encourage close follow-up (6)[C]

COMPLICATIONS
- Breast abscess 3% of women with puerperal mastitis
- Recurrent mastitis with resumption of breastfeeding or with breastfeeding after next pregnancy
- Bacteremia
- Sepsis

REFERENCES

SEE ALSO
Algorithms: Breast Discharge; Breast Pain

CODES

ICD10
- N61 Inflammatory disorders of breast
- O91.22 Nonpurulent mastitis associated with the puerperium
- O91.23 Nonpurulent mastitis associated with lactation

CLINICAL PEARLS
- Complete emptying of the breasts on a regular schedule, avoiding constrictive clothing or bras that might obstruct breast ducts, meticulous attention to nipple care, “adequate rest,” and a liberal intake of oral fluids for the mother can all reduce the risk of a breastfeeding mother’s developing mastitis.
- First-line treatment for puerperal mastitis is dicloxacillin 500 mg PO QID for 10 to 14 days. Most mastitis can be treated with oral therapy.
- Among breastfeeding mothers, if the symptoms of mastitis fail to resolve within several days of appropriate management, including antibiotics, further investigations may be required to confirm resistant bacteria, abscess formation, an underlying mass, or inflammatory or ductal carcinoma.
- More than two recurrences of mastitis in the same location or with associated axillary lymphadenopathy warrant evaluation with US or mammography to rule out an underlying mass.
BASICS

An inflammatory process of the mastoid air cells and/or posterior process of the temporal bone, most commonly a suppurative complication of acute otitis media (AOM)

DESCRIPTION

- Clinical manifestations of mastoiditis typically appear 3 weeks after the first middle ear symptoms.
- Stiffness and thickening of the tympanic membrane (TM) is common.
- Acute mastoiditis: symptoms <1 month in duration; subdivided according to the pathologic stages:
  - Acute mastoiditis with periostitis (incipient mastoiditis): purulent material in the mastoid cavities
  - Coalescent mastoiditis (acute mastoid osteitis): destruction of the thin bony septae between air cells; followed by the formation of abscess cavities pus dissecting into adjacent areas
- Masked mastoiditis (subacute mastoiditis): low grade, persistent infection with destruction of the bony septae between air cells; occurs in patients with persistent middle ear effusion or recurrent episodes of inadequately treated AOM
- Chronic mastoiditis: associated with failed treatment of chronic otitis media. Often associated with cholesteatoma; symptoms last months to years.

EPIDEMIOLOGY

- Highest incidence in children <2 years

- Routine prescription of antibiotics and routine childhood immunizations have reduced the number of cases of AOM and mastoiditis.

Incidence

1 to 4 cases per 100,000 children per year (1)
ETIOLOGY AND PATHOPHYSIOLOGY

- Subclinical stage begins with AOM and inflammation of mastoid air cells.
- Obstruction of the aditus ad antrum (connecting the tympanic cavity and mastoid)
  - Blocks outflow tract of mastoid air cells
  - Edema and accumulation of purulent material with penetration of periosteum (acute mastoiditis with periostitis)
- Increased pressure from fluid within the air cells leads to destruction of bony septae (acute mastoid osteitis/acute coalescent mastoiditis).
- Acute mastoid osteitis can spread to adjacent areas in head and neck with abscess formation:
  - Subperiosteal abscess (most common complication), Bezold abscess, suppurative labyrinthitis, suppurative CNS complications
- AOM: *Haemophilus influenzae*, *Streptococcus pneumoniae*
- Acute mastoiditis: *S. pneumoniae* (most common), *Streptococcus pyogenes, H.influenzae*, *Staphylococcus aureus* (including methicillin-resistant *S. aureus* [MRSA])
- Chronic mastoiditis: *Pseudomonas aeruginosa, S. aureus*, Enterobacteriaceae, anaerobic bacteria, polymicrobials (2)

Genetics
No known genetic pattern

RISK FACTORS

- Cholesteatoma
- Recurrent AOM or chronic suppurative otitis media
- Immunocompromised state

GENERAL PREVENTION

- Ensure appropriate vaccinations (particularly pneumococcal vaccine).
- Referral to ENT for chronic otitis media
- Appropriate diagnosis and treatment of AOM
- Prevent recurrent AOM.
- Treat chronic eustachian tube dysfunction (pressure equalization tubes).
- Early diagnosis of cholesteatoma
**DIAGNOSIS**

**HISTORY**

- Most common symptoms in infancy (1)[A]
  - Lethargy/malaise/irritability
  - Fever
  - Poor feeding/decreased appetite
- Otalgia/possible otorrhea
- Hearing loss
- Headache
- Pain/redness/swelling noted over mastoid
- At time of admission (1)[A]
  - 42% of children have history of otologic disease.
  - 54% on antibiotic therapy
  - Average duration of symptoms: 10 days
- Suspicion for mastoiditis increases when symptoms of AOM persist >2 weeks.

**PHYSICAL EXAM**

- Postauricular changes: erythema, tenderness, edema, and/or fluctuance (81–85%) (1)[A]
- Bulging, erythematous, or dull TM (60–71%)
- Protrusion of auricle (79%)
- Fever (76%)
- Otorrhea if TM is perforated
- Edema of external auditory canal
- TM normal in 10%

**DIFFERENTIAL DIAGNOSIS**

- Postauricular cellulitis or inflammatory adenopathy
- Severe otitis externa
- Benign neoplasm: aneurysmal bone cyst, fibrous dysplasia
- Malignant neoplasm: rhabdomyosarcoma, neuroblastoma
- Deep neck space infections
- Parotitis

**DIAGNOSTIC TESTS & INTERPRETATION**
**Initial Tests (lab, imaging)**

- CBC with differential: elevated WBC count (3)[C]
- Elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) (2,3)
- Blood cultures
- **Myringotomy/tympanocentesis:** Send for cultures, Gram stain, acid-fast stain (1)[B].

Plain mastoid radiographs have low diagnostic yield. They may show distortion of mastoid outline or clouding of mastoid air cells. These changes are not diagnostic and can also be seen in AOM.

- Preferred: CT of the temporal bone (97% sensitivity; 94% positive predictive value) (4). Findings:
  - Clouding/opacification of air cells (also in AOM)
  - Mastoid air cell coalescence
  - Cortical bone erosion
  - Rim-enhancing fluid collections
  - Absence of mastoid opacification excludes the diagnosis.
- Use CT with contrast if complications are suspected (suppurative extension) (5)[C].
- **Indications for CT scan in children** (4)[C]:
  - Neurologic signs
  - Vomiting/lethargy
  - Suspected cholesteatoma
  - Fever after 48 to 72 hours of therapy
  - Concern for local disease progression
- Technetium-99m bone scan is more sensitive to osteolytic changes than CT.
- MRI: partial-to-complete opacification of the mastoid air cells +/- middle ear cleft

**Follow-Up Tests & Special Considerations**

Interpret normal WBC with caution in symptomatic, immunocompromised patients.

**Diagnostic Procedures/Other**

- Tympanocentesis to obtain middle ear fluid for culture and sensitivity (1)[B]
- Myringotomy with culture (also therapeutic)
- Audiography if suspected hearing loss
- Obtain CSF if intracranial extension suspected.
• Biopsy tissue protruding through TM or tympanostomy tube

**TREATMENT**

• IV antibiotics and myringotomy (± tympanostomy tubes) is the preferred treatment for uncomplicated acute mastoiditis (reflecting a shift away from more invasive surgical treatment).
• To avoid intracranial complications, simple mastoidectomy is recommended if patients do not respond to treatment after 3 to 5 days (6)[C].

**GENERAL MEASURES**

• Inpatient care during acute phase for IV antibiotics
• Keep the affected ear dry.

**MEDICATION**

*First Line*

• Empiric antibiotics against most common organisms: *S. pneumoniae* (including multiple resistant strains), *S. pyogenes*, *S. aureus* (including MRSA), *P. aeruginosa*
• Use combination therapy with 3rd-generation cephalosporin (ceftriaxone or cefotaxime) plus clindamycin with coverage for resistant strains (5,6)[C].
• Ceftriaxone 2 g IV q24h
  – Pediatric dosing: 50 to 75 mg/kg/day IV divided q12–24h
  – Precaution: Adjust dose with renal impairment.
  – Consider levofloxacin 750 mg IV q24h if severe β-lactam allergy.
• Clindamycin for coverage of ceftriaxone-resistant *S. pneumoniae* in pediatric patients (5)[C]:
  – Clindamycin pediatric dosing: 20 to 40 mg/kg/day IV divided q6–8h
• Cefotaxime 1 to 2 g IV q4–8h, depending on severity
  – Pediatric dosing: 100 to 200 mg/kg/day q6–8h
• Add vancomycin 30 to 60 mg/kg/day divided q8–12h if concerned for MRSA or acute on chronic exacerbation:
  – Pediatric dosing: 15 mg/kg/dose q6–8h
  – Precaution: Adjust dose with renal impairment.
• For patients with a history of recurrent AOM or recent antibiotic administration, treat with piperacillin and tazobactam 3.375 g IV q6h:
  – Pediatric dosing: 300 mg/kg/day based on piperacillin component divided
For other significant contraindications, precautions, or interactions, refer to the manufacturer’s literature.

**Second Line**

- Oral antibiotics after 7 to 10 days of IV antibiotics and once myringotomy/blood cultures identify pathogen and sensitivities. Common oral antibiotics:
  - Amoxicillin-clavulanate (Augmentin) or clindamycin + 3rd-generation cephalosporin for 3 weeks or total treatment duration of 4 weeks
- For chronic mastoiditis: Use topical drops, ofloxacin otic solution (0.3%) or neomycin, polymyxin B, hydrocortisone 3 drops, 3 to 4 times per day.

**ISSUES FOR REFERRAL**

Consult ENT for mastoiditis in adults and children.

**SURGERY/OTHER PROCEDURES**

- Perform tympanocentesis to obtain cultures and guide antibiotic choice (1)[B].
- Myringotomy and tympanostomy tubes allow for middle ear drainage (6)[C].
- Mastoidectomy is the definitive treatment for patients who fail to improve within 24 to 48 hours despite IV antibiotics and myringotomy and for those with meningeal or intracranial complications (4,6)[C].
- Simple mastoidectomy is most effective for management of subperiosteal abscesses, if a trial of conservative therapy with drainage, myringotomy, and IV antibiotics fails (7)[C].
- Clean ear canal under microscopic guidance to ensure pressure-equalization tube patency and adequate drainage of middle ear.
- Topical antibiotic drops after insertion of pressure-equalization tubes

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Admission criteria/initial stabilization
  - Clinical or imaging evidence of acute mastoiditis
  - Hospitalize patients with acute mastoiditis and start IV antibiotics immediately.
- Avoid getting affected ear wet.
- Discharge criteria
  - Afebrile for 48 hours before IV antibiotics are discontinued
– Clinical improvement
– Able to tolerate oral antibiotics

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Oral antibiotics for 3 weeks following course of IV antibiotics (total duration of antibiotics is 4 weeks)
- For chronic mastoiditis, consider several months of antimicrobial prophylaxis with amoxicillin.

**Patient Monitoring**

- Assess for hearing loss postoperatively (audiogram) after acute condition has subsided.
- Follow-up with ENT, particularly patients with intracranial complications or hearing loss

**PATIENT EDUCATION**

Avoid getting the affected ear wet.

**PROGNOSIS**

- Depends on severity and stage of disease
- Conductive hearing loss may require reconstructive surgery.
- Most cases of mastoiditis recover fully if the diagnosis is made early and treated appropriately.

**COMPLICATIONS**

Complication rate is ~18% (2).

- Extracranial
  - Subperiosteal abscess (most common)
  - Bezold abscess (abscess of sternocleidomastoid muscle, insidious, risk of mediastinitis)
  - Citelli abscess (osteomyelitis of the calvaria)
  - Osteomyelitis of the temporal bone
  - Suppurative labyrinthitis (resulting in deafness)
  - Facial nerve paralysis
- Intracranial
– Intracranial abscess: epidural/subdural/cerebral
– Meningitis/cerebritis/periostitis
– Gradenigo syndrome (palsy of the 6th cranial nerve, draining ear, and retro-orbital pain)
– Sigmoid sinus thrombophlebitis
– Central venous sinus thrombosis

REFERENCES

ADDITIONAL READING

CODES

ICD10
- H70.90 Unspecified mastoiditis, unspecified ear
- H70.009 Acute mastoiditis without complications, unspecified ear
- H70.099 Acute mastoiditis with other complications, unspecified ear

CLINICAL PEARLS
- Suspect mastoiditis if symptoms of AOM persist >2 weeks despite a normal-appearing TM.
- Hospitalize patients with acute mastoiditis for IV antibiotics. Consult ENT for drainage procedure.
- Treat with broad-spectrum IV antibiotics; collect middle ear fluid cultures to guide-specific therapy. Total duration of antibiotics is 4 weeks.
- If conservative treatment fails after 3 to 5 days, perform mastoidectomy to avoid intracranial complications.
MEASLES (RUBEOLA)

Nicholas E. Seeliger, MD

BASICS

DESCRIPTION

- A highly communicable, acute viral illness characterized by an exanthematous maculopapular rash that begins at the head and spreads inferiorly to the trunk and extremities.
- Rash is preceded by fever and the classic triad of cough, coryza, and conjunctivitis (3 Cs). Koplik spots are pathognomonic lesions of the oral mucosa.
- Public health problem in the developing world, with significant morbidity and mortality.
- System(s) affected: hematologic; lymphatic; immunologic; pulmonary; skin.
- Synonym(s): rubeola.

EPIDEMIOLOGY

- Transmission: direct contact with infectious droplets; highly contagious; 90% of nonimmune close contacts likely to become infected on exposure.
  - Droplets can remain in the air for hours.
- Infectivity is greatest during the prodromal phase.
  - Patients are considered contagious from 4 days before symptoms until 4 days after rash appears.
  - Immunocompromised patients are considered contagious for the entire duration of disease.
- Incubation period: averages 12.5 days from exposure to onset of prodromal symptoms.
- Predominant age: varies based on local vaccine practices and disease incidence. In developing countries, most cases occur in children <2 years.

Incidence

- No longer considered an endemic disease in the United States; isolated outbreaks still occur.
- In 2016, 70 cases of measles were reported, including 31 cases in an Arizona immigration and customs facility. Between January and June 2017, 108 cases
occurred including an outbreak in Minnesota with at least 65 cases related to a
decline in MMR vaccination coverage in the Somali-American community
attributed to a misunderstanding regarding the MMR vaccine and autism.

- Worldwide: An estimated 20 million measles cases occur each year, with
  122,000 measles deaths in 2012. Over 95% of measles deaths occur in poor
countries with limited health infrastructure (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**

Measles virus enters through the respiratory mucosa and replicates locally. It
spreads to regional lymphatic tissues and other reticuloendothelial sites via the
bloodstream.

- Measles virus is a spherical, enveloped, nonsegmented, single-stranded,
negative-sense RNA virus of genus *Morbillivirus*, family *Paramyxoviridae*.
- Humans are the only natural host.

**RISK FACTORS**

- For developing measles:
  - Lack of adequate vaccination (2 doses)
  - Travel to countries where measles is endemic
  - Contact with exposed individuals
- For severe measles or measles complications:
  - Immunodeficiency
  - Malnutrition
  - Pregnancy
  - Vitamin A deficiency
  - Age <5 years or >20 years

**GENERAL PREVENTION**

- 100% preventable with proper vaccination
- Measles vaccine (active immunization)
  - Vaccine is usually given in combination with measles, mumps, and rubella
    (MMR) or with added varicella (MMRV; ProQuad)
  - Primary vaccination requires 2 doses
    - First dose at 12 to 15 months of age; 95% develop immunity
    - Second dose at time of school entry (4 to 6 years of age) or any time >4
      weeks after first measles vaccine; the 5% of initial nonresponders almost
      always develop immunity after the second dose.
    - Health care workers should have immunity verified and if not immune,
should receive the vaccine if not contraindicated.

**Common adverse reactions to vaccine**
- Fever
  - Febrile seizures are rare (<5%) and occur 6 to 12 days after vaccination. Risk of febrile seizures increases if initial immunization is delayed past age 15 months (2).
  - Transient, mild, measles-like rash 7 to 10 days after vaccination (2%, with decreasing incidence during second vaccination)
  - If hypersensitivity reaction occurs, test for immunity; if immune, second dose is not needed.
  - There is no substantiated link between MMR vaccine and autism.

**Contraindications**
- Live viral vaccines are contraindicated in immunosuppressed patients.
  - For MMR, vaccinate asymptomatic HIV-infected children with adequate CD4 count.
- Live vaccine is contraindicated in pregnancy (risk of fetal infection).
- Anaphylactic reaction to gelatin or neomycin; consult allergist before vaccination.
- Egg anaphylaxis is not a contraindication.

### COMMONLY ASSOCIATED CONDITIONS
- Immunosuppression
- Malnutrition

### DIAGNOSIS

#### HISTORY
- Prodromal period: usually 2 to 3 days before rash (may be up to 8 days)
  - Fever
    - May begin 8 to 12 days after exposure; can persist until 2 to 3 days after rash onset
    - Temperature often >102°F (39–40.5°C); can precipitate febrile seizures
    - Fever onset >3 days after rash suggests complicated course.
  - “3 Cs” triad: cough, coryza, and conjunctivitis
  - Cough may persist for 2 weeks.
  - Prodromal symptoms typically intensify over 2 to 4 days, peaking on first day of rash before subsiding.
Other symptoms: loose stools, malaise, irritability, photophobia (from iridocyclitis), sore throat, headache, and abdominal pain

**PHYSICAL EXAM**
- Koplik spots
  - Pathognomonic of prodromal measles
  - 2- to 3-mm, gray–white, raised lesions on erythematous base on buccal mucosa
  - Occur ~48 hours before measles exanthem
- Exanthematous rash (characteristic but not pathognomonic)
  - Maculopapular blanching rash
  - Begins at ears and hairline and spreads head to toe, reaching hips by day 2
  - Discrete erythematous patches become confluent over time, particularly on the upper body.
  - Clinical improvement usually occurs within 48 hours after rash appears.
  - Rash fades in 3 to 4 days changing to a brownish color, followed by fine desquamation.
- Lymphadenopathy and pharyngitis may be seen during exanthematous period.

**DIFFERENTIAL DIAGNOSIS**
- Drug eruptions
- Rubella
- *Mycoplasma pneumoniae* infection
- Infectious mononucleosis
- Parvovirus B19 infection, roseola
- Enteroviruses
- Rocky Mountain spotted fever, dengue
- Toxic shock syndrome
- Meningococcemia
- Kawasaki disease

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Obtain serum sample and throat (or nasopharyngeal) swab. Molecular testing of serum and respiratory specimens is the most accurate method to confirm measles infection; IgM assay and measles RNA by real-time polymerase chain reaction (RT-PCR)
- Measles virus–specific IgM assay from serum and saliva. Antibodies may be
undetectable on first day of exanthema but are usually detectable by day 3.
- Sensitivity: 77% within 72 hours of rash onset; 100% within 4 to 11 days after rash onset. If negative but rash lasts >72 hours, repeat.
- IgM falls to undetectable levels 4 to 8 weeks after rash onset.
- Measles virus–specific IgG may be undetectable up to 7 days after exanthem; levels peak 14 days after exanthem.
- A 4-fold increase in IgG titers 14 days after an initial titer that was measured at least 7 days after rash onset is confirmatory.
- Viral cultures for measles are not usually performed.
- Mild neutropenia is common.
- Liver transaminases and pancreatic amylase may be elevated, particularly in adults.
- Chest x-ray if concern for secondary pneumonia

**ALERT**
Report suspected measles cases to public health authorities.

**TREATMENT**

**GENERAL MEASURES**
- Place all patients with measles in respiratory isolation until 4 days after onset of rash; immunocompromised patients should be isolated for duration of illness.
- Supportive therapy (i.e., antipyretics, antitussives, humidification, increased oral fluid consumption)

**MEDICATION**
- No approved antiviral therapy is available. Immunosuppressed children with severe measles have been treated with IV or aerosolized ribavirin. No controlled trial data exist, and this use is not FDA-approved.
- Vitamin A: WHO recommends daily dosages for 2 consecutive days:
  - Children <6 months of age 50,000 IU
  - Children 6 to 12 months of age 100,000 IU
  - Children >12 months of age 200,000 IU
- Ribavirin
  - Measles virus is susceptible to ribavirin in vitro; data is limited.
  - In one randomized trial including 100 children with measles treated with
ribavirin or supportive care, ribavirin group had a shorter duration of fever, constitutional symptoms, and length of hospitalization.

- **Antibiotics**
  - Reserve for patients with clinical signs of bacterial superinfection (pneumonia, purulent otitis, pharyngitis/tonsillitis) (3)
  - A small randomized, double-blinded trial resulted in an 80% (number needed to treat [NNT] = 7) decrease in measles-associated pneumonia with prophylactic antibiotics; consider antibiotic use prophylactically in patients with a high risk of complications (4).

- **Outbreak control**
  - A single case of measles constitutes an outbreak.
  - Immunize contacts (individuals exposed or at risk of having been exposed) within 72 hours.
    - Monovalent vaccine may be given to infants 6 months to 1 year of age, but 2 further doses of vaccine after 12 months must be given for adequate immunization.
    - Monovalent or combination vaccine may be given to all measles-exposed susceptible individuals age >1 year if not contraindicated.
    - Individuals not immunized within 72 hours of exposure should be excluded from school, child care, and health care settings (social quarantine) until 2 weeks after onset of rash in last case of measles.
  - Immunoglobulin therapy (passive immunity) for high-risk individuals exposed to measles for whom vaccine is inappropriate:
    - Children age <1 year (Infants 6 to 12 months of age may receive MMR vaccine in place of immunoglobulin if given within 72 hours of exposure.)
    - Pregnant women
    - Severe immunosuppression
      - Give IM immunoglobulin within 6 days of measles exposure; CDC recommends 0.25 mL/kg to maximum of 15 mL for infants and pregnant women; dose for immunocompromised is 0.5 mL/kg to a maximum of 15 mL.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Inpatient setting: airborne transmission precautions for 4 days after the onset of rash in otherwise healthy patients and for the duration of illness in immunocompromised patients
Outpatient care is appropriate, except where complications develop (e.g., encephalitis, pneumonia).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Signs of complications needing close follow-up:
- Difficulty breathing or noisy breathing
- Changes in vision
- Changes in behavior, confusion
- Chest or abdominal pain

**PATIENT EDUCATION**

- Adhere to recommended immunization schedules.
- Avoid exposure, particularly to unimmunized children and adults, pregnant women, and immunocompromised persons, until 4 days after rash onset.
- Avoid contact with potential pathogens until respiratory symptoms resolve.
- Centers for Disease Control and Prevention. Measles.
  [www.cdc.gov/measles/about/index.html](http://www.cdc.gov/measles/about/index.html)

**PROGNOSIS**

- Typically self-limited; prognosis good
- High fatality rates may be seen among malnourished or immunocompromised children, particularly in developing countries.

**COMPLICATIONS**

- Otitis media (5–15%)
- The immune response to measles infection paradoxically depresses response to non–measles-virus antigens, rendering individuals more susceptible to pneumonia and diarrhea.
- Respiratory complications:
  - Bronchopneumonia (5–10%)
    - Accounts for most measles-related deaths
    - May be viral or bacterial
  - Interstitial pneumonitis (immunocompromised patients)
  - Laryngotracheobronchitis (“measles croup”): occurs in younger age group (<2 years)
GI complications: diarrhea (may lead to dehydration)

Neurologic complications
- Febrile seizures
- Acute disseminated encephalomyelitis with seizures and neurologic abnormalities (occurs in 1/1,000 cases): presents within 2 weeks of rash, probably an autoimmune response
- Inclusion body encephalitis is rare but fatal in those with defective cellular immunity.
- Subacute sclerosing panencephalitis
  o Rare degenerative CNS disease resulting from persistent measles infection following natural disease; usually fatal
  o Presents 5 to 15 years after infection
  o Most often in persons infected before age 2 years

Ocular complications
- Keratitis
  o Can lead to permanent scarring, blindness
  o Vitamin A deficiency predisposes to more severe keratitis and its complications.

Other secondary bacterial infections

Death: results from complications, mainly pneumonia, rather than the virus itself. CDC statistics show that for every 1,000 children who get measles, 1 or 2 will die.

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**

- B05.9 Measles without complication
- B05.2 Measles complicated by pneumonia
- B05.89 Other measles complications

**CLINICAL PEARLS**

- There is no substantiated link between MMR vaccine and autism.
- Measles is a highly communicable viral disease whose natural transmission has been halted in the United States by mass immunization.
- A single case of measles constitutes an outbreak.
- Report suspected measles cases to state or local health departments immediately.
- Immunization requires 2 doses: one at 12 to 15 months of age and one at school age (4 to 6 years of age).
- The clinical presentation of measles includes a prodrome of fever, cough, coryza, and conjunctivitis, followed by a descending maculopapular rash beginning on the face and progressing to the chest and lower body (centrifugal).
- Consider measles in the differential diagnosis of a febrile rash illness (especially in unvaccinated individuals with recent international travel).
- Measles-associated pneumonia is the most common cause of mortality.
MEASLES, GERMAN (RUBELLA)

Cody D. Mead, DO • Jeffrey M. Milch, DO

BASICS

DESCRIPTION

- A generally self-limited viral infection of children and adults, characterized by a mild, maculopapular rash, lymphadenopathy, and slight fever. Complications in normal populations are rare; however, nonimmune women who become infected with rubella while pregnant may have devastating fetal effects.
- 25–50% of all rubella infections are asymptomatic (1,2)[A].
- System(s) affected: hematologic; nervous; pulmonary; exocrine; ophthalmologic; skeletal
- Synonym(s): German measles; 3-day measles

Pregnancy Considerations

- Pregnancy-associated rubella infection may lead to congenital rubella syndrome (CRS) with potentially devastating fetal outcomes.
- CRS is present in up to 90% of fetuses exposed during the 1st trimester (2)[A].
- Screening pregnant women for rubella immunity and vaccinating nonimmune women is the most effective strategy for preventing CRS (2)[A].
- Although no case of vaccine-associated CRS has been reported, women should not become pregnant for at least 28 days after vaccination because vaccine-type virus can cross the placenta (2)[A].
- Polymerase chain reaction (PCR) detection of viral RNA in amniotic fluid and fetal blood sampling allow for rapid diagnosis of fetal infection after 15 weeks’ gestation (3)[B].

EPIDEMIOLOGY

- 50- to 70-nm RNA togavirus of genus Rubivirus (1)[A]
- 13 genotypes have been identified (4)[A].
- A live attenuated vaccine has been available in the United States since 1969—primarily to prevent CRS.
- Since 2004, all U.S. cases of rubella have been imported, most are...
inadequately immune travelers (1)[A].

- Average incubation: 14 days; range 12 to 23 days
- Infectious period between 7 days before and 5 to 7 days after rash onset
- Transmitted primarily via respiratory droplets
- Most common in late winter and early spring
- Humans are only natural hosts (1)[A].

**Incidence**

- U.S. incidence: <10/100,000 since 2001
- Declared eliminated (the absence of endemic transmission for 12 months or more) from the United States in 2004. However, primarily due to disease in international travelers, vaccine avoidance, and lack of routine pediatric care in migrant populations, cases are still reported annually.
- 667 cases from 27 states (a record number) reported to the CDC in 2015
- Still occurs in developing countries with 100,000 cases of CRS reported annually worldwide

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Virus invades the respiratory epithelium, replicates in nasopharynx and regional lymph nodes, and spreads hematogenously. Infected patients shed virus from the nasopharynx 3 to 8 days after inoculation. Shedding lasts 7 or more days after onset of rash.
- Disease typically progresses from a prodromal stage (1 to 5 days) to lymphadenopathy (5 to 10 days) to an exanthematous, pruritic, maculopapular rash. Petechiae on the soft palate (Forchheimer spots), may precede or accompany the rash. Rash starts on the face and spreads outward to the trunk and extremities, sparing the palms and soles (14 to 17 days after onset of prodromal symptoms). The rash typically lasts an average of 3 days.
- Rubella first described by German scientists in the early 1800s as a variant of measles or scarlet fever
- 1962 to 1965: global pandemic resulting in an estimated 12.5 million cases in the United States, with 2,000 cases of encephalitis; 11,250 cases of therapeutic or spontaneous abortions; 2,100 neonatal deaths; and 20,000 infants born with CRS (1)[A]

**Genetics**

Children with CRS and children with type 1 diabetes share a high frequency of HLA-DR3 histocompatibility Ag and a high prevalence of islet cell Ab.
**RISK FACTORS**
Inadequate immunization, inadequate immunity after prior vaccination, immunodeficiency states, immunosuppressive therapy, crowded living/working conditions, international travel (1)[A]

**GENERAL PREVENTION**
- Vaccination is the most effective preventive strategy.
- Available combined with mumps, measles, rubella (MMR) or with varicella (MMR-V). Isolated rubella vaccine is not available in the United States.
  - Adults: 1- or 2-dose MMR vaccine schedule is recommended for those born after 1957. When 2 doses are used, each must be ≥28 days apart.
  - Pediatric: A 2-dose MMR vaccine schedule is recommended with the first dose given at ages 12 to 15 months; second dose recommended either at 4 to 6 years or at 11 to 12 years of age
  - Special pediatric cases: In special circumstances (e.g., upcoming international travel), the second dose may be given prior to 4 years of age but no sooner than 28 days since the initial dose. Children 6 to 11 months of age may also receive a single dose prior to international travel but should be revaccinated with full 2-dose schedule starting at 12 months of age. Children with HIV should receive MMR vaccine at 12 months of age if no contraindications exist. In the event of an outbreak, immediate vaccination of infants 6 to 11 months old is also recommended (2)[A].
  - Vaccination is recommended for nonimmune people in the following groups: prepubertal boys and girls, all women of reproductive age, college students, daycare personnel, health care workers, and military personnel.
- Contraindicated: pregnancy, immunodeficiency (except HIV infection), within 3 months of IVIG or blood administration, severe febrile illness, or hypersensitivity to vaccine components. Patients who receive rubella vaccine do not transmit rubella to others, although the virus can be isolated from the pharynx. Breastfeeding is not a contraindication to vaccination (1)[A].
- During outbreaks, serologic screening before vaccination is not recommended because rapid mass vaccination is necessary to stop disease spread (2)[A].
- The MMR vaccine is not associated with autism (4)[A],(5)[B].
- Children who receive the MMR-V vaccine have a 2-fold increase in risk of febrile seizures compared with those who receive MMR and varicella vaccines separately (5)[B].
- Routine rubella antibody (IgG) screening is recommended during pregnancy (4)[A].
**DIAGNOSIS**

Council of State and Territorial Epidemiologists (CSTE) case definition classifications of rubella (1)[A]

- **Clinical case definition**
  - Acute onset of pink, coalescent macules on the face spreading to the trunk and extremities, becoming discrete macules then fading in previously affected areas; on average, within 3 days
  - Temperature >99°F (37.2°C; if measured)
  - Arthralgia or arthritis, lymphadenopathy, or conjunctivitis
- **Laboratory criteria for diagnosis**
  - Isolation of virus from throat or nasopharynx, serum, CSF, urine, or cataracts (postmortem)
  - 4-fold rise in acute- and convalescent-phase titers of serum IgG Ab
  - Positive serologic test for IgM Ab
  - PCR positive for virus

**HISTORY**

- Most cases of postnatal rubella are due to inadequately immunized travelers returning from endemic areas.
- Rubella can spread quickly among persons residing in close quarters.
- Postnatal rubella: low-grade fever, lymphadenopathy (postcervical, occipital, and postauricular), sore throat, nausea, anorexia, arthritis, arthralgia, malaise. 25–50% are asymptomatic.
- CRS: parental concerns about hearing or vision impairment, jaundice, or developmental delay
- Deafness could be the only manifestation and may not be noticed until 2nd year of life (2)[A].

**PHYSICAL EXAM**

- Postnatal rubella: low-grade fever, lymphadenopathy (posterior auricular, occipital, posterior cervical), exanthem (mild, pink, discrete 1- to 4-mm maculopapular rash), soft palate petechiae (Forchheimer sign) (20%) (1)[A]
- CRS: microcephaly, large anterior fontanelle, sensorineural hearing loss (58%), cataracts, glaucoma, microphthalmia, pigmentary retinopathy, purpuric (“blueberry muffin”) skin lesions, murmur (50%) consistent with patent ductus arteriosus (PDA), hepatosplenomegaly, jaundice, cryptorchidism, inguinal hernia, radiolucent bone disease (2)[A]
DIFFERENTIAL DIAGNOSIS

- Postnatal rubella
  - Measles virus (rubeola)
  - Scarlet fever (strep A)
  - Infectious mononucleosis
  - Erythema infectiosum (parvovirus B19)
  - Roseola infantum (i.e., exanthem subitum)
  - Toxoplasmosis
  - Drug eruptions
  - Other exanthematous enteroviral infections

- Congenital rubella
  - Measles
  - Parvovirus B19
  - Human herpesvirus 6
  - Other exanthematous entero- or arboviruses

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Because 50% of cases are subclinical, laboratory testing is preferred to confirm the diagnosis (1,2)[A].
- Detection of wild-type virus is gold standard (1)[A].
- Enzyme immunoassay (EIA): preferred testing for IgM antibodies, which may not be detectable until 5 days after the onset of rash (1)[A]
- Hemagglutination inhibition (HAI) test: A 4-fold increase of IgG Ab levels from acute to convalescent phase is diagnostic for recent infection (1)[A].
- Latex agglutination (LA) test: sensitive and specific but dependent on experience of lab personnel (1)[A]
- Immunofluorescent antibody (IFA) assay: used for detection of viral IgG and IgM Ab (1)[A]
- Avidity test: not routinely used; only perform in reference labs; distinguishes between recent and past infections (1)[A]
- Most rubella cases are virus positive on the day of the rash onset and remain positive for the next 7 to 10 days. Perform serum collection during this period. When testing for IgM, repeat collection may be necessary if the sample was taken before day 5. When testing for seroconversion, collect a second IgG sample 2 to 3 weeks after the first (acute to convalescent phase). In most cases, IgG is detectable 8 days after rash onset (1)[A].
- Virus may also be isolated from 1 week prior to 2 weeks after the onset of
rash. Maximal viral shedding occurs up to day 4 after rash onset. Best results are from throat swab samples (1)[A].

- Epidemiologically, viral genotyping by reverse transcription (RT)-PCR helps determine the country of origin. Collect throat swabs 4 days after the rash onset and send to CDC (1)[A].
- Reserve viral cultures of CSF for suspected cases of CRS or rubella encephalitis (1)[A].
- If a pregnant female is exposed, amniotic fluid PCR or fetal blood sampling may be done at 15 weeks’ gestation for viral detection. Placental biopsy (less common) may be done at 12 weeks’ gestation. If positive, offer genetic counseling (1)[A].
- As the incidence of rubella decreases, the positive predictive value (PPV) of IgM results decreases. False-positive findings occur in patients with parvovirus B19, mononucleosis, and positive rheumatoid factor (1)[A].
- After reexposure, a person with a low level of Ab from past infection or prior vaccination may experience an acute, small rise in Ab levels. This is not associated with a high risk of contagion to others or fetal complications (1) [A].

Follow-Up Tests & Special Considerations

- Reporting: state-dependent. Samples should be sent to the CDC for genotyping. Cases of CRS are reported to the National Congenital Rubella Syndrome Registry (1,2)[A].
- Infants with CRS may shed virus up to 1 year. Observe contact isolation during all hospitalizations until child turns 1 year old (unless child has two negative throat cultures and urine specimens a month apart after 3 months of age) (2)[A].

TREATMENT

- Supportive for mild cases
- Isolate patients for 5 to 7 days after rash onset.
- Postnatal rubella: mild and self-limited; treat symptomatically. Hospitalize for complications: idiopathic thrombocytopenic purpura (ITP) or encephalitis (1) [A].
- CRS: supportive care unless neurologic or hemorrhagic complications develop; phototherapy may be indicated for jaundice; multidisciplinary management of long-term complications (2)[A]
MEDICATION
No specific therapy available for mild cases.

First Line
- Age- and dose-appropriate antipyretics
- NSAIDs can be used for arthritis and arthralgias in adults and infants age >6 months.
- IVIG can be given for severe thrombocytopenia; most cases, however, are self-limited.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Individuals immune to rubella through natural infection or vaccine may be reinfected when reexposed; such infection is usually asymptomatic and detectable only by serology. Those who have received the vaccine have lower measurable IgG levels than those who had the natural disease.

> In CRS, it is important to detect auditory and visual impairment early (2)[A].
> 2/3 of internationally adopted children have no written record of immunizations (4)[A].

PATIENT EDUCATION
http://www.cdc.gov/rubella/

PROGNOSIS
- Postnatal rubella: Complete recovery is typical.
- CRS
  - Varied and unpredictable spectrum, ranging from stillbirth to normal infancy/childhood (1,2)[A]
  - Detectable levels of IgG persist for years and then may decline (does not drop at the expected 2-fold dilution/month). By age 5 years, 20% have no detectable antibody (2)[A].
  - IgM may not be detectable until 1 month after birth and may persist for 6 to 12 months (2)[A].
  - Overall mortality (up to 10%) is greatest during first 6 months.
– 70% of encephalitis cases develop residual neurologic defects, including autistic syndrome.
– Prognosis is excellent if only minor congenital defects are present.

**COMPLICATIONS**

- Frequently leads to arthralgia/arthritis in women (up to 70%) (6)
- Postinfectious encephalitis (1/5,000 cases)
- Thrombocytopenic purpura (1/3,000 cases)
- CRS: incidence dependent on trimester exposed
- Rubella vaccine may rarely cause encephalitis or ITP.
  – ITP is self-limited and is not a contraindication to vaccination.

**REFERENCES**

ADDITIONAL READING

CODES

ICD10

- B06.9 Rubella without complication
- B06.00 Rubella with neurological complication, unspecified
- P35.0 Congenital rubella syndrome

CLINICAL PEARLS

- Rubella is typically a self-limited viral exanthematous infection of children and adults.
- Nonimmune women who are infected with rubella while pregnant may have devastating fetal effects due to CRS.
- Immunization is the key prevention strategy.
MEDIAL TIBIAL STRESS SYNDROME (MTSS)/SHIN SPLINTS

Kanad Mukherjee, DO, MPH • Michael Y. Yang, MD • Marc W. McKenna, MD

BASICS

DESCRIPTION

- The term medial tibial stress syndrome (MTSS) is currently preferred to “shin splints.” MTSS is aching pain along the inner edge of the tibial shaft that develops when the musculature and/or periosteum in the (lower) leg become irritated by repetitive activity. The condition is part of a continuum of stress-related injuries to the lower leg. MTSS does not encompass pain from ischemia (compartment syndrome) or stress fractures.
- Tendonitis/periostitis of the medial soleus muscles, anterior tibialis, and posterior tibialis muscles
- Synonyms: tibial stress reaction, anterior muscle syndrome, tibial periostitis, perimyositis, soleus syndrome, shin splints

EPIDEMIOLOGY

Incidence

Common, can account for between 5% and 35% of novice-running injuries; frequently occurs bilaterally (1)

Pediatric Considerations

MTSS may account for up to 31% of all overuse injuries in high school athletes.

ETIOLOGY AND PATHOPHYSIOLOGY

- Multifactorial anatomic and biomechanical factors
  - Overuse injuries causing or limited by
    - Microtrauma from repetitive motion leading to periosteal inflammation
    - Overpronation of the subtalar joint and tight gastrocnemius/soleus complex with increased eccentric loading of musculature inserting along the medial shin
- Interosseous membrane pain
- Periostitis
- Tears of collagen fibers
- Enthesopathy
- Anatomic structures affected include:
  - Flexor hallucis longus
  - Tibialis anterior
  - Tibialis posterior
  - Soleus
  - Crural fascia

Pathogenesis: theorized to be due to (i) calf muscle traction on periosteum and (ii) persistent repetitive loading on tibia, which leads to inadequate bone remodeling with subsequent tibial cortex changes and possible microfissures causing pain without evidence of fracture or ischemia

**RISK FACTORS**

- Intrinsic (personal) risk factors:
  - Greater ranges of internal and external (>65 degrees) hip rotation
  - Significant overpronation at the ankle
  - Imbalance of musculature of the ankle and foot (inversion/eversion misbalance)
  - Female gender
  - Lean calf girth
  - Femoral neck anteversion
  - Navicular drop
  - Genu varum
  - History of previous MTSS

- External (environmental) risk factors
  - Lack of physical fitness
  - Inexperienced runners—particularly those with rapid increases in mileage and inadequate prior conditioning
  - Excessive overuse or distance running, particularly on hard or inclined (crowned) surfaces
  - Prior injury
  - Equipment (shoe) failure

- Other risk factors
  - Elevated BMI
  - Lower bone mineral density
  - Tobacco use
Those typically affected by MTSS include:

- Runners
- Military personnel—common in recruit/boot camp
- Gymnasts, soccer, and basketball players
- Ballet dancers

GENERAL PREVENTION

- Proper technique for guided calf stretching and lower extremity strength training, although supplementary gastrocnemius and soleus stretching has no statistical significance in reducing risk of shin splints
- Rehabilitate prior injuries adequately.
- Other recommendations
  - Gait analysis and retraining, particularly for overpronation
  - Orthotic footwear inserts

COMMONLY ASSOCIATED CONDITIONS

- Rule out stress fracture and compartment syndrome.
- Pes planus (flat feet)

DIAGNOSIS

HISTORY

- Patients typically describe dull, sharp, or deep pain along the lower leg that is resolved with rest.
- Patients are often able to run through the pain in early stages.
- Pain is commonly associated with exercise (also true with compartment syndrome), but in severe cases, pain may persist with rest.

PHYSICAL EXAM

- Tenderness to palpation is typically elicited along the posteromedial border of the middle-to-distal 3rd of the tibia.
- Pain with plantar flexion
- Preservation of neurovascular integrity via palpable distal pulses, intact sensation, reflexes, and muscular strength

DIFFERENTIAL DIAGNOSIS

- Bone
– Tibial stress fractures
  o Typically, pain persists at rest or with weight-bearing activities.
  o Focal tenderness over the anterior tibia

● Muscle/soft tissue injury
  – Strain, tear, tendinopathy
  – Muscle hernia

● Fascial
  – Chronic exertional compartment syndrome (2)[C]
    o Pain without direct tenderness on exam
    o Pain increases with exertion and resolves at rest.
    o Pain is described as cramping or squeezing.
    o Pain with possible weakness or paresthesias on exam
  – Interosseous membrane tear

● Nerve
  – Spinal stenosis
  – Lumbar radiculopathy
  – Common peroneal nerve entrapment

● Vascular
  – DVT
  – Popliteal arterial entrapment
    o Rare but limb-threatening disease
    o History of intermittent unilateral claudication
    o MRI reveals compression of the artery by the medial head of the gastrocnemius muscle.

● Infection
  – Osteomyelitis

● Malignancy
  – Bone tumors

**DIAGNOSTIC TESTS & INTERPRETATION**

● Plain radiographs help rule out stress fractures if >2 weeks of symptoms (3).

● Bone scintigraphy
  – Diffuse linear vertical uptake in the posterior tibial cortex on the lateral view
  – Stress fractures demonstrate a focal ovoid uptake.

● High-resolution MRI reveals abnormal periosteal and bone marrow signals, which are useful for early discrimination of tibial stress fractures.

● Increased pain and localized tenderness warrant further imaging with MRI due to concern for tibial stress fracture.
Exclude compartment syndrome using intracompartmental pressure testing.

TREATMENT

GENERAL MEASURES

- Activity modification with a gradual return to training based on improvement of symptoms
- Running on flat and firm surfaces can help minimize pain.
- Patients should maintain fitness with low-impact activities such as swimming and cycling.
- Continue activity modification until pain free on ambulation.

MEDICATION

- Analgesia with acetaminophen or other oral nonsteroidal anti-inflammatory agent
- Cryotherapy (ice massage) is also advised to relieve acute-phase symptoms (4)[C].

ADDITIONAL THERAPIES

- Calf stretch, peroneal stretch, TheraBand exercises, and eccentric calf raises may improve endurance and strength (5)[A].
- Compression stockings have been used to treat MTSS with mixed results.
- Structured running programs with warm-up exercises have not been demonstrated to reduce pain in young athletes (6)[B].

SURGERY/OTHER PROCEDURES

- Surgical intervention includes a posterior medial fascial release in individuals with both
  - Severe limitation of physical activity and
  - Failure of 6 months of conservative treatment
  - Counsel patients that complete return of activity to sport may not be always achieved postoperatively. Surgical risks include infection and hematoma formation.
- Extracorporeal shock wave therapy (ESWT) may decrease recovery time when added to a running program (5)[A].

COMPLEMENTARY & ALTERNATIVE
MEDICINE
- Individualized polyurethane orthoses may help chronic running injuries.
- Special insoles, low-energy laser treatment, pulsed electromagnetic field, and knee braces have not been shown to improve outcomes (5)[A].
- Ultrasound, acupuncture, aquatic therapy, electrical stimulation, whirlpool baths, cast immobilization, taping, and steroid injection may help improve pain.
- Physical therapy approaches including Kinesio tape and fascial distortion massage may yield quicker return to activity.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Avoid premature return to preinjury running pace.
- Maintain stretching and strengthening exercises.
- Identify and correct preinjury training errors.
- Good supportive footwear is recommended as is replacing running shoes every 350 to 450 miles.
- Allow a gradual return to activity dictated by symptoms (pain).

PROGNOSIS
The condition is usually self-limiting, and most patients respond well with rest and nonsurgical intervention.

COMPICATIONS
- Stress fractures and compartment syndrome
- Undiagnosed MTSS or chronic exertional compartment syndrome can lead to a complete fracture or tissue necrosis, respectively.

REFERENCES

ADDITIONAL READING

CODES

ICD10

- S86.899A Other injury of other muscle(s) and tendon(s) at lower leg level, unspecified leg, initial encounter
- S86.891A Other injury of other muscle(s) and tendon(s) at lower leg level, right leg, initial encounter
- S86.892A Other injury of other muscle(s) and tendon(s) at lower leg level, left leg, initial encounter
CLINICAL PEARLS

- MTSS is the preferred term for “shin splints.”
- Diagnosis is based on a reliable history of repetitive overuse accompanied by characteristic shin pain; imaging only if strong suspicion for stress fracture.
- MTSS pain is typically along the middle and distal 3rd of the posteromedial tibial surface, worsened with activity and relieved with rest.
- Treatment includes ice, activity modification, analgesics, eccentric stretching, gait retraining, and a gradual return to activity.
- Symptoms recur if return to activity is “too much too fast.”
MEDICAL MARIJUANA

Debra A. Koenigsberger, MD

BASICS

Medical marijuana refers to the use of cannabis or cannabinoids as medical therapy to treat disease or alleviate symptoms.

DESCRIPTION

- Marijuana contains approximately 60 pharmacologically active compounds ("cannabinoids").
- The exact compounds and mechanisms of action of the cannabinoids in marijuana is an area of ongoing research.
- The most commonly isolated active ingredients include Δ-9-tetrahydrocannabinol (THC) and cannabidiol (CBD). Most of the psychoactive properties come from THC.
- Routes of administration include inhaled, intranasal, oral (extract, mixed into food, or made into tea), sublingual, and topical.
- Cannabinoids can be taken in herbal form, extracted naturally from the plant, gained by isomerization of CBD, or manufactured synthetically.

EPIDEMIOLOGY

- Cannabis is the most widely consumed illicit substance worldwide.
- An estimated 178 million people aged 15 to 64 years used cannabis at least once in 2012.
- In the United States in 2010, 6.9% of individuals 12 years old had smoked cannabis in the previous month, and it is estimated that 25% of the American population has used it at least once.
- Use among high school seniors now exceeds tobacco use (32% vs. 25%).
- In the United States, as of 2016, 30 states and Washington, DC had introduced laws to permit the medical use of cannabis.
- Under federal law, marijuana remains a schedule 1 substance.

TREATMENT

In order to qualify for medical marijuana in states where it is legal, patients have
to fail first- and second-line therapies, including an FDA-approved cannabinoid, and cannot have a substance-use disorder, psychotic disorder, or unstable mood disorder.

**MEDICATION**

FDA-approved cannabinoids and indications

- **Dronabinol (Marinol):** capsule with synthetically derived THC dissolved in oil
  - Refractory chemotherapy-induced nausea and vomiting
  - Anorexia resulting in weight loss in patients with AIDS
- **Nabilone (Cesamet):** capsule with synthetic cannabinoid that mimics THC
  - Indications above as dronabinol, additionally
  - Spasticity due to spinal cord injury
- **Nabiximols (Sativex):** whole-plant extract of marijuana, contains THC and CBD, oral mucosal spray
  - In phase 3 clinical trials for multiple sclerosis, cancer-related pain, and neuropathic pain

**CONDITIONS**

- **Chronic pain (1)[B]**
  - May be of benefit in refractory pain, neuropathic pain, and pain associated with cancer. However, in a systematic review of 79 studies with 6,400 patients, improvements failed to reach statistical significance.
  - Head-to-head studies have failed to show superiority to codeine or amitriptyline.
  - Dronabinol has been shown to have longer-lasting pain reduction and fewer side effects than non–FDA-approved cannabinoids.

- **Multiple sclerosis (2)[B]**
  - Spasticity: A small number of studies showed reduction with nabiximols and oral cannabis extracts. The reduction was only in patient-reported scores and not in objective measures. Several studies failed to replicate these results.
  - Pain: Oral cannabinoid extracts reduced pain in a small number of studies, but these results were limited by significant placebo effect and were also lacking statistical power.
  - Bladder dysfunction: no consistent evidence showing benefit
  - Tremor: Available data shows probably ineffective.
  - Smoked marijuana has unclear efficacy and has been shown to negatively affect posture and balance.
– Several studies showed an increase in cognitive impairment among MS patients who use cannabis. This occurred even in patients who used as infrequently as once per month.
– Side effects of increased weakness, mood changes including suicidal ideation, dizziness, and fatigue were noted, which MS patients are already at risk of experiencing.

**HIV/AIDS**
– Low-quality evidence showed some weight gain on dronabinol, although the effect was similar to megestrol (1)[A].
– Concern for exacerbation of HIV-associated cognitive deficits (3)[C]
– Evidence of any long-term benefit and/or change in morbidity and mortality is lacking.

**PTSD (4)[B]**
– 47 patients, studied nabilone for treatment-resistant nightmares
– 59% had total cessation of nightmares, and additional 12% had significant improvement.
– Other benefits: improved sleep time, reduced daytime flashbacks
– 28% of patients had side effects resulting in discontinuation.

**Seizures (5)[B]**
– Unclear efficacy
– Best available meta-analysis includes only 48 patients in 4 studies. Included studies have multiple major flaws including no information on randomization, data reported only on side effects but not primary outcome. One study is an abstract only with no statistical analysis performed.
– One study showed totally seizure freedom compared to placebo group (two patients); all other studies showed no improvement.
– Overall well tolerated, mild drowsiness noted in one study.

**Chemotherapy-induced nausea and vomiting**
– Low-quality evidence suggests that cannabinoids are associated with improvements in nausea and vomiting due to chemotherapy (dronabinol and nabiximols) (3)[C].
– Improvement was more noticeable for nausea than vomiting due to limitations of oral route of administration and length of time to peak plasma level.
– Repeated use has been linked with increased nausea and vomiting in some patients.

**Inflammation**
– Cannabinoids induce apoptosis, inhibit cell proliferation, and suppress cytokine production.
– Initial studies in animal models suggest possible benefit in rheumatoid arthritis and inflammatory bowel disease, but this research is in very preliminary stages.
– A recent study in patients with multiple sclerosis failed to show any disease-modifying effects.

• Probably not effective
  – Acute pain
  – Glaucoma
  – Other neurologic conditions: tremor, Tourette syndrome, Huntington disease, and Parkinson disease

ONGOING CARE

Side effects
• Dizziness, dry mouth, nausea, fatigue, somnolence, vomiting, disorientation, drowsiness, confusion, loss of balance, and hallucination
• Acute psychological effects include euphoria, dysphoria, sedation, and altered perception.
• Acute intoxication at high doses can cause paranoia and psychosis.
• Withdrawal syndrome can include symptoms of irritability, sleeping difficulties, dysphoria, craving marijuana, and anxiety.

ALERT
Overdose by children can cause respiratory depression. Several states with legalized marijuana have noted an increase in hospitalizations after accidental ingestion by children.

• Long-term complications
  – Respiratory (3)[C]:
    o Chronic bronchitis
    o Increased rates of respiratory infections and pneumonia
  – Cardiovascular risk:
    o Associated with hypertension, dyslipidemia, and increased caloric intake
    o 4.8-fold increase in incidence of myocardial infarction (MI) in first hour after use
    o 4.2-fold increase in MI mortality rate for marijuana users versus nonusers
    o Several case reports of cerebrovascular events related to marijuana in patients with no other risk factors
Possible mechanisms include increased platelet coagulability, detrimental effects on microcirculation, and artery spasm.

- Cancer risk:
  - Associated with increased incidence of lung cancer and upper airway/esophageal cancer; however, association disappeared when adjusted for cigarette smoking.
  - Risk of cancer is probably lower than tobacco use but cannot be excluded.

- Psychological (3)[C]:
  - Increased anxiety and depression (noncausal association)
  - Increased risk of chronic psychosis disorders (schizophrenia) in those predisposed
  - Addiction occurs in 9% of all users, with higher rates among adolescents (17%) and daily users (20–25%).
  - Interference with cognitive function and short-term memory results in difficulty learning.

- Increased motor vehicle accidents relative risk (RR) = 2, compared to RR = 5 for blood alcohol level > .08
- “Gateway drug” phenomenon persists even in states where marijuana use is legal.
  - Marijuana reduces dopamine activity in reward centers, increasing susceptibility to drug abuse.
  - Concurrent use primes brain for enhanced response to other drugs.

**Pediatric Considerations**

Adolescents have increased vulnerability to adverse long-term outcomes (3)[C].
- Brain endocannabinoid system actively develops during adolescence.
- Initial use during adolescence is associated with long-term brain changes:
  - Increased school drop out
  - Lower IQ
  - Diminished life satisfaction

**Pregnancy Considerations**
- Marijuana use is associated with decreased sperm count and reduced sperm motility.
- Also thought to interfere with ovulation
- Chemicals produced by marijuana use are known to cross the placenta and into breast milk.
Marijuana use during pregnancy has no proven risk of low birth weight, preterm delivery, or congenital anomalies, but data are limited by small sample size and multiple confounding factors.

Use is strongly discouraged because of concern for impact on fetal and infant neurocognitive development.

Areas of future consideration
- The risk of secondhand marijuana smoke exposure is unstudied.
- Increasing legal status contributes to public misconception of safety. The frequency of use and population health effects of recent changes in law should be carefully monitored.

REFERENCES

ADDITIONAL READING

ICD10
F12.90 Cannabis use, unspecified, uncomplicated

CLINICAL PEARLS

- There is little robust clinical evidence supporting benefits of medical marijuana, and little to no evidence that alternate formulations have increased benefits compared to FDA-approved formulations.
- Medical marijuana has a narrow therapeutic index, with significant patient-to-patient variability in benefits and side effects.
- Use in adolescents must be strongly discouraged due to increased risk of long-term negative outcomes.
MELANOMA

Amit Bhojwani, DO, MBS, MSHM • Edward Scheiner, DO, FOCOO

BASICS

DESCRIPTION

- Melanoma is a tumor arising from malignant transformation of pigment-containing cells called melanocytes, which are found in the stratum basale of the epidermis.
  - Most arise in the skin but may also present as a primary lesion in any tissue: ocular (uveal), GI, GU, lymph node, paranasal sinuses, nasal cavity, anorectal mucosa, and leptomeninges.
  - Extracutaneous sites have an adverse prognosis.
  - Metastatic spread to any site in the body.
- Types of cutaneous melanoma include (1):
  - Superficial-spreading melanoma: 50–80% of cases; occurs in sun-exposed areas (trunk, back, and extremities); most ~6 mm diameter at diagnosis; when seen in younger patients, presents as a flat, slow growing, irregularly bordered lesion
  - Nodular: 20–30% of cases; present in older patients; tendency to ulcerate and hemorrhage; most commonly thick and pigmented
  - Lentigo maligna (subtype of melanoma in situ): slowest growing; older population; occurs in sun-exposed areas (head, neck, forearms). Lentigo maligna melanoma (LMM) is its invasive counterpart seen in (5–15% of cases); it is most commonly seen in elderly patients most often in the head and neck regions.
  - Amelanotic melanoma (<5%): can be missed and diagnosed at a later stage, as it can mimic benign skin conditions, and thus is referred to as a “great pretender”
  - Acral lentiginous: 2–8% of all melanomas; however, most common melanoma in black or Asian patients; found in palmar, plantar, and subungual areas
  - Subungual melanoma (0.7–3.5%): dark longitudinal stripe under the nail plate; Hutchinson nail sign is when brown or black pigment extends from the nail to the cuticle and proximal or lateral nail folds.
- Desmoplastic melanoma (~1%): “neurotropic melanoma” or “spindled melanoma” with an abundance of fibrous tissue; demonstrates sarcoma-like tendencies with increased hematogenous spread; presents as a slow-growing lesion that is scar-like (no history of injury at the site is noted); often seen in the head and neck
- System(s) affected: skin/exocrine

**Geriatric Considerations**
Lentigo maligna, slowly enlarging pigmented lesion, is most common in elderly patients. This type is usually found on the face, beginning as a circumscribed macular patch of mottled pigmentation showing shades of dark brown, tan, or black.

**Pediatric Considerations**
Large congenital nevi (>5 cm) are risk factors and have a >2% lifetime risk of malignant conversion. Blistering sunburns in childhood significantly increase risk.

**Pregnancy Considerations**
No increased risk of melanoma in pregnancy. In the case of recent melanoma treatment, it is recommended to wait 1 to 2 years prior to becoming pregnant, as melanoma can spread to the placenta.

**EPIDEMIOLOGY**

**Incidence**
- In 2017, an estimated 87,110 Americans were diagnosed with melanoma, with approximately 9,730 expected deaths (2).
- Predominant age: median age: 62 and 54 years for men and women respectively; >50% of all individuals with melanoma are between 20 and 40 years of age.
- Predominant sex: male > female (1.5 times)
- Melanoma is more than 20 times more common in whites than in African Americans (2).
- Minority groups demonstrate increased rates of metastasis, advanced stages at diagnosis, thicker initial lesions, earlier age at diagnosis, and overall poorer outcomes.
- Low socioeconomic status associated with higher incidence of melanoma
Prevalence
- Lifetime risk: men: 1/37; female: 1/56
- Lifetime risk in whites is ~2.5% (1/40), 0.1% (1/1,000) in blacks, and 0.5% (1 in 200) in Hispanics (2)
- 2% of all cancer deaths
- The most common cancer affecting women 25 to 29 years of age and second only to breast cancer in women 30 to 34 years of age (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- DNA damage by UVA/UVB exposure
- Tumor progression: initially may be confined to epidermis with lateral growth, may then grow into dermis with vertical growth

Genetics
- Dysplastic nevus syndrome is a risk factor for development of melanoma. Close surveillance is warranted.
- 8–12% of patients with melanoma have a family history of disease.
- Mutation in CDKN2A (p16) is found in 1/3 of patients with family incidence of melanoma.
- Mutations in BRAF (V600E) implicated in 50–60% of cutaneous melanomas
- Familial atypical mole malignant melanoma (FAMMM) syndrome characterized by >50 atypical moles, +FH of melanoma, clinical diagnosis (3)

RISK FACTORS
- Genetic predisposition, persona/family history of melanoma
- UV-A and UV-B exposure
- History of >5 sunburns during lifetime
- History of intense intermittent sun exposure
- Previous pigmented lesions (especially dysplastic melanocytic nevi)
- Fair complexion, freckling, blue eyes, blond/red hair
- Highest predictor of risk is increased number of nevi (>100).
- Tanning bed use: 75% increased risk if first exposure before age 35 years
- Changing nevus (see ABCDE criteria)
- Large (>5 cm) congenital nevi
- Chronic immunosuppression (chronic lymphocytic leukemia, non-Hodgkin lymphoma, AIDS, or posttransplant)
- Blistering sunburns in childhood
- Living at high altitude (>700 meters or 2,300 feet above sea level)
- Occupational exposure to ionizing radiation

**GENERAL PREVENTION**
- Avoidance of sunburns, especially in childhood
- Use of sunscreen with at least SPF 30 to all skin exposed to sunlight, reapplying regularly and after toweling or swimming
- Avoid tanning beds; class 1 carcinogen by World Health Organization (WHO)
- Screening of high-risk individuals, especially males >50 years
- Education for proper diagnosis plays a large factor in prevention.
- Any suspicious lesions should be biopsied with a narrow excision encompassing the entire breadth plus sufficient depth of the lesion. Options include elliptical excisions, punch, or shave biopsies.

**COMMONLY ASSOCIATED CONDITIONS**
- Dysplastic nevus syndrome
- >50 nevi. These individuals have higher lifetime risk of melanoma than the general population, as 50% of all melanoma arise in preexisting nevi.
- Giant congenital nevus: 6% lifetime incidence of melanoma
- Xeroderma pigmentosum is a rare condition associated with an extremely high risk of skin cancers, including melanoma.
- Psoriasis after psoralen-UV-A (PUVA) therapy

**DIAGNOSIS**

**HISTORY**
- Change in a pigmented lesion: either hypo- or hyperpigmentation, bleeding, scaling, ulceration, or changes in size or texture
- Obtain family and personal history of melanoma or nonmelanoma skin cancer.
- Obtain social history including occupation, sunbathing, tanning, and other sun exposure.

**PHYSICAL EXAM**
- ABCDE: **A**symmetry, **B**order irregularity, **C**olor variegation (especially red, white, black, blue), **D**iameter >6 mm, **E**volution over time
- Any new and/or changing nevus, bleeding/ulcerated
- Location on Caucasians is primarily back and lower leg; on African Americans, it is the hands, feet, and nails.
May include mucosal surfaces (nasopharynx, conjunctiva)
Individuals at high risk for melanoma should have careful ocular exam to assess for presence of melanoma in the iris and retina.

DIFFERENTIAL DIAGNOSIS
- Dysplastic and blue nevi
- Vascular skin tumor
- Pigmented actinic keratosis
- Traumatic hematoma
- Pigmented squamous cell and basal cell carcinomas, seborrheic keratoses, other changing nevi

DIAGNOSTIC TESTS & INTERPRETATION
- Lactate dehydrogenase (LDH), chest/abdomen/pelvic CT, MRI, and/or PET CT at baseline and in monitoring progression in metastatic disease (stage IV) (4)
- Imaging studies only helpful in detecting and evaluating for progression of metastatic disease

Diagnostic Procedures/Other
- Dermoscopy allows for magnification of lesions, allowing for a decreased number of biopsies of benign skin lesions in addition to providing increased sensitivity in detecting melanoma and basal cell carcinoma (5)[B].
- Surgical biopsy remains the standard of care. Any suspicious nevus should be excised, either by elliptical excision; a scoop shave (sacularization) technique may be appropriate, as long as a full-thickness can be achieved (1)[C].
- Sentinel lymph node biopsy, a staging procedure, remains an important factor for prognosis (4)[A].

Test Interpretation
- Nodular melanoma is primarily vertical growth, whereas the other three types are horizontal.
- Estimated that 1/10,000 dysplastic nevi become melanoma annually.
- Immunohistochemical testing increases sensitivity of lymph node biopsies.
- Staging is based on the tumor-node-metastasis (TNM) criteria by current American Joint Committee on Cancer (AJCC) criteria, including:
  - (T) Thickness (mm) and ulceration
  - (N) Number of regional lymph nodes involved
– (M) Distant metastases and serum LDH

**TREATMENT**

**GENERAL MEASURES**

Full surgical excision of melanoma is the standard of care. See below for recommended surgical margins.

**MEDICATION**

- For stages I to III, surgical excision is curative in most cases; in patients with stage IV disease, systemic treatment with chemotherapy is recommended.
- Preferred regimens (4)[A] include the following:
  - Ipilimumab (monoclonal antibody against CTLA-4) in combination with nivolumab (anti-PD-1 monoclonal antibody) demonstrated 61% response versus ipilimumab alone (6)[B].
  - In phase 3 of the randomized, open label study (KEYNOTE-006) comparing pembrolizumab to ipilimumab, pembrolizumab demonstrated superior progression-free survival for advanced, metastatic disease (6).
  - Vemurafenib (Zelboraf) or dabrafenib are BRAF inhibitors approved for metastatic, unresectable melanoma expressing BRAF V600E or V600K mutations.
  - High-dose interleukin-2 controversial (significant toxicity, 1–2% mortality related to treatment)
  - Referral for enrollment in clinical trials
- Additional active regimens (e.g., dacarbazine [DTIC], temozolomide, paclitaxel, carmustine [BCNU], cisplatin, carboplatin, vinblastine); often limited to those who are not candidates to preferred regimens
- Imatinib (Gleevec) in tumors with c-kit mutation
  - Interferon-α as adjuvant therapy received FDA approval in 1995 (high dose) and 2011 (pegylated) to treat stage IIB to III melanoma; shown to improve 4-year relapse rate but no overall effect on survival; 1/3 of patients will discontinue due to toxicity (granulocytopenia, hepatotoxicity) (4)[B].

**ISSUES FOR REFERRAL**

- Consultation with oncologist for consideration of chemotherapeutic options
Surgical specialties may be required based on the extent of nodal and/or metastatic disease, if present.

**SURGERY/OTHER PROCEDURES**
- Standard of care for melanoma includes early surgical excision with the following recommended margins (4)[A]:
  - In situ tumors: 0.5 cm margin has been the standard of care but may be insufficient in lentigo maligna.
  - Thickness of 1.01 to 2.00 mm: 1 to 2 cm margins
  - Thickness of >2.00 mm: 2 cm margins
- Sentinel lymph node biopsy is indicated in patients with T1b, T2-, T3-, and T4-staged melanomas.
  - Not recommended in melanoma in situ or T1a
- Mohs micrographic surgery is being increasingly used for melanoma in situ, but in general, it is not considered a treatment modality for melanoma because it relies on frozen section technique.
- Radiotherapy can be used to treat lentigo maligna in addition to certain head and neck lesions.
- Palliative radiation therapy can be used with metastatic melanoma.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Molecular and mouse tumor model studies support role of topical silymarin (milk thistle derivative) in decreasing UV radiation–induced inflammation, oxidative stress, and carcinogenesis.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Most monitoring and treatment are carried out in the outpatient setting.

**ONGOING CARE**
**FOLLOW-UP RECOMMENDATIONS**
After diagnosis and treatment, close follow-up and skin protection (i.e., sunblock, UV protective clothing) are highly advised.
**Patient Monitoring**

- Routine screening clinical skin examination annually for all persons >40 years is controversial and without proven benefit.
- Total body photography and dermoscopy should be used for surveillance of skin lesions, most commonly used for patients with >5 atypical nevi.
- For patients with a history of cutaneous melanoma, NCCN guidelines recommend screening every 3 to 12 months depending on recurrence risk (4) [C], with annual examinations if there is no disease progression for 5 years.
- Lab and imaging tests after diagnosis and treatment of stage I to II melanoma are low yield, have high false-positive rates, and are not recommended (4)[B].

**PATIENT EDUCATION**

- Teach patients who are at risk, or have had melanoma, the principles of ABCDE examinations.
- High-risk patients should perform monthly skin self-examinations and be taught to examine inaccessible areas. Educate patients on regular skin examinations.
- Patients with a history of melanoma or dysplastic nevus syndrome should have regular total body examinations by a dermatologist.

**PROGNOSIS**

- Breslow depth (thickness) in millimeters remains among strongest predictors of prognosis.
- Median age at death is 68 years.
- Highest survival seen in women <45 years of age at diagnosis
- Metastatic melanoma has an average survival of 6 to 9 months; 15–20% 5-year survival with current treatment
- Stages I and II, appropriately treated, have 20-year survival rates of 90% and 80%, respectively.

**COMPLICATIONS**

- Metastatic spread and subsequent death
- Often referred to as the “great imitator,” given that metastatic disease may present in a variety of ways often confusing the clinician
- Unsatisfactory cosmetic results following the primary surgery

Atypical Mole (Dysplastic Nevus) Syndrome

**CODES**

mebooksfree.com
ICD10
- C43.9 Malignant melanoma of skin, unspecified
- C43.30 Malignant melanoma of unspecified part of face
- C43.4 Malignant melanoma of scalp and neck

CLINICAL PEARLS
- Remember that amelanotic melanomas exist; pigmentation is not required.
- 80% of cutaneous melanomas arise in existing nevi. Any changing nevi should be biopsied, preferably utilizing an excisional method to ensure that complete margins are taken.
- The prognosis is excellent with early detection and treatment.
MÉNIÈRE DISEASE
Jason E. Cohn, DO, MS • Nadir Ahmad, MD, FACS • Thomas C. Spalla, MD

BASICS

DESCRIPTION
- An inner ear (labyrinthine) disorder characterized by recurrent attacks of hearing loss, tinnitus, vertigo, and sensations of aural fullness due to an increase in the volume and pressure of the inner ear endolymph fluid (endolymphatic hydrops)
- Often unilateral initially; nearly half become bilateral over time.
- Severity and frequency of vertigo may diminish with time, but hearing loss is often progressive and/or fluctuating.
- Usually idiopathic (Ménière disease) but may be secondary to another condition causing endolymphatic hydrops (Ménière syndrome)
- System(s) affected: nervous
- Synonym(s): Ménière syndrome; endolymphatic hydrops

EPIDEMIOLOGY
- Predominant age of onset: 40 to 60 years
- Predominant gender: female > male (1.3:1)
- Race/ethnicity: white, Northern European > blacks

Incidence
Estimates 1 to 150/100,000 per year

Prevalence
Varies from 7.5 to >200/100,000

ETIOLOGY AND PATHOPHYSIOLOGY
- Not fully understood; theories include increased pressure of the endolymph fluid due to increased fluid production or decreased resorption. This may be caused by endolymphatic sac pathology, abnormal development of the vestibular aqueduct, or inflammation caused by circulating immune complexes. Increased endolymph pressure may cause rupture of membranes
and changes in endolymphatic ionic gradient.
- Ménière syndrome may be secondary to injury or other disorders (e.g., reduced middle ear pressure, allergy, endocrine disease, lipid disorders, vascular, viral, syphilis, autoimmune). Any disorder that could cause endolymphatic hydrops could be implicated in Ménière syndrome.

**Genetics**
Some families show increased incidence, but genetic and environmental influences are incompletely understood.

**RISK FACTORS**
*May include*
- Stress
- Allergy
- Increased salt intake
- Caffeine, alcohol, or nicotine
- Chronic exposure to loud noise
- Family history of Ménière
- Certain vascular abnormalities (including migraines)
- Certain viral exposures (especially herpes simplex virus [HSV])

**GENERAL PREVENTION**
Reduce known risk factors: stress; salt, alcohol, and caffeine intake; smoking; noise exposure; ototoxic drugs (e.g., aspirin, quinine, aminoglycosides).

**COMMONLY ASSOCIATED CONDITIONS**
- Anxiety (secondary to the disabling symptoms)
- Migraines
- Hyperprolactinemia
- Hypothyroidism

**DIAGNOSIS**
Diagnosis is clinical.

**HISTORY**
- Symptomatic episodes are typically spontaneous but may be preceded by an
aura of increasing fullness in the ear and tinnitus. These may occur in clusters, with long periods of symptom-free remissions.

- Formal criteria for diagnosis from American Academy of Otolaryngology–Head and Neck Surgery:
  - At least two episodes of rotational-horizontal vertigo >20 minutes in duration
  - Tinnitus or aural fullness
  - Hearing loss: Low frequency (sensorineural) is confirmed by audiometric testing.
  - Other causes (e.g., acoustic neuroma) excluded
  - During severe attacks: pallor, sweating, nausea, vomiting, falling, prostration
  - Symptoms are exacerbated by motion.

**PHYSICAL EXAM**

- Physical exam rules out other conditions; no finding is unique to Ménière disease.
- Horizontal nystagmus may be seen during attacks.
- Otoscopy is typically normal.
- Triggering of attacks in the office with Dix-Hallpike maneuver suggests diagnosis of benign paroxysmal positional vertigo, not Ménière disease.

**DIFFERENTIAL DIAGNOSIS**

- Acoustic neuroma or other CNS tumor
- Syphilis
- Third window syndromes
- Endolymphatic sac tumor
- Viral labyrinthitis
- Transient ischemic attack (TIA), migraine
- Vertebrobasilar disease
- Other labyrinthine disorders (e.g., Cogan syndrome, benign positional vertigo, temporal bone trauma)
- Diabetes or thyroid dysfunction
- Vestibular neuronitis
- Medication side effects
- Otitis media
- Autoimmune inner ear disease
- Autosomal dominant sensorineural hearing loss
DIAGNOSTIC TESTS & INTERPRETATION

Testing is done to rule out other conditions but does not necessarily confirm or exclude Ménière disease.

Initial Tests (lab, imaging)
- Consider serologic tests specific for *Treponema pallidum* in at-risk populations.
- Thyroid, fasting blood sugar, and lipid studies
- Consider MRI to rule out acoustic neuroma or other CNS pathology, including tumor, aneurysm, and multiple sclerosis (MS).

Diagnostic Procedures/Other
- Auditory
  - Audiometry using pure tone and speech to show low-frequency sensorineural (nerve) loss and impaired speech discrimination; usually shows low-frequency sensorineural hearing loss
  - Tuning fork tests (i.e., Weber and Rinne), ABR, or MRI to rule out acoustic neuroma
  - Electrocochleography may be useful to confirm etiology.
- Vestibular
  - Caloric testing: Reduced activity on either side is consistent with Ménière diagnosis but is not itself diagnostic.
  - Head-impulse testing (1)[C]

Test Interpretation
- Histologic temporal bone analysis (at autopsy); dilation of inner ear fluid system, neuroepithelial damage with hair cell loss, basement membrane thickening, and perivascular microvascular damage
- Cytochemical analysis can reveal altered AQP4 and AQP6 expression in the supporting cell, altered cochlin, and mitochondrial protein expression (2)[B].
- Familial Ménière disease has been associated with DTNA and FAM136A genes (3)[B].

TREATMENT
- Usually managed in outpatient setting
- A paucity of evidence-based guidelines exists; therefore, there is no gold
standard treatment.
- Medications are primarily for symptomatic relief of vertigo and nausea.
- During attacks, bed rest with eyes closed prevents falls. Attacks rarely last >4 hours.

**MEDICATION**

**First Line**
- Acute attack: Initial goal is stabilization and symptom relief; for severe episodes
  - Benzodiazepines (such as diazepam): decrease vertigo and anxiety
  - Antihistamines (meclizine/dimenhydrinate): decrease vertigo and nausea
  - Anticholinergics (transdermal scopolamine): reduces nausea and emesis associated with motion sickness
  - Antidopaminergic agents (metoclopramide, promethazine): decrease nausea, anxiety
  - Rehydration therapy and electrolyte replacement
  - Steroid taper for acute hearing loss
- Maintenance (goal is to prevent/reduce attacks)
  - Lifestyle changes (e.g., low-salt diet) are needed.
  - Diuretics may help reduce attacks by decreasing endolymphatic pressure and volume; there is insufficient evidence to recommend routine use:
    - Hydrochlorothiazide; hydrochlorothiazide/triamterene (Dyazide, Maxzide)
    - Acetazolamide (Diamox)
- Contraindications/warnings:
  - Atropine: cardiac disease, especially supraventricular tachycardia and other arrhythmias, prostatic enlargement
  - Scopolamine: children and elderly, prostatic enlargement
  - Diuretics: electrolyte abnormalities, renal disease
- Precautions:
  - Sedating drugs should be used with caution, particularly in the elderly.
  - Patients are cautioned not to operate motor vehicles or machinery. Atropine and scopolamine should be used with particular caution.
  - Diuretics: Monitor electrolytes.
- Significant possible interactions: transdermal scopolamine: anticholinergics, antihistamines, tricyclic antidepressants, other

**Second Line**
● Steroids, both intratympanic and systemic (PO or IV) have been used for longer treatment of hearing loss:
  – Addition of prednisone 30 mg/day to diuretic treatment reduced severity and frequency of tinnitus and vertigo in one pilot study.
● In Europe, betahistine, a histamine agonist, is routinely used (unavailable in the United States). Other vasodilators, such as isosorbide dinitrate, niacin, and histamine, have also been used; evidence of their effectiveness is incomplete.
● Evidence is lacking for routine use of Famvir; may improve hearing more than balance.

Intratympanic gentamicin has shown to improve vertigo (4)[B].

ISSUES FOR REFERRAL
● Consider ear, nose, throat/neurology referral.
● Patients should have formal audiometry to confirm hearing loss.

ADDITIONAL THERAPIES
● Application of intermittent pressures via a myringotomy using a Meniett device has been shown to relieve vertigo (5)[B]:
  – Safe; requires a long-term tympanostomy tube
● Vestibular rehabilitation may be beneficial for patients with persistent vestibular symptoms:
  – Safe and effective for unilateral vestibular dysfunction

SURGERY/OTHER PROCEDURES
● Interventions that preserve hearing:
  – Endolymphatic sac surgery, either decompression or drainage of endolymph into mastoid or subarachnoid space
    o Less invasive; may decrease vertigo; may influence hearing/tinnitus
  – Endolymphatic sac surgery is effective in controlling vertigo in short- and long-term follow-up in at least 75% of patients with Ménière disease who failed medical therapy (6)[A].
  – Vestibular nerve section (intracranial procedure)
    o More invasive
    o Decreases vertigo and preserves hearing
  – Tympanostomy tube: may decrease symptoms by decreasing the middle ear pressure
● Interventions for patients with no serviceable hearing:
  – Labyrinthectomy: very effective at controlling vertigo but causes deafness
– Vestibular neurectomy
– Endoscopic vestibular nerve section (7)[B]
– Cochlear implantation

COMPLEMENTARY & ALTERNATIVE MEDICINE

Insufficient evidence to support effectiveness, but many integrative techniques have been tried, including the following:

- Acupuncture, acupressure, tai chi
- Niacin, bioflavonoids, Lipoflavonoids, ginger, Ginkgo biloba, and other herbal supplements

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Due to the possibility of progressive hearing loss despite decrease in vertiginous attacks, it is important to monitor changes in hearing and to monitor for more serious underlying causes (e.g., acoustic neuroma).

DIET
- Diet is usually not a factor, unless attacks are brought on by certain foods.
- A low salt is often recommended but not proven effective in randomized controlled trials.

PROGNOSIS
- Alert patients about the nature of alternating attacks and remission.
- Between attacks, patient may be fully active but is often limited due to fear or lingering symptoms. This can be severely disabling.
- 50% resolve spontaneously within 2 to 3 years.
- Some cases last >20 years.
- Severity and frequency of attacks diminish, but hearing loss is often progressive.
- 90% can be treated successfully with medication; 5–10% of patients require surgery for incapacitating vertigo.
COMPLICATIONS
Loss of hearing; injury during attack; inability to work

REFERENCES

SEE ALSO
- Hearing Loss; Labyrinthitis; Tinnitus
- Algorithm: Dizziness

CODES

ICD10

- H81.09 Meniere’s disease, unspecified ear
- H81.01 Meniere’s disease, right ear
- H81.02 Meniere’s disease, left ear
CLINICAL PEARLS

- Ménière disease is characterized by vertigo, hearing loss, and tinnitus +/- aural fullness.
- There is a wide differential diagnosis for Ménière disease; therefore, one must fully investigate symptoms.
- Multiple medical, surgical, and rehabilitative treatments are available to decrease the severity and frequency of attacks.
MENINGITIS, BACTERIAL

Felix B. Chang, MD, DABMA, FAAMA

BASICS

DESCRIPTION
- A potentially life-threatening bacterial infection of the meninges
- System affected: nervous

EPIDEMIOLOGY
- Predominant age: neonates, infants, and elderly
- Predominant sex: male = female

Incidence
- <2 months: 80/100,000
- 2 to 23 months: 7/100,000
- 2 to 10 years: 0.5/100,000
- 11 to 17 years: 0.4/100,000
- 18 to 34 years: 0.66/100,000
- 35 to 49 years: 0.95/100,000
- 50 to 64 years: 1.73/100,000
- ≥65 years: 1.92/100,000
- Varies with pathogen
  - Streptococcus pneumoniae: 0.81/100,000
  - Group B Streptococcus: 0.25/100,000
  - Neisseria meningitidis: 0.19/100,000
  - Haemophilus influenzae: 0.08/100,000
  - Listeria monocytogenes: 0.05/100,000

ETIOLOGY AND PATHOPHYSIOLOGY

Bacterial infection causes inflammation of the pia mater, arachnoid, and the fluid of the ventricles. Age and likely pathogens guide empiric choice of antibiotics. Tailor therapy by culture results whenever possible (1):

- Newborns (<2 months)
  - Group B Streptococcus
  - Escherichia coli
- *L. monocytogenes*

**Infants and children**
- *S. pneumoniae*
- *N. meningitidis*
- *H. influenzae*

**Adolescents and young adults**
- *N. meningitidis*
- *S. pneumoniae*

**Immunocompromised adults**
- *S. pneumoniae, L. monocytogenes,* gram-negative bacilli such as *Pseudomonas aeruginosa*
- *Mixed bacterial infection in <1% of cases*

**Older adults**
- *S. pneumoniae 50%*
- *N. meningitidis 30%*
- *L. monocytogenes 5%*
- 10% gram-negatives bacilli: *E. coli, Klebsiella, Enterobacter, P. aeruginosa*

**Genetics**
Navajo Indians and American Eskimos appear to have genetic or acquired susceptibility to invasive disease.

**RISK FACTORS**
- Immune compromise
- Alcoholism, diabetes, chronic disease
- Neurosurgical procedure/head injury
- Abdominal surgery
- Neonates: prematurity, low birth weight, premature rupture of membranes, maternal peripartum infection, and urinary tract abnormalities
- Abnormal communication between nasopharynx and subarachnoid space (congenital, trauma), dural fistula
- Parameningeal source of infection: otitis, sinusitis, mastoiditis
- Trauma: skull fracture

**GENERAL PREVENTION**
- Treat infections appropriately.
- Strict aseptic techniques for patients with head wounds or skull fractures
- Consider CSF fistula in patients with recurrent meningitis.
Meningitis caused by *H. influenzae* type B has decreased 55% with routine vaccination.

Conjugate vaccines against *S. pneumoniae* may reduce the burden of disease in childhood.

Close contacts of meningococcal meningitis patients should receive chemoprophylaxis (2)[A].

**COMMONLY ASSOCIATED CONDITIONS**

Conditions associated with a worse prognosis:

- Alcoholism, old age, infancy
- Diabetes mellitus, multiple myeloma
- Head trauma, seizures
- Coma, bacteremia, sepsis
- Bacteremia, sepsis, sinusitis

**DIAGNOSIS**

**HISTORY**

- Antecedent upper respiratory infection
- Fever, headache, vomiting, photophobia
- Seizures, confusion, nausea, rigors
- Profuse sweats, weakness
- Elderly: subtle findings including confusion
- Infants: irritability, lethargy, poor feeding
- Altered mental status

**PHYSICAL EXAM**

The triad of fever, neck stiffness, and altered mental status has low sensitivity (44%) (3). 95% of patients present with at least two of the following: headache, fever, neck stiffness, and altered mental status.

- Meningismus
- Focal neurologic deficits
- Meningococcal rash: macular and erythematous at first, then petechial or purpuric
- Purpura fulminans: more common with meningococcus
- Papilledema
- Brudzinski sign: Passive flexion of neck elicits involuntary flexing of knees in
supine position.
- Kernig sign: resistance or pain with passive knee extension following 90-degree hip flexion in supine position
- Late signs and symptoms: hemiparesis, stroke, cognitive impairment, coma, epilepsy, hearing loss, permanent visual impairment

DIFFERENTIAL DIAGNOSIS
- Bacteremia, sepsis, brain abscess
- Seizures, other nonbacterial meningitides
- Aseptic meningitis
- Drug-induced: NSAIDs, cotrimoxazole, amoxicillin, cephalosporin, isoniazid
- Inflammatory noninfectious: Behçet disease, systemic lupus erythematosus (SLE), sarcoidosis
- Stroke

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Prompt lumbar puncture (1)[A]
  - Head CT first if focal neuro findings, papilledema, or altered mentation
- Typical CSF analysis: turbid
  - Adults
    - >500 cells/mL WBCs
    - Glucose <40 mg/dL
    - <2/3 blood-to-glucose ratio
    - CSF protein >200 mg/dL
    - CSF opening pressure >30 cm
    - Suspect ruptured brain abscess when WBC count is unusually high (>100,000).
- CSF Gram stain and cultures
- Polymerase chain reaction (PCR) of CSF (particularly in suspected viral meningitis)
- Bacterial antigen tests should be reserved for cases in which the initial CSF Gram stain is negative and CSF culture is negative at 48 hours of incubation.
- Serum blood cultures, serum electrolytes
- Evaluate clotting function when petechiae or purpura are present.
- Chest radiograph may reveal pneumonitis or abscess.
- Later in course: head CT if hydrocephalus, brain abscess, subdural effusions, and subdural empyema are suspected or if no clinical response after 48 hours
of appropriate antibiotics

- C-reactive protein (CRP): Normal CRP has high negative predictive value (3) [A].
- Lactate concentration not recommended for suspected community-acquired bacterial meningitis

**Diagnostic Procedures/Other**

Lumbar puncture

- IDSA head CT recommendations (prior to lumbar puncture): immunocompromised, history of central nervous system disease (stroke, mass lesion, focal infection), papilledema, focal neurologic defect including fixed dilated pupil, gaze palsy, weakness of extremity, visual field cut, new-onset seizure <12 weeks prior to presentation, abnormal level of consciousness (3) [A]
- Contraindications to lumbar puncture: signs of increased intracranial pressure (decerebrate posturing, papilledema), skin infection at site of lumbar puncture, CT or MRI evidence of obstructive hydrocephalus, cerebral edema, herniation

**TREATMENT**

**GENERAL MEASURES**

- Initiate empiric antibiotic therapy immediately after lumbar puncture (LP > Abx), or if head CT scan is needed, then immediately after blood cultures (Abx > CT > LP).
- Vigorous supportive care to ensure prompt recognition of seizures and prevention of aspiration

**MEDICATION**

Empiric antibiotic IV therapy (with dexamethasone when indicated) until culture results are available

- Consider local patterns of bacterial sensitivity.

**First Line**

- Neonates
- Ampicillin: 150 mg/kg/day divided q8h AND
- Cefotaxime 150 mg/kg/day divided q8h
- Infants >4 weeks of age (3,4)[A]
– Ceftriaxone: 100 mg/kg/day divided q12–24h or cefotaxime 225 to 300 mg/kg/day divided q6–8h AND
– Vancomycin: 60 mg/kg/day divided q6h

**Adults (3,4)[A]**
– Vancomycin: loading dose 25 to 30 mg/kg IV then 15 to 20 mg/kg q8–12h with goal trough of 15 to 20 AND
– Ceftriaxone: 2 g IV q12h OR
– Cefotaxime: 2 g IV q4–6h
– >50 years, add ampicillin: 2 g IV q4h for *Listeria*
– Immunocompromised use vancomycin, ampicillin, ceftazidime, and acyclovir.

**Precaution:** aminoglycoside ototoxicity

**Penicillin-allergic patients (3,4)[A]**
– Chloramphenicol: 1 g IV q6h AND
– Vancomycin: loading dose 25 to 30 mg/kg IV then 15 to 20 mg/kg q8–12h (goal trough of 15 to 20)

**Treatment duration**
– *S. pneumoniae*: 10 to 14 days
– *N. meningitidis, H. influenzae*: 7 to 10 days
– Group B *Streptococcus* organisms, *E. coli, L. monocytogenes*: 14 to 21 days
– Neonates: 12 to 21 days or at least 14 days after a repeated culture is sterile

– No reliable evidence to support the use pre-admission antibiotics for suspected cases of non-severe meningococcal disease (5)[A]

**Corticosteroids (5)[A]**
– Pediatrics
  o Early treatment with dexamethasone (0.15 mg/kg IV q6h for 2 to 4 days) decreases mortality and morbidity for patients >1 month of age with acute bacterial meningitis with no increased risk of GI bleeding.
  o Corticosteroids are associated with lower rates of hearing loss and neurologic sequelae.

**Adults (5)[A]**
– Initiate in adults and continue only if CSF Gram stain is gram-positive diplococcus or if blood or CSF positive for *S. pneumoniae*.
– Nonsignificant reduction in mortality (RR) 0.90, 95% CI 0.53–1.05; *p* value = .009
– Lower rates of severe hearing loss (RR 0.67, 95% CI 0.51–0.88), any hearing loss (RR 0.74, 95% CI 0.63–0.87), and neurologic sequelae (RR 0.83, 95% CI 0.69–1.00)
– Decreased mortality in *Streptococcus* pneumonia (RR 0.8, 95% CI 0.20–0.59) but not in *H. influenza* or *N. meningitidis*
– Associated with increased recurrent fever (RR 1.27, 95% CI 1.09–1.47)
- Dexamethasone: 0.15 mg/kg IV q6h (start 15 to 20 minutes before or with antibiotic) for 4 days
- Dexamethasone should only be continued if the CSF Gram stain and/or CSF or blood culture reveal *Streptococcus* pneumonia.

**Second Line**
Antipseudomonal penicillins
- Aztreonam
- Quinolones (e.g., ciprofloxacin)
- Meropenem

**ISSUES FOR REFERRAL**
Consultation from infectious disease and/or critical care specialist

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Bacterial meningitis requires hospitalization.
  - ICU monitoring may be needed.
  - Patients with suspected meningococcal infection require respiratory isolation for 24 hours.
- Consider home therapy to complete IV antibiotics once clinically stable and culture/sensitivity results are known.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Brainstem auditory—evoked response hearing test for infants before hospital discharge
- Vaccinations
  - 4 doses *Hib* conjugate vaccine recommended during infancy
  - Meningococcal conjugate vaccine quadrivalent (MCV4) is given to children aged 11 to 12 years with a booster at 16 years.
– Immunizing infants <3 months old with MCV4 does not reduce morbidity or mortality, and vaccinating pregnant women does not reduce infant infections.
– Administer 2 doses MCV4 at least 2 months apart to adults with the following:
  o HIV, functional asplenia
  o Persistent complement deficiencies
– Administer 1 dose of meningococcal vaccine to:
  o Military recruits
  o Microbiologists routinely exposed to isolates of *N. meningitidis*
  o Those who travel to or live in countries where meningitis is hyperendemic or epidemic
  o 1st-year college students up through age 21 years who live in residence halls if they have not received a dose on or after their 16th birthday
– MCV4 is preferred for adults with any of the preceding indications who are ≤55 years of age; meningococcal polysaccharide vaccine (MPSV4) is preferred for adults aged ≥56 years.
– Revaccination with MCV4 every 5 years is recommended for adults previously vaccinated with MCV4 or MPSV4 who are at increased risk.

### Prophylaxis (2)[A]
– Only for close contacts of patients
– Rifampin is effective in eradicating *N. meningitidis* up to 4 weeks after treatment but may lead to resistance.
– Rifampin: 600 mg PO BID for 2 days
  o Ciprofloxacin and ceftriaxone are effective up to 2 weeks after treatment without leading to resistance.
  o Ciprofloxacin: 500 mg PO for 1 dose
  o Ceftriaxone: 250 mg IM for 1 dose

### DIET
Regular, as tolerated, except with syndrome of inappropriate secretion of antidiuretic hormone

### PROGNOSIS
Overall case fatality: 21%
– Bacterial meningitis is fatal in 5–40% of children and 20–50% of adults despite treatment with adequate antibiotics.
– The mortality rate of untreated disease approaches 100%.
COMPLICATIONS

- Seizures: 20–30%; focal neurologic deficit
- Cranial nerve palsies (III, VI, VII, VIII)
  - Comprises 10–20% of the cases
  - Usually disappear within a few weeks
- Sensorineural hearing loss: 10% in children
- Neurodevelopmental sequelae: 30% have subtle learning deficits.
- Obstructive hydrocephalus, subdural effusion
- Syndrome of inappropriate secretion of antidiuretic hormone
- Elevated intracranial pressure: herniation, brain swelling

REFERENCES

ADDITIONAL READING

CODES

ICD10
- G00.9 Bacterial meningitis, unspecified
- G00.2 Streptococcal meningitis
- G00.8 Other bacterial meningitis

CLINICAL PEARLS
- Classic triad of fever, neck stiffness, and altered mental status has low sensitivity for bacterial meningitis.
- Adjunctive dexamethasone should not be given to adults who have already received antimicrobial therapy because it is unlikely to improve patient outcomes.
- A potential problem with rifampin therapy is the induction of hepatic CYP isoenzymes, thereby increasing the metabolism of a variety of drugs.
- Careful management of fluid and electrolyte balance is important because both over- and underhydration are associated with adverse outcomes.
MENINGITIS, VIRAL

Christine M. Broszko, MD • James E. Hougas III, MD, FAAFP

BASICS

DESCRIPTION

• A clinical syndrome characterized by signs/symptoms of acute meningeal inflammation from a viral etiology
• Viral meningitis (VM) is the most common cause of aseptic meningitis (no identifiable bacterial pathogen in CSF).
• System(s) affected: nervous

EPIDEMIOLOGY

Incidence

• Estimated 30,000 to 75,000 VM cases and 26,000 to 42,000 VM hospitalizations annually in United States
• Most common form of infectious meningitis
  – Annual incidence of VM is higher than all other causes of meningitis combined.
• Peaks June 1 to October 31
  – Nonpolio enteroviruses and arthropod-borne viruses predominate in warm months (70% of cases July to October).
  – Mumps usually occurs in the winter and spring, often in epidemics.
• Occurs in both outbreak and sporadic forms

ETIOLOGY AND PATHOPHYSIOLOGY

• In immunocompetent hosts, VM is generally caused by a systemic viral infection with neurotropic predilection.
• Less commonly, direct neural transmission occurs from an acute flare of a chronic viral illness (such as HSV) already present in an immunocompetent host.
• 85–95% of cases are caused by enterovirus family, (often transmitted by the fecal–oral route) including coxsackievirus A and B, echovirus, and nonpolio E variants: E9 and E30.
Less common: HSV-1, HSV-2, varicella-zoster virus (VZV), adenovirus, lymphocytic choriomeningitis virus (LCMV), cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV, parvovirus B19, mumps virus, Toscana virus
- Parechovirus 3 is the most common cause of VM in infants <90 days old.
- Arthropod-borne viruses: West Nile virus, St. Louis encephalitis virus, California encephalitis virus
- Recurrent benign lymphocytic (Mollaret) meningitis is 80% associated with HSV-2.

**Genetics**
None identified

**RISK FACTORS**
- Close contact with known cases of VM
- Age (common in children <5 years)
- Immunocompromised hosts may be more susceptible to CMV, HSV, and adenovirus.
- LCMV is transmitted via exposure to rodent feces, bite, bodily fluids, or nesting materials.

**Geriatric Considerations**
Cases of VM in the elderly are rare (most common cause is VZV); consider alternative diagnoses (e.g., carcinomatous meningitis, medication-induced aseptic meningitis).

**GENERAL PREVENTION**
Limit exposure to known hosts; hand washing and general hygiene procedures

**COMMONLY ASSOCIATED CONDITIONS**
Encephalitis; neurologic deficits; myopericarditis; neonatal enteroviral sepsis

**DIAGNOSIS**

**HISTORY**
Predominant symptoms include acute onset (hours to days) of:
- Fever (in 76–100% of patients)
- Headache (prominent early symptom)
Photophobia
Myalgias
Nausea, vomiting
Malaise
Nuchal rigidity (>50%)
  – Note: If altered mental status (AMS), consider encephalitis. Encephalitis is associated with neurologic dysfunction, such as behavioral change, focal neurologic deficits, seizure, etc. There is a continuum between meningitis and encephalitis “meningoencephalitis.”

Also document:
- Travel and exposure history
- Sexual activity (e.g., HSV, HIV)
- Outdoor activities (Lyme disease)
- Exposure to rodent feces and/or urine (LCMV)
- Solid-organ transplant (LCMV, CMV)
- Immunocompromised host (CMV, HSV, adenovirus)
- History of VZV infection
- Immunization status (mumps virus, VZV)

**PHYSICAL EXAM**
- AMS (consider encephalitis)
- Fever (>100.4°F/38°C)
- Full neurologic exam
- Meningeal signs (should not be used exclusively to diagnose or rule out meningitis):
  – Nuchal rigidity: new neck stiffness
  – Brudzinski sign: Neck flexion elicits involuntary hip and knee flexion in supine patient.
  – Kernig sign: resistance to knee extension following flexion of hips to 90 degrees by physician
  – Jolt accentuation test: Rapid horizontal rotation of the head accentuates the headache.
- Genital lesions (10–36% of HSV-2 cases will have active lesions; can precede meningeal symptoms by up to a week)
- Parotitis (mumps)
- Asymmetric flaccid paralysis (West Nile virus)
- Mucocutaneous findings
  – Vesicular rash in hand, foot, and mouth disease (coxsackievirus)
- Herpangina (coxsackievirus A)
- Herpes zoster rash or recent VZV vaccination
- Erythema migrans or cranial neuropathy (Lyme disease [Borrelia burgdorferi])
- Generalized maculopapular rash (echovirus 9, syphilis, HIV, Rocky Mountain spotted fever)
- Oropharyngeal thrush (HIV)
- Petechial rash (Neisseria meningitidis)

**DIFFERENTIAL DIAGNOSIS**
- Bacterial meningitis (BM)
- Encephalitis
- Other infectious agents:
  - Tuberculosis; syphilis; leptospirosis; Lyme disease; Rocky Mountain spotted fever; ehrlichiosis; Coccidioides; Cryptococcus neoformans; amebiasis; Rickettsial infection
- Parameningeal infections (e.g., subdural empyema)
- Postinfectious encephalomyelitis
- Viral syndrome (e.g., influenza)
- Leukemia, lymphoma, or carcinomatous meningitis
- Migraine/tension headache
- Acute metabolic encephalopathy
- Chemical meningitis
- Postoperative aseptic meningitis
- Drug-induced meningitis (NSAIDs, IVIG, TMP/SMX, amoxicillin, cetuximab, natalizumab, lamotrigine)
- Brain/epidural abscess
- Inflammatory disorders (e.g., Behçet, sarcoidosis, SLE)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Rule out BM:
  - There is debate over whether patients with low suspicion of BM need a lumbar puncture (LP). At this time, LP remains the standard of care for suspected BM.
  - Bacterial Meningitis Score (BMS): a validated clinical decision rule to identify children (≥29 days of age) at very low risk of BM. Sensitivity of 99%. Not all institutions support use of clinical decision tools to rule in/out
BM.
- CSF bacterial culture is positive in 80–90% of BM patients who did not receive antibiotics for 2 to 4 hours prior to LP.
- Contraindications for LP: signs of increased intracranial pressure (e.g., focal neurologic findings, papilledema, AMS, vomiting), known ventricular obstruction, new-onset seizure, immunocompromised state, local infection over potential LP site, suspected epidural abscess, use of anticoagulation or coagulopathy, and possibility of cardiorespiratory compromise due to patient positioning during procedure.
- Post-LP headache: occurs in 37% of patients within 48 hours.
- CSF analysis: glucose, protein, WBC count with differential, RBC count, Gram stain, culture; consider CSF lactate.
  - CSF lactate elevation helps differentiate BM from VM (decreased sensitivity if pretreated with antibiotics) (1,2)[A].

- Typical CSF findings in VM
  - Elevated WBC count: 10 to 500/mm$^3$ (can be up to 1,000), classically lymphocyte predominance (>50% lymphocytes—less consistent in younger patients). Note: more cases without lymphocytic pleocytosis noted in enterovirus VM; may show neutrophilic predominance in first 48 hours.
  - Decreased or normal glucose (relative to serum).
  - Protein normal to slightly elevated (<150 mg/dL).
  - Negative Gram stain and bacterial culture.
  - Elevated opening pressure.
  - RBCs in CSF (Consider HSV meningitis/encephalitis.)
  - Pathogen identification
    - Current practice: polymerase chain reaction (PCR), with sensitivity of 95–100% for HSV-1 and 2, EBV, enterovirus. Sensitivity for enterovirus may decrease if CSF collected >48 hours after onset of symptoms.
    - RT PCR test is approved for enteroviral meningitis; results in 2 to 3 hours.
    - Serology can be performed for many arthropod-borne viruses.

- Other labs: CBC, blood culture, blood glucose; consider serum CRP and procalcitonin (PCT).
  - CBC: normal or mildly elevated WBC.
  - Serum PCT elevation has been correlated with BM. PCT levels of >0.25 to 0.28 are 96% sensitive and 99% specific for BM. Elevated serum CRP was 82% sensitive and 81% specific (1)[B],(3)[A].
  - PCT has also been validated in children (sensitivity 87.5–100%, specificity 66–100%); however, cutoff ranges vary from 0.2 to 3.3 ng/mL between
studies and are assay dependent (4)[A]. There may be a role for CSF PCT to help differentiate BM from VM.

- EEG if concern for encephalitis
- Fungal, mycobacterial cultures, VDRL if clinically indicated
- Indication for imaging depends on clinical scenario. Perform CT prior to LP if papilledema, spinal cord trauma, AMS, or focal neurologic findings. Consider CT versus MRI if abnormal hospital course of VM (e.g., prolonged course or increased symptoms).
- Historic gold standard: CSF viral culture for enteroviruses, HSV, and mumps. This has low sensitivity (<6–20%); viral culture may yield no additional information over nucleic acid amplification alone.

**Follow-Up Tests & Special Considerations**

Disorders that may alter lab results:

- Diabetes: Consider current blood sugar level to correlate with CSF glucose level.
- Preexisting neurologic diseases (e.g., intracranial neoplasm, demyelinating disease)

---

**TREATMENT**

**GENERAL MEASURES**

Management includes supportive care (e.g., pain control, IV fluids) and a low threshold for empiric antibiotics for BM.

**MEDICATION**

**First Line**

- Analgesics (adult doses; titrate doses to pain relief)
  - Morphine 2.5 to 5.0 mg IV q3–4h
  - Hydromorphone (Dilaudid) 0.2 to 2.0 mg IV q2–3h
  - Hydrocodone (Norco) 5/325 mg 1 to 2 tablets PO q6h OR oxycodone (Percocet) 5/325 mg 1 to 2 tablets PO q4–6h
- Antiemetics
  - Ondansetron (Zofran) 4 to 8 mg IV q8h
  - Metoclopramide (Reglan) 10 to 20 mg IV/IM q4–6h
- Antipyretics: acetaminophen (Tylenol) 650 mg PO or rectal suppository q4h
Antiviral agents (adult dose): Initiate empiric acyclovir at 10 mg/kg IV q8h for patients with CSF pleocytosis, negative Gram stain, and suspicion for HSV while awaiting results of definitive (e.g., HSV PCR) testing.

- Antibiotics
  - Not indicated for treatment of VM; however, low threshold for empiric treatment if BM is suspected. Consider especially in elderly, <3 months old, or immunocompromised patient.
  - If unclear etiology but very low risk for BM, treat symptomatically and observe in the inpatient setting pending laboratory results.

- IVIG
  - Research currently underway investigating possible benefit

- Corticosteroids
  - Not indicated for treatment in VM
  - Consider if concerned for BM.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Generally VM is treated as outpatient once BM is excluded. Hospitalize for VM with complications (e.g., encephalitis), empiric antibiotic therapy, pain/fluid control, immunocompromised patient, or <1 year old.
  - Most children with VM are hospitalized (91%).
- IV fluids: crystalloid bolus or continuous infusion, based on hydration status and clinical presentation
- Neurologic monitoring for changes in mental status, fever, neck stiffness, HA, etc., to assess disease progression
- Contact precautions; private room indicated until BM is ruled out
- Encourage hand washing.
- Discharge depends on likelihood of BM, WBC count, and clinical parameters such as dehydration, functional level, social circumstances, and ability to follow up.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Primary care follow-up to ensure resolution

Patient Monitoring
Monitor for relapse or exacerbation of symptoms.

Monitor for neurologic/neuroendocrine complications:
- Seizures, cerebral edema, syndrome of inappropriate antidiuretic hormone (SIADH)
- Assess ability to have companion monitor change in mental/neurologic status if patient discharged.

**DIET**
Consider NPO if nausea or vomiting. Advance to clear fluids/regular diet as tolerated.

**PATIENT EDUCATION**
- Discuss low probability of transmission to contacts.
- Expected duration of illness is 5 to 10 days.
- Recurrence of headache, myalgia, weakness is possible over 2 to 3 weeks.

**PROGNOSIS**
- Complete recovery generally within 7 to 10 days
- Headaches and other neurologic symptoms may intermittently persist for weeks to months.
- Only 0.6% of hospitalizations for VM result in death.
- European studies suggest potential residual postmeningeal cognitive impairment.
- In neonatal population, enteroviral meningitis has been associated with normal growth and development at 1 year in most patients.

**COMPlications**
- Common: fatigue, irritability, muscle weakness
- Rare: seizures, abscess, mastoiditis

**REFERENCES**
3. Vikse J, Henry BM, Roy J, et al. The role of serum procalcitonin in the

**ADDITIONAL READING**

**SEE ALSO**

- Meningitis, Bacterial
- Algorithm: Delirium

**CODES**

**ICD10**

- A87.9 Viral meningitis, unspecified
- A87.1 Adenoviral meningitis
- A87.0 Enteroviral meningitis

**CLINICAL PEARLS**

- VM cannot be reliably distinguished from BM based on clinical findings alone.
Potential cases of BM should be hospitalized for evaluation and treatment with broad-spectrum antibiotics until BM has been ruled out.

VM is more common than BM, especially if vaccine rates are high.

Antibiotic administration in the hours prior to LP and CSF analysis may result in “partially treated” BM mimicking VM.

Administer IV acyclovir if HSV is suspected.

Morbidity with VM is low but increases if there is associated encephalitis.
MENINGOCOCCAL DISEASE

Han Q. Bui, MD, MPH

BASICS

DESCRIPTION

- Meningococcemia is a blood-borne infection caused by Neisseria meningitidis.
- Bacteremia without meningitis: Patient is acutely ill and may have skin manifestations (rashes, petechiae, and ecchymosis) and hypotension.
- Bacteremia with meningitis: sudden onset of fever, nausea, vomiting, headache, decreased ability to concentrate, and myalgias
- Disease progresses rapidly (within hours).
- Skin findings and hypotension may be present.
  - A petechial rash appears as discrete lesions 1 to 2 mm in diameter; most frequently on the trunk and lower portions of the body; seen in >50% of patients on presentation
  - Purpura fulminans is a severe complication of meningococcal disease and occurs in up to 25% of cases. It is characterized by acute onset of cutaneous hemorrhage and necrosis due to vascular thrombosis and disseminated intravascular coagulopathy.

EPIDEMIOLOGY

Incidence

- The mortality rate is ~13%.
  - 11–19% of survivors suffer serious sequelae, including deafness, neurologic deficits, or limb loss due to peripheral ischemia.
- Disease is seasonal, peaks in December/January.
- In 2015, there were 375 cases of reported meningococcal disease (incidence rate of 0.18 cases per 100,000 persons) (1).
  - Most common in adolescents and young adults, followed by infants <1 year

ETIOLOGY AND PATHOPHYSIOLOGY

- N. meningitidis is a gram-negative diplococcus with at least 13 serotypes.
- N. meningitidis has an outer coat that produces disease-causing endotoxin.
Serogroup B is the predominant cause of meningococcemia in children <1 year.
Serogroup C is the most common cause of meningococcal disease in the United States.
Serogroup Y is the predominant cause of meningococcemia in the elderly (2).

- Major serogroups worldwide are A, B, C, Y, and W-135.
- W-135 is the major cause of disease in the “meningitis belt” of sub-Saharan Africa.

**Genetics**
Late complement component deficiency has an autosomal recessive inheritance.

**RISK FACTORS**
- Age: 3 months to 1 year
- Late complement component deficiency (C5, C6, C7, C8, or C9)
- Asplenia (1)
- Living in close quarters (e.g., household contacts, nursery/daycare, dormitories, military barracks)
- Exposure to active and passive tobacco smoke (1)

**GENERAL PREVENTION**
- Two vaccines are currently licensed for use in the United States. Each contains antigens to serogroups A, C, Y, and W-135. Neither provides immunity against serotype B, which is responsible for 1/3 of U.S. cases (3).
  - Meningococcal polysaccharide vaccine (MPSV-4): recommended for patients ≥55 years at elevated risk (1)
    - Short duration of protection: 1 to 3 years for patients age <5 years; 3 to 5 years for adolescents and adults (3)
    - Often used for patients requiring short duration of protection—traveling to endemic areas, college freshmen, community outbreaks (3)
  - Meningococcal conjugate vaccine (MCV-4): recommended for patients 2 to 55 years of age (1)
- In October 2014, the FDA licensed the first serogroup B meningococcal (MenB) vaccine (MenB-FHbp) as a 3-dose series. In January 2015, FDA licensed a second MenB vaccine (MenB-4C) as a 2-dose series. Both vaccines were approved for use in persons aged 10 to 25 years. Individuals aged ≥10 years who are at increased risk for meningococcal disease due to persistent
complement component deficiencies, anatomic or functional asplenia, should receive MenB vaccine (3).

- Protective levels of antibody are achieved ~7 to 10 days after primary immunization (2).
- Vaccine is recommended for everyone aged 11 to 18 years and individuals 19 to 55 years who are at increased risk for meningococcal disease.
  - Guillain-Barré syndrome has been associated with the MCV-4 vaccine; therefore, a personal history of Guillain-Barré is a relative contraindication for this vaccine.
- CDC International Travel Advisory
  - Vaccine is required by the government of Saudi Arabia for Hajj pilgrims >2 years of age.
  - The vaccine should be given to travelers to sub-Saharan Africa (“meningitis belt”).

DIAGNOSIS

HISTORY

- Symptoms
  - Sudden onset of fever, nausea, vomiting, headache, myalgias, chills, rigor, and/or sore throat (nonsuppurative)
    - Pharyngitis may be mistaken for streptococcal pharyngitis.
    - Myalgia may be mistaken for severe “flu,” with a peak incidence coinciding in winter months.
  - Changes in mental status, decreased ability to concentrate, stiff neck, convulsions
  - Atypical presentations include acute arthritis or neuritis (4).
- Assess possible exposures.

PHYSICAL EXAM

- Fever, hypotension, tachycardia
- Neurologic: nuchal rigidity, focal neurologic findings, coma, seizure
  - Focal neurologic findings and seizures are more commonly seen with *Haemophilus influenzae* or *Streptococcus pneumoniae*.
- Cardiopulmonary: signs of heart failure with pulmonary edema—gallop, rales
- Dermatologic: maculopapular rash, petechiae, ecchymosis, purpura
- Onset of specific meningitis symptoms (e.g., neck stiffness, photophobia,
bulging fontanelle) is as fast as 12 to 15 hours (4).
- Late signs of meningitis (e.g., unconsciousness, delirium, or seizures) occur after ~15 hours in infants <1 year and after ~24 hours in older children.

**DIFFERENTIAL DIAGNOSIS**
- Sepsis; bacterial meningitis (other organisms)
- Gonococcemia
- Acute bacterial endocarditis
- Rocky mountain spotted fever
- Hemolytic uremic syndrome
- Gonococcal arthritis dermatitis syndrome
- Influenza

**DIAGNOSTIC TESTS & INTERPRETATION**

**ALERT**
- Isolation of *N. meningitidis* from a sterile site (blood or CSF) is the gold standard for diagnosing systemic meningococcal infection.
- Antibiotic administration may render blood and/or CSF culture negative within 2 hours. Treat and then test.

**Initial Tests (lab, imaging)**
- CBC with differential
  - Leukocytosis (left shift; toxic granulation) or leukopenia, thrombocytopenia
- Lactic acidosis
- Procalcitonin; often elevated in bacterial meningitis (5)
- Coagulation studies
  - Prolonged prothrombin time/partial thromboplastin time
  - Low fibrinogen
  - Elevated fibrin degradation products
- Blood culture
  - Blood culture positive for *N. meningitidis*
  - Cultures positive in 50–60% of cases
- CSF
  - Grossly cloudy
  - Increased WBCs with polymorphonuclear predominance
  - Gram stain showing gram-negative diplococci
  - Glucose-to-blood glucose ratio <0.4
  - Protein >45 mg/dL
– Positive for *N. meningitidis* antigen (MAT or PCR)
– CSF culture positive in 80–90% of cases
  ● Head CT if concern for space-occupying lesions

**Test Interpretation**

*●* Disseminated intravascular coagulation (DIC)
*●* Exudates on meninges
*●* Polymorphonuclear infiltration of meninges
*●* Hemorrhage of adrenal glands

---

**TREATMENT**

**MEDICATION**

**First Line**

*●* Antibiotics
  – Begin treatment as soon as meningococcal meningitis is suspected.
  – Age guides empiric treatment.
    o Preterm to <1 month: ampicillin plus cefotaxime or ampicillin plus gentamicin
      ■ Cefotaxime
        □ 0 to 7 days: 50 mg/kg q12h
        □ 8 to 28 days: 50 mg/kg q8h
      ■ Ampicillin
        □ >2,000 g
          ● 0 to 7 days: 50 mg/kg q8h
          ● 8 to 28 days: 50 mg/kg q6h
        □ <2,000 g
          ● 0 to 7 days: 50 mg/kg q12h
          ● 8 to 28 days: 50 mg/kg q8h
    o 1 month to 50 years: cefotaxime or ceftriaxone plus vancomycin
      ■ If severe penicillin allergy: chloramphenicol plus trimethoprim-sulfamethoxazole (TMP-SMX) plus vancomycin
    o >50 years of age or patients with alcoholism, debilitating disease, or impaired immunity: ampicillin plus ceftriaxone plus vancomycin
      ■ Ampicillin: 2 g IV q4h
      ■ Ceftriaxone: 2 g IV q12h
      ■ Vancomycin: 30 to 45 mg/kg/day IV divided q6h
If severe penicillin allergy: TMP-SMX plus vancomycin

- Penicillin G
  - Effective if the isolate is penicillin-sensitive
  - Penicillin can be used if the isolate has a penicillin minimum inhibitory concentration (MIC) of <0.1 μg/mL.
  - For isolates with a penicillin MIC of 0.1 to 1.0 μg/mL, treatment with high-dose penicillin is effective, but a 3rd-generation cephalosporin is preferred.
  - Penicillin G: 4 million units IV q4h (pediatric dose: 0.25 mU/kg/day IV divided q4–6h) OR ampicillin: 2 g IV q4h (pediatric dose: 200 to 300 mg/kg/day IV divided q6h)

- Duration of treatment: 7 days

- Dexamethasone
  - Indications
    - Known or suspected pneumococcal meningitis in selected adults
    - Children with *H. influenzae* type B meningitis
  - Dexamethasone is often given initially in adults and children with suspected bacterial meningitis while awaiting microbiologic study results.
  - Dexamethasone has not been shown to be of benefit in meningococcal meningitis and should be discontinued once the diagnosis is established.
  - Dosage
    - Infants and children >6 weeks: IV 0.15 mg/kg/dose q6h for the first 2 to 4 days of antibiotic treatment
    - Start 10 to 20 minutes before or with the first dose of antibiotic.

- Chemoprophylaxis
  - Indications
    - Close contacts: those with prolonged (>8 hours) close contact (<3 feet) to the patient or those directly exposed to the patient’s oral secretions between 1 week before the onset of the patient’s symptoms and until 24 hours after initiation of appropriate antibiotic therapy
          - Examples: household members; close contacts in nursery, daycare centers, nursing homes, dormitories, military barracks, correctional facilities, and other closed institutional settings
    - No chemoprophylaxis is indicated for casual contacts, including most health care workers, unless exposed to respiratory secretion.
  - Timing
    - Ideally <24 hours after case identification
    - Chemoprophylaxis should not be administered if >14 days since exposure.
– Prophylactic regimens
  o Rifampin, ciprofloxacin, and ceftriaxone
    ■ Ceftriaxone
      □ Recommended for pregnant women
      □ Adults: 250 mg IM as a single dose
    ■ Rifampin (meningococcal meningitis prophylaxis)
      □ Adult: 600 mg IV or PO q12h for 2 days
      □ Pediatric
        ● <1 month: 10 mg/kg/day in divided doses q12h for 2 days
        ● Infants and children: 20 mg/kg/day in divided doses q12h for 2 days (max 600 mg/dose)
    □ Ciprofloxacin
      □ Adults: 500 mg PO as a single dose

  ● Vaccination
    – For household contacts (if the case is from a vaccine-preventable serogroup)
  ● Precautions
    – Adjust the dosage of medications in patients with severe renal dysfunction.

**Second Line**

● For meningitis
  – Chloramphenicol: 1 g IV q6h (pediatric dose: 75 to 100 mg/kg/day divided q6h) or ceftriaxone 2 g IV q12h (pediatric dose: 80 to 100 mg/kg/day divided q12–24h)
  – In large outbreaks, a single dose of long-acting chloramphenicol has been used. Single-dose ceftriaxone shows equal efficacy in one randomized controlled trial.

● Precautions
  – Ceftriaxone should not be used in patients with a history of anaphylactic reactions to penicillin (e.g., hypotension, laryngeal edema, wheezing, hives).
  – Chloramphenicol may cause aplastic anemia.

**ISSUES FOR REFERRAL**

Potential complications

● Seizure activity
● DIC
● Acute respiratory distress syndrome
- Renal failure
- Adrenal failure
- Multisystem organ failure

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Begin antibiotics (± corticosteroids) and obtain lumbar puncture immediately if meningitis is suspected.
- Droplet isolation for 24 hours after starting antibiotics
- IV fluids: Replace volume as needed; with septic shock, large volumes of crystalloid may be required.

**ONGOING CARE**

**PATIENT EDUCATION**
Educate family and close contacts regarding the risk of contracting meningococcal infection.

**PROGNOSIS**
Overall mortality is 13%.

**COMPLICATIONS**
- DIC
- Acute tubular injury
- Neurologic: sensorineural hearing loss, cranial nerve palsy, seizures
- Obstructive hydrocephalus
- Subdural effusions
- Acute adrenal hemorrhage
- Waterhouse-Friderichsen syndrome

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- A39.4 Meningococcemia, unspecified
- A39.0 Meningococcal meningitis
- A39.2 Acute meningococcemia

**CLINICAL PEARLS**

- Invasive meningococcal disease can be rapidly fatal. Rapid identification and early treatment is essential to promote good clinical outcomes. Treat then test in suspected cases.
- Provide chemoprophylaxis to close contacts.
- Vaccinate at-risk populations to prevent disease.
MENISCAL INJURY
Jennifer B. Schwartz, MD

BASICS

DESCRIPTION
- The menisci are fibrocartilaginous structures between the femoral condyles and tibial plateaus.
- Each meniscus has a body, anterior and posterior horn.
- The menisci help stabilize the knee, lubricate, and distribute forces across the joint.
- There are acute/traumatic and degenerative meniscal tears.
- The inner 2/3 of the menisci are avascular and heal poorly after injury.

Geriatric Considerations
Meniscal tears in older patients are typically due to chronic degeneration.

Pediatric Considerations
- Meniscal injuries are rare in children <10 years old.
- Meniscal tears in children are often due to a discoid meniscus (anatomic variant with thicker and wider meniscus).
- MRI is less sensitive and specific for diagnosing meniscal tears in children <12 years of age.

EPIDEMIOLOGY
- More common in the 3rd to 5th decades of life
- More common in males

Incidence
Medial meniscus more commonly injured

Prevalence
One of the most common musculoskeletal injuries

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute/traumatic tears occur due to a twisting motion of the knee with foot
planted.
- More common <40 years old
- Degenerative tears occur with minimal trauma.
  - More common >40 years old

**Genetics**
Presence of a discoid meniscus increases the risk for a meniscal tear. No specific gene locus has been identified.

**RISK FACTORS**
- Acute/traumatic:
  - High degree of physical activity (especially cutting sports)
  - Anterior cruciate ligament (ACL) insufficiency
- Degenerative:
  - Increased age (>60 years), male
  - Obesity

**GENERAL PREVENTION**
- Treatment and rehabilitation of previous knee injuries, particularly ACL injuries
- Strengthening and increased flexibility of quadriceps and hamstring muscles

**COMMONLY ASSOCIATED CONDITIONS**
- Acute/traumatic:
  - ACL is concomitantly torn in 1/3 of cases.
  - Medial and lateral collateral ligament tears
- Degenerative:
  - Baker cyst—strong association with medial meniscal tears
  - Osteoarthritis (OA)—degenerative tears can be considered as an early stage of OA in older patients.

**DIAGNOSIS**

**HISTORY**
- Noncontact twisting or hyperflexion mechanism
- Delayed swelling, typically >24 hours postinjury
- Knee pain (on affected side):
Increased with knee flexion (i.e., stairs, squatting)
- Locking, catching, popping
- Sensation of buckling or giving out

**PHYSICAL EXAM**
- Effusion (mild–moderate)
- Joint line tenderness
- Decreased range of motion, locking
- Pain with full flexion (posterior horn tear) or extension (anterior horn tear)
- Accuracy of special tests varies.
  - Positive McMurray test: pain, clicking of meniscus being stressed. Apley grind test is neither sensitive nor specific.
- Thessaly test reported with higher sensitivity and specificity

**DIFFERENTIAL DIAGNOSIS**
- ACL or collateral ligament tear
- Pathologic plica
- Osteochondritis dissecans
- Loose body or fracture
- OA
- Patellofemoral syndrome
- Gout, pseudogout, rheumatoid arthritis

**DIAGNOSTIC TESTS & INTERPRETATION**
- Laboratory evaluation not indicated unless signs of septic arthritis
- Plain radiographs can detect fractures, loose bodies, or arthritic changes.
- Ultrasound may help identify meniscal tears.

**Follow-Up Tests & Special Considerations**
- MRI is the primary imaging study for meniscal tears.
- Increased signal within a meniscus corresponds to degenerative changes; signal contacting the articular surface indicates an acute tear.
- Meniscal tears are often found incidentally on MRI and may not be the cause of patient’s symptoms. Asymptomatic tears increase with age and OA.
- Meniscal tears are present on MRI in ~20% of people without knee symptoms (1).

**Diagnostic Procedures/Other**
Arthroscopy may be needed if the MRI is indeterminate.

**TREATMENT**

**GENERAL MEASURES**
- Conservative treatments include rest, ice, compression, elevation, activity modification, physical therapy, intra-articular corticosteroid injections.
  - Effective first-line options for many patients, especially those with degenerative tears
    - Recommend physical therapy for patients with degenerative meniscal tears (+/− OA)—no increased benefit from surgery and PT has less risk and results in better muscle strengthening than surgery (2–4)[B]
- Consider surgical intervention if:
  - Concurrent injuries (i.e., ACL tear)
  - Persistent symptoms following 3 to 6 months of conservative treatment
  - Young patients (<30 years) or very active patients with an acute tear
  - Mechanical symptoms/locking—may or may not be justification for arthroscopy with degenerative meniscal tears
  - Medial meniscus posterior root tear

**MEDICATION**

*First Line*
NSAIDs, opioid analgesics if severe pain

**ISSUES FOR REFERRAL**
Surgical consult for patients meeting operative criteria or wishing surgical repair

**ADDITIONAL THERAPIES**
- Rehabilitation is required for both surgical and nonsurgical patients.
- Weight control: Weight gain is associated with increased cartilage loss and pain in adults with medial meniscal tears.
- Platelet-rich plasma (PRP) may or may not improve symptoms of meniscal tears.

**SURGERY/OTHER PROCEDURES**
- Meniscectomy removes the injured portion of the meniscus.
Both partial and total meniscectomy can lead to articular cartilage degeneration and OA.

Higher risk if >40 years of age, high BMI, valgus malalignment

Meniscal repair or replacement decreases future OA and may have better outcomes than meniscectomy.

Arthroscopy may or may not have better long-term clinical outcomes when performed for traumatic versus degenerative tears (5).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Return to play requires that the patient be pain-free, have full range of motion, and full strength.

Following meniscal repair, patients can generally return to all activities in 3 to 6 months.

Combined ACL and meniscal repair requires 6 months of postoperative rehabilitation before the patient can return to sports.

PATIENT EDUCATION

Patients should be aware of the risks and benefits of surgery compared with conservative treatment.

PROGNOSIS

Prognosis better if surgery is done within 8 weeks, patient is <30 years of age, or tear is peripheral/lateral <2.5 cm

COMPLICATIONS

Meniscectomies may eventually lead to OA. Consequently, meniscal repair is preferred to meniscectomy whenever possible.

Risk of developing OA increases 6-fold 20 years after a meniscectomy.

REFERENCES

partial meniscectomy for degenerative meniscal tear in middle aged patients: randomised controlled trial with two year follow-up. BMJ. 2016;354:i3740.

SEE ALSO
Algorithm: Knee Pain

CODES

ICD10
- S83.209A Unsp tear of unsp meniscus, current injury, unsp knee, init
- S83.249A Oth tear of medial meniscus, current injury, unsp knee, init
- S83.289A Oth tear of lat mensc, current injury, unsp knee, init

CLINICAL PEARLS

- Degenerative meniscal tears are common in patients >40 years of age and generally do not require surgical repair.
- MRI is imaging modality of choice to identify meniscal tears.
- Functional outcomes following meniscal injury are improved with comprehensive rehabilitation.
- In patients opting for surgery, meniscal preservation is important. Meniscal repairs have a better functional outcome and decreased risk of OA compared with meniscectomy.
MENOPAUSE

Jill Patton, DO  Ashokmathew Poozhikunnel, DO

BASICS

DESCRIPTION

- Natural menopause: defined retrospectively after 12 consecutive months of amenorrhea in a nonpregnant woman ≥40 years of age:
  - Results from loss of ovarian activity
  - Not associated with a pathologic etiology
- Perimenopause/menopausal transition (MT): defined as the period from the onset of irregular menses to the final menstrual cycle. Begins on average 4 years before menopause; starts at mean age of 47 years
- Postmenopause: usually >1/3 of a woman’s life
- Primary ovarian insufficiency: irregular or cessation of menses before age 40 years
- Surgical menopause: Removal of functioning ovaries leads to immediate menopause.

EPIDEMIOLOGY

- The median age of menopause is 51 years.
- 5% of women undergo menopause after age 55 years; another 5% between ages 40 and 45 years
- Occurs earlier in Hispanic women and later in Japanese American women as compared with Caucasians
- Tobacco use hastens menopause by approximately 2 years.

Incidence

In the United States, 1.3 million women reach menopause annually.

ETIOLOGY AND PATHOPHYSIOLOGY

Normal physiologic process:

- As women age, the number of ovarian follicles decreases: Ovarian production of estrogen varies and then decreases. Follicle-stimulating hormone (FSH) production varies and then increases.
- Inadequate estradiol production leads to absence of the luteinizing hormone

mebooksfree.com
(LH) surge and failure to ovulate. These cycles result in anovulation and lack of progesterone production.
- Eventual failure to produce estradiol leads to thinning of endometrial lining and eventual menses cessation.
- Estrone (produced by adipose tissue) becomes the dominant form of estrogen during menopause.

**RISK FACTORS**
- Aging
- Oophorectomy/hysterectomy
- Sex chromosome abnormalities (e.g., Turner syndrome and fragile X syndrome)
- Family history of early menopause
- Chemotherapy and/or pelvic radiation

**GENERAL PREVENTION**
Menopause is a physiologic event. Increased risk of long-term medical issues includes cardiovascular disease (CVD) and osteoporotic fractures:
- Decrease risk of CVD by:
  - Increased exercise; healthy diet and weight loss
  - Avoiding smoking
  - Treating hypertension (HTN), hyperlipidemia (HLD), diabetes mellitus (DM)
- Decrease risk of osteoporotic fractures by:
  - Weight-bearing exercise and fall prevention
  - Avoiding smoking/excessive alcohol intake
  - Dietary calcium of 1,200 mg/day
  - Adequate vitamin D (800 to 1,200 IU daily)
  - Prevention of early menopause. Using epidemiologic data, there was a 17% reduced risk of early menopause in women with higher vitamin D (528 IU/d) versus low vitamin D intake (148 IU/d) and a modest decrease in risk with higher calcium intake (1,246 mg/d) when they came from dairy sources rather than nondairy sources (1).

**DIAGNOSIS**

**HISTORY**
Cessation of menses:
- Generally preceded by a period of irregular cycles with heavy vaginal bleeding followed by diminished vaginal bleeding
Vasomotor symptoms: sudden feeling of warmth, most commonly over face, neck, and chest, with average duration of ~3 minutes; intervals unpredictable
- Most commonly reported symptom; reported by over 80% of women
- Frequency and duration varies. 87% of women who report flushes experience them daily; ~33% have >10 per day. Mean duration of symptoms lasts 4 to 10.2 years and may begin during MT and extend well past menopause.
- Varies with ethnicity; greatest in African and Hispanic women and least in Asian women
- More common in obese women
Urogenital atrophy in up to 50%:
- Vaginal/vulvar dryness discharge, itch, dyspareunia, and possible sexual dysfunction
- Alkaline vaginal pH and atrophy increases risk of vaginal infections and UTIs.
- Persists or worsens with aging
- Urologic symptoms (urgency, frequency, dysuria, incontinence) not clearly correlated with MT
Anxiety, depression: Some studies show a new diagnosis of depression is 2.5 times more likely to occur during the MT as compared to premenopause.
Sleep disturbance: Arousal from sleep and chronic insomnia may be linked with vasomotor symptoms.
Joint pain with unclear link to loss of estrogen
Change in intensity and severity of migraines
Skin thinning, mild hirsutism, brittle nails

Geriatric Considerations
Vaginal bleeding in postmenopausal women is abnormal; endometrial cancer/endometrioid adenocarcinoma (EAC) must be ruled out via transvaginal ultrasound (TVUS) and/or endometrial biopsy (EMB).

PHYSICAL EXAM
- Decrease in breast size and change in breast texture
- External, speculum, and bimanual pelvic exams: atrophic vulva and vaginal mucosa; increased risk for uterine prolapse
DIFFERENTIAL DIAGNOSIS
Pregnancy, hyperthyroidism and other thyroid disease, pituitary adenoma, Sheehan syndrome, hypothalamic dysfunction, anorexia nervosa, Asherman syndrome, obstruction of uterine outflow tract

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Lab testing for menopause is not required; the patient’s age and symptoms establish the diagnosis.
- If laboratory confirmation is desired:
  - Elevated serum FSH level >30 mIU/mL indicates ovarian failure.
  - Symptoms may precede lab changes.
  - Infertility evaluation: may use elevated day 3 FSH, decreased anti-müllerian hormone levels, and decreased antral follicle count to predict decreased ovarian reserve
- Estrogens, androgens, and oral contraceptive pills (OCPs) may alter lab results.

Follow-Up Tests & Special Considerations
- Pregnancy test
  - Perimenopausal women still need contraception. The rate of unintended pregnancy is second only to teenagers.
- TSH and prolactin level if pituitary disease is suspected
- Vaginal bleeding in a postmenopausal patient should be evaluated by TVUS and/or EMB. If endometrial stripe is <5 mm on TVUS, EAC is unlikely.
- U.S. Preventive Service Task Force (USPSTF) recommends mammogram every 2 years from ages 50 to 74 years.
- USPSTF recommends bone mineral density (BMD) screening with dual energy x-ray absorptiometry (DEXA) scan in postmenopausal women >65 years, or <65 years if the risk for fracture is equivalent to that of a 65-year-old woman (using the FRAX tool to assess, http://www.shef.ac.uk/FRAX/). Risk factors include a previous history of fractures, low body weight, cigarette smoking, and family history of osteoporotic fracture.

Test Interpretation
Abnormal BMD and DEXA scan results:
- T-score on DEXA of −1 to −2.5 = osteopenia
(green)dw8w32c&d2
T-score ≤ −2.5 = osteoporosis
Defer to femoral neck T-score over spine T-score.

TREATMENT

MEDICATION

First Line
Hormone therapy (HT): developing an individual risk–benefit profile is essential. Treatment goal is to minimize menopausal symptoms to improve quality of life.

- The primary indication for HT is the treatment of moderate to severe vasomotor symptoms.
  - Oral estrogen or estrogen-progestin mix can reduce weekly hot flush frequency ~75% (2)[A].
- HT also helpful with sleep disorders, urogenital atrophy, and lowers risk of osteoporotic fractures and colorectal cancer; may help with mood symptoms
- In women with an intact uterus, give estrogen with progestin as unopposed estrogen carries an increased risk of EAC.
- Per Endocrine Society Guidelines, patients should undergo risk stratification in regards to CVD and breast cancer before HT.
- MenoPro app is free for iPhones and iPad from The North American Menopause Society (NAMS). It has two modes: one for clinicians and one for patients to aid in shared decision making. It allows users to progress through questions to evaluate cardiovascular and reproductive organ cancer risk (3).
- Treatment regimens include, but are not limited to:
  - Standard dose: conjugated equine estrogen (CEE) 0.625 mg/day OR micronized estradiol 17β 1.0 mg/day OR transdermal estradiol 17β 0.0375 to 0.050 mg/day
- American Congress of Obstetricians and Gynecologists (ACOG) recommends HT should be individualized with lowest effect dose given for the shortest duration of time needed to relieve vasomotor symptoms. Lower doses have similar symptom reduction profiles for many patients. Results of ultra-low-dose regimens are mixed (4)[A].
- Cochrane review: Women with intolerable menopausal symptoms may wish to weigh the benefits of symptom relief against the small absolute risk of harm arising from short-term use of low-dose HT, provided they do not have
specific contraindications (5)[A].

- Although generally well tolerated, side effects of HT include breast tenderness, vaginal bleeding, bloating, and headaches.

- Precautions:
  - Women’s Health Initiative (WHI) study demonstrates that every 10,000 women who take CEE with MPA, each year, there were seven more CHD events, eight more strokes, eight more PEs, and eight more invasive breast cancers independent of mammography screening frequency. Absolute risk reductions revealed six fewer colorectal cancers and five fewer hip fractures.
  - Breast cancer risk not seen until 5 years of use
  - Cardiovascular risks not seen until after age 60 years or 10 years from menopause
  - Women on estrogen alone had no increased risk of breast cancer in the 8 years of the study and showed later cardiovascular risk compared to estrogen + progestin.
  - HT should NOT be used for cardioprotective benefit as risk outweighs benefit (5)[A].
  - Higher doses of estrogen can cause hypercoagulability, breast tenderness, gallbladder disease, and HTN.
  - Contraindications to HT:
    - Estrogen-dependent malignancies
    - Unexplained uterine bleeding
    - History of thromboembolism or stroke
    - CAD
    - Active liver disease

- For osteoporosis: Women with a history of hip or vertebral fracture or personal history of osteoporosis should be treated with one of the following:
  - Bisphosphonates to inhibit osteoclast action and resorption of bone:
    - Alendronate: 70 mg/week or 10 mg/day
    - Risedronate: 35 mg once a week or 5 mg/day
    - Zoledronic acid: 5 mg IV annually
    - Ibandronate: 150 mg/month PO or 3 mg IV q3mo
  - Selective estrogen receptor modulators (SERMs) selectively inhibit or stimulate estrogen-like action with stimulation of osteoblasts:
    - Raloxifene: 60 mg/day
      - Decreases the risk of vertebral fracture
    - Bazedoxifene + conjugated estrogens (0.45 mg/20 mg)
      - FDA-approved for moderate to severe vasomotor symptoms and
osteoporosis
- Denosumab (60 mg SC every 6 months) is a monoclonal antibody that prevents RANKL (receptor activator of nuclear factor kappa-B ligand) from accelerating osteoclast generation; reduces incidence of vertebral and hip fractures in postmenopausal women
- Parathyroid hormone—rarely used due to the adverse effect on bone but shown to reduce fracture risk in menopausal women with osteoporosis

For vulvar/vaginal atrophy:
- Topical estrogen therapy (ET) reverses vaginal atrophy, enhances blood flow, and reduces UTI. Continue for as long as distressing symptoms remain. Initiate treatment daily for 1 to 2 weeks and then decreased to 2 times weekly. Comes as estradiol cream, tablet, or ring. Apply vaginally:
  - Estradiol cream 0.01% (1 g), conjugated estrogen 0.625 mg/g (0.5 g), vaginal tablet (10 μg) used twice weekly, or vaginal ring (7.5 μg daily lasting for 3 months)
  - Ospemifene: 60 mg PO daily. SERM for moderate to severe dyspareunia associated with vaginal atrophy

Although there is no increased risk of endometrial hyperplasia or EAC, women with bleeding on these treatments should be evaluated with TVUS or EMB. Patients with h/o hormone-dependent cancer should meet with a gynecologist before using medication.

**Second Line**
Nonhormonal treatments may be helpful to treat vasomotor symptoms in women who wish to or need to avoid HT (e.g., breast cancer):
- Paroxetine (7.5 mg/day) is approved for treatment of vasomotor symptoms. This SSRI demonstrated modest decrease in hot flushes.
- Other SSRI/SRNIs: Venlafaxine (37.5 to 75 mg/day) or fluoxetine (20 mg/day) and citalopram (20 mg/day) shown to reduce hot flushes as compared to placebo.
- Gabapentin (300 to 900 mg/day) shown to have an effect on lowering hot flushes compared to placebo.
- Clonidine (0.05 mg BID) may be used to treat mild hot flashes, less effective than SSRI/SRNIs.
- Note that most trials of second-line therapies have been brief (i.e., a few months).

**COMPLEMENTARY & ALTERNATIVE**
MEDICINE
Trials of nonprescribed therapies are difficult to interpret due to variability of components and doses:

- Soy isoflavone in placebo-controlled trials showed a mixed effect in reducing hot flashes.
- Red clover, black cohosh, reflexology, aerobics, and magnet therapy showed no impact on hot flashes when compared with placebo.
- Small clinical trials of evening primrose, dong quai, ginseng, and wild yam do not support use for relief of hot flashes.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
A DEXA scan is indicated at age 65 years for all women and for younger women with risk equivalent to age 65 years.

DIET
Calcium-rich diet and vitamin D supplementation. Calcium supplements may have adverse effects including increased risk of kidney stone and increased risk of cardiac events.

PATIENT EDUCATION
Encourage lifestyle modifications:

- Smoking cessation, reducing alcohol intake
- Weight-bearing exercise >30 minutes, 3 times weekly
- Healthy diet to maintain appropriate weight
- Address cardiovascular risk factor modification.

PROGNOSIS
If untreated:

- Vasomotor symptoms may persist up to 10 years for most women.
- Worsening of vaginal/vulvar atrophy
- Osteoporosis: possible fractures of the hip, vertebrae, and wrists
COMPLICATIONS

- Osteoporosis: At menopause, women have accelerated bone loss up to 3–5% per year for 5 to 7 years.
- Increased risk of CVD following menopause

REFERENCES

ADDITIONAL READING

CODES

ICD10
- E28.310 Symptomatic premature menopause
- N95.1 Menopausal and female climacteric states
- Z78.0 Asymptomatic menopausal state

CLINICAL PEARLS
- Menopause is usually diagnosed by history alone.
- HT can be used short term for relief of moderate to severe vasomotor symptoms but should not be used for long-term prevention of CVD.
MENORRHAGIA (HEAVY MENSTRUAL BLEEDING)
Miguel A. Palacios, MD • Maizal Cuauhtemoc Rivera, FNP

BASICS

DESCRIPTION

- The current preferred terminology for menorrhagia is “heavy menstrual bleeding” (HMB).
- HMB is an excessive amount (≥80 mL/cycle, compared with normal average of 30 to 60 mL/cycle) or periods lasting longer than 7 days.
- Clinically, HMB is an excessive menstrual blood loss which interferes with the woman’s physical, emotional, social, and material quality of life.
- Other patterns of AUB which may overlap with HMB include:
  - Intermenstrual bleeding (IMB; previously metrorrhagia): bleeding between regular menses
  - Polymenorrhea: menstrual cycle length <21 days
- HMB applies only to ovulatory menses and is a subcategory of “abnormal uterine bleeding” (AUB).
- A classification system called the PALM-COEIN was developed to describe AUB in women of reproductive age.
- It includes the structural causes (polyp, adenomyosis, leiomyoma [submucosal or other myoma], and malignancy and hyperplasia) and nonstructural causes (coagulopathy, ovulatory dysfunction, endometrial, Iatrogenic, and not yet classified).
- System affected: reproductive

EPIDEMIOLOGY

Prevalence

- HMB affects >10 million American women each year or about one out of every five women (1).
- Puberty and the perimenopause typically are associated with AUB and are considered to be physiologic in these circumstances (2).
**Pediatric Considerations**
- Genital bleeding before puberty is not menstrual bleeding by definition and requires further evaluation.
- Due to immaturity of the hypothalamic-pituitary-ovarian axis, adolescents are at risk of irregular bleeding and HMB.
- Adolescents with HMB should be evaluated for possible bleeding disorders, especially von Willebrand disease (3)[C].

**Pregnancy Considerations**
Bleeding in pregnancy is not menstrual bleeding by definition and requires further evaluation. Pregnancy test should be obtained as part of the evaluation of AUB.

**Geriatric Considerations**
Menopause is diagnosed after 12 months of amenorrhea in the absence of other causes and is typically preceded by irregular bleeding. All postmenopausal bleeding requires additional workup for malignancy.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- No cause is identified in about 1/2 of patients.
- Bleeding disorders
  - Von Willebrand disease
  - ITP and other platelet disorders
  - Factor deficiencies
  - Medication side effect most commonly related to anticoagulants including warfarin
  - Renal failure leading to uremic platelet dysfunction
  - Cirrhosis leading to coagulopathy
- Uterine fibroids, typically submucosal
- Endometrial polyps
- Hypothyroidism
- Iatrogenic causes including copper intrauterine device (IUD)
- Endometriosis
- Adenomyosis
- Pelvic inflammatory disease
- Some causes more typically presenting as irregular menstrual bleeding include:
  - Polycystic ovarian syndrome (PCOS)
– Hypothalamic-pituitary dysfunction, often postmenarchal or during menopausal transition
– Endometrial or ovarian neoplasia
– Some forms of hormonal birth control
– Hyperthyroidism
– Hyperprolactinemia

HMB has been associated with increased production and sensitivity to prostaglandins.

**GENERAL PREVENTION**

- Combined oral contraceptives may prevent HMB, particularly when progesterone is dominant. Lower estrogen doses result in less menstrual bleeding.
- NSAIDs including ibuprofen inhibit prostaglandin production and result in decreased blood loss and pain during menses.
- Progesterone-only contraceptives may reduce overall blood loss but often result in irregular bleeding.

**COMMONLY ASSOCIATED CONDITIONS**

Iron deficiency anemia

**DIAGNOSIS**

**HISTORY**

- Suggestive historical features for HMB:
  – Bleeding substantially heavier than patient’s usual flow
  – Changing sanitary products every 1 to 2 hours or the need to change protection overnight
  – Menses lasting >7 days
  – Passage of clots larger than a quarter in diameter
- Symptoms that suggest bleeding is ovulatory:
  – Regular menstrual interval
  – Midcycle pain (mittelschmerz)
  – Premenstrual symptoms: breast soreness, mood changes
- Abdominal pain or cramps at other times of the cycle may be associated with structural causes:
  – Polyps
– Adenomyosis
– Leiomyoma
– Ovarian tumors
• Symptoms that suggest an underlying bleeding disorder include:
  – Epistaxis
  – Mucosal bleeding (e.g., gums)
  – Easy bruising
  – Family history of bleeding disorder
• Review of medications, with particular attention to contraceptive and anticoagulant medication
• Other medical conditions that may relate to HMB:
  – Renal or hepatic disease
  – Thyroid disease
• Evaluate for symptoms of anemia including fatigue and dyspnea.

PHYSICAL EXAM
• Prompt assessment for signs of hemodynamic instability, including orthostatic vital signs (4)
• Thyroid nodule or goiter suggests thyroid disease.
• Signs of a bleeding disorder include petechiae and ecchymoses.
• Pelvic examination, including speculum and bimanual examination, may reveal the following:
  – Cervical or vaginal source of bleeding
  – Pelvic or adnexal mass
  – Evidence of reproductive tract infection such as cervical motion tenderness
  – Uterine enlargement
• Hirsutism, acne, and obesity are suggestive of PCOS.

DIFFERENTIAL DIAGNOSIS
• Normal menses
• Anovulatory bleeding
• IMB
• Complications of pregnancy
  – Spontaneous abortion
• Other sources of bleeding:
  – Cervical
  – Vaginal
  – Gastrointestinal
**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Pregnancy test
- CBC to assess for:
  - Anemia
  - Thrombocytopenia
  - Leukocytosis may suggest infection.
- Thyroid-stimulating hormone (TSH) test (2)[B]

**Labs to consider in select cases:**

- Coagulation panel for evaluation for bleeding disorder in adolescent or adult with history suggestive of bleeding disorder (2)[A]
- Workup of anovulatory bleeding may also include prolactin, androgens, FSH, LH, and estrogen.
- Appropriate cervical cancer screening
- Evaluation for infection including gonorrhea and chlamydia (2)[B]

**Imaging should be obtained based on clinician judgment and should begin with transvaginal ultrasonography.**

**Transabdominal ultrasonography should be performed if transvaginal approach does not provide full assessment of anatomy.**

**Some experts recommend transvaginal ultrasonography as the initial screening test for AUB and MRI as a second-line test to be used when the diagnosis is inconclusive, when further delineation would affect patient management, or when coexisting uterine myomas are suspected (2)[C].**

**Endometrial biopsy should be performed in patients with AUB who are >45 years as a first-line test (2)[C].**

**Follow-Up Tests & Special Considerations**

- Saline infusion sonohysterography is recommended if ultrasound suggests intracavitary pathology and is more sensitive and specific than transvaginal ultrasound (2)[C].
  - Sonohysterography is superior to transvaginal ultrasonography in the detection of intracavitary lesions, such as polyps and submucosal leiomyomas (2)[A].
- Hysteroscopy can be performed if direct visualization is desired.

**Diagnostic Procedures/Other**

Endometrial biopsy to assess for malignancy and hyperplasia is recommended in
some situations including (2,4)[C]:
- Any AUB, including HMB, after age 45 years in an ovulatory (premenopausal) woman
- Woman <45 years with persistent or refractory AUB, risk factors such as unopposed estrogen exposure, or concerning endometrial imaging

**TREATMENT**

**GENERAL MEASURES**

Treat underlying conditions (e.g., hypothyroidism) when possible.

**MEDICATION**

**First Line**
- For acute control of severe bleeding (5):
  - Obtain IV access and consider blood transfusion or clotting factor administration.
  - Estrogen, conjugated equine: 25 mg IV every 4 to 6 hours for 24 hours
  - Monophasic combined oral contraceptive that contains 35 μg ethinyl estradiol: 3 times per day for 7 days
  - Medroxyprogesterone acetate: 20 mg orally 3 times per day for 7 days
  - Tranexamic acid: 1.3 g orally or 10 mg/kg IV 3 times per day for 5 days, antifibrinolytic agent
- For less severe bleeding (typical case) or after control of acute bleeding has been achieved (5):
  - Levonorgestrel IUD (Mirena IUD): typically results in light bleeding or amenorrhea with patient satisfaction similar to hysterectomy and endometrial ablation (6)[A]
  - Combination estrogen-progestin oral contraceptive: may be prescribed in cyclic, extended, or continuous dosing and typically results in regular, lighter, and less painful menses
  - Depot medroxyprogesterone acetate: 150 mg/1 mL IM every 3 months, typically results in amenorrhea or light irregular bleeding
  - Tranexamic acid: 1.3 g orally for 5 days during menses; antifibrinolytic agent that is option for women who desire nonhormonal treatment
  - NSAIDs (e.g., naproxen, mefenamic acid, ibuprofen) can reduce blood loss and dysmenorrhea. Those with bleeding disorders or platelet function
abnormalities should avoid NSAIDs (5).

**Second Line**
- Noncontraception estrogen-progestin oral contraceptives (ultra-low-dose estrogen): may be considered when a relative contraindication to estrogen is present
- Oral progestins: multiple formulations and dosing; typically used in women who have contraindications to estrogen or are trying to conceive

**SURGERY/OTHER PROCEDURES**
- Dilation and curettage can be considered in the setting of acute severe bleeding.
- For women who desire fertility, myomectomy may be considered for treatment of uterine leiomyomas (fibroids).
- For women who do not desire fertility, consider endometrial ablation, uterine artery embolization, or hysterectomy.

---

- Patients that undergo endometrial ablation still require contraception.
- Uterine artery embolization is used to treat uterine leiomyomas.
- In women of reproductive age with chronic HMB, hysterectomy is the most effective treatment for controlling symptoms (1).
  - Hysterectomy is curative but with more severe adverse effects and is typically reserved for failure of medical management or presence of another indication such as malignancy (1).

---

**ONGOING CARE**

**DIET**
Iron supplementation may help correct for increased blood loss.

**PATIENT EDUCATION**
Patient and provider should engage in informed decision making with understanding of treatment risks and benefits.
PROGNOSIS
Most patients respond well to medical management, and surgical interventions are curative options in appropriate cases. Surgical interventions (hysterectomy or conservative surgeries) are initially more effective and satisfactory than medical treatments, but that the levonorgestrel-releasing intrauterine system yields similar long-term results and patient satisfaction compared with conservative surgical interventions (1).

COMPLICATIONS
- Iron deficiency anemia
- Acute severe blood loss

REFERENCES

CODES
ICD10
- N92.0 Excessive and frequent menstruation with regular cycle
- N92.3 Ovulation bleeding
N92.2 Excessive menstruation at puberty

**CLINICAL PEARLS**

- Women with HMB are at high risk for iron deficiency anemia.
- A thorough menstrual history is critical to differentiate HMB from similar conditions including anovulatory bleeding.
- Teenagers presenting with HMB should be evaluated for an underlying bleeding disorder.
- All postmenopausal bleeding and bleeding during pregnancy requires additional workup.
- The levonorgestrel (Mirena, Kyleena, generics) IUD may be used for HMB and is associated with high patient satisfaction rates.
MESOTHELIOMA

Khalid Bashir, MD

BASICS

DESCRIPTION

- Mesothelioma is a rare, aggressive malignancy of the mesothelial or serous tissues primarily found in the pleura (65–70%) or peritoneum (20–33%), tunica vaginalis (1–2%) or pericardium (1–2%) (1).
- Inhalation of asbestos is the predominant cause of mesothelioma, most often from occupational exposure.

EPIDEMIOLOGY

Incidence

- The incidence in the United States is decreasing, but it is increasing in other countries, particularly Great Britain and Australia.
- It is expected that rates of mesothelioma will start to drop after 2015 to 2025 related to reduced exposure and better understanding of the process of development of mesothelioma after exposure to asbestos (2).
- The incidence increases with age, peaking in the 6th decade, with 70% of pleural disease occurring in males. Peritoneal involvement is slightly higher in women.
- Main risk factor is asbestos exposure, but tumors have arisen after prior radiation or exposure to talc, erionite, or mica or in patients with familial Mediterranean fever and diffuse lymphocytic leukemia.

Prevalence

There are 3,300 cases of mesothelioma diagnosed in the United States annually (3).

ETIOLOGY AND PATHOPHYSIOLOGY

- The predominant cause of mesothelioma is exposure to asbestos (hydrated magnesium silicate fibrous minerals).
- There is a long latent period of up to 44 years between exposure and development of mesothelioma (2).
- Inhaled or ingested asbestos fibers become trapped in pleural or peritoneal
membranes causing changes of irritation and inflammation.

**Genetics**
Loss of nuclear deubiquitinase BAP1 is associated with incidence of mesothelioma in some families as well as with other cancers such as melanoma.

**RISK FACTORS**
- The predominant risk factor is exposure to asbestos.
- Occupational exposures involve mining or milling of fibers, work with textiles, cement, friction materials, insulation, or shipbuilding.
- Nonoccupational exposures include renovation or destruction of asbestos-containing buildings, exposure to industrial sources in the community or natural geologic sources, or exposure to soiled clothing of asbestos workers (1,3,4).
- Radiation exposure, smoking, proximity to naturally occurring asbestos deposits, or inhalation of other fibrous silicates can contribute to malignant mesothelioma.

**GENERAL PREVENTION**
- Avoidance of asbestos exposure
- Strict adherence to protective protocols for workers in buildings where asbestos is found
- Continued aggressive remediation of asbestos-affected buildings and homes

**DIAGNOSIS**

**HISTORY**
- Symptoms are usually nonspecific and occur when disease is advanced. General fatigue, night sweats, and weight loss may be present.
- Pleural mesothelioma presents with gradual onset of pulmonary symptoms, chest pain, dyspnea, and cough.
- Peritoneal disease presents with vague abdominal pain, increased abdominal girth, nausea, anorexia, and weight loss.

**PHYSICAL EXAM**
- Pulmonary findings consistent with pleural effusion including decreased breath sounds, dullness to percussion, asymmetric chest wall expansion are
Abdominal findings consistent with ascites including abdominal distension, fluid wave, and tenderness are found.

**DIFFERENTIAL DIAGNOSIS**

- Pleural mesothelioma’s differential diagnosis includes inflammatory reactions (empyema, pleural effusion), metastatic tumor from other sites, fibrosarcoma, malignant fibrous histiocytoma, sarcomatoid carcinoma, and synovial sarcoma.
- Peritoneal mesothelioma’s differential diagnosis includes peritoneal carcinomatosis, serous peritoneal carcinoma, ovarian carcinoma in women, lymphomatosis, and tuberculous peritonitis.

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- At present, there is no tumor marker or serum chemistry that is of value in establishing the diagnosis of mesothelioma.
- Biomarkers that may be elevated in mesothelioma include fibulin-3, mesothelin, and osteopontin. However, they do not have an established role in diagnosis or monitoring response to therapy (2)[A].
- Pleural mesothelioma diagnosis requires tissue. Thoracentesis for cytology and closed pleural biopsy may be adequate, but often, more invasive procedures such as video-assisted thoracoscopic surgery (VATS) is needed to obtain an adequate specimen (1,2)[A].

*Follow-Up Tests & Special Considerations*

Seeding of biopsy sites and tracks may occur in mesothelioma, which can be prevented with prophylactic radiation therapy to the scar or biopsy site (5)[A].

*Diagnostic Procedures/Other*

- CT, MRI, PET, or integrated PET-CT helps with clinical staging in pleural and peritoneal disease (1–4),(5)[A].
- Mediastinoscopy, bronchoscopy, and laparoscopy can assist in full surgical staging of pleural disease (2)[A].
- Endobronchial ultrasound for staging is under investigation for pleural disease.

*Test Interpretation*
The tumor, node, metastasis (TNM) staging system is most commonly used although some centers use other staging systems. Butchart staging system is the oldest and still used in some parts of the world. Brigham staging system attempts to define resectability and lymph node involvement.

**TREATMENT**

**GENERAL MEASURES**

- A multidisciplinary team is important in management and should include thoracic surgery, oncology, pathology, pulmonary, and radiology for patient-specific planning of management.
- Pain assessment and control should follow principles of cancer pain management (5).

**MEDICATION**

**First Line**

- In pleural disease, combined therapy with cisplatin + gemcitabine or cisplatin + pemetrexed are associated with longer median survival than cisplatin alone (2),(4)[A].
- Vinflunine is showing some potential for first-line treatment in pleural disease (2)[A].
- Hyperthermic intraoperative or early postoperative intraperitoneal chemotherapy can increase drug concentration in the peritoneum and decrease systemic side effects. Use cisplatin, mitomycin C, fluorouracil, doxorubicin, and/or paclitaxel (1,2),(3)[A].

**Second Line**

- Palliative benefit in pleural disease with mitomycin C, vinblastine, cisplatin, and pemetrexed alone or in combination with carboplatin (2,3),(4)[A]
- Systemic therapy for peritoneal disease may include pemetrexed + cisplatin; vinorelbine or gemcitabine alone or in combination (1),(5)[A]

**ISSUES FOR REFERRAL**

- Pulmonary, oncology, and surgical follow-up after discharge as indicated
- Anger and depression may require psychological or psychiatric services (5).
ADDITIONAL THERAPIES
Immunotherapy in pleural disease uses humanized anti-CB3 AB (OKT3), cytotoxic T lymph (CTL), interferon α-2a, and autovaccine in advanced disease (1–5).
- Gene therapy
- Photodynamic therapy
- Radiotherapy in some cases of pleural disease
- Vascular endothelial growth factor (anti-VEGF-2) in combination with chemotherapy (2)
  - Vaccines are under study (5).

SURGERY/OTHER PROCEDURES
- For pleural mesothelioma, the role of surgery is not as clear cut. Pleurectomy with tumor decortication and extrapleural pneumonectomy reduce the tumor load, but there remains no clear effect on mortality (2,4,5).
- Radical resection of the peritoneum and cytoreductive surgery is associated with a better prognosis (1).

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Based on overall condition
- IV fluids as indicated by general condition
- Nursing as indicated by condition
- Discharge criteria as indicated by general condition

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Smoking cessation
- Immunization for pneumococcal pneumonia and influenza

Patient Monitoring
Monitor for paraneoplastic phenomenon including fever, thrombocytosis, malignancy-related thrombosis, hypoglycemia, and rare Coombs-positive hemolytic anemia.
DIET
No specific restrictions

PROGNOSIS
- Prognosis is based on gender, stage, and level of completeness of cytoreduction.
- Poorly differentiated tumor grade, failure to undertake surgical resection, advanced age, and male gender are all independent predictors of poorer prognosis (2,3).
- Average survival is 17 to 92 months, with 5-year survival rate at 63%.

COMPLICATIONS
Relapses and progression, infection and dysphagia

Geriatric Considerations
Age >65 years is associated with significantly increased morbidity and mortality.

Pediatric Considerations
Rarely a pediatric issue, as most disease occurs after the 5th decade of life

Pregnancy Considerations
Rarely an issue with pregnancy, as most disease occurs after the 5th decade of life

REFERENCES

CODES
ICD10
- C45.9 Mesothelioma, unspecified
- C45.0 Mesothelioma of pleura
- C45.1 Mesothelioma of peritoneum

CLINICAL PEARLS
- Mesothelioma remains a rare but universally fatal disease in part due to long latency.
- Multimodal treatment has decreased recurrence rates and has extended survival time.
- Main risk factor is asbestos exposure, but tumors have arisen after prior radiation or exposure to talc, erionite, or mica or in patients with familial Mediterranean fever and diffuse lymphocytic leukemia.
METABOLIC SYNDROME
Naomi Parrella, MD, FAAFP

BASICS
DESCRIPTION
- Progressive metabolic abnormalities including insulin resistance, a proinflammatory and prothrombotic state that manifest with at least three of:
  - Increased waist circumference (WC)
  - Elevated blood pressure (BP)
  - Elevated triglycerides (TG)
  - Decreased high-density lipoprotein (HDL-C)
  - Elevated fasting glucose
- Metabolic syndrome (MetS) predicts increased risk for type 2 diabetes mellitus (T2DM), cardiovascular disease, stroke, nonalcoholic fatty liver disease (NAFLD), certain cancers, and all-cause mortality.

EPIDEMIOLOGY
Prevalence
- Affects 34.2% of U.S. adults aged ≥18 years; increasing with the aging population and the prevalence of obesity (1)
- MetS is a rapidly growing epidemic worldwide. From 1988 to 2012, prevalence of MetS in the United States had the largest increase in non-Hispanic black men, non-Hispanic white women, non-Hispanic black women, and persons of low socioeconomic status (1).
- Predominant sex: female (34.9%) > male (33.4%) (1)
- Prevalence increases with age with >50% of person >70 years old with MetS (1).
- Predominant ethnicity: non-Hispanic white men and women and non-Hispanic black women (1)

Pediatric Considerations
- Obese children and adolescents are at high risk of MetS (prevalence of 6.4% in the United States). Risk factors in children and adolescents include heredity, low birth weight, childhood weight gain and obesity, endocrine abnormalities, hostility, maternal gestational diabetes, and poor health habits.
International Diabetes Federation consensus report defined criteria in three age groups (6 to ≤10 years; 10 to ≤16 years; 16+ years, adult criteria applicable). Obesity defined by WC ≥90th percentile; rest of the diagnostic criteria (TG, HDL-C, hypertension [HTN], and fasting blood sugar/T2DM) are largely the same as in adults for children ≥10 years, with some exceptions, and warrant treatment to optimize diet and physical activity.

Clinical significance of MetS in pediatric population is not well established using these criteria. WC alone is better than using IDF criteria to predict development of MetS, abnormal BP, dyslipidemia, and insulin resistance (2). Focus on promoting healthy lifestyle habits and weight management rather than diagnosis.

ETIOLOGY AND PATHOPHYSIOLOGY

- Increase in intra-abdominal and visceral adipose tissue
- Adipose tissue dysfunction, insulin resistance, and leptin resistance
- Decreased levels of adiponectin, an adipocytokine, known to protect against T2DM, HTN, atherosclerosis, and inflammation
- Abnormal fatty acid metabolism, endothelial dysfunction, systemic inflammation (increased IL-6, tumor necrosis factor-α [TNF-α], resistin, CRP) oxidative stress, elevated renin-angiotensin system activation, and a prothrombotic state (increased tissue plasminogen activator inhibitor-1) are also associated.

The main etiologic factors are the following:
- Central obesity (particularly abdominal)/excess visceral adipose tissue
- Insulin resistance
- Other contributing factors:
  - Advancing age
  - Proinflammatory state
  - Genetics
  - Sedentary lifestyle

- Endocrine (e.g., postmenopausal state)
- Prescription medications (e.g., corticosteroids, antipsychotics, β-blockers)

**Genetics**

Genetic factors contribute to causation. Most identified genes are transcription factors or regulators of transcription and translation. It is a multifactorial disease with evidence of complex interactions between genetics and environment.
RISK FACTORS
- Obesity/intra-abdominal obesity
- Childhood obesity
- Insulin resistance
- Older age
- Ethnicity
- Family history
- Physical inactivity
- High-carbohydrate diet
- Sugar-sweetened beverages daily
- Smoking
- Postmenopausal status
- Low socioeconomic status
- Alteration of gut flora

GENERAL PREVENTION
- Effective weight loss and maintenance of normal body weight long term
- Built environment to promote healthy lifestyle choices
- Regular and sustained physical activity
- Diet low in processed carbohydrates and simple sugars; avoidance of sugar-sweetened beverages

COMMONLY ASSOCIATED CONDITIONS
- Polycystic ovary syndrome
- NAFLD
- Acanthosis nigricans
- Chronic renal disease
- Depression
- Cognitive impairment
- Obstructive sleep apnea
- Gallstones (cholesterol)
- Erectile dysfunction
- Hyperuricemia and gout
- Vitamin D deficiency
- Subclinical hypothyroidism
**DIAGNOSIS**

**HISTORY**

Not necessary for diagnosis of MetS; useful in identifying risk factors and beneficial preventive strategies

- Family history of MetS, T2DM, and cardiovascular disease
- Symptoms indicating cardiovascular disease or diabetes
- Comprehensive lifestyle history:
  - Diet, including timing and intake of carbohydrates especially added sugars
  - Weight history, including onset of obesity and previous weight loss attempts
  - Exercise regimen, daily activity level
  - Alcohol intake
  - Sleep patterns, duration, and quality
- Cigarette smoking

**PHYSICAL EXAM**

Various criteria-based definitions have been proposed and in 2009, harmonized (3). A diagnosis of MetS can be made when ≥3 of the following 5 characteristics are present:

- Abdominal obesity: men >102 cm, women >88 cm (ATP III recommends lowering threshold in population susceptible to insulin resistance, especially Asian Americans)
- BP ≥130/85 mm Hg or treatment
- TGs ≥150 mg/dL or treatment
- HDL: men >40 mg/dL, women <50 mg/dL or treatment
- Fasting glucose ≥100 mg/dL or treatment

**DIFFERENTIAL DIAGNOSIS**

- T2DM
- Obstructive sleep apnea, thyroid abnormalities, Cushing syndrome, medication effect (especially psychotropic, chronic steroids, β-blockers, and thiazide diuretic medications) may also be considered in the differential.

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- Fasting lipids (particularly TGs and HDL)
Fasting glucose

**Follow-Up Tests & Special Considerations**

- Formal 75-mg oral glucose tolerance test or hemoglobin A1C for diagnosis of impaired glucose tolerance (IGT) or chronically elevated blood glucose
- Liver function tests (assess for NAFLD, consider use of statin)
- Measurement of fasting insulin levels is controversial.
- Microalbuminuria
- Increased WBC count
- Increased C-reactive protein
- Increased fibrinogen
- Increased proinflammatory cytokines (e.g., TNF-α)
- Increased uric acid
- Increased homocysteine
- Vitamin D deficiency

**Diagnostic Procedures/Other**

- Home BP monitoring or 24-hour BP monitoring may be used to rule out white coat HTN.
- ECG, stress test, and coronary angiography may be used for diagnosis of cardiovascular disease arising as a complication of the syndrome.
- Ultrasound of liver may be considered to evaluate for fatty liver.

**TREATMENT**

Primary therapeutic goal is to prevent or reduce obesity and risk factors. Aggressive lifestyle modification (diet and exercise) is considered first-line therapy and most clinically effective (4)[C].

**GENERAL MEASURES**

- Aggressive treatment of individual risk factors
- Increase daily physical activity.
- Stop smoking.
- Avoid excess alcohol intake.
- Avoid sugar sweetened beverages.
- Avoid high glycemic load meals and snacks that cause rapid insulin release.
- Increase leafy green vegetables.
- Maintain healthy sleep patterns and stress management.
MEDICATION

- Consider daily aspirin for patients with cardiovascular disease or those at high risk.
- Consult clinical guidelines for treatment of dyslipidemia, HTN, IGT, prediabetes, and diabetes.
- Multiple medications may be required to achieve adequate BP control.
- Diagnosis and treatment of insulin resistance is controversial.

First Line

Lifestyle modification alone as initial strategy is applicable to individuals with low 10-year risk for coronary artery disease (CAD). In individuals with higher 10-year risk, more aggressive risk factor–based approach is recommended in addition to lifestyle modifications:

- Obesity: Lifestyle changes are the cornerstone of treatment. Aim for a ~5–10% weight reduction. Any amount of weight loss is associated with significant benefits. See section on “Obesity.”

  Physical activity: Endurance exercise may reverse MetS (5)[A]. 30 to 60 minutes of moderate-intensity aerobic activities such as brisk walking 5 to 7 days/week; increase in daily lifestyle activities and resistance training 1 to 2 days/week. In patients with established CAD, assess detailed history of physical activity and exercise tolerance to guide activity prescription. Advise medically supervised programs for high-risk population (recent acute coronary syndrome [ACS], congestive heart failure, recent revascularization). Cumulative exercise time over the day contributes to health benefit.

- Tobacco use: See section on “Smoking Cessation.”

- Dyslipidemia: Drug therapy can be commenced after 6 weeks of lifestyle modification. See section on “Dyslipidemia.”

- HTN: Aim for similar targets to patients with diabetes. See section on “Hypertension.” β-Blockers may lead to weight gain and worsen MetS.

- IGT and/or prediabetes: Intensive lifestyle interventions (ILI) to decrease the development of diabetes. Metformin (875 mg twice daily), although less efficacious than ILI, has also been demonstrated to decrease the incidence of diabetes in patients with MetS (6)[A] GLP-1 receptor agonists. If CAD or T2DM is already evident, treat as per guidelines. Use ASA 81 mg for primary prevention as indicated per USPSTF if benefits outweigh bleeding risk.

ISSUES FOR REFERRAL

- Obesity management
Nutrition therapy
Exercise planning
Smoking cessation
Cardiovascular disease
Suspected obstructive sleep apnea
Weight-related mental health concerns (e.g., binge eating disorder)

SURGERY/OTHER PROCEDURES
- Bariatric surgery can treat MetS in severely obese patients who have failed trials of lifestyle modification and pharmacotherapy; surgery is recommended in appropriate individual if body mass index (BMI) >40 or BMI >35 with obesity-related comorbidities.
- Liposuction of abdominal adipose tissue does not reduce insulin resistance or cardiovascular risk factors.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Fish oils and plant sterol esters may be used for cardioprotective effects. Insufficient evidence on the use of cinnamon for improved insulin sensitivity.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Management usually does not require admission.
- Admission criteria/initial stabilization
  - Serious complications (e.g., ACS, hypertensive crisis, diabetic coma)

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Regular exercise will improve all components of the MetS. Cumulative small periods of exercise over the day provide significant health benefits. Encourage small increases in physical activity over time.
- Encourage replacing sedentary activity choices (e.g., sitting at desk, driving car, taking elevator, and the like) to more active ones (e.g., standing desk, walking, cycling, stationary walking during commercials).
- Weight reduction to correct abdominal obesity is a primary goal achieved by
dietary modification and increased physical activity.

- Regular monitoring of weight, WC, and BP. Fasting lipids and sugar levels should be checked at least annually.

**DIET**

- Dietary recommendations may include limiting simple carbohydrates in diet especially at breakfast, eating a Mediterranean, or DASH (Dietary Approaches to Stop Hypertension) diet.
- Increased consumption of leafy green vegetables may decrease risk of developing T2DM [7][A]. Encourage increasing intake of vegetables and fiber and keep fruit and alcohol in moderation.
- Avoid fruit juice and sugar-sweetened beverages.

**PROGNOSIS**

Increased risk of T2DM (~5-fold), CAD (~1.5- to 3-fold), acute myocardial infarction (~2.5-fold), and all-cause mortality (~1.5-fold)

**COMPLICATIONS**

Long-term complications are primarily CAD and T2DM. Recent evidence demonstrates an increased risk of NAFLD, stroke, chronic kidney disease, cognitive decline, and an increased risk of developing certain cancers, especially breast cancer in postmenopausal women.

**REFERENCES**

**CODES**

**ICD10**

E88.81 Metabolic syndrome

**CLINICAL PEARLS**

- Routine WC should be measured as part of a cardiovascular risk assessment.
- Consider further evaluation for MetS when history and/or physical exam demonstrates findings consistent with sedentary lifestyle, sleep apnea, increasing WC, elevation of BP or treatment, evidence of insulin resistance, or abnormal screening labs or treatment for lipids or blood glucose.
- Recognizing MetS in the clinic can help prioritize treatment goals and guidance to work to reduce associated risk factors.
- Prevention or reduction of obesity and cardiovascular risk factors is the cornerstone of management of MetS.
- Consider alternatives for medications known to increase risk of MetS such as atypical antipsychotic medications and chronic steroids.
- In addition to regular 30- to 60-minute exercise regimen, there is significant benefit to increasing cumulative physical activity over the day.
- Aggressive lifelong lifestyle modification is the first-line and most potent treatment for all patients.
METATARSALGIA

Michael Y. Yang, MD • Marc W. McKenna, MD

BASICS

DESCRIPTION

- Metatarsalgia is a generic term referring to pain in the forefoot in the region of the metatarsal heads.
- System affected: musculoskeletal

EPIDEMIOLOGY

Incidence

Especially common in athletes engaging in high-impact sports (running, jumping, dancing), in rock climbers (12.5%), and in older active adults

Prevalence

Common

ETIOLOGY AND PATHOPHYSIOLOGY

- The 1st metatarsal head bears significant weight when walking or running. A normal metatarsal arch ensures this balance. The 1st metatarsal head normally has adequate padding to accommodate increased forces.
- Reactive tissue can build a callus around the metatarsal head, compounding the pain.
  - Excessive or repetitive stress. Forces are transmitted to the forefoot during several stages (midstance and push-off) of walking and running. These forces are translated across the metatarsal heads at nearly three times the body weight (1)[C].
  - A pronated splayfoot disturbs this balance, causing equal weight bearing on all metatarsal heads.
  - Any foot deformity changes distribution of weight, impacting areas of the foot that do not have sufficient padding.
  - Soft tissue dysfunction: intrinsic muscle weakness, laxity in the Lisfranc ligament
  - Abnormal foot posture: forefoot varus or valgus, cavus or equinus deformities, loss of the metatarsal arch, splayfoot, pronated foot,
inappropriate footwear
- Dermatologic: warts, calluses (2)[C]
- Great toe
  - Hallux valgus (bunion), either varus or rigidus
- Lesser metatarsals
  - Freiberg infraction (i.e., aseptic necrosis of the metatarsal head usually due to trauma in adolescents who jump or sprint)
  - Hammer toe or claw toe
  - Morton syndrome (i.e., long 2nd metatarsal)

RISK FACTORS
- Obesity
- High heels, narrow shoes, or overly tight-fitting shoes (rock climbers typically wear small shoes)
- Competitive athletes in weight-bearing sports (e.g., ballet, basketball, running, soccer, baseball, football)
- Foot deformities or changes in ROM (e.g., pes planus, pes cavus, tight Achilles tendon, tarsal tunnel syndrome, hallux valgus, prominent metatarsal heads, excessive pronation, hammer toe deformity, tight toe extensors) (2)[C]

Geriatric Considerations
- Concomitant arthritis
- Metatarsalgia is common in older athletes.
- Age-related atrophy of the metatarsal fat pad may increase the risk for metatarsalgia.

Pediatric Considerations
- Muscle imbalance disorders (e.g., Duchenne muscular dystrophy) cause foot deformities in children.
- In adolescent girls, consider Freiberg infraction.
- Salter I injuries may affect subsequent growth and healing of the epiphysis.

Pregnancy Considerations
- Forefoot pain during pregnancy usually results from change in gait, center of mass, and joint laxity.
- Wear properly fitted, low-heeled shoes.

GENERAL PREVENTION
- Wear properly fitted shoes with good padding.
- Start weight-bearing exercise programs gradually.

COMMONLY ASSOCIATED CONDITIONS
- Arthritis
- Morton neuroma
- Sesamoiditis
- Plantar keratosis–callous formation

DIAGNOSIS

HISTORY
- Pain gradually develops and persists over the heads of one or more metatarsals. Pain is usually on the plantar surface and worse during midstance gait phase.
- Pain is often chronic.
- Predisposition with pes cavus and hyperpronation
- Pain often described as walking with a pebble in the shoe; aggravated during midstance or propulsion phases of walking or running.

PHYSICAL EXAM
- Point tenderness over plantar metatarsal heads
- Pain in the interdigital space or a positive metatarsal squeeze test suggests Morton neuroma.
- Plantar keratosis
- Tenderness of the metatarsal head(s) with pressure applied by the examiner’s finger and thumb
- Erythema and swelling (occasionally)

DIFFERENTIAL DIAGNOSIS
- Stress fracture (most commonly 2nd metatarsal)
- Morton neuroma (i.e., interdigital neuroma)
- Tarsal tunnel syndrome
- Sesamoiditis or sesamoid fracture
- Salter I fracture in children
- Arthritis (e.g., gouty, rheumatoid, inflammatory, osteoarthritis, septic, calcium pyrophosphate dihydrate crystal deposit disease [CPPD])
Lisfranc injury
Avascular necrosis of the metatarsal head
Ganglion cyst
Foreign body
Vasculitis (diabetes)
Bony tumors

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Weight-bearing radiographs: anteroposterior, lateral, and oblique views:
  - Occasionally, metatarsal or sesamoid axial films (to rule out sesamoid fracture) or skyline view of the metatarsal heads to assess the plantar declination of the metatarsal heads: obtained with the metatarsophalangeal (MTP) joints in dorsiflexion (to evaluate alignment)
  - Ultrasound and MRI in recalcitrant cases especially if concern for stress fracture (3)[C]
  - MR arthrography of the MTP joint can delineate capsular tears, typically of the distal lateral border of the plantar plate (an often underrecognized cause of metatarsalgia).
- Only if diagnosis is in question
  - Erythrocyte sedimentation rate or C-reactive protein
  - Rheumatoid factor
  - Uric acid
  - Glucose
  - CBC with differential

Diagnostic Procedures/Other

Plantar pressure distribution analysis may help distinguish pressure distribution patterns due to malalignment.

TREATMENT

Treatment for metatarsalgia is typically conservative.

- Relieve pain.
- Ice initially
- Rest: temporary alteration of weight-bearing activity; use of cane or crutch.
  For more physically active patients, suggest an alternative exercise or cross-
training:
- Moist heat later
- Taping or gel cast
- Stiff-soled shoes will act as a splint.
- Relieve the pressure beneath the area of maximal pain by redistributing the pressure load of the foot, which can be achieved by weight loss.

MEDICATION
Nonsteroidal anti-inflammatory medications for 7 to 14 days if no contraindications toward use

ISSUES FOR REFERRAL
High-level athletes may benefit from early podiatric or orthopedic evaluation.

ADDITIONAL THERAPIES
- Physical therapy to restore normal foot biomechanics
- Low-heeled (<2 cm height) wide-toe-box shoes
- Metatarsal bars, pads, and arch supports. Metatarsal bars are often more effective than pads.
- Orthotics/rocker bar (prescriptive orthotics have been shown to be effective treatment)
- Thick-soled shoes
- Shaving the callus may provide temporary relief. Callus excision is not recommended.
- Corticosteroid injection may benefit interdigital neuritis but should be used with caution as it may cause MTP instability and fat pad atrophy.
- Improve flexibility and strength of the intrinsic muscles of the foot with:
  - Exercises (e.g., towel grasps, pencil curls)
  - Physical therapy to maintain range of motion and restore normal biomechanics

SURGERY/OTHER PROCEDURES
- If no improvement with conservative therapy for 3 months, refer to foot/ankle orthopedic surgeon or podiatrist.
- Surgery may help correct anatomic abnormality: bunionectomy, partial osteotomy, or surgical fusion. Success rates vary depending on procedure.
- Direct plantar plate repair (grade II tear) combined with Weil osteotomy can restore normal alignment of the MTP joint, leading to diminished pain with
improved functional scores.
- Callus removal is generally not recommended.
- Morton neurectomy or ultrasound-guided alcohol ablation of Morton neuroma are options (4)[C].
- Surgery only as a last resort if no anatomic abnormality is present.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Magnetic insoles are not effective for chronic nonspecific foot pain.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Patients generally admitted only for surgery

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
If stress fracture has been ruled out and patient’s condition has not improved >3 months of conservative treatment, consider surgical evaluation.

PATIENT EDUCATION
- Instruct about wearing proper shoes and gradual return to activity.
- Cross-training until symptoms subside. Goal is to restore normal foot biomechanics, relieve abnormal pressure on the plantar metatarsal heads, and relieve pain (5)[C].

PROGNOSIS
Outcome depends on the severity of the problem and whether surgery is required to correct it.

COMPLICATIONS
- Back, knee, and hip pain due to change in gait
- Transfer metatarsalgia following surgical intervention, which subsequently transfers stress to other areas.
REFERENCES

ADDITIONAL READING

SEE ALSO

Morton Neuroma (Interdigital Neuroma)

CODES

ICD10
• M77.40 Metatarsalgia, unspecified foot
• G57.60 Lesion of plantar nerve, unspecified lower limb
• M77.42 Metatarsalgia, left foot

**CLINICAL PEARLS**

• Metatarsalgia refers to pain of the plantar surface of the forefoot in the region of the metatarsal heads.
• Metatarsalgia is common in athletes who participate in high-impact sports involving the lower extremities.
• Patients describe as “walking with a pebble in the shoe.” Pain is worse during midstance or propulsion phases of walking or running.
• The most common physical finding is point tenderness over plantar metatarsal heads.
• Pregnant patients should wear properly fitted, low-heeled shoes to reduce incidence of metatarsalgia.
METHICILLIN-RESISTANT
STAPHYLOCOCCUS AUREUS (MRSA)
SKIN INFECTIONS

Stephen A. Martin, MD, EdM • Paul P. Belliveau, PharmD

BASICS

DESCRIPTION

- Community-acquired methicillin-resistant Staphylococcus aureus (CA-MRSA) has unique properties that allow the organism to cause skin and soft tissue infections (SSTIs) in healthy hosts:
  - CA-MRSA has a different virulence and disease pattern than hospital-acquired MRSA (HA-MRSA).
- CA-MRSA infections impact patients who have not been recently (<1 year) hospitalized or had a medical procedure (e.g., dialysis, surgery, catheters).
- CA-MRSA typically causes mild to moderate SSTIs (abscesses, furuncles, and carbuncles):
  - Severe or invasive CA-MRSA disease is less frequent but can include:
    o Necrotizing pneumonia with abscesses
    o Necrotizing fasciitis
    o Septic thrombophlebitis
    o Sepsis
    o Osteomyelitis
- Although less frequent, HA-MRSA can still cause SSTIs in the community.
- System(s) affected: skin, soft tissue

EPIDEMIOLOGY

- Predominant age: all ages, generally younger
- Predominant sex: female > male

Incidence
- 316/100,000/year (2004 to 2005)
- 46/100,000/year pediatric MRSA SSTI hospitalizations

**Prevalence**
- Local epidemiology patterns vary.
- 25–30% of U.S. population colonized with *S. aureus*; up to 7% are colonized with MRSA.
- CA-MRSA isolated in ~60% of SSTIs presenting to emergency departments (range 15–74%)
- CA-MRSA accounts for up to 75% of all community staphylococcal infections in children.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- First noted in 1980. Current epidemic began in 1999. The USA300 clone is predominant.
- CA-MRSA is distinguished from HA-MRSA by
  - Lack of a multidrug-resistant phenotype
  - Presence of exotoxin virulence factors
  - Type IV *Staphylococcus* cassette cartridge (contains the methicillin-resistance gene *mecA*)

**RISK FACTORS**
- ~50% of patients have no obvious risk factor.
- Antibiotic use in the past month
- Abscess
- Reported “spider bite”
- History of MRSA infection
- Close contact with a similar infection
- Children, particularly in daycare centers
- Competitive athlete
- Incarceration
- Hospitalization in the past 12 months

**GENERAL PREVENTION**
- Colonization (particularly of the anterior nares) is a risk factor for subsequent *S. aureus* infection. Not certain if similar for CA-MRSA. Oropharyngeal and inguinal colonization are equally prevalent.
- CA-MRSA transmitted easily through environmental and household contact
Health care workers are a primary MRSA vector for hospitalized patients, reinforcing the need for meticulous cleaning of hands and medical equipment.

- Vaccine under development

**COMMONLY ASSOCIATED CONDITIONS**
Many patients are otherwise healthy.

**DIAGNOSIS**

**HISTORY**
- Review risk factors.
- “Spider bite” is commonly confused with MRSA—patients often report an unclear history of spider bite.
- Prior MRSA skin infection
- Risk factors alone cannot rule in or rule out a CA-MRSA infection.

**PHYSICAL EXAM**
- Furuncles and/or carbuncles, sometimes with surrounding cellulitis.
  - Nonsuppurative cellulitis is a less common presentation of CA-MRSA.
- Erythema, warmth, tenderness, swelling
- Fluctuance
- Folliculitis, pustular lesions
- Appearance like an insect or spider bite
- Tissue necrosis

**DIFFERENTIAL DIAGNOSIS**
SSTIs due to other organisms

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Wound cultures establish definitive diagnosis. Recent guidelines recommend culture of a purulent lesion with systemic signs of illness or if the patient is immunocompromised (1)[B].
- Susceptibility testing; many labs use oxacillin instead of methicillin.
“D-zone disk-diffusion test” evaluates for inducible clindamycin resistance if CA-MRSA is resistant to erythromycin.

Ultrasound may help identify abscesses (2,3)[A].

Look for fascial plane edema on CT or MRI if necrotizing fasciitis is suspected. DO NOT DELAY surgical intervention to obtain imaging in such cases.

**Diagnostic Procedures/Other**

Incision and drainage (I&D) purulent lesions; needle aspiration not recommended (1)

---

**TREATMENT**

- Recent guidelines recommend antibiotics that are active against MRSA for patients with carbuncles or abscesses if patients do not respond to initial antibiotic treatment, have markedly impaired host defenses, or present with systemic inflammatory response (SIRS) and hypotension (1).

- Nonsuppurative cellulitis does not warrant extended antibiotic coverage for CA-MRSA (4)[A].

- Routine use of agents to eliminate MRSA colonization in patients with active infection or their close contacts is not recommended.

- Most CA-MRSA infections are localized SSTIs and do not require hospitalization or vancomycin.

- Base initial antibiotic coverage on local CA-MRSA prevalence and individual risk factors.

---

**GENERAL MEASURES**

- Modify therapy based on culture and susceptibility.

- Determine if household/close contacts have SSTI.

- Treat underlying conditions (e.g., tinea pedis).

- Restrict contact (e.g., sports competition) if wound cannot be covered.

- Elevate affected area.

---

**MEDICATION ALERT**

Consider surgical drainage, wound culture, and narrow-spectrum antimicrobials
for purulent infections:

- I&D may have more impact than antibiotics in mild cases for both adults and children.
- Patients with an abscess are frequently cured by I&D alone. The addition of clindamycin or Trimethoprim/sulfamethoxazole (TMP/SMX) for abscesses <5 cm results in modestly improved cure rates at 7 to 14 days (number needed to treat: 7 to 14) (5).
- Packing may not improve outcomes (3)[A].
- Moist heat may work for small furuncles.

**First Line**

Antibiotics for CA-MRSA SSTIs: 7- to 14-day course (depends on severity and clinical response):

- **TMP/SMX:** DS (160 mg TMP and 800 mg of SMX) 1 to 2 tablet(s) PO q12h; children, 8 to 12 mg/kg/day PO of trimethoprim component in 2 divided doses
- **Doxycycline or minocycline:** 100 mg PO q12h. Children, >8 years and <45 kg, 2 to 5 mg/kg/day PO in 1 to 2 divided doses, not to exceed 200 mg/day; >8 years and >45 kg, use adult dosing; taken with a full glass of water
- **Clindamycin:** 300 to 450 mg PO q6h. Children, 30 to 40 mg/kg/day PO in 3 divided doses. Taken with full glass of water. Check D-zone test in erythromycin-resistant, clindamycin-susceptible S. aureus isolates (a positive test indicates induced resistance—choose a different antibiotic).
- **CA-MRSA** is resistant to β-lactams (including oral cephalosporins and antistaphylococcal penicillins) and often macrolides, azalides, and quinolones.
- Although most CA-MRSA isolates are susceptible to rifampin, this drug should never be used as a single agent because of concerns regarding resistance. The role of combination therapy with rifampin in CA-MRSA SSTIs is not clearly defined.
- There has been increasing resistance to clindamycin, both initial (~33%) and induced.
- Although CA-MRSA isolates are susceptible to vancomycin, oral vancomycin cannot be used for CA-MRSA SSTIs due to limited absorption.

**Second Line**

Treat severe CA-MRSA SSTIs requiring hospitalization and HA-MRSA SSTIs using:

- **Vancomycin:** Generally, 1 g IV q12h (30 mg/kg/day IV in 2 divided doses). Children: 40 mg/kg/day IV in 4 divided doses. Vancomycin-like antibiotics
that require only 1 or 2 doses may soon be more broadly available (6)[A].

- Linezolid: 600 mg IV/PO q12h. Children, uncomplicated: <5 years of age, 30 mg/kg/day IV/PO in 3 divided doses; 5 to 11 years of age, 20 mg/kg/day IV/PO in 2 divided doses; >11 years, use adult dosing. Children, complicated: birth to 11 years, 30 mg/kg/day IV/PO in 3 divided doses; older, use adult dosing.
  - Linezolid seems to be more effective than vancomycin for treating people with SSTIs, but current studies have high risk of bias.

- Clindamycin: 600 mg IV q8h; children, 10 to 13 mg/kg/dose IV q6–8h up to 40 mg/kg/day

- Daptomycin: 4 mg/kg/day IV; children, 1 to <2 years, 10 mg/kg IV once daily; 2 to 6 years, 9 mg/kg IV once daily; 7 to 11 years, 7 mg/kg IV once daily; 12 to 17 years, 5 mg/kg IV once daily; ≥18 years, adult dosing
  - Do not use if pulmonary involvement.

- Ceftaroline: 600 mg IV q12h; children, 2 months to <2 years, 8 mg/kg IV q8h; ≥2 years to <18 years and ≤33 kg, 12 mg/kg IV q8h; ≥2 years to <18 years and >33 kg, 400 mg IV q8h OR 600 mg IV q12h; ≥18 years, adult dosing

**Pediatric Considerations**

- Tetracyclines not recommended for patients age <8 years
- TMP/SMX not recommended for patients <2 months
- Daptomycin is not recommended in pediatric patients <1 year of age (risk of potential muscular, neuromuscular, and/or nervous system side effects).
- Daptomycin dosage adjustment for pediatric patients with renal impairment has not been established.
- Ceftaroline dosage adjustment for pediatric patients with CrCl <50 mL/min/1.73 m² has not been established.

**Pregnancy Considerations**

- Tetracyclines are contraindicated.
- TMP/SMX not recommended in 1st or 3rd trimester

**Geriatric Considerations**

A recent review notes no prospective trials in this age group and recommends use of general adult guidelines.

**ISSUES FOR REFERRAL**

Consider consultation with infectious disease if
• Refractory CA-MRSA infection
• Plan to attempt decolonization

SURGERY/OTHER PROCEDURES
Concern for serious SSTIs (including necrotizing fasciitis) mandates prompt surgical evaluation.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Consider admission if:
  – Systemically ill
  – Comorbidities that may delay or complicate resolution of SSTI
  – Presence of SSTI complications (sepsis, necrotizing fasciitis) and comorbidities
  – Alternatives to inpatient admission include observation units and outpatient parenteral antimicrobial therapy (OPAT) in carefully selected cases.
• Nursing: contact precautions
• If admitted for IV therapy, assess the following before discharge:
  – Afebrile for 24 hours
  – Clinically improved
  – Able to take oral medication
  – Has adequate social support and is available for outpatient follow-up

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient Monitoring
For outpatients:
• Promptly return for care with systemic symptoms, worsening local symptoms, or failure to improve within 48 hours. Consider a follow-up within 48 hours of initial visit to assess response and review culture.

PATIENT EDUCATION
• Cover draining wounds with clean, dry bandages.
• Clean hands regularly with soap and water or alcohol-based gel; hot soapy shower daily
Do not share items that may be contaminated (including razors or towels).
- Clean clothes, towels, and bed linens.
- National MRSA Education Initiative: www.cdc.gov/mrsa/
- A mixture of 1/4 cup household bleach diluted in 1 gallon of water can be used to clean surfaces.

**PROGNOSIS**
In outpatients, improvement should occur within 48 hours.

**COMPLICATIONS**
- Necrotizing pneumonia or empyema (after an influenza-like illness)
- Necrotizing fasciitis
- Sepsis syndrome
- Pyomyositis and osteomyelitis
- Purpura fulminans
- Disseminated septic emboli
- Endocarditis

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- A49.02 Methicillin resis staph infection, unsp site
- A41.02 Sepsis due to Methicillin resistant Staphylococcus aureus
- J15.212 Pneumonia due to Methicillin resistant Staphylococcus aureus

**CLINICAL PEARLS**

- Incise and drain abscesses and send purulent material for culture and sensitivity.
- CA-MRSA skin lesions are commonly misidentified as “spider bites.”
MILD COGNITIVE IMPAIRMENT
Birju B. Patel, MD, FACP, AGSF • N. Wilson Holland, MD, FACP, AGSF

BASICS
DESCRIPTION
• Mild cognitive impairment (MCI) is defined as significant cognitive impairment in the absence of dementia, as measured by standard memory tests:
  – Concern regarding change in cognition
  – Preservation of independence in functional activities (ADLs)
  – Impairment in ≥1 cognitive domains (attention, executive dysfunction, memory, visuospatial, language)
  – Other terms used in the literature relating to MCI: isolated memory impairment; cognitive impairment not dementia (CIND); predementia; mild cognitive disorder; age-associated memory impairment; age-related cognitive decline; benign senescent forgetfulness. Some of these conditions do not progress to dementia (i.e., benign senescent forgetfulness, age-associated memory impairment, age-related cognitive decline). DSM-5 mentions “mild neurocognitive disorder” (NCD) which may be a precursor to Alzheimer disease and has many of the same features as MCI.
• Annual rates of conversion of MCI to dementia are 5–6% in the elderly.

EPIDEMIOLOGY
Incidence
• Predominant sex: male > female
• Predominant age:
  – Higher in older persons and in those with less education
  – 12 to 15/1,000 person-years in those age ≥65 years
  – 54/1,000 person-years in those age ≥75 years

Prevalence
• MCI is more prevalent than dementia in the United States.
• 12–18% for those age ≥60 years (1)[B]
ETIOLOGY AND PATHOPHYSIOLOGY

- Subtypes of MCI:
  - Single-domain amnestic
  - Multiple-domain amnestic
  - Nonamnestic single-domain
  - Nonamnestic multiple-domain
- The amnestic subtype is higher risk for progression to Alzheimer disease.
- Vascular, degenerative, traumatic, metabolic, psychiatric, or a combination

Genetics

Apolipoprotein (APO) E4 genotype: Various pathways exist leading to amyloid accumulation and deposition thought to be associated with dementia.

RISK FACTORS

- Age
- Diabetes
- Hypertension
- Hyperlipidemia
- Cerebrovascular disease
- Smoking
- Sleep apnea
- APO E4 genotype

COMMONLY ASSOCIATED CONDITIONS

See “Risk Factors.”

DIAGNOSIS

HISTORY

- Focus on cognitive deficits and impairment. MCI is meant to reflect a change in cognition and not lifelong impaired cognition.
- Review all medications that may affect cognition; give particular emphasis to anticholinergic medications (patients on these may mistakenly be classified as having MCI).
- Rule out depression.
- Assess function (ADLs, instrumental ADLs) and subtle changes in daily function (e.g., in the workplace).
• Impact on interpersonal relationships and caregiver stress
• Assess vascular risk factors (hypertension, diabetes, hyperlipidemia, and cerebrovascular disease).
• Assess behavioral changes.
• Olfactory dysfunction may be associated with amnestic MCI and progression to Alzheimer dementia. This can be easily evaluated in patients with memory impairment (2)[C].

PHYSICAL EXAM
• A general exam focusing on clinical clues to identifying vascular disease (e.g., bruits, abnormal BP)
• Neurologic exam to rule out reversible CNS causes cognitive impairment or other causes of cognitive impairment (e.g., Parkinson disease).
• Office measures of cognitive function, depression, and functional status

DIFFERENTIAL DIAGNOSIS
• Delirium
• Dementia
• Depression
• “Reversible” cognitive impairment
  – Medications (anticholinergics and medications with anticholinergic properties)
  – Hypothyroidism
  – Vitamin B₁₂ deficiency
• Reversible CNS conditions
• Give consideration to sleep conditions, especially sleep apnea, that can contribute to cognitive deficits.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• CBC
• Comprehensive metabolic profile
• Thyroid-stimulating hormone
• Vitamin B₁₂
• Lipids
• Consider HIV testing in the appropriate risk setting.
• Imaging tests are helpful when there are focal neurologic deficits or rapid or atypical presentations:
– CT scan can detect structural CNS conditions leading to cognitive impairment:
  o Subdural hematoma
  o Normal pressure hydrocephalus
  o Metastatic disease
– MRI further evaluates vascular, infectious, neoplastic, and inflammatory conditions.

• Cognitive testing is important (e.g., Montreal Cognitive Assessment [MOCA] and Saint Louis University Mental Status [SLUMS]); MOCA may be more sensitive for detecting and following MCI.
• Neuropsychological testing is recommended for all patients with MCI.
• Vascular risk factor reduction and treatment

**Follow-Up Tests & Special Considerations**
• Document progression of functional impairment, cognitive decline, concurrent depression, and comorbid conditions.
• Advanced planning while patient is competent.
• Early education of caregivers on safety, maintaining structure, managing stress, and future planning
• Neuropsychological testing should be done at 1- to 2- year intervals depending on subjective concerns and ongoing diagnosis of MCI.

**Test Interpretation**
• Little is known about MCI pathology due to a lack of longitudinal studies.
• Alzheimer dementia pathophysiology:
  – Neurofibrillary tangles in hippocampus
  – Senile plaques (amyloid deposition)
  – Neuronal degeneration
• Those with MCI have intermediate amounts of pathologic findings of Alzheimer disease with amyloid deposition and neurofibrillary tangles in the mesial temporal lobes compared with those with dementia.
• Amnestic MCI is associated with white matter hyperintensity volume on MRI, whereas nonamnestic MCI is associated with infarcts.

**TREATMENT**
**GENERAL MEASURES**
Atherosclerotic risk factors should be treated aggressively.

**MEDICATION**
The use of cholinesterase inhibitors (ChEIs) in MCI is not associated with any delay in the onset of Alzheimer disease or dementia. Moreover, the safety profile showed that the risks associated with ChEIs are significant. Therefore, ChEIs are not routinely recommended (3)[C].

**ISSUES FOR REFERRAL**
Consider referral to a memory specialist (i.e., geriatrician, neurologist, geropsychiatrist, neuropsychologist) to evaluate and differentiate subtypes of MCI and specific cognitive deficits.

**ADDITIONAL THERAPIES**
There may be benefit in terms of improvement in performance on tests for global cognitive functioning with cognitive training and physical exercise.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
No evidence suggests the efficacy of vitamin E in the prevention or treatment of people with MCI. More research is needed to identify the role of vitamin E, if any, in the management of cognitive impairment.

- Long-term use of ginkgo biloba extract has shown to have no benefit in the treatment of MCI and in terms of progression to dementia. In addition, ginkgo biloba can be associated with increase in bleeding risk including CNS bleeds (4)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Delirium is more common in patients hospitalized with all forms of cognitive impairment.

- Avoid medications that may worsen or precipitate cognitive decline (e.g., anticholinergics, antihistamines).
- Patients may be extremely sensitive to the hospital environment:
  - Moderate level of stimulation is best.
  - Avoid sensory deprivation. Make sure that patients have access to hearing aids and eyeglasses.
Use frequent cueing and have caregivers or family in the room whenever possible with patient.
Frequently orient patients to date and time.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patients should be reevaluated every 6 to 12 months to determine if symptoms are progressing.

Patient Monitoring
Appropriate cognitive and functional testing should be used to evaluate progression, along with clinical history and exam. If a medication is started, patients need to be followed more frequently to evaluate for efficacy, side effects, dose titration, and so forth. Declining executive function may be an early marker to progression of MCI to dementia, and clinicians should monitor and advise patients and families proactively to look for this. Impairments in ADL function is a good clue to progression to dementia from MCI.

DIET
Diets that are promoted by the American Heart Association to minimize atherosclerotic risk factors should be emphasized.

PATIENT EDUCATION
- Encourage lifestyle changes:
  - Physical activity, such as walking 30 minutes daily on most days of the week
  - Mental activity that stimulates language skills and psychomotor coordination should be encouraged. Computer activities, reading books, crafts, crossword puzzles, and games may be linked to decreased risk of development of MCI (5)[C],(6)[B].
- Cognitive rehabilitation strategies may be beneficial in helping with daily activities relating to memory tasks in MCI.
- Participation in exercise programs modestly improved some measures of cognition in some studies.
- Treatment of vascular risk factors (hypertension, diabetes, cerebrovascular disease, and hyperlipidemia) is important in lowering risk of progression to
dementia.

**PROGNOSIS**

- Conversion rates from MCI to dementia range from 5% to 6% annually.
- Amnestic subtypes of MCI are most likely to progress to dementia.
- Neuropsychological testing measures, cerebrospinal fluid (CSF) biomarkers, and neuroimaging studies are being used in specialty settings to predict conversion to dementia. These lack standardization and are not used in general use.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

G31.84 Mild cognitive impairment, so stated
CLINICAL PEARLS

- Amnestic MCI affects primarily memory and is more likely to progress to Alzheimer dementia.
- Screen for reversible factors, particularly anticholinergic medications, depression, and sleep disorders.
- Look closely at vascular risk factors and modify them as best as possible.
- ChEIs should not be used routinely unless memory complaints are affecting quality of life in patients. Potential side effects of these medications should be thoroughly discussed with patients and their families. A baseline ECG should be done prior to initiation of ChEIs due to risk of bradycardia and syncope.
- Neuropsychological testing is recommended in individuals suspected of having MCI. Patients with MCI and with prominent subjective complaints should have follow-up testing to evaluate for progression between 1 and 2 years after the initial assessment.
- Brain MRI should be performed in those with MCI to exclude structural disease and assess the extent of atrophy and vascular disease.
MISCARRIAGE (EARLY PREGNANCY LOSS)
Clara M. Keegan, MD

BASICS

DESCRIPTION

- Miscarriage, also known as spontaneous abortion (SAb), is the failure or loss of a pregnancy before 13 weeks’ gestational age (WGA).
- Related terms
  - Anembryonic gestation: gestational sac on ultrasound (US) without visible embryo after 6 WGA
  - Complete abortion: entire contents of uterus expelled
  - Ectopic pregnancy: pregnancy outside the uterus
  - Embryonic or fetal demise: cervix closed; embryo or fetus present in the uterus without cardiac activity
  - Incomplete abortion: abortion with retained products of conception, generally placental tissue
  - Induced or therapeutic abortion: evacuation of uterine contents or products of conception medically or surgically
  - Inevitable abortion: cervical dilatation or rupture of membranes in the presence of vaginal bleeding
  - Recurrent abortion: ≥3 consecutive pregnancy losses at <15 WGA
  - Threatened abortion: vaginal bleeding in the 1st trimester of pregnancy
  - Septic abortion: a spontaneous or therapeutic abortion complicated by pelvic infection; common complication of illegally performed induced abortions
- Synonym(s): miscarriage; early pregnancy loss
  - Missed abortion and blighted ovum are used less frequently in favor of terms representing the sonographic diagnosis.

EPIDEMIOLOGY

Predominant age: increases with advancing age, especially >35 years; at age 40 years, the loss rate is twice that of age 20 years.

Incidence
- Threatened abortion (1st-trimester bleeding) occurs in 20–25% of clinical pregnancies.
- Between 10% and 15% of all clinically recognized pregnancies end in SAb, with 80% of these occurring within 12 weeks after last menstrual period (LMP) (1).
- When both clinical and biochemical (β-hCG detected) pregnancies are considered, about 30% of pregnancies end in SAb.
- One in four women will have a SAb during her lifetime (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Chromosomal anomalies (50% of cases)
- Congenital anomalies
- Trauma
- Maternal factors: uterine abnormalities, infection (toxoplasma, other viruses, rubella, cytomegalovirus, herpesvirus), maternal endocrine disorders, hypercoagulable state

**Genetics**
Approximately 50% of 1st-trimester SAb's have significant chromosomal anomalies, with 50% of these being autosomal trisomies and the remainder being triploidy, tetraploidy, or 45X monosomies.

**RISK FACTORS**
Most cases of SAb occur in patients without identifiable risk factors; however, risk factors include the following:
- Chromosomal abnormalities
- Advancing maternal age
- Uterine abnormalities
- Maternal chronic disease (antiphospholipid antibodies, uncontrolled diabetes mellitus, polycystic ovarian syndrome, obesity, hypertension, thyroid disease, renal disease)
- Other possible contributing factors include smoking, alcohol, cocaine use, infection, and luteal phase defect.

**GENERAL PREVENTION**
- Insufficient evidence supports the use of aspirin and/or other anticoagulants, bed rest, hCG, immunotherapy, progestogens, uterine muscle relaxants, or vitamins for general prevention of SAb, before or after threatened abortion is
diagnosed.
- By the time hemorrhage begins, half of pregnancies complicated by threatened abortion already have no fetal cardiac activity.

**Recurrent miscarriage:** Women with a history of ≥3 prior SAbS may benefit from progestogens (OR 0.39, 95% CI 0.21–0.72) (2)[A].
- Antiphospholipid syndrome: The combination of unfractionated heparin and aspirin reduces risk of SAb in women with antiphospholipid antibodies and a history of recurrent abortion (RRR 46%, 95% CI 0.29–0.71).

## DIAGNOSIS

### HISTORY
- The possibility of pregnancy should be considered in a reproductive-age woman who presents with nonmenstrual vaginal bleeding.
- Vaginal bleeding
  - Characteristics (amount, color, consistency, associated symptoms), onset (abrupt or gradual), duration, intensity/quantity, and exacerbating/precipitating factors
  - Document LMP if known: allows calculation of estimated gestational age
- Abdominal pain/uterine cramping, as well as associated nausea/vomiting/syncope
- Rupture of membranes
- Passage of products of conception
- Prenatal course: toxic or infectious exposures, family or personal history of genetic abnormalities, past history of ectopic pregnancy or SAb, endocrine disease, autoimmune disorder, bleeding/clotting disorder

### PHYSICAL EXAM
- Orthostatic vital signs to estimate hemodynamic stability
- Abdominal exam for tenderness, guarding, rebound, bowel sounds (peritoneal signs more likely with ectopic pregnancy)
- Speculum exam for visual assessment of cervical dilation, blood, and products of conception (confirms diagnosis of SAb)
- Bimanual exam to assess for uterine size–dates discrepancy and adnexal tenderness or mass

## DIFFERENTIAL DIAGNOSIS
- Ectopic pregnancy: potentially life-threatening; must be considered in any woman of childbearing age with abdominal pain and vaginal bleeding
- Physiologic bleeding in normal pregnancy (implantation bleeding)
- Subchorionic bleeding
- Cervical polyps, neoplasia, and/or inflammatory conditions
- Hydatidiform mole pregnancy
- hCG-secreting ovarian tumor

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Quantitative hCG
  - Particularly useful if intrauterine pregnancy (IUP) has not been documented by US
  - Serial quantitative serum hCG measurements can assess viability of the pregnancy. Serum hCG should rise at least 53% every 48 hours through 7 weeks after LMP. An inappropriate rise, plateau, or decrease of hCG suggests abnormal IUP or possible ectopic pregnancy.
- Complete blood count (CBC) with differential
- Rh type
- Cultures: gonorrhea/chlamydia

<table>
<thead>
<tr>
<th>US exam to evaluate fetal viability and to rule out ectopic pregnancy (3)[A]</th>
</tr>
</thead>
<tbody>
<tr>
<td>hCG &gt;2,000 mIU/mL necessary to detect IUP via transvaginal US (TVUS), &gt;5,500 mIU/mL for abdominal US</td>
</tr>
<tr>
<td>TVUS criteria for nonviable intrauterine gestation: 7-mm fetal pole without cardiac activity or 25-mm gestational sac without a fetal pole, IUP with no growth over 1 week, or previously seen IUP no longer visible</td>
</tr>
<tr>
<td>Structures and timing: with TVUS, gestational sac of 2 to 3 mm generally seen around 5 WGA; yolk sac by 5.5 WGA; fetal pole with cardiac activity by 6 WGA</td>
</tr>
</tbody>
</table>

**Follow-Up Tests & Special Considerations**

- In the case of vaginal bleeding with no documented IUP and hCG <2,000 mIU/mL, follow serum hCG levels weekly to zero.
- If levels plateau, consider ectopic pregnancy or retained products of conception. If levels are very high, consider gestational trophoblastic disease.
- If initial hCG level does not permit documentation of IUP by TVUS, follow serum hCG in 48 hours to document appropriate rise.
- Repeat US once hCG is at a level commensurate with visualization on US (see
above).
- Provide patient with ectopic precautions in interim: worsening abdominal pain, dizziness/syncope, nausea/vomiting.
- In a pregnancy of unknown location with hCG rise <53% in 48 hours, offer methotrexate for treatment of presumed ectopic pregnancy.

**Diagnostic Procedures/Other**
- Fetal heart tones can be auscultated with Doppler starting between 10 and 12 WGA in a viable pregnancy.
- In threatened abortion, fetal cardiac activity at 7 to 11 WGA is 90–96% predictive of continued pregnancy (1).

**TREATMENT**

**GENERAL MEASURES**
- Discuss contraception plan at the time of diagnosis of SAb, as ovulation can occur prior to resumption of normal menses.
- Expectant management ("watchful waiting") is 90% effective for incomplete abortion, although it may take several weeks for the process to be complete (1)[A]. This approach is only recommended in the 1st trimester and is more effective in women with symptoms of impending pregnancy loss (4)[C].

**MEDICATION**
- Rates of complete miscarriage and of need for surgical evacuation are equivalent with expectant management and medication (5)[A].
- Long-term conception rate and pregnancy outcomes are similar for women who undergo expectant management, medical treatment, or surgical evacuation.
- Infection rates are lower with medical versus surgical management.

**First Line**
- Misoprostol: most common agent for inducing passage of tissue in incomplete abortion or embryonic demise
  - Off-label use; has not been submitted to the FDA for consideration for use in treatment of early pregnancy failure; recognized by the World Health Organization (WHO) as a life-saving medication for this indication
  - Efficacy: complete expulsion of products of conception in 71% by day 3,
84% by day 8
- Efficacy depends on route of administration, gestational age of pregnancy, and dose.
- Recommended dose is 800 μg vaginally; alternate regimens include the WHO regimen of 600 μg sublingually q3h for up to 3 doses; multidose regimens and oral dosing (including buccal and sublingual) may result in increased side effects.
- Common adverse effects include abdominal pain/cramping, nausea, and diarrhea. Pain increases at higher doses but is manageable with oral analgesia.
- Recommended for stable patients who decline surgery but do not want to wait for spontaneous passage of products of conception.

**Second Line**
- Rh-negative patients should be given Rh immunoglobulin (RhoGAM) 50 μg IM following a SAb.
- Women with evidence of anemia should receive iron supplementation.

**ISSUES FOR REFERRAL**
Patients should be monitored for up to 1 year for the development of pathologic grief. There is insufficient evidence to support counseling to prevent development of anxiety or depression related to grief following SAb.

**SURGERY/OTHER PROCEDURES**
- Uterine aspiration (suction dilation and curettage [D&C] or manual uterine aspiration [MUA]), also known as manual vacuum aspiration (MVA), is the conventional treatment.
- Indications: septic abortion, heavy bleeding, hypotension, persistent IUP after medical or expectant management, patient choice
- Risks (all rare): anesthesia (usually local), uterine perforation, intrauterine adhesions, cervical trauma, infection that may lead to infertility or increased risk of ectopic pregnancy
- When compared with expectant management, surgical intervention leads to fewer days of vaginal bleeding, with a lower risk of incomplete abortion and heavy bleeding and a similar risk of infection (6)[A].
- Vacuum aspiration (manual or electric) is considered preferable to sharp curettage, as aspiration is less painful, takes less time, involves less blood loss, and does not require general anesthesia. The WHO supports use of suction curettage over rigid metal curettage.
Although data from induced abortions suggest that antibiotic prophylaxis with doxycycline 100 mg BID reduces the already rare risk of postprocedure infection, data are insufficient to support use of antibiotics after aspiration for SAb.

COMPLEMENTARY & ALTERNATIVE MEDICINE
A systematic review of Chinese herbal medicine alone and in conjunction with Western medicine showed benefit over Western medicine alone in achieving continued viability at 28 weeks (number needed to treat [NNT] = 4.8 pregnancies with combined therapy). However, the available studies did not meet international standards for reporting quality.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- If the patient has orthostatic vital signs, initiate resuscitation with IV fluids and/or blood products, if needed.
- Hemodynamically unstable patients may require IV fluids and/or blood products to maintain BP.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
All patients should be offered follow-up in 2 to 6 weeks to monitor for resolution of bleeding, return of menses, and symptoms related to grief, as well as to review the contraception plan.

Patient Monitoring
- If SAb occurs in setting of previously documented IUP and abortion is completed with resumption of normal menses, it is not necessary to check or follow serum hCG to 0.
- After medical management, confirm complete expulsion with US or serial serum β-hCG (4)[C].
- If pregnancy is not immediately desired, offer effective contraception. Immediate insertion of an intrauterine device is both acceptable and safe.
- If pregnancy is desired, provide preconception counseling. There is no
evidence that it is necessary to wait a certain number of cycles before attempting conception again.

DIET
NPO if patient is to undergo D&C under general anesthesia

PATIENT EDUCATION
- Pelvic rest for 1 week after D&C or MVA
- Advise patients to call with excessive bleeding (soaking two pads per hour for 2 hours), fever, pelvic pain, or malaise, which could indicate retained products of conception or endometritis.

PROGNOSIS
- Prognosis is excellent once bleeding is controlled.
- Recurrent miscarriage: Prognosis depends on etiology; up to 70% rate of success with subsequent pregnancy

COMPLICATIONS
- D&C or MVA: uterine perforation, bleeding, adhesions, cervical trauma, and infection that may lead to infertility or increased risk of ectopic pregnancy. Bleeding and adhesions more common with D&C than with MUA; all complications rare
- Retained products of conception

CODES

ICD10

- O03.9 Complete or unspecified spontaneous abortion without complication
- O03.4 Incomplete spontaneous abortion without complication
- O02.1 Missed abortion

CLINICAL PEARLS

- Any pregnant woman with abdominal pain and/or vaginal bleeding must be evaluated to rule out ectopic pregnancy, which is potentially life threatening.
- As all options have similar long-term outcomes, patient preference should determine whether management is expectant, medical, or surgical.
MITRAL REGURGITATION

Yongkasem Vorasettakarnkij, MD, MSc

BASICS

DESCRIPTION

- Disorder of mitral valve (MV) closure, either primary or secondary (functional), resulting in a backflow of the left ventricular (LV) stroke volume into the left atrium (LA); uncompensated, this leads to LV and LA enlargement, elevated pulmonary pressures, atrial fibrillation, heart failure (HF), and sudden cardiac death.

- Types of mitral regurgitation (MR):
  - Acute versus chronic
  - Primary versus secondary (functional)
    - Primary: abnormalities at any level of the MV structures (annulus, leaflets, chordae tendineae, and papillary muscles)
    - Secondary: No valvular abnormalities are found. The abnormal and dilated LV causes papillary muscle displacement, resulting in leaflet tethering with annular dilatation that prevents coaptation.

- System(s) affected: cardiac; pulmonary

EPIDEMIOLOGY

Moderate to severe MR affects 2.5 million people in the United States (2000 data). It is the most common valvular disease and is expected to double by 2030 (1).

Prevalence

- By severity on echocardiography:
  - Mild MR: 19% (up to 40% if trivial jets included)
  - Moderate MR: 1.9%
  - Severe MR: 0.2%

- By category (1)
  - Degenerative (myxomatous disease, annular calcification): 60–70%
  - Ischemic: 20%
  - Endocarditis: 2–5%
  - Rheumatic: 2–5%
ETIOLOGY AND PATHOPHYSIOLOGY

- Acute MR
  - Leaflet perforation: infective endocarditis, trauma
  - Chordae tendineae rupture: trauma, spontaneous rupture, infective endocarditis, or rheumatic fever
  - Papillary muscle rupture or dysfunction: acute myocardial infarction (MI), severe myocardial ischemia, or trauma

- Chronic MR
  - Primary
    - Degenerative: mitral annular calcification, MV prolapse (MVP)
    - Infective endocarditis
    - Rheumatic heart disease (RHD)
    - Inflammatory diseases: lupus, eosinophilic endocardial disease
    - Anorectic drugs
    - Congenital (cleft leaflet)
  - Secondary (functional)
    - Ischemic: coronary artery disease (CAD)/MI
    - Nonischemic: cardiomyopathy from any cause, annular dilatation from chronic atrial fibrillation, dyssynchrony from right ventricular pacing

- Acute MR: Acute MV damage leads to sudden LA and LV volume overload. Sudden rise in LV volume load without LV remodeling results in impaired forward cardiac output and possible cardiogenic shock.

- Chronic MR: LV eccentric hypertrophy compensates for increased regurgitant volume to maintain forward cardiac output and alleviate pulmonary congestion. However, LV remodeling can result in LV dysfunction. LA compensatory dilatation for the larger regurgitant volume predisposes patients to develop AF.

- Ischemic MR: papillary muscle rupture, ischemia during acute MI, and incomplete coaptation of leaflets or restricted valve movement from chronic ischemia

RISK FACTORS
Age, hypertension, RHD, endocarditis, anorectic drugs

GENERAL PREVENTION
- Risk factor modification for CAD
- Antibiotic prophylaxis for poststreptococcal RHD
- Endocarditis prophylaxis is no longer recommended.
COMMONLY ASSOCIATED CONDITIONS
MVP with MR common in Marfan syndrome

DIAGNOSIS

HISTORY
- Associated conditions: RHD, prior MI, connective tissue disorder
- Acute MR
  - Sudden onset of dyspnea
  - Orthopnea, paroxysmal nocturnal dyspnea
- Chronic MR
  - Exertional dyspnea, fatigue
  - Palpitation: paroxysmal/persistent AF

PHYSICAL EXAM
- Acute MR
  - Rapid and thready pulses
  - Signs of poor tissue perfusion with peripheral vasoconstriction
  - Hyperdynamic precordium without apical shift
  - S₃ and S₄ (if in sinus rhythm)
  - Systolic murmur at left sternal border and base
    - Early, middle, or holosystolic murmur
    - Often soft, low-pitched decrescendo murmur
  - Rales
- Chronic MR
  - Brisk upstroke of arterial pulse
  - Leftward displaced LV apical impulse
  - Systolic thrill at the apex (suggests severe MR)
  - Soft S₁ and widely split S₂, S₃ gallop
  - Loud P₂ (if pulmonary hypertension)
  - Holosystolic murmur at apex that radiates to axilla or to left parasternal boarder
  - Ankle edema, jugular venous distension, and ascites, if development of right-sided HF

DIFFERENTIAL DIAGNOSIS
Aortic stenosis (AS): usually midsystolic but can be long; difficult to distinguish from holosystolic, at apical area, and radiating to the carotid arteries (unlike MR)

Tricuspid regurgitation: holosystolic but at left lower sternal border, does not radiate to axilla, and may increase in intensity with inspiration (unlike MR)

Ventricular septal defect (VSD): harsh holosystolic murmur at lower left sternal border but radiates to right sternal border (not axilla)

**DIAGNOSTIC TESTS & INTERPRETATION**

- **Chest x-ray (CXR)**
  - Acute MR: pulmonary edema, normal heart size
  - Chronic MR: LA and LV enlargement

- **ECG**
  - Acute MR: varies depending on etiologies (e.g., AMI)
  - Chronic MR
    - P mitrale from LA enlargement, AF
    - LV hypertrophy
    - Q waves from prior MI

**Initial Tests (lab, imaging)**

- Cardiac enzymes brain natriuretic peptide, if proper
- Transthoracic echocardiogram (TTE)
  - Indications for TTE (2)
    - Baseline evaluation of LV size and function, right ventricular function and LA size, pulmonary artery pressure, and severity of MR
    - Delineation of mechanism of MR
    - Surveillance of asymptomatic moderate to severe LV dysfunction (ejection fraction [EF] and end-systolic dimension [ESD])
    - Evaluate MV apparatus, LV size and function after a change in sign/symptom in MR patient.
    - Evaluate after MV repair or replacement.
  - Findings in acute MR
    - Evidence of etiology: flail leaflet or vegetations
    - Normal LA and LV size
  - Findings in chronic MR
    - Evidence of degenerative, rheumatic, ischemic, congenital, and other causes
    - Enlarged LA and LV
**Follow-Up Tests & Special Considerations**

- Intervals for follow-up TTE: See “Follow-Up Recommendations.”
- Cardiovascular magnetic resonance (CMR):
  - TTE results are not satisfactory to assess LV and RV volumes, function, or MR severity (2)[B].
- Transesophageal echocardiogram (TEE)
  - Intraoperatively to define the anatomic basis of MR and to guide repair (2)[B]
  - Nondiagnostic information about severity, mechanism of MR, and/or status of LV function from noninvasive imaging (2)[C]
- Exercise hemodynamics with either Doppler echocardiography or cardiac catheterization (2)[B].
  - Discrepancy between symptoms and the severity of MR from resting TTE in symptomatic patients with chronic primary MR
- Exercise treadmill testing (2)[C]
  - To establish symptom status and exercise tolerance in asymptomatic patients with chronic primary MR
- Noninvasive imaging (stress nuclear/position emission tomography, CMR, stress echocardiography, cardiac CT angiography)
  - To establish etiology of chronic secondary MR and/or to assess myocardial viability (2)[C]

**Diagnostic Procedures/Other**

Cardiac catheterization (2)[C]

- Left ventriculography and hemodynamic measurement
  - Noninvasive tests are inconclusive regarding severity of MR, LV function, the need for surgery.
- Coronary angiography: prior to MV surgery in patients at risk for CAD

**Test Interpretation**

Quantification of severe MR requires integration of the following structural parameters:

- LA size: dilated, unless acute
- LV size: dilated, unless acute
- Leaflets: abnormal
- Doppler parameters
- Quantitative parameter
**TREATMENT**

**MEDICATION**

- Acute, severe MR
  - Medical therapy has a limited role and is aimed to stabilize hemodynamics preoperatively.
  - Vasodilators (nitroprusside, nicardipine): to improve hemodynamic compensation but is often limited by systemic hypotension (2,3)[C]

- Chronic MR
  - Primary
    - Asymptomatic: no proven long-term medical therapy
    - Symptomatic: diuretics, β-blockers, angiotensin-converting enzyme inhibitors (ACE-I) or angiotensin receptor blockers (ARBs), and possibly aldosterone antagonists as indicated in standard therapy for HF (2)[B],(3)[C]
  - Secondary: LV dysfunction or symptomatic (stages B to D)
    - ACE-I or ARBs, β-blockers, and/or aldosterone antagonists as indicated in standard therapy for HF (2)[B],(3)[C]

**SURGERY/OTHER PROCEDURES**

- Isolated MV surgery is not indicated for patients with mild to moderate MR.
- Acute, severe MR secondary to acute MI
  - Acute rupture of papillary muscle: emergency MV repair/replacement
  - Papillary muscle displacement
    - Aggressive medical stabilization and intra-aortic balloon pump
    - Valve surgery usually required in addition to revascularization
- Chronic severe MR
  - Severe primary MR (2–4)
    - MV surgery
      - Symptomatic patients (stage D)
        - Absence of severe LV dysfunction (EF >30%) (2,3)[B]
        - May be considered if presence of severe LV dysfunction (EF ≤30%) (2)[C]
      - Asymptomatic patients
        - Mild/moderate LV dysfunction (EF 30–60% and/or ESD ≥40 mm, stage C2) (2)[B]
        - MV repair is reasonable for asymptomatic patients (stage C1) with preserved LV function (EF >60% and ESD <40 mm):
The likelihood of a successful and durable repair without residual MR is >95% and expected mortality <1% when performed at a heart valve center of excellence (2)[B].

- Progressive increase in LV size or decrease in EF on serial imaging studies (4)[B]
- Nonrheumatic MR with new onset of AF or resting pulmonary hypertension (pulmonary artery systolic pressure >50 mm Hg) and the likelihood of a successful and durable repair is high (2)[B], (3)[C].

- MV repair is recommended over MV replacement in patients with
  - MR limited to the posterior leaflet (2)[B]
  - MR involving the anterior leaflet or both leaflets when a successful and durable repair can be accomplished (2)[B]

Transcatheter MV repair:
- May be considered for severely symptomatic patients (NYHA class III/IV) despite optimal GDMT for HF, who have a reasonable life expectancy but a prohibitive surgical risk from severe comorbidities (2)[B]
  - Severe secondary MR (2,4)
- MV surgery
  - Undergoing coronary artery bypass graft (CABG) or aortic valve replacement (2)[C]
  - May be considered for severely symptomatic patients (NYHA class III to IV) despite optimal GDMT for HF (2)[B]
  - Chordal-sparing MVR is preferred over downsized annuloplasty repair in ischemic MR patients (4)[B].

- Cardiac resynchronization therapy is recommended for symptomatic patients (stage B to D) who meet the indications for device therapy (2)[C].

Geriatric Considerations
- Medical therapy alone for patients >75 years of age with MR is preferred, owing to increased operative mortality and decreased survival (compared with those with AS), especially with preexisting CAD or need for MV replacement.
- MV repair is preferable than MV replacement.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Acute MR: Stabilize ABCs (airway, breathing, circulation). Initiate IV, O₂, and
monitoring. Nitroprusside (+dobutamine and/or aortic balloon counterpulsation if hypotensive). Treat underlying causes (e.g., MI). Treat acute pulmonary edema with furosemide and morphine. Obtain urgent surgical consultation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Chronic MR: asymptomatic

- Mild MR with normal LV size and function and no pulmonary hypertension: annual clinical evaluation and TTE every 3 to 5 years
- Moderate MR: annual clinical evaluation and TTE every 1 to 2 years
- Severe MR: clinical evaluation, TTE every 6 to 12 months
- Consider serial CXRs and ECGs, and consider stress test if exercise capacity is doubtful.

PATIENT EDUCATION

- Exercise after MV repair: Avoid sports with risk for bodily contact or trauma. Low-intensity competitive sports are allowed.
- Competitive athletes with MR
  - Asymptomatic with normal LV size and function, normal pulmonary artery pressures, and sinus rhythm: no restrictions
  - Mildly symptomatic and those with LV dilatation: activities with low to moderate dynamic and static cardiac demand allowed
- AF and anticoagulation: no contact sports

PROGNOSIS

- Acute, severe MR: Mortality risk with surgery is 50%; mortality risk with medical therapy alone is 75% in first 24 hours and 95% at 2 weeks.
- Chronic MR: asymptomatic severe MR with normal LVEF: 10% yearly rate of progression to symptoms and subnormal resting LVEF. Symptomatic severe MR: 8-year survival rate, 33% without surgery; mortality rate, 5% yearly

Pregnancy Considerations

MR with NYHA functional class III to IV at high risk for maternal and/or fetal risk

COMPLICATIONS
Acute pulmonary edema, CHF, AF, bleeding risk with anticoagulation, endocarditis, sudden cardiac death

REFERENCES

ADDITIONAL READING

CODES

ICD10
- I34.0 Nonrheumatic mitral (valve) insufficiency
- I05.1 Rheumatic mitral insufficiency
- Q23.3 Congenital mitral insufficiency

**CLINICAL PEARLS**

- Follow-up for mild to moderate MR: serial exam and/or echo unless LV structural changes
- Severe MR is usually managed with MV repair.
- Endocarditis prophylaxis is not recommended.
MITRAL STENOSIS
Harish C. Devineni, MD • Gene Pershwitz, MD

BASICS
DESCRIPTION
- The mitral valve apparatus is made up of anterior and posterior leaflets which are attached to the anterolateral and posteromedial papillary muscles via the chordae.
- Mitral stenosis (MS) is a narrowing of the valve area causing obstruction of the left ventricular inflow, resulting in increased left atrial pressures and consequent elevation of pulmonary venous and atrial pressures.
- Staging of the disease is used to guide appropriate treatment regimen. Stages vary from A (with risk factors), B (hemodynamic obstruction), C (severe but no symptoms), to D (symptomatic) (1).
- The most common etiology for MS is rheumatic heart disease (RHD), and MS is the most common valvular disease secondary to RHD.

EPIDEMIOLOGY
- Globally, the prevalence of RHD is 15.6 million every year. Approximately 282,500 new cases are reported and 233,000 deaths have been attributed to RHD.
- Predominant age: Symptoms primarily occur in 3rd to 4th decades; predominant sex: female > male (3:1)

Incidence
Incidence of rheumatic disease in the continental United States remains very low. Annual incidence of acute rheumatic fever in the continental United States is 0.04 to 0.06 cases per 1,000 children. However, global burden remains significant (2).

ETIOLOGY AND PATHOPHYSIOLOGY
- Narrowing of the valve orifice leads to obstruction of blood flow between LA and LV. This impairs LV filling during diastole and causes increased LA pressure. Increased LA pressure is transmitted passively (“back pressure”) to the pulmonary circulation causing pulmonary hypertension and pulmonary
congestion over time.
- Chronic LA pressure overload results in atrial dilation and fibrosis and may cause Afib.
- Rheumatic fever: most common etiology (see “Risk Factors”)
- Pathognomonic commissural fusion, leaflet thickening and “fish mouth appearance” seen with RHD
- Aging (extension of mitral annular calcification)
- Rare causes: congenital (associated with mucopolysaccharidoses), autoimmune: systemic lupus erythematosus (SLE); rheumatoid arthritis; malignant carcinoid; Whipple disease; methysergide therapy; and other acquired pathologies such as LA myxoma, LA thrombus, endomyocardial fibrosis

**RISK FACTORS**
- Rheumatic fever is the greatest risk factor.
  - 30–40% of rheumatic fever patients eventually develop MS, presenting 20 years after diagnosis of rheumatic fever.
  - Acute rheumatic fever occurs 2 to 3 weeks after an episode of untreated pharyngitis caused by rheumatogenic group A streptococci (GAS) organism in a genetically susceptible host.
  - Recurrent infections can accelerate the progression of the disease.
  - Low socioeconomic status (i.e., crowded conditions) favors the spread of streptococcal infection.
- Aging (increasing valvular calcification)
- Chest irradiation (increasing tissue fibrosis)

**GENERAL PREVENTION**
- Prompt recognition and treatment of GAS infection; recognition of cardinal signs and symptoms of acute rheumatic fever via Jones criteria
- Ultrasound-based screening has been shown to increase diagnosis of RHD in asymptomatic patients residing in areas of high prevalence.

**COMMONLY ASSOCIATED CONDITIONS**
- Afib (30–40% of symptomatic patients)
- Associated valve lesions due to chronic inflammation (aortic stenosis, aortic insufficiency)
- Pulmonary HTN and right heart failure
- Systemic embolism, stroke, pulmonary embolism (10%)
- Infection, including infectious endocarditis (1–5%)
- Chronic rheumatic myocarditis

**DIAGNOSIS**

**HISTORY**

- History of rheumatic fever
- Severity depends on valve area; most early cases will be asymptomatic.
- Mean age of symptom onset in rheumatic valvular disease is in the late 30s to 40s. Latent period 20 to 40 years after infection. Rapid progression can be seen in some high prevalence areas.
- Presenting features usually include dyspnea on exertion, decreased exercise tolerance, chest pain, embolic events, palpitations, hoarseness, hemoptyisis, fatigue, paroxysmal nocturnal dyspnea, Afib, and embolic events.
- In advanced disease, symptoms of pulmonary HTN and right heart failure predominate: jugular venous distention, hepatomegaly, ascites, and peripheral edema
- Other presentations: hemoptyisis (due to pulmonary vein rupture and bronchial circulation causing intraparenchymal hemorrhage), hoarseness (compression of recurrent laryngeal nerve by enlarged pulmonary artery or LA, Ortner syndrome), dysphagia (compression of bronchi), chronic cough (due to LA compressing the bronchi) and infective endocarditis
- Not infrequently, symptoms are first noted in pregnancy: mitral faces, plethoric cheeks, and bluish patches.

**PHYSICAL EXAM**

- Elevated jugular venous pressure, left parasternal heave; apical impulse may be displaced, diastolic thrill in the left lateral decubitus position
- Auscultation
  - Classic murmur: accentuated $S_1$, opening snap, apical early decrescendo diastolic rumble with presystolic accentuation (presystolic accentuation of murmur is lost with AF). Murmur is low pitch and best heard at the apex in the left lateral decubitus position.
  - Murmur is accentuated with exercise and decreased with rest and Valsalva.
    o With mobile, noncalcified valve, murmur persists throughout diastole and $S_1$, and the opening snap remains loud.
    o With increasing severity of MS, murmur often is difficult to hear.
Duration of murmur reflective of severity. $S_1$ and the opening snap may be soft to absent.
- A shorter $S_2$ to $O_2$ interval indicates more severe MS.
- Further evaluation is required while looking for concomitant murmurs.
- If pulmonary HTN is present, increased $P_2$, high-pitched decrescendo diastolic murmur of pulmonic insufficiency is heard (Graham Steell murmur); may have signs of right heart failure. RV lift can also be seen.
- May also find associated aortic or tricuspid murmurs due to involvement from RHD

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- **ECG (3,4)[C]**
  - LA enlargement (manifested by broad, notched P waves in lead II [P mitrale], with P wave duration $>0.12$ seconds with a negative terminal deflection of the P wave in lead $V_1$)
  - Afib is a common finding.
  - Right ventricular hypertrophy (RVH), right axis deviation, and an R-to-S ratio $>1$ in $V_1$ are possible.
- **Chest radiograph (3,4)[C]**
  - LA enlargement, straightening of the left heart border, a “double density,” in the cardiac silhouette, and elevation of the left main stem bronchus
  - Prominent pulmonary arteries at the hilum with rapid tapering, RVH, and edema pattern with Kerley A and B lines (late presentation)
- **Transthoracic echo (TTE) recommended in all patients with signs and symptoms of MS (1)[B]**
  - Used for diagnosis of MS
    - Assess doming of the valve, mitral orifice size, and commissural fusion.
    - Extent of involvement based on degree of commissural fusion, calcification, and subvalvular fibrosis
    - Hockey stick, fish mouth appearance, which is due to narrowing of the valve orifice
    - Normal valve orifice 4 to 5 cm$^2$; symptoms typically seen when orifice is $<2.5$ cm$^2$ (1)
  - Assess for concomitant valvulopathies.
- **TEE should be performed if TTE images are nondiagnostic or if being considered for a percutaneous mitral balloon commissurotomy (PMBC) to**
exclude thrombus in left atrium and evaluate severity of MR (1)[B].
- Exercise stress testing can also be considered in patients with MS who have a discrepancy in their symptoms and signs and resting echo findings (1)[C].
- Cardiac catheterization indications (1,4)[C]
- Using Gorlin formula; pressures obtained via transseptal puncture
  - Class I recommendation
    - When echo is inconclusive
    - Discrepancy between echo, symptoms, and severity
  - Class II recommendation
    - Assess cause of severe pulmonary HTN that is out of proportion to echo results.
  - Class III recommendation: satisfactory result of echo
- CT ordered prior to surgery as many at risk for CAD

**Follow-Up Tests & Special Considerations**
- If valve area >1.5 cm² and mean pressure gradient <5 mm Hg, clinical f/u in 3 to 5 years is recommended.
- Otherwise, f/u is usually symptom based. Symptomatic patients with severe MS need further evaluation for interventional/surgical treatment.
- Holter monitor placement in order to r/o paroxysmal Afib

**Diagnostic Procedures/Other**
- Exercise testing is recommended for those with clinical discrepancy.
- Wilkins score evaluates valvular anatomy from a TTE in order to see if patient is a candidate for surgery.

**Test Interpretation**
- Rheumatic fever–induced pathologic changes: leaflet thickening, leaflet calcification, commissural fusion, chordal shortening
- MV area defined (1)
  - Normal: 4 to 6 cm², progressive MS: >1.5 cm², severe MS: <1.5 cm², very severe: <1.0 cm²

**TREATMENT**

**GENERAL MEASURES**
- Treatment is dependent on severity of stenosis and symptoms.
Patients who have a valvular area >1.5 cm² and no symptoms can be managed medically

MS is generally progressive, and medical therapy only delays the need for definitive therapy. It entails (i) treatment to prevent recurrence of rheumatic fever, (ii) treatments aimed at improving dyspnea and exercise tolerance, (iii) controlling the ventricular rate whether in sinus rhythm or Afib, (iv) and anticoagulation for prevention of thromboembolic events.

**MEDICATION**

**First Line**

- Antibiotic prophylaxis against rheumatic fever and/or carditis is recommended for patients with history of rheumatic fever (1)[C].
- Secondary prophylaxis is dependent on many factors: number of previous attacks, time since previous infection, risk for getting GAS, age of patient, and absence or presence of cardiac involvement (5).
  - Penicillin V (PCN) PO or penicillin G IM: IM is more effective than PO.
  - If allergic to PCN, can use sulfadiazine and macrolides alternatively
  - Duration of rheumatic fever prophylaxis is variable (5):
    o Rheumatic fever without carditis: Take for 5 years or until age 21 years, whichever is longer.
    o Rheumatic fever with carditis but no residual heart disease: Take for 10 years or well into adulthood, whichever is longer.
    o Rheumatic fever with carditis plus residual heart disease: Take for 10 years or until 40 years old, whichever is longer.
- **Antibiotic prophylaxis against infective endocarditis is not routinely recommended, unless there are other indications (1)[B].**
- **Diuretics for congestive symptoms (1)[A]**
- **β-Blockers or nondihydropyridine calcium channel blockers used for controlling heart rate both in SR and AF to allow adequate diastolic filling and decrease LA diastolic pressure tachycardia or exertional symptoms (class IIa) (1)**
- Ivabradine helpful as it doesn’t affect myocardial contraction
- **Consider cardioversion, especially in patients with mild MS and recent dx of Afib (<6 months).**
- **Use of anticoagulation (1)[B]**
  - **Class I recommendations**
    o MS and Afib or history of Afib, MS and prior embolic event, or
    o MS and LA thrombus
– Class IIB recommendations
  o Patients with enlarged LA and spontaneous contrast on echo
- Warfarin is the only accepted modality for anticoagulation in patients with rheumatic mitral valve disease (international normalized ratio) range 2 to 3.
- Heparin in the acute Afib setting
- The new oral anticoagulants (factor Xa inhibitor and direct thrombin inhibitor) are not approved for use in Afib that is secondary to MS.

**Second Line**
One can also consider amiodarone or digitalis if β-blockers and CCBs are not proven beneficial.

**SURGERY/OTHER PROCEDURES**
- Surgical techniques include balloon valvotomy, open mitral commissurotomy, or closed mitral commissurotomy and mitral valve replacement.
- Patients with severe MS and symptoms consistent with NYHA class III to IV are candidates for surgery.
- Any patient with a valve area >1.5 cm², LA thrombus, moderate MR, severe bicommissural calcifications, severe aortic valve disease, moderate TR or TS, concomitant coronary artery disease are not candidates for PMBC.
- PMBC is recommended for those with severe MS symptoms and favorable valve morphology (1)[A], in asymptomatic patient with very severe MS and favorable valve anatomy in the absence of symptoms (1)[C], and in patients with suboptimal valvular anatomy, with a high risk for surgery (1)[C].
- Balloon valvotomy: symptomatic patients with NYHA class II, III, or IV symptoms with valves that look favorable and with favorable comorbidities (1)[A]
- MV surgery: When MS is severe with severe symptoms (NYHA class III to IV), patients who are not high-risk surgical candidates and balloon valvotomy is contraindicated or failed PMBC (1)[B]; patients with MS requiring left atrial appendage excision
- Consider patient age, bleeding risk, and other comorbidities prior to deciding if patient should have a prosthetic versus mechanical valve.

**Pregnancy Considerations**
- Volume expansion during pregnancy can exacerbate heart failure symptoms. Patients with known severe MS, prepregnancy discussions should be pursued with a cardiologist.
• Pregnant patients can safely use β-blockers. Despite some concerns of teratogenic affects with diuretics, furosemide has been used in symptomatic MS patients during pregnancy with minimal adverse effects.
• Coumadin is considered relatively safe in the 2nd and 3rd trimesters if anticoagulation is required. However, unfractionated heparin is preferred prior to labor and delivery.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
• Counsel patients with MS that is usually slowly progressive but can have sudden onset of Afib, which could become rapidly fatal. Call 911 for marked worsening of symptoms.
• Echocardiographic surveillance in asymptomatic patients in any degree of MS: very severe (<1.0 cm²) MS: yearly, severe (≤1.5 cm²) MS: every 1 to 2 years, mild or moderate MS: every 3 to 5 years
• Follow-up will depend on the severity of the MS and the patient’s symptoms.
  – Asymptomatic patients: annual history and examination
  – Symptomatic patients are followed closely based on clinical response to adjust therapy and plan-definitive treatment (1)[C].

**DIET**
Salt restriction for pulmonary congestion

**PROGNOSIS**
Natural history
• Asymptomatic latent period after rheumatic fever for 10 to 30 years. 10-year survival for asymptomatic or minimally symptomatic patients is 80%. 10-year survival after onset of debilitating symptoms is only 0–15%.
• Mean survival with significant pulmonary HTN is <3 years.
• Commissurotomy is an effective means of reducing stenosis but is not curative. Restenosis sometimes occurs and can be early (<5 years) or late (>20 years).

**COMPLICATIONS**
• Left and right heart failure, Afib and systemic embolization, pulmonary HTN, pulmonary vasoconstriction hepatic congestion, and bacterial endocarditis
Pulmonary pressures >50 mm Hg increase surgical risk.

REFERENCES

CODES

ICD10

- I05.0 Rheumatic mitral stenosis
- I05.8 Other rheumatic mitral valve diseases
- I34.2 Nonrheumatic mitral (valve) stenosis

CLINICAL PEARLS

- Asymptomatic patients may be followed clinically with yearly exams for development of symptoms with periodic echo to evaluate valve area.
- Once symptoms of MS develop, initiate appropriate medical therapy but advise patient that for most, surgical therapy will be needed to prolong survival. Almost all cases of MV stenosis progress in severity over time.
- Pregnancy in a patient with severe MS has a high rate of both maternal and
fetal complications, including death.
MITRAL VALVE PROLAPSE

Praneeth Katrapati, MD • Brandon D. Coons, MD • Prashanth S. Katrapati, MD, FACC

BASICS

DESCRIPTION

- Mitral valve prolapse (MVP) is a systolic billowing of one or both mitral leaflets into the left atrium (LA) during systole ± mitral regurgitation (MR).
- More specifically, MVP is a single or bileaflet prolapse of at least 2 mm superior displacement into the LA during systole on the parasternal long-axis annular plane of the valve on echocardiogram ± leaflet thickening.
  - Classic: prolapse with >5 mm of leaflet thickening
  - Nonclassic: prolapse with <5 mm of leaflet thickening
- Synonym(s): systolic click-murmur syndrome; billowing mitral cusp syndrome; myxomatous mitral valve; floppy valve syndrome; redundant cusp syndrome; Barlow syndrome

EPIDEMIOLOGY

Incidence

- Predominant age: MVP has been described in all age groups.
- Initial descriptions based on clinical examinations suggested a 2:1 female predominance. Using modern echocardiogram criteria, men and women are affected equally (1).
- The most serious consequences of hemodynamically significant MR occur in patients age >50 years (1).

Prevalence

MVP is the most common valvular abnormality, affecting 2–3% of the general population (1).

ETIOLOGY AND PATHOPHYSIOLOGY

- The pathology causing MVP is multifactorial and includes the following:
  - Abnormal valve tissue
    - Myxomatous degeneration: redundant layers of leaflet “hooding” the
cords, chordal elongation, and annular dilatation
  - Myxoid leaflets are more elastic and less stiff than normal valves.
  - Chordal rupture is more common.
- Disparity in size between the mitral valve and the left ventricle (LV)
- Connective tissue disorders
- MVP is often associated with variable degrees of MR which occurs in 9% of patients.
- The degree of MR depends on the degree of leaflet thickening and amount of flail or partially flail segments (2). When this occurs, 10-year mortality is 37% (2).
- Frequently, there is enlargement of the LA and LV.
- Mitral annulus is often dilated.
- Involvement of other valves may occur (tricuspid valve prolapse 40%, pulmonic prolapse and aortic prolapse 2–10%).
- Possible increased vagal tone
- Possible increased urine epinephrine and norepinephrine
- MVP patients often have orthostatic hypotension and tachycardia.
- Genetics causes proliferation of the spongiosa layer of the leaflets and fibrosis on the surface of them (1).
- Thinning and elongation of chordae tendineae
- The mitral valve differentiates during days 35 to 42 of fetal development, the same time as differentiation of the vertebrae and ribs.

**Genetics**
- Familial MVP is inherited as an autosomal dominant trait but with variable expressivity and incomplete penetrance.
- Two genetic loci identified
  - *MMVP1* on chromosome 16p11.2–p12.1
  - *MMVP2* on chromosome 11p15.4

**RISK FACTORS**
- MVP is a primary cardiovascular disorder.
- MVP is more likely to occur in patients with connective tissue disorders (see “Commonly Associated Conditions”).
- Physical characteristics associated with MVP
  - Straight thoracic spine
  - Pectus excavatum
  - Asthenic body habitus
  - Low body mass index (BMI)
– Scoliosis or kyphosis
– Hypermobility of the joints
– Arm span > height
– Narrow anteroposterior (AP) diameter of the chest

COMMONLY ASSOCIATED CONDITIONS
• Marfan syndrome (91% of Marfan syndrome patients have MVP, although large majority of MVP patients do not meet criteria for Marfan.)
• Ehlers-Danlos syndrome
• Hypertrophic cardiomyopathy
• Pseudoxanthoma elasticum
• Osteogenesis imperfecta
• von Willebrand disease
• Primary hypomastia
• Graves disease
• Rheumatic heart disease

DIAGNOSIS
Physical exam and echocardiography

HISTORY
• Most patients are asymptomatic.
• The most frequent symptom is palpitations.
• Symptoms related to autonomic dysfunction
  – Anxiety and panic attacks
  – Arrhythmias
  – Exercise intolerance
  – Palpitations and chest pains that are atypical for coronary artery disease (CAD)
  – Fatigue
  – Orthostasis, syncope, or presyncope
  – Neuropsychiatric symptoms
• Symptoms related to progression of MR
  – Fatigue
  – Dyspnea
  – Exercise intolerance
  – Orthopnea
- Paroxysmal nocturnal dyspnea
- Congestive heart failure (CHF)

Symptoms occur as a result of an associated complication (stroke, arrhythmia).

**PHYSICAL EXAM**

- Auscultatory examination
  - Mid-to-late systolic click
    - May vary in timing and intensity based on ventricular beat-to-beat volume variations
    - At low ventricular volumes, the valve may prolapse earlier during systole and further into the LA than during volume overload.
    - It may or may not be followed by a high-pitched, mid- to late systolic murmur at the cardiac apex.
  - Murmur: a mid- to late-crescendo systolic murmur best heard at apex, middle- to high-pitched, occasionally musical or honking in quality
  - Occasionally, only the ejection click is present.
  - The duration of the murmur corresponds with the severity of MR.
- Dynamic auscultation
  - Maneuvers that move the click and murmur toward S₁
    - Arterial vasodilation
    - Amyl nitrite
    - Valsalva
    - Augmented contractility
    - Decreased venous return (which can be induced by standing up)
  - Maneuvers that move the click and murmur toward S₂
    - Squatting
    - Leg raise
    - Isometric exercise
  - Valsalva maneuver may help differentiate hypertrophic obstructive cardiomyopathy (HOCM) from MVP because it increases the intensity of the murmur in HOCM, whereas it makes it longer but not louder in MVP.

**DIFFERENTIAL DIAGNOSIS**

- MR
- Tricuspid regurgitation
- Tricuspid valve prolapse
- Papillary muscle dysfunction
- Hypertrophic cardiomyopathy
- Ejection clicks (do not change timing with systole)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Echocardiogram (test of choice) (3)[B]
  - In asymptomatic individuals with physical signs of MVP, an echocardiogram is indicated for diagnosis (3)[B].
  - Parasternal long-axis view is most specific for diagnosis (3).
  - Findings that may be seen with MVP
    - Anterior leaflet billowing
    - Leaflet thickening of ≥5 mm
    - Leaflet redundancy
    - MR
    - Posterior leaflet displacement
  - Nondiagnostic transthoracic echocardiogram: ≤10%
  - Transesophageal echocardiography particularly with 3D imaging may be considered to further visualize the anatomy if an intervention is being planned (2)[B].
  - Stress echocardiograms may reveal exercise-induced MR or latent LV dysfunction (3)[B].

- Angiography
  - Rarely used for diagnostic purposes
  - Recommended for hemodynamic assessment when noninvasive options or inconclusive (3)[C]

- ECG is usually normal.
  - May be nonspecific ST to T wave changes
  - T-wave inversions, prominent Q waves, or prolonged QT may also occur.

- A chest x-ray (CXR) is not necessary for diagnosis.
  - Typically, the CXR is normal.
  - Other findings
    - Possible pulmonary edema: Pulmonary edema may be asymmetric with acute chordal rupture and flail leaflet.
    - Possible calcification of the mitral annulus

- Holter monitoring is optional if patient has palpitations. Order Holter monitoring as usual for syncope or dizziness.

- Tilt table testing may be of value in patients with MVP who presents with syncope of unknown etiology.
Follow-Up Tests & Special Considerations

- Periodic monitoring with TTE is recommended in asymptomatic patients with known VHD at intervals depending on valve lesion, severity, ventricular size, and ventricular function (3)[C].
- Patients with a family history of MVP should be screened with echocardiography (3)[B].

Test Interpretation

- Myxomatous proliferation of the middle layer (spongiosa) of the valve, resulting in increased mucopolysaccharide deposition and myxomatous degeneration
- By electron microscopy, the collagen fibers in the valve leaflets are disorganized and fragmented.
- With increased stroma deposition, the valve leaflets enlarge and become redundant.
- The endothelium is usually noncontiguous and a frequent site for thrombus or infective vegetation.

TREATMENT

GENERAL MEASURES

Treat MVP with orthostatic symptoms by liberalizing fluid and salt intake. If severe, mineralocorticoids may rarely be used. Support stockings may also be beneficial. In the absence of MR, no definitive treatment for MVP (2).

MEDICATION

- Asymptomatic MVP is treated with reassurance; normal lifestyle and regular exercise is encouraged.
- MVP with palpitations is treated with β-blockers and/or recommendation to discontinue alcohol, cigarettes, and caffeine.
- MVP and transient ischemic attacks are treated with aspirin 75 to 325 mg daily (3)[C].
- MVP with history of cryptogenic stroke or atrial fibrillation with CHADS₂ (acronym for Congestive heart failure, Hypertension, Age >75 years, Diabetes mellitus, and prior Stroke or transient ischemic attack) score <2 is generally treated with aspirin 75 to 325 mg daily (3)[C].
MVP with atrial fibrillation with CHADS$_2$ score $\geq$2 is treated with warfarin (3)[C].
MVP with high-risk echocardiographic features (thickening $>$5 mm or valve redundancy) and a history of stroke; warfarin therapy may be considered (3)[C].

**ADDITIONAL THERAPIES**
- Endocarditis prophylaxis is no longer recommended for patients with MVP.
- Patients with prior endocarditis undergoing dental, respiratory tract, infected skin, or musculoskeletal procedures should receive prophylaxis for endocarditis with amoxicillin 30 to 60 minutes prior to procedure. Ampicillin, cefazolin, or ceftriaxone IM or IV may be used if unable to tolerate oral medications (3)[B].

**SURGERY/OTHER PROCEDURES**
- Referral for surgery is recommended based on severity of symptoms for patients with severe MR or impaired LV systolic function or flail leaflet owing to ruptured chordae tendineae (3)[B].
- One recent meta-analysis of observational studies suggests a benefit for an early surgical approach to MVP with severe MR (4)[A] even for asymptomatic patients; prospective studies are lacking.
- Minimally invasive mitral valve repair currently being used for high-risk patients; did not reduce MR as much as surgery but similar clinical outcomes (2)[C]
- Surgical repair of MR due to isolated posterior leaflet prolapse is associated with a low reoperation rate (5)[A].
- Asymptomatic patients with atrial fibrillation or pulmonary hypertension should be considered for intervention as well (3)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Asymptomatic MVP patients with no significant MR can be followed clinically every 3 to 5 years (3)[C].
- Patients who are symptomatic or have high-risk features on initial echocardiogram, including moderate to severe MR, may need serial echocardiograms and should be followed clinically once per year (3)[C].
• Patients with MVP and severe MR may require coronary angiography and transesophageal echocardiography if cardiac surgical referral is planned (3) [C].

PATIENT EDUCATION
• No contraindication to pregnancy
• Restriction from competitive sports if patient has MVP with one of the following features:
  – A history of syncope associated with documented arrhythmia
  – A family history of MVP-related sudden cardiac death
  – Sustained or repetitive and nonsustained supraventricular tachycardia or frequent and/or complex ventricular tachyarrhythmias on ambulatory Holter monitoring
  – Severe MR
  – A prior embolic event
  – LV systolic dysfunction
• Explain the hereditary nature of familial MVP.

PROGNOSIS
• Excellent prognosis for asymptomatic patients
• For patients with severe MR or reduced ejection fraction, the prognosis is similar to that for nonischemic MR.

COMPLICATIONS
• Sudden cardiac death: not clearly established; may be secondary to ventricular arrhythmias especially if significant MR is present
• Chordae rupture with acute mitral insufficiency (higher risk of cardiac death; up to 2% per year)
• Infectious endocarditis (risk increased if murmur present)
• Cerebrovascular ischemic event
• Fibrin emboli
• Heart failure with progressive MR
• Arrhythmias such as atrial and ventricular premature beats, paroxysmal supraventricular tachycardias may all be seen. Risk increases with coexistent MR.
• Pulmonary hypertension

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

I34.1 Nonrheumatic mitral (valve) prolapse

**CLINICAL PEARLS**

- MVP patients may have orthostatic hypotension and tachycardia.
- Asymptomatic MVP patients with no significant MR can be followed clinically every 3 to 5 years. Patients who are symptomatic or have high-risk features on initial echocardiogram, including moderate to severe MR, may need serial echocardiograms and should be followed clinically once per year.
- Consider an early surgical approach for MVP with severe MR.
- Endocarditis prophylaxis is no longer recommended for MVP.
MOLLUSCUM CONTAGIOSUM

Erica F. Crannage, PharmD, BCPS, BCACP • Dawn M. Davis, MD, MPH

BASICS

DESCRIPTION
Molluscum contagiosum is a common, benign, viral (poxvirus) skin infection, characterized by small (2 to 5 mm), waxy white or flesh-colored, dome-shaped papules often with central umbilication. Lesions contain a cheesy grayish white material. Molluscum contagiosum is highly contagious and spreads by autoinoculation, skin-to-skin contact, sexual contact, and shared clothing/towels. Molluscum contagiosum is a self-limited infection in immunocompetent patients but can be difficult to treat and disfiguring in immunocompromised patients.

EPIDEMIOLOGY

Prevalence
- 1% in the United States, occurring mainly in children 2 to 15 years and sexually active young adults
- 5–18% HIV population

ETIOLOGY AND PATHOPHYSIOLOGY
- DNA virus; Poxviridae family
- Four genetic virus types, clinically indistinguishable
- Virions invade and replicate in cytoplasm of epithelial cells causing abnormal cell proliferation.
- Genome encodes proteins to evade host immune system.
- Incubation period: 2 to 6 weeks
- Time to resolution: 6 to 24 months
- Not associated with malignancy
- No cross-hybridization or reactivation by other poxviruses

RISK FACTORS
- Skin-to-skin contact with infected person
- Contact sports
- Swimming
- Eczema, atopic dermatitis
- Sexual activity with infected partner
- Immunocompromised: HIV, chemotherapy, corticosteroid therapy, transplant patients

**GENERAL PREVENTION**
- Avoid skin-to-skin contact with host (e.g., contact sports, sexual activity).
- Avoid sharing clothing and towels.

**COMMONLY ASSOCIATED CONDITIONS**
- Atopic dermatitis
- Immunosuppression medications: corticosteroids, biologics, chemotherapy, etc.
- HIV/AIDS

**DIAGNOSIS**

**HISTORY**
- Contact with known infected person
- Participation in contact sports
- Sexual activity

**PHYSICAL EXAM**
- Perform thorough skin exam including conjunctiva and anogenital area.
- Discrete, firm papules with a central umbilication
- White curdlike core under umbilicated center
- Lesions are flesh, pearl, or red in color and frequently located in intertriginous areas.
- May have surrounding erythema or dermatitis
- Immunocompetent hosts: average of 11 to 20 lesions, 2 to 5 mm diameter (range: 1 to 10 mm)
- Hosts with HIV/AIDS: hundreds of widespread lesions
- Sexually active: inner thighs, anogenital area

**Pediatric Considerations**
- Infants <3 months: Consider vertical transmission.
• Children: fever, >50 lesions, limited response to therapy; consider immunodeficiency.
• Children: anogenital lesions; consider autoinoculation/possible sexual abuse.

Differential Diagnosis
• Verruca vulgaris
• AIDS patients: cryptococcus, penicilliosis, histoplasmosis, coccidioidomycosis
• Basal cell carcinoma
• Benign appendageal tumors: syringomas, hidrocystomas, ectopic sebaceous glands
• Condyloma acuminatum
• Dermatofibroma
• Eyelid: abscess, chalazion, foreign-body granuloma
• Folliculitis/furunculosis
• Keratoacanthoma
• Oral squamous cell carcinoma
• Trichoepithelioma
• Warty dyskeratoma
• Amelanotic melanoma

Diagnostic Tests & Interpretation
Initial Tests (lab, imaging)
• Virus cannot be cultured.
• Culture lesion if concern is secondary infection
• Sexual transmission: Test for other sexually transmitted infections, including HIV.
• Microscopy: scrape lesion
  – Core material has characteristic Henderson-Paterson intracytoplasmic viral inclusion bodies.
  – Crush prep with 10% potassium hydroxide will show characteristic inclusion bodies as well.
  – Alternatively, hematoxylin-eosin-stained formalin-fixed tissue shows same confirmatory features.

Diagnostic Procedures/Other
Clinical; using magnifying lens
**Test Interpretation**
Molluscum cytoplasmic inclusion bodies within keratinocytes

**TREATMENT**

**GENERAL MEASURES**
- In healthy patients, molluscum contagiosum is generally self-limited and resolves spontaneously; therefore, treatment is optional (1)[A].
- No single intervention is shown to be convincingly more effective than any other in treating molluscum contagiosum (1)[A].
- There are no FDA-approved treatments for molluscum contagiosum.
- Three categories of treatment: destructive, immune-enhancing, and antiviral
- Imiquimod is no longer recommended as treatment.

**MEDICATION**

**First Line**
- Cantharidin 0.7–0.9% solution: In office application to lesions, cover with dressing; wash off in 2 to 6 hours or sooner if blistering. Repeat treatment every 2 to 4 weeks until lesions resolve (1)[B].
  - Not commercially available in the United States but may be prepared in United States by compounding pharmacy from powder; might be available as solution from Canada
  - Adverse effects: blistering, erythema, pain, pruritus
  - Precautions: Do not use on face or on genital mucosa.

**Second Line**
- Benzoyl peroxide 10% cream: Apply to each lesion twice daily for 4 weeks (1)[B].
  - Inexpensive
  - Adverse effects: mild dermatitis
- For immunocompromised patients with refractory lesions, consider
  - Starting or maximizing HAART in patients with HIV/AIDS (2)[C]
  - Cidofovir
    - 3% cream applied to lesions once daily, 5 days/week for 8 weeks or 1% cream applied to lesions once daily, 5 days/week for 2 weeks; repeat in 1 month, if necessary (2)[C].
- Adverse effects with topical use: erythema, pain, pruritus, erosions
- 3 to 5 mg/kg IV weekly for 1 to 2 weeks, followed by IV infusions every other week, until clinical clearance or up to 9 infusions (3)[C]
- Adverse effects with IV use: nephrotoxicity, neutropenia
- Monitoring with IV use: renal function and complete blood counts prior to and 24 to 48 hours after infusions
- Precaution: must coadminister oral probenecid and provide IV hydration with each IV infusion; refer to cidofovir manufacturer’s recommendations on probenecid dosing.

**SURGERY/OTHER PROCEDURES**
Considered first-line treatment, if treatment is pursued

- Cryotherapy: 5 to 10 seconds with 1- to 2-mm margins; repeat every 3 to 4 weeks as needed until lesions disappear (4)[B].
  - Adverse effects: erythema, edema, pain, blistering
  - Contraindications: cryoglobulinemia, Raynaud disease
- Curettage under local or topical anesthesia (1)[A]
  - Adverse effects: pain, scarring

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

- Australian lemon myrtle oil: Apply 10% solution once daily for 21 days (1)[B].
- Potassium hydroxide 5–10% solution: Apply 1 to 2 times a day until the lesions disappeared completely (1)[B].

**Pediatric Considerations**
- Due to the self-limiting nature of the disease, for immunocompetent children, treatment is optional.
- Surgical interventions: second line in small children due to associated pain
- Pain control: Pretreat with topical lidocaine or EMLA before surgical treatment.
- Note: Adverse effect:
  - Lidocaine or EMLA over large body surface area: Methemoglobinemia and CNS toxicity. Refer to manufacturer’s recommendations on dosing and use in children.

**Pregnancy Considerations**
Treatments safe in pregnancy: curettage, cryotherapy, incision, and expression

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

Depends on type of treatment

PATIENT EDUCATION

- Cover lesions to prevent spread.
- Avoid scratching to prevent autoinoculation.
- Avoid sharing towels and clothing.
- Avoid sexual activity when lesions present.

PROGNOSIS

- Immunocompetent: self-limited, resolves in 3 to 12 months (range: 2 months to 4 years)
- Immunocompromised: lesions difficult to treat; may persist for years

COMPLICATIONS

- Secondary infection
- Scarring, hyper-/hypopigmentation—(generally only occurs as a result of treatment, not when lesions resolve spontaneously)

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

B08.1 Molluscum contagiosum

CLINICAL PEARLS

- Observation is preferred treatment in healthy patients as lesions will spontaneously resolve.
- Reassure parents that lesions will heal naturally and generally resolve without scarring.
- No specific treatment has been identified as superior to any other.
- Consider topical corticosteroids for pruritus or associated dermatitis.
MORTON NEUROMA (INTERDIGITAL NEUROMA)

Scott Goldberg, MD • J. Herbert Stevenson, MD

BASICS

DESCRIPTION

- Painful condition of the webbed spaces of the toes
- Features perineural fibrosis of the common digital nerve as it passes between metatarsals
  - The interspace between the 3rd and 4th metatarsals is most commonly affected.
  - The interspace between the 2nd and 3rd metatarsals is the next most common site.
- Systems affected: musculoskeletal, nervous
- Synonyms: plantar digital neuritis; Morton metatarsalgia; intermetatarsal neuroma

EPIDEMIOLOGY

Prevalence

- Unknown
- Mean age: 45 to 50 years
- Predominant sex: female > male (8:1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Lateral plantar nerve joins a portion of medial plantar nerve, creating a nerve with a larger diameter than those going to other digits.
- Etiology not fully understood. Four main theories:
  - Chronic traction damage
  - Inflammatory environment due to intermetatarsal bursitis
  - Compression by the deep transverse intermetatarsal ligament
  - Ischemia of vasa nervorum
- Nerve lies in SC tissue, deep to the fat pad of foot, just superficial to the digital artery and vein.
- Overlying, the nerve is the strong, deep transverse metatarsal ligament that

mebooksfree.com
holds the metatarsal bones together.

- With each step the patient takes, the inflamed nerve becomes compressed between the ground and the deep transverse metatarsal ligament. This can generate perineural fibrotic reaction with subsequent neuroma formation.

**RISK FACTORS**

- High-heeled shoes  
  - Transfer more weight to the forefoot.
- Shoes with tight toe boxes  
  - Cause lateral compression
- Pes planus (flat feet)  
  - Pulls nerve medially, increasing irritation
- Obesity
- Female gender
- Ballet dancing, particularly associated with the demi-pointe position
- Basketball, aerobics, tennis, running, and similar activities
- Hyperpronation

**GENERAL PREVENTION**

- Wear properly fitting shoes.
- Avoid high heels and shoes with narrow toe boxes.

**DIAGNOSIS**

**HISTORY**

- Most common complaint is pain localized to interspace between 3rd and 4th toes.
- Pain is less severe when not bearing weight.
- Pain, cramping, or numbness of the forefoot during weight bearing or immediately after strenuous foot exertion
- Radiation of pain to the toes
- Pain is relieved by removing shoes and massaging the foot.
- Patients often complain of “walking on a marble.”
- Burning pain in the ball of the foot radiating to the toes
- Tingling or numbness in the toes
- Aggravated by wearing tight or narrow shoes
PHYSICAL EXAM
- Intense pain when pressure applied between metatarsal heads, sometimes with a palpable nodule
- Assess midfoot motion and digital motion to determine if arthritis or synovitis.
- Palpate along metatarsal shafts to assess for metatarsalgia or stress fractures.
- Special testing (see "Diagnostic Procedures/Other")

DIFFERENTIAL DIAGNOSIS
- Stress fracture
- Hammer toe
- Metatarsophalangeal synovitis
- Metatarsalgia
- Arthritis
- Traumatic neuroma
- Osteomyelitis
- Bursitis
- Foreign body
- Freiberg infraction (avascular necrosis of the metatarsal head, most commonly in adolescent females at the 2nd metatarsal)
- Neoplasm (malignancy, osteochondroma, neurofibroma)
- Gout

DIAGNOSTIC TESTS & INTERPRETATION

*Initial Tests (lab, imaging)*
- Predominantly a clinical diagnosis; imaging should be reserved for when the diagnosis is unclear (1)[A].
- Imaging may be helpful if more than one web space is involved.
- Radiographs may help to rule out osseous pathology if diagnosis is in question, but plain films usually are normal in patients with a Morton neuroma (1)[A].
- Ultrasound (US) has 79% specificity and 99% sensitivity for Morton neuromas but is poor at assessing the size of the lesion. Specificity declines to 50% for lesions <6 mm (1)[A].
- MRI can rule out an osseous tumor and help with surgical planning; MRI has a sensitivity of 83% and a specificity of 99% for diagnosis of Morton neuroma (1)[A].
**Diagnostic Procedures/Other**

- Five special tests have been described: thumb index finger squeeze test, Mulder sign, foot squeeze test, plantar percussion test, and toe tip sensation deficit.
  - Thumb index finger squeeze test is the most sensitive and specific (96% and 96%, respectively). Positive when pain elicited by squeezing the symptomatic intermetatarsal space between the index finger and thumb (2)[B].
  - Mulder sign is a painful “click” produced by squeezing the metatarsal heads together while compressing the neuroma between the thumb and index finger of the other hand; sensitivity 40–84% (1)[A]
  - Foot squeeze test is positive when pain is induced in the symptomatic web space when the metatarsal heads are compressed by grasping the foot; sensitivity 40% (2)[B]
  - Plantar and dorsal percussion tests are positive when percussion of the affected webspace elicits pain.
  - Toe tip sensation deficit exists when the sensation of the toe distal to the affected web space is decreased relative to the other toes.
- More than one of the above tests being positive increases the diagnostic accuracy (3)[B].

**Test Interpretation**

Pathologic examination shows chronic fibrosis and thickening within and around the digital nerve. Arterial thickening and thrombosis of the common digital artery is sometimes present.

**TREATMENT**

**GENERAL MEASURES**

- Stepwise treatment, with typical progression from conservative measures followed by infiltrative treatment, and ultimately surgical treatment.
  - Surgical treatments are the most successful (89%) followed by infiltrative (84%) then conservative (48%) as assessed by patient satisfaction with pain reduction at 6 months or greater (4)[A].
- Conservative treatments include
  - Flat shoes with a roomy toe box
  - Plantar pads may help with alignment of metatarsal heads to provide relief.
NSAIDs for temporary symptom relief. There is no evidence for the use of supinatory insoles (5)[A].

**MEDICATION**

*First Line*

Injectable steroids (e.g., betamethasone phosphate/acetate or methylprednisolone): number needed to treat (NNT) for significant benefit over conservative measures at 6 months = 2.3 (4,6)[A]

*Second Line*

US-guided alcohol ablation therapy to sclerose the nerve is effective and has a lower complication rate than surgery (4)[A].

**ISSUES FOR REFERRAL**

- Continued pain despite conservative treatments and injections
- Large interdigital neuromas (>5 mm diameter) or young patients, who may benefit from earlier operative intervention

**SURGERY/OTHER PROCEDURES**

- Surgical removal of the neuroma or shortening of the metatarsals, with or without release of the transverse metatarsal ligament, have an 89% success rate at 6 months defined by satisfaction scores (4)[A].
- Small trials have been conducted using other invasive, nonsurgical techniques including injection with botulinum toxin, cryoablation, radiofrequency ablation, and platelet-rich plasma, but evidence is limited at this time.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

At diagnosis, or if no improvement after 3 months of conservative treatment, consider corticosteroid injection.

- May repeat injection if no improvement after 2 to 4 weeks, or consider referring for surgical management.
- 21–51% of patients receiving a single corticosteroid injection require surgical intervention within 2 to 4 years (7)[B].
- Size >5 mm and younger patients are more likely to undergo invasive
PATIENT EDUCATION
Wear properly fitting comfortable shoes.

PROGNOSIS
- 48% satisfaction rate with conservative treatment
- 85% satisfaction rate with infiltrative treatment
- 89% satisfaction rate with operative treatment (4)[A]

COMPLICATIONS
- Hip and knee pain can develop secondary to gait changes.
- Complications vary by treatment type.
- Failure rate is 47% with conservative treatment; 9–23% with invasive, nonsurgical treatment; 4% with surgical treatment (4)[A].
- Surgical complications vary by specific procedure and include keloid, CRPS, and stiffness. There was a global complication rate of 21% with operative treatment (4)[A].

REFERENCES
ADDITIONAL READING

CODES

ICD10

- G57.60 Lesion of plantar nerve, unspecified lower limb
- G57.61 Lesion of plantar nerve, right lower limb
- G57.62 Lesion of plantar nerve, left lower limb

CLINICAL PEARLS

- Morton neuroma is usually a clinical diagnosis but can be further evaluated with US or MRI.
- Typical treatment is stepwise with conservative, then infiltrative, and then operative treatment.
- Morton neuromas with >5 mm diameter are more likely to require operative treatment.
- Younger patients are more likely to require operative treatment.
- Neurectomy is the definitive treatment. Patients should be aware of surgical complications.
MOTION SICKNESS

Courtney I. Jarvis, PharmD • Allison Hargreaves, MD

BASICS

DESCRIPTION

• Motions sickness is not a true sickness but a normal response to a situation in which sensory conflict about body motion exists among visual receptors, vestibular receptors, and body proprioceptors.
• Also can be induced when patterns of motion differ from those previously experienced
• System affected: nervous
• Synonym(s): car sickness; sea sickness; air sickness; space sickness; physiologic vertigo

EPIDEMIOLOGY

Incidence
Predominant sex: female > male

Prevalence
Estimation is complex; syndrome occurs in ~25% due to travel by air, ~29% by sea, and ~41% by road. Estimates for vomiting are 0.5% by air, 7% by sea, and 2% by road.

ETIOLOGY AND PATHOPHYSIOLOGY

• Precise etiology unknown; thought to be due to a mismatch of vestibular and visual sensations
• Rotary, vertical, and low frequency motions produce more symptoms than linear, horizontal, and high-frequency motions.
• Nausea and vomiting occur as a result of increased levels of dopamine and acetylcholine, which stimulate chemoreceptor trigger zone and vomiting center in CNS.

Genetics
Heritability estimates range from 55% to 75%.
RISK FACTORS
- Motion (auto, plane, boat, amusement rides)
- Visual stimuli (e.g., moving horizon)
- Poor ventilation (fumes, smoke, carbon monoxide)
- Emotions (fear, anxiety)
- Zero gravity
- Pregnancy, menstruation, oral contraceptive use
- History of migraine headaches, especially vestibular migraine

GENERAL PREVENTION
See “General Measures.”

Pediatric Considerations
- Rare in children <2 years of age
- Incidence peaks between 3 and 12 years of age.
- Antihistamines may cause excitation in children.

Geriatric Considerations
- Age confers some resistance to motion sickness.
- Elderly are at increased risk for anticholinergic side effects from treatment.

Pregnancy Considerations
- Pregnant patients are more likely to experience motion sickness.
- Treat with medications is thought to be safe during morning sickness (e.g., meclizine, dimenhydrinate).

COMMONLY ASSOCIATED CONDITIONS
- Migraine headache
- Vestibular syndromes

DIAGNOSIS
HISTORY
Presence of the following signs and symptoms in the context of a typical stimulus (1)[C]:
- Nausea
- Vomiting
- Stomach awareness (feeling of fullness in epigastrium)
- Diaphoresis
- Facial and perioral pallor
- Hypersalivation
- Yawning
- Hyperventilation
- Anxiety
- Panic
- Malaise
- Fatigue
- Weakness
- Confusion
- Dizziness

**PHYSICAL EXAM**
No specific findings

**DIFFERENTIAL DIAGNOSIS**
- Mountain sickness
- Vestibular disease, central and peripheral
- Gastroenteritis
- Metabolic disorders
- Toxin exposure

**DIAGNOSTIC TESTS & INTERPRETATION**
None indicated

**TREATMENT**
- Follow guidelines under “General Measures” section to prevent motion sickness (1)[C].
- Premedicate before travel with antidopaminergic, anticholinergic, or antihistamine agents (1)[A]:
  - For extended travel, consider treatment with scopolamine transdermal patch (2)[A].
  - 2nd-generation (nonsedating) antihistamines are not effective at preventing motion sickness (3)[B].
- Serotonin (5-HT3) antagonists (e.g., ondansetron) are not effective in preventing motion sickness (4)[B].
- Conflicting data exist on the efficacy of acupressure for nausea and vomiting associated with motion sickness (5)[B].
- Benzodiazepines suppress vestibular nuclei but would not be considered first line due to sedation and addiction potential (6)[C].
- Serotonin receptor agonist (rizatriptan) may be effective for migraineurs with motion sickness (7)[C].

GENERAL MEASURES
- Avoid noxious types of motions.
- Choose locations within vehicle that minimizes motion (airplanes: over the wing; automobiles: driver’s or front passenger seat, facing forward; boat: facing toward the waves, away from rocking bow, near surface of the water; buses: near the front, at lowest level, facing forward; trains: at lowest level, facing forward).
- Improve ventilation; avoid noxious stimuli.
- Use semirecumbent seating or lay supine.
- Fix vision on horizon; avoid fixation on moving objects; keep eyes fixed on still, distant objects.
- Avoid reading while actively traveling.
- Frequent and graded exposure to stimulus that triggers nausea (habituation)
- Eat before travel, avoid empty stomach; eat light, soft, bland, low-fat, and low-acid foods; avoid alcohol.
- Increase airflow around face.

Acupressure on point PC6 has been shown to reduce feelings of nausea but not the incidence of vomiting during pregnancy, after surgery, and in cancer chemotherapy. However, conflicting evidence of efficacy has been found for motion sickness; point PC6 (Neiguan on pericardium meridian): 2 cm proximal of transverse crease of palmar side of wrist between tendons of the palmaris longus and the flexor carpi radialis (5)[B]

MEDICATION

First Line
- Scopolamine transdermal patch (Transderm Scop): Apply 2.5-cm² (4 mg) patch behind ear at least 4 hours (preferably 6 to 12 hours) before travel and replace every 3 days (2)[A].
- Dimenhydrinate (Dramamine): Take 30 to 60 minutes before travel.
– Adults and adolescents: 50 to 100 mg q4–6h, maximum 400 mg/day
– Children 6 to 12 years of age: 25 to 50 mg q6–8h, maximum 150 mg/day
– Children 2 to 5 years of age: 12.5 to 25.0 mg q6–8h, maximum 75 mg/day
• Meclizine (Antivert): Take 60 minutes before travel.
  – Adults and adolescents >12 years of age: 25 to 50 mg q24h
  – Children <12 years of age: not recommended
• Diphenhydramine (Benadryl): Take 30 to 60 minutes before travel.
  – Adults and adolescents: 25 to 50 mg q6–8h, maximum 300 mg/day
  – Children 6 to 12 years of age: 5 mg/kg or 12.5 to 25.0 mg q6–8h, maximum 300 mg/day
• Promethazine (Phenergan): Take 30 to 60 minutes before travel.
  – Adults and adolescents: 25 mg q12h; 25 to 50 mg IM if already developed severe motion sickness
  – Children 2 to 12 years of age: 0.5 mg/kg q12h, maximum 25 mg BID; caution: increased risk of dystonic reaction in this age group
• Contraindications: patients at risk for acute angle-closure glaucoma
• Precautions:
  – Young children
  – Elderly
  – Pregnancy
  – Urinary obstruction
  – Pyloric-duodenal obstruction
• Adverse reactions:
  – Drowsiness
  – Dry mouth
  – Blurred vision
  – Confusion
  – Headache
  – Urinary retention
• Significant possible interactions:
  – Sedatives (antihistamines, alcohol, antidepressants)
  – Anticholinergics (belladonna alkaloids)

**Second Line**
• Benzodiazepines: Take 1 to 2 hours before travel.
  – Diazepam 2 to 10 mg PO q6–12h
  – Lorazepam 1 to 2 mg PO q8h
• Contraindications:
  – Severe respiratory dysfunction
– Severe liver dysfunction

Precautions:
– Alcohol/drug abuse
– Elderly
– Sedation
– Addiction is possible.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Ginger: 940 mg or 1 g; take 4 hours before travel (evidence controversial) [8] [B].

ONGOING CARE

DIET

– Eat before travel, avoid empty stomach; eat light, soft, bland, low-fat, and low-acid foods.
– Avoid alcohol.

PROGNOSIS

– Symptoms should resolve when motion exposure ends.
– Resistance to motion sickness seems to increase with age.

COMPLICATIONS

– Hypotension
– Dehydration
– Depression
– Panic
– Syncope

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Dizziness

**CODES**

**ICD10**
T75.3XXA Motion sickness, initial encounter

**CLINICAL PEARLS**

- The scopolamine patch should be applied at least 4 hours before travel, although it may be more effective if placed 6 to 12 hours before departure.
- Oral medications should be administered 30 to 60 minutes before departure.
- Although acupressure wristbands have been found to be effective by systematic reviews in postoperative and chemotherapy-induced nausea and vomiting, conflicting data exist for motion sickness.
MULTIPLE MYELOMA

Yen H. Phan, DO • Nida Emko, MD

BASICS

DESCRIPTION

- Multiple myeloma (MM) is a clonal proliferation of malignant plasma cells.
- This clonal proliferation in the bone marrow (BM) can cause extensive skeletal destruction with osteolytic lesions and pathologic fractures.
- The malignant plasma cells produce monoclonal protein in the blood and urine.
- MM is also characterized by hypercalcemia, increased susceptibility to infections, renal impairment, and end-organ damage.
- Monoclonal gammopathy of undetermined significance (MGUS) is a common disorder with limited monoclonal plasma cell proliferation that progresses to MM at rate of ~1% per year.
- MGUS progresses to smouldering or asymptomatic MM and eventually to symptomatic MM.
- Synonym(s): plasma cell myeloma; plasma cell leukemia

EPIDEMIOLOGY

- Accounts for ~1% of all cancers and slightly >10% of hematologic malignancies in the United States
- Median age of diagnosis is 66 years.
- Slight male predominance. Blacks about 2 to 3 times more commonly affected than whites; less common in Asians

Incidence

4 to 5 new cases/100,000 annually

Prevalence

In 2012, there were 89,658 cases in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY

- Clonal proliferation of plasma cells derived from postgerminal center B cells
- Plasma cells undergo multiple chromosomal mutations to progress to MM.
Genetic damage in developing B lymphocytes at time of isotype switching, transforming normal plasma cells into malignant cells, arising from single clone.

Earliest chromosomal translocations involve immunoglobulin (Ig) heavy chains on chromosome 14q32, with the translocation at t(4;14), t(14;16), t(14;20), and deletion, del(17p) having a poorer prognosis.

Malignant cells multiply in BM, suppressing normal BM cells and producing large quantities of monoclonal Ig (M) protein.

Malignant cells stimulate osteoclasts that cause bone resorption and inhibit osteoblasts that form new bone, causing lytic bone lesions.

**Genetics**

Rare family clusters; the hyperphosphorylated form of Paratarg-7, a protein of unknown significance, is inherited as an autosomal dominant trait in familial cases of MM and MGUS, suggesting a potential pathogenic role.

**RISK FACTORS**

- Most cases have no known risks associated.
- Older age; immunosuppression; and chemicals like dioxin, herbicides, insecticides, petroleum, heavy metals, plastics, and ionizing radiation increase the risk of MM.
- MGUS stage consistently precedes MM.

**COMMONLY ASSOCIATED CONDITIONS**

Secondary amyloidosis commonly due to MM.

**DIAGNOSIS**

**HISTORY**

- 34% of patients are asymptomatic at the time of presentation.
- Hypercalcemia (28%): anorexia, nausea, somnolence, and polydipsia
- Elevated creatinine (48%)
- Anemia (73%)
- Bony lesions (80%): lytic lesions causing bone pain (58%) (1), osteoporosis, or pathologic fracture (26–34%)
- Other symptoms: fatigue (32%), peripheral neuropathy, weight loss (24%), recurrent infections, hyperviscosity syndrome, and cord compression
PHYSICAL EXAM

- Dehydration
- Skin findings of amyloidosis: waxy papules, nodules, or plaques that may be evident in the eyelids, retroauricular region, neck, or inguinal and anogenital regions; petechiae and ecchymosis; “pinch purpura”
- Extramedullary, plasmacytomas can present as large, purplish, subcutaneous masses.
- Hyperviscosity syndrome in 7%: retinal hemorrhages, prolonged bleeding, neurologic changes
- Tender bones and masses

DIFFERENTIAL DIAGNOSIS

- MGUS
- Smoldering MM
- Metastatic carcinoma (kidney, breast, non–small cell lung cancer)
- Waldenström macroglobulinemia
- AL amyloidosis
- Solitary plasmacytoma
- Polyneuropathy, organomegaly, endocrinopathy, M protein, skin changes (POEMS) syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Criteria for diagnosis: The diagnosis of MM requires the following (2)[A]:

- BM involvement with ≥10% of plasma cells or the presence of a plasmacytoma and any one or more of the following myeloma defining events:
  - Evidence of end-organ damage that can be attributed to the underlying plasma cell proliferative disorder, specifically:
    - Hypercalcemia: serum calcium >0.25 mmol/L (>1 mg/dL) higher than the upper limit of normal or >2.75 mmol/L (>11 mg/dL)
    - Renal insufficiency: creatinine clearance <40 mL/min or serum creatinine >177 µmol/L (>2 mg/dL)
    - Anemia: hemoglobin value of >20 g/L below the lower limit of normal or a hemoglobin value <100 g/L
    - Bone lesions: one or more osteolytic lesions on skeletal radiography, CT, or PET-CT
  - Any one or more of the following biomarkers of malignancy:
    - Clonal BM plasma cell percentage ≥60%
Involved: uninvolved serum free light chain (FLC) ratio ≥100
>1 focal lesions on MRI studies

**Initial Tests (lab, imaging)**
- CBC with differential to evaluate anemia and other cytopenias with evaluation of peripheral blood smear
- BUN, creatinine (elevated creatinine due to myeloma cast nephropathy)
- Serum electrolytes, serum albumin, serum calcium
- Serum lactate dehydrogenase (LDH), β2-microglobulin
- Serum protein electrophoresis (SPEP), serum immunofixation electrophoresis (SIFE): M protein level elevated
- Quantitative serum Ig levels: IgG, IgA, and IgM
- Quantitative serum FLC levels: κ and λ chains
- Elevated ESR, C-reactive protein
- Urine analysis: 24-hour urine for protein, urine protein electrophoresis (UPEP), urine immunofixation electrophoresis (UIFE); 20% positive urine protein (3)[A]:
  - Urinalysis dip is often negative for protein, as this test identifies albumin, and the protein in MM is Bence-Jones (BJ) monoclonal protein.
- Cross sectional imaging is preferred over plain radiographs for the detection of bone involvement (4)[B].
- Recommend whole body low-dose CT as a baseline assessment of bone involvement because it is quick, convenient, relatively sensitive, and cost effective.
- Skeletal surveys are reserved for patients who are unable to undergo low-dose whole body CT, MRI, and PET.

**Follow-Up Tests & Special Considerations**
- For patients with suspected smoldering MM (no bone lesions on CT), a whole body MRI or MRI of the spine and pelvis is recommended for concern of cord compression.
- For patients with suspected extramedullary disease outside of the spine, a whole body PET/CT is recommended.
- Baseline bone densitometry may be indicated (3)[A].
- BM aspiration and biopsy for histology, immunohistochemistry, flow cytometry, cytogenetics, and fluorescence in situ hybridization (FISH) as well as to monitor response to treatment
- SPEP with SIFE: M protein helps to track progression of myeloma and
response to treatment.

- Serum immunoglobulins and FLCs can be used to monitor response or relapse.
- Plasma cell labeling index may be helpful to identify the fraction of the myeloma cell population that is proliferating (3)[A].

**Diagnostic Procedures/Other**

**Staging:**

- Durie-Salmon stage
  - Stage I: low cell mass: \(<0.6 \times 10^{12}\) cells/m\(^2\) plus all of the following: hemoglobin >10 g/dL, M protein <5 g/dL if IgG or <3 g/dL if IgA, normal serum calcium, urine BJ protein <4 g/24 hr, no generalized lytic bone lesions
  - Stage II: neither stage I nor stage III
  - Stage III: high cell mass: \(>1.2 \times 10^{12}\) cells/m\(^2\) plus one or more of the following: hemoglobin <8.5 g/L, serum calcium >12 mg/dL, bone lesions, M protein >7 g/dL if IgG and >5 g/dL if IgA, urine BJ protein >12 g/24 hr, advanced lytic bone lesions
- International staging system (ISS)
  - Stage I: albumin \(\geq 3.5\) g/dL and \(\beta_2\)-microglobulin <3.5 \(\mu\)g/mL
  - Stage II: neither stage I nor stage III
  - Stage III: \(\beta_2\)-microglobulin \(\geq 5.5\) \(\mu\)g/mL
- Mayo Clinic risk stratification (mSMART)
  - Standard risk: t(11:14), t(6:14), and hyperdiploidy
  - Intermediate risk: t(4:14), del(13q) by cytogenetics, hypodiploidy
  - High risk: t(14:16), t(14:20), del(17 p), and plasma cell labeling index >3%

**Test Interpretation**

BM involvement with plasma cells \(\geq 10\%\); Russell bodies

**TREATMENT**

- Treatment varies depending on level of disease activity and stage of MM.
- Key determinant factor in choosing chemotherapy regimen is to establish if the patient is an autologous stem cell transplant (ASCT) candidate or not.
- Treatment protocols vary by institution and patient.
- ASCT following induction chemotherapy is standard of care for patients with
symptomatic disease.

**GENERAL MEASURES**
Maintain adequate hydration to prevent renal insufficiency. All patients receiving primary melanoma therapy should be given bisphosphonates initially (3)[A].

**MEDICATION**
- Induction chemotherapy for ASCT-eligible patients (1)[C]:
  - Standard risk: lenalidomide/low-dose dexamethasone
  - Intermediate risk: bortezomib/cyclophosphamide/dexamethasone
  - High risk: bortezomib/lenalidomide/dexamethasone
- After ASCT, maintenance can include a bortezomib compound for the high- or intermediate-risk group; lenalidomide can be considered for the standard group. Maintenance lenalidomide after ASCT has shown to improve progression-free survival (PFS) of 41 versus 23 months with placebo and has shown to be an effective treatment for MM (5)[A].
- Induction chemotherapy for ASCT-ineligible patients:
  - Same regimens as ASCT-eligible patients; however, the number of treatment cycles are increased (1)[C].

**First Line**
- Bortezomib
  - A proteasome inhibitor; it blocks the ubiquitin-proteasome catalytic pathway in cells by binding to the 20S proteasome complex.
  - Toxicity: peripheral neuropathy, cytopenia, nausea
  - Consider herpes simplex virus (HSV) prophylaxis.
- Cyclophosphamide
  - Nitrogen mustard–derivative alkylating agent
  - Often used in combination with prednisone or thalidomide in cases of relapsed disease
  - Toxicity: cytopenia, anaphylaxis, interstitial pulmonary fibrosis, secondary malignancy, impaired fertility
- Immunomodulators
  - Thalidomide and lenalidomide
    - Works by antiangiogenesis inhibition, immunomodulation, and inhibition of tumor necrosis factor
    - Toxicity: birth defects, deep vein thrombosis (DVT), neuropathy, rash,
nausea, bradycardia
- DVT prophylaxis, usually with aspirin

- **Dexamethasone**
  - Low doses (40 mg/week) superior to higher doses
  - Increases risk of DVT

- **Bisphosphonates** (6)[A]
  - No effect on mortality but decrease pain, pathologic vertebral fractures, and fractures of other bones
  - IV pamidronate or zoledronic acid can be used; evidence that zoledronic acid may be superior in preventing skeletal-related events
  - Dose-adjust/monitor renal function.
  - Monitor for osteonecrosis of jaw.

- **Alternative options:**
  - As first-line treatment for transplant-ineligible patients with newly diagnosed MM, bortezomib/melphalan/prednisone was associated with significantly increased PFS compared with melphalan/prednisone (7)[A].

### Second Line
- May be treated with any of the agents not already used
- The following agents can be used as salvage therapy to treat relapsed or refractory MM:
  - Bortezomib/lenalidomide
  - Liposomal doxorubicin
  - Carfilzomib: 2nd-generation selective proteasome inhibitor

- Emerging options: pomalidomide, thalidomide analog
- Bortezomib is a highly effective option in previously treated/relapse patients and is well-tolerated.
- Interferon-α may be appropriate in selected patients, but because of its toxicity and availability of better alternatives, it has a limited role in treating MM.

### ISSUES FOR REFERRAL
For spinal or other bone pathology, refer to orthopedics for support.

### ADDITIONAL THERAPIES
- Local radiation therapy for bone pain
- Effective pain management: Avoid NSAIDs due to nephrotoxicity.
- Kyphoplasty/vertebroplasty: Consider for symptomatic vertebral compressions.
- Plasmapheresis: for hyperviscosity syndrome (a rare complication)
- Erythropoietin: for selected patients with anemia
- Patients should receive vaccines for pneumococcus and influenza.
- Do not administer zoster and other live-virus vaccines.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Indications: pain, infections, cytopenia, renal failure, bone complications, spinal cord compression

- Avoid IV radiographic contrast materials due to risk for contrast-induced nephropathy.
- Adequate hydration
- Manage hypercalcemia and control hyperuricemia.

**ONGOING CARE**

**PATIENT EDUCATION**

- [http://myeloma.org/Main.action](http://myeloma.org/Main.action)

**PROGNOSIS**

- Median survival overall is 3 years. The 5-year survival rate is around 35%.
- Median survival by ISS stage:
  - Stage I: 62 months
  - Stage II: 44 months
  - Stage III: 29 months
- Median survival in patients with high-risk MM (see staging for definition) is <2 to 3 years, even after ASCT; standard risk has median overall survival of 6 to 7 years.

**COMPLICATIONS**

Many; including infection, pain, lytic bone lesions, hypercalcemia, hyperuricemia, spinal cord compression, anemia, hyperviscosity syndrome, amyloidosis, renal insufficiency

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- C90.00 Multiple myeloma not having achieved remission
- C90.01 Multiple myeloma in remission
C90.02 Multiple myeloma in relapse

CLINICAL PEARLS

- MM is a plasma cell malignancy that causes end-organ damage.
- Look for presence of “CRAB” (hypercalcemia, renal insufficiency, anemia, and bone lesions).
- Suspect MM if high total protein-to-albumin ratio is present.
- Maintain high index of suspicion for spinal cord compression.
- Avoid nephrotoxins (radiographic contrast material, NSAIDs, dehydration).
- Patients with MM are immunocompromised.
MULTIPLE SCLEROSIS

Jack R. Stacey, MD • Andrew J. McDermott, MD

BASICS

DESCRIPTION

- An autoimmune disease directed against components of the myelin sheath causing demyelination often leading to progressive axonal loss and eventual CNS atrophy affecting primarily white matter but may also damage grey matter and overlying meninges
- Four clinical subtypes of multiple sclerosis (MS):
  - Clinically isolated syndrome (CIS): a patient’s initial symptom characteristic of CNS demyelination that may be due to MS but does not fulfill the criteria of dissemination in time. Approximately 60% of individuals diagnosed with CIS will later relapse and be diagnosed with MS.
  - Relapsing-remitting multiple sclerosis (RRMS): episodic flare-ups occurring over days to weeks between periods of neurologic stability. During attacks, new symptoms may present, whereas previous symptoms may worsen. Complete recovery or residual deficits may ensue following each bout (~90% of patients).
  - Secondary progressive multiple sclerosis (SPMS): a gradual decline in disease status after an initial relapsing-remitting disease course. Progressive phase may be associated with acute exacerbations. SPMS is often diagnosed retrospectively.
  - Primary progressive multiple sclerosis (PPMS): a progressive decline in disease status and accumulation of disability from onset of disease without an initial relapsing-remitting disease course (~10% of patients) (1)

Pregnancy Considerations

- Pregnancy is not precluded in MS; however, multidisciplinary pregnancy planning is essential.
- In most cases, MS treatment should be discontinued during pregnancy.
- A majority of patients experience reduced disease exacerbations during pregnancy, but frequency of relapse typically increases in the postpartum period.
- MS therapy should be promptly resumed after delivery, particularly for individuals with very active disease prior to conception.
- All drugs licensed for MS treatment are contraindicated during breastfeeding. Patients desiring to breastfeed should carefully consider risk of delaying MS treatment (2).

**Epidemiology**

MS is a complex condition that is multifactorial, and although advances in genomics and immunology have increased our understanding of the disease process, much is yet to be discovered. It most often affects Caucasian women in their 2nd and 3rd generations of life and is more common in those with first-degree relatives with the disease.

**Incidence**
- Women (worldwide): 3.6 cases/100,000 person-years
- Men (worldwide): 2.0 cases/100,000 person-years

**Prevalence**
- United States: ~400,000 MS patients
- Worldwide: ~2,500,000 MS patients

**Etiology and Pathophysiology**
- Predominately an autoimmune process driven by T-cells and B-cells against the myelin sheath. Dysregulation and mistaken antigen identity lead CD4 T-cells to cross the blood–brain barrier and recognize proteins on the surface of the myelin sheath. Cytokines, interferon-γ, and tumor necrosis factor-α are subsequently released, and activation of macrophages and B-cells leads to oligodendrocyte and myelin destruction.
- Following demyelination, faster salutatory nerve conduction velocities (impulses jumping between nodes of Ranvier) are replaced with considerably slower continuous nerve velocities. These changes in the acute setting lead to the focal neurologic deficits associated with MS.
- Oligodendrocytes, which have survived, or ones formed from precursor cells, are able to partially remyelinate stripped axons, producing scars which overtime can lead to irreversible axonal loss and brain atrophy.
- The majority of axons are typically lost from the lateral corticospinal (motor) tracts of the spinal cord. MS was once thought to be a disease of strictly affecting white matter tracts; however, there is increasing evidence of
inflammatory damage within the cortical grey matter and overlying meninges (1).

Genetics
- MS is polygenic and does not follow a Mendelian inheritance pattern. Those with affected first-degree relatives are 5 to 7 times more likely to be diagnosed.
- Over 100 genetic loci have been associated with MS suggesting that it is ultimately an antigen-specific autoimmune process. Most commonly, these are mapped to the class II region of the HLA gene cluster. The most common being the HLA-DRB1 locus on chromosome 6. These produce major histocompatibility complexes with high-binding affinity for myelin basic proteins.
- Although not fully understood, variations of natural killer cells and their polymorphic killer-immunoglobulin-like receptors are thought to play a major role in the MS disease process (1).

RISK FACTORS
- Age: peak incidence ages 15 to 45 years, mean age 28 to 31 years (slightly earlier in women than men)
- Race: Caucasian > African Caribbean > East-Asian
- Gender: 2 to 3 times more common in women
- Infectious: prior infections with Epstein-Barr virus and history of infectious mononucleosis
- Substance: tobacco smoking
- Geographic: Historically, proximity to the equator and its correlation with increased vitamin D exposure were inversely proportional to MS incidence. However, recently, this association has been less obvious and may be due to lifestyle changes that have led to decreased sun exposure in these locations (1).

GENERAL PREVENTION
No known prevention strategies

COMMONLY ASSOCIATED CONDITIONS
- Internuclear ophthalmoplegia: Injury to the medial longitudinal fasciculus causes impaired adduction of the affected eye.
- Optic neuritis: inflammation of optic nerve resulting in loss of vision
• Associated with numerous other autoimmune processes

**DIAGNOSIS**

A person with MS can present with a number of neurologic signs and symptoms depending on the locations of the lesion. The essential means of diagnoses is to demonstrate evidence of CNS lesions that are separated by both time and space that are not more likely due to a separate disease process.

**HISTORY**

Symptoms can vary widely but may include fatigue, epilepsy, dizziness, visual disturbances, facial palsy, dysphagia, muscle weakness or spasms, hyperesthesia or paresthesia, pain, bowel or bladder incontinence, urinary frequency or retention, or impotence (1).

**PHYSICAL EXAM**

• Weakness
• Internuclear ophthalmoplegia
• Gait disturbance
• Foot drop
• Hyperesthesia or paresthesia
• Cerebellar dysarthria (scanning speech)
• Spasticity (especially in lower extremities)
• Uhthoff phenomenon: Symptoms worsen with exposure to higher than usual temperature.
• Lhermitte sign: electric-like shocks extending down the spine caused by neck movement, especially flexion

**DIFFERENTIAL DIAGNOSIS**

• Lyme disease
• Systemic lupus erythematosus
• Antiphospholipid antibody syndrome
• Neuromyelitis optica
• Epilepsy
• Progressive multifocal leukoencephalopathy
• CNS neoplasms
• Guillain-Barré syndrome
• Metachromatric leukodystrophy
• Neurosarcoidosis
• Stroke
• Primary cerebral angiitis
• Neurosyphilis
• Cobalamin (vitamin B₁₂) deficiency
• Acute disseminated encephalomyelitis
• Behçet disease
• Normal pressure hydrocephalus

**DIAGNOSTIC TESTS & INTERPRETATION**

- MRI of head/spine: Periventricular and callosal lesions are relatively specific for MS. The additions of gadolinium can help identify active lesions.
- Lumbar puncture: Cerebrospinal fluid can reveal elevated or normal total protein levels. Oligoclonal immunoglobulin G bands are seen in approximately 90% of MS but may be absent early in the disease process. Positive findings are not diagnostic for MS but may be beneficial if other diagnostic criteria are equivocal.
- Blood tests: Antinuclear antibody, antineutrophil cytoplasmic antibody, anti–double-stranded DNA antibody, extractable nuclear antigen, antiphospholipid antibody, compliment, erythrocyte sedimentation rate, immunoglobulin G, immunoglobulin M, rheumatoid factor, and Lyme disease antibody can be used to rule out alternative diagnosis (1)[B].
- McDonald criteria for diagnosing MS: must demonstrate dissemination in space and time of CNS lesions (3)[C]
  - Dissemination in space: ≥1 T₂ lesion on MRI in at least 2 of 4 CNS regions typically affected by MS: periventricular, juxtacortical, infratentorial, or spinal cord or by waiting for another clinical event implying a different CNS location
  - Dissemination in time: simultaneous presentation of asymptomatic gadolinium-enhanced and nonenhancing lesions at any moment or a new T₂ and/or gadolinium-enhanced lesion on an MRI when compared baseline scans

*Diagnostic Procedures/Other*

Evoked potentials: Assess function of visual, auditory, and somatosensory motor CNS pathways by measuring CNS electric potentials evoked by neural stimulation. A marked delay, without a clinical manifestation, is suggestive of a demyelinating disorder. Visual evoked potentials are delayed in 80–90% of
individuals with MS (1).

**TREATMENT**

**GENERAL MEASURES**
- Holistic multidisciplinary team approach is paramount.
- Three main categories currently exist for MS treatment: treatment for acute relapses, treatment for reducing MS-related activity using disease-modifying agents, and symptomatic therapy.
- The use of disease-modifying treatments early in the disease process is likely to slow overall disease progression and should be managed by a MS specialist (1)[C].

**MEDICATION**
- **Acute relapse treatment (1,4)[A]**
  - Methylprednisolone 0.5 g PO daily for 5 days or 1 g IV daily for 3 to 5 days; without subsequent oral tapering; a second course may be given.
    - Side effects: increased infection risk, adrenal insufficiency, Cushing syndrome, fluid retention, hypokalemia, GI disturbances, headache, emotional lability
  - ACTH gel 80 units IM or SQ daily for 5 to 15 days
    - Side effects: similar to methylprednisolone
  - Plasmapheresis

- **Disease-modifying treatment (1,5)[B]**
  - IFN-β1a (Avonex) 30 μg IM weekly
  - IFN-β1a (Rebif) 22 or 44 μg SC 3 times per week
  - IFN-β1b (Betaseron/Betaferon/Extavia) 250 μg SC every other day
    - Monitoring: CBC, LFTs, TSH
    - Side effects: flu-like symptoms, depression, skin site reactions, thyroid dysfunction, liver enzyme abnormalities
  - Glatiramer acetate (Copaxone) 20 mg SC daily
    - Monitoring: none
    - Side effects: skin site reactions, immediate post injection reaction, lipoatrophy
  - Dimethyl fumarate (Tecfidera) 120 to 240 mg PO twice daily
    - Monitoring: CBC, LFTs
    - Side effects: diarrhea, cramps, LFT elevation, nausea, flushing
- Teriflunomide (Aubagio) 7 to 14 mg PO daily
  - Monitoring: CBC, LFTs, UA
  - Side effects: nasopharyngitis, headache, diarrhea, fatigue, back pain, influenza, hair thinning, LFT elevation, nausea, UTI
- Natalizumab (Tysabri) 300 mg IV every 28 days
  - Monitoring: CBC, LFTs
  - Side effects: headache, fatigue, UTI, hypersensitivity reaction
- Alemtuzumab (Lemtrada) 12 to 24 mg IV for 5 days then 3 days 12 months after initial treatment
  - Monitoring: CBC, LFTs, TSH
  - Side effects: immune thrombocytopenic purpura, autoimmune thyroid related problems, headaches, flushing
- Fingolimod (Gilenya) 0.5 mg PO daily
  - Monitoring: ECG, CBC, LFTs, eye exam
  - Side effects: first-degree AV block, bradycardia, macular edema, shingles, worsening pulmonary function, skin cancer, back pain

Symptomatic therapies (1)[B]
- Spasticity: baclofen, dantrolene, diazepam, tizanidine, cannabis extract (nabiximols), botulinum toxin, physiotherapy
- Pain: amitriptyline, pregabalin, gabapentin, cannabis extract (nabiximols)
- Bladder dysfunction: oxybutynin, tolterodine, cannabis extract (nabiximols), catheterization, intravesical botulinum toxin
- Constipation: natural or other laxatives, stool softeners, bulk-producing agents
- Erectile dysfunction: sildenafil
- Fatigue: amantadine, modafinil
- Tremors: clonazepam, primidone, β-blockers
- Depression: SSRI (citalopram), SSNRI (venlafaxine), TCA (amitriptyline)
- Walking: fampridine

ADDITIONAL THERAPIES
- Cognitive behavioral therapy
- Physical, occupational, and speech therapy
- Yoga and water-based exercise
- Massage therapy
ONGOING CARE

Patient Monitoring

Assessing the severity of neurologic impairment from MS can be done using the Kurtzke Expanded Disability Status Scale (EDSS): The EDSS quantifies severity of disability using eight functional systems (FS): pyramidal, cerebellar, brainstem, sensory, bowel and bladder, visual, and cerebral. EDSS scoring system (6)[C]:

- 1.0—no disability, minimal signs in 1 FS
- 2.0—minimal disability in 1 FS
- 3.0—moderate disability in 1 FS or mild disability in 3 to 4 FS, but fully ambulatory
- 4.0—ambulatory without aid or rest for ~500 m
- 5.0—ambulatory without aid or rest for ~200 m
- 6.0—intermittent/constant unilateral assistance (cane, crutch, or brace) must be able to walk 100 m
- 7.0—unable to walk beyond 5 m even with aid; essentially restricted to wheelchair, wheels self, and transfers alone; active in wheelchair for ~12 hr/day
- 8.0—essentially restricted to bed, chair, or wheelchair; may be out of bed most of the day; retains self-care functions, generally effective use of arms
- 9.0—helpless, bed-bound; but patient can communicate, eat
- 10.0—death due to MS

DIET

High fiber and fluids to prevent constipation

PATIENT EDUCATION

National Multiple Sclerosis Society: 1-800-344-4867 or www.nationalmssociety.org/

PROGNOSIS

Differs in each individual

- Approximately half of all patients will be unable to maintain a career 10 years after MS onset.
- Almost a third will ultimately be wheelchair bound.
- Average life expectancy is 5 to 10 years less than the unaffected population
COMPlications
Mortality secondary to MS relapse is unusual; death more commonly associated with a complication of MS such as infection in a person with more disability

REFERENCES

ADDITIONAL READING

CODES
ICD10
G35 Multiple sclerosis

CLINICAL PEARLS
• MS is an immune-mediated inflammatory disease causing demyelination,
neuronal loss, and scarring within the CNS.

- Diagnosis is made with the McDonald criteria and must demonstrate damage to the CNS disseminated in space and time.
- Disease treatments consist of acute relapse, disease-modifying, and symptomatic therapies.
- MS treatment modalities are complex and rapidly changing. A patient’s treatment should be guided by an MS specialist, but multiprofessional therapy is necessary.
- New approaches to manipulate inflammation, neurodegeneration, and remyelination such as hematopoietic stem cell transplants are being tested in clinical trials and may dramatically alter treatment and prevention of MS in the future.
MUMPS
Frances Yung-tao Wu, MD

BASICS
An acute, generalized paramyxovirus infection typically presenting with unilateral or bilateral parotitis

DESCRIPTION
- Can be asymptomatic in 1/3 of nonimmune individuals and 60% of previously vaccinated cases
- Painful parotitis occurs in 95% of symptomatic mumps cases.
- Epidemics in late winter and spring; transmission by respiratory secretions
- Incubation period is 14 to 24 days.
- System(s) affected: hematologic/lymphatic/immunologic, reproductive, skin, exocrine
- Synonym(s): epidemic parotitis; infectious parotitis

EPIDEMIOLOGY
- 85% of mumps cases occur prior to 15 years of age.
- Adult cases are typically more severe.
- Predominant sex: male = female
- Geriatric population: Most adults are immune.
- Acute epidemic mumps
  - Most cases occur in unvaccinated children 5 to 15 years of age.
  - Recent (2015 to 2016) U.S. outbreaks in college students Illinois/Iowa:
    o Another U.S. epidemic in 2009 to 2010 in New York/New Jersey: >1,500 cases
- Mumps is unusual in children <2 years of age; most infants <1 year are immune.
  - Period of maximal communicability is 24 hours before to 72 hours after onset of parotitis.

Incidence
- 5,833 cases in the United States in 2016
- Since 1967 (national vaccination program), case rate has dropped from 100/100,000 to 1.8/100,000.
Occasional regional epidemic outbreaks

**Prevalence**
- 0.0064/100,000 persons in United States
- 90% of adults are seropositive.

**ETIOLOGY AND PATHOPHYSIOLOGY**
Mumps virus replicates in glandular epithelium of parotid gland, pancreas, and testes, leading to interstitial edema and inflammation.
- Interstitial glandular hemorrhage may occur.
- Pressure caused by testicular edema against the tunica albuginea can lead to necrosis and loss of function.

**RISK FACTORS**
- Foreign travel: Some nations do *not* vaccinate for mumps, including most of Africa and Asia.
- Crowded environments such as dormitories, barracks, or detention facilities increase risk of transmission.
- Immunity wanes after single-dose vaccination:
  - With two dose schedule, immunity drops from 95% to 86% after 9 years.

**GENERAL PREVENTION**
- Vaccination
  - Two doses of live mumps vaccine or measles-mumps-rubella (MMR) vaccine are recommended, first at 12 to 15 months and second at 4 to 6 years.
  - 95% effective in clinical studies; field trials show 68–95% efficacy, which may be below level for herd immunity to prevent spread.
  - Prevention may require 95% 1st dose and >80% second-dose adherence.
  - Adverse effects: fever 8/100,000; seizure 25/100,000; thrombocytopenic purpura 3/100,000
  - *No relationship between MMR vaccine and autism celiac disease or multiple sclerosis* (1)
- Immunoglobulin (Ig) does not prevent mumps.
- Postexposure vaccination does not protect from recent exposure (2)[B].
- Isolate hospitalized patients for 5 days after onset.
- Isolate nonimmune individuals for 26 days after last case onset (social quarantine).
In an epidemic situation, a 3rd dose of MMR may decrease the attack rate (3).
Vaccine neutralizing antibodies are still effective against variant strains of mumps virus (4).

**Pregnancy Considerations**
- Live viral vaccines are typically contraindicated in pregnancy; however, vaccination of children should not be delayed due to a pregnant family member.
- Immunization of contacts protects against future (but not current) exposures.

**DIAGNOSIS**

**HISTORY**
- Parotid swelling peaks in 1 to 3 days; lasts 3 to 7 days
- Clinical diagnosis (swelling of one or both parotid glands):
  - Lasting ≥2 days
  - No other apparent cause
  - Meningitis without parotitis (rare; 1–10%)
- 1/3 of individuals with mumps may be asymptomatic.
- Rare prodrome of fever, neck ache, and malaise
- Sour foods cause pain in parotid gland region.
- Moderate fever, usually not >104°F (40°C):
  - High fever frequently is associated with complications.

**PHYSICAL EXAM**
- Painful parotid swelling (unilateral or bilateral) obscures angle of mandible and elevates earlobe.
- Meningeal signs (15%); encephalitis (<1%)
- 2–6% orchitis, polyarthritis, thyroiditis, mastitis, pancreatitis, oophoritis, myocarditis, profound hearing loss. Complications may occur after days to weeks.
- Rare maculopapular, erythematous rash
- Up to 50% of cases are mild.
- Redness at opening of Stensen duct without pus
- Sternal swelling (rare and pathognomonic for mumps)

**DIFFERENTIAL DIAGNOSIS**
If not epidemic, other viruses are more common: parainfluenza parotitis, Epstein-Barr virus, coxsackievirus, adenovirus, parvovirus B19

Suppurative parotitis: often associated with *Staphylococcus aureus* (presence of pus within Wharton duct when parotid is massaged essentially excludes diagnosis of mumps)

Recurrent allergic parotitis

Salivary calculus with intermittent swelling

Lymphadenitis from any cause, including HIV infection

Cytomegalovirus parotitis (immunocompromised)

Mikulicz syndrome: chronic, painless parotid and lacrimal gland swelling of unknown cause that occurs in tuberculosis, sarcoidosis, lupus, leukemia, lymphosarcoma, and salivary gland tumors

Sjögren syndrome, diabetes mellitus, uremia, malnutrition

Drug-related parotid enlargement (iodides, guanethidine, phenothiazine)

Complications of mumps: meningoencephalitis, orchitis, oophoritis, pancreatitis, polyarthritis, nephritis, myocarditis, prostatitis

Mumps orchitis must be differentiated from testicular torsion and from chlamydial or bacterial orchitis.

**DIAGNOSTIC TESTS & INTERPRETATION**

Three special tests to confirm an outbreak—if positive, report to health department (3)[A].

- IgM titer (positive by day 5 in 100% of nonimmunized patients)
- Swab of parotid duct or other affected salivary ducts for viral culture
- Rise in IgG titer samples; order if patient previously immunized: first sample within 5 days of onset, and second, 2 weeks later

Other potential findings: elevated serum amylase; CSF leukocytosis, or leukopenia

Testicular ultrasound may help differentiate mumps orchitis from testicular torsion.

**Diagnostic Procedures/Other**

If meningitis is present, lumbar puncture to exclude bacterial process; CSF pleocytosis, usually lymphocytic, in 65% of patients with parotitis

**Test Interpretation**

Periductal edema and lymphocytic infiltration of affected glands on biopsy
TREATMENT

- No specific antiviral therapy, only supportive care (3)[A], (4)[C]
- Analgesics to relieve pain
- Avoid corticosteroids for mumps orchitis as they can reduce testosterone and increase testicular atrophy.
- IVIG can reduce certain autoimmune-based sequelae:
  - Postinfectious encephalitis
  - Guillain-Barré syndrome
  - ITP
- Interferon-α2b improves bilateral orchitis but not testicular atrophy (5)[B].

GENERAL MEASURES

- Hospitalize patients with high fever, pancreatitis, or CNS symptoms for supportive care, steroids, or interferon. Use isolation precautions.
- Orchitis
  - Ice packs to scrotum can help to relieve pain.
  - Scrotal support with adhesive bridge while recumbent and/or athletic supporter while ambulatory

MEDICATION

First Line

- Analgesics and anti-inflammatory medications (acetaminophen, nonsteroidal anti-inflammatory drugs [NSAIDs]) may diminish pain and swelling in acute orchitis and arthritis mumps.
- May use acetaminophen for fever and/or pain
- Precautions: Avoid aspirin for pain in children as previously associated with Reye syndrome.

Second Line

- Interferon-α2b (5)[B]
- Medicinal herbs and acupuncture have not shown benefit in randomized controlled trials.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Hospitalize only if CNS symptoms occur.
- Outpatient supportive care if no complications
- IV fluids if severe nausea or vomiting accompanies pancreatitis

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

Mumps orchitis:
- Bed rest and local supportive clothing (e.g., two pairs of briefs) or adhesive-tape bridge
- Withhold from school until no longer contagious (9 days after onset of pain).

**Patient Monitoring**

Most cases will be mild. Monitor hydration status.

**DIET**

Liquid diet if unable to chew

**PATIENT EDUCATION**

Orchitis is common in older children but rarely results in sterility, even if bilateral.

**PROGNOSIS**

- Complete recovery is typical; immunity is lifelong.
- Transient sensorineural hearing loss in 4% of adults
- Recurrence after 2 weeks may be nonepidemic parotitis.

**COMPLICATIONS**

- May precede, accompany, or follow salivary gland involvement and may occur (rarely) without primary involvement of the parotid gland
- Orchitis is more common (6–30%) in postpubertal boys:
  - It starts within 8 days of onset of parotitis.
  - Impaired fertility in 13%; absolute sterility is rare.
- Meningitis may present 5 to 10 days after first symptoms of illness. Aseptic meningitis is typically mild, but meningoencephalitis may lead to seizures, paralysis, hydrocephalus, or (in 2% of encephalitis cases) death.
- Acute cerebellar ataxia has been reported after mumps infections; self-resolving in 2 to 3 weeks
- Oophoritis in 7% of postpubertal females; no decreased fertility
- Pancreatitis, usually mild
- Nephritis, thyroiditis, and arthralgias are rare.
- Myocarditis: usually mild, but may depress ST segment; may be linked to endocardial fibroelastosis
- Deafness: 1/15,000 unilateral nerve deafness; may not be permanent
- Inflammation about the eye (keratouveitis) is rare.
- Dacryoadenitis, optic neuritis

**Pediatric Considerations**
- Orchitis is more common in adolescents.
- Young children are less likely to develop complications.
- Most complications occur in postpubertal group.
- Avoid aspirin use in children with viral symptoms.

**Pregnancy Considerations**
Disease may increase the rate of spontaneous pregnancy loss in 1st trimester. Perinatal mumps often has a benign course.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- B26.9 Mumps without complication
- B26.1 Mumps meningitis
- B26.2 Mumps encephalitis

**CLINICAL PEARLS**
- Mumps is a clinical diagnosis based on swelling of ≥1 parotid glands for ≥2 days without other obvious cause. Confirmatory testing must be done in epidemic settings.
- Ultrasound is useful to distinguish testicular torsion from testicular pain related to mumps orchitis.
- A history of vaccination with MMR does not exclude mumps. The MMR vaccine is 68–95% effective after a series of two immunizations. Immunity wanes over time.
MUSCULAR DYSTROPHY

Nimmy Thakolkaran, MD • George G.A. Pujalte, MD, FACSM

BASICS

- Primary inherited myopathies caused by dysfunctional proteins of muscle fibers and extracellular matrix
- Distribution of weakness, other associated symptoms, and disease prognosis depend on the specific gene affected and severity of the mutation.

DESCRIPTION

- Duchenne muscular dystrophy (DMD)
  - Highest incidence muscular dystrophy, X-linked inheritance, early onset, progressive
  - Patients are wheelchair-dependent by age 13 years.
- Becker muscular dystrophy (BMD)
  - Less severe phenotype compared to DMD; also caused by mutation in DMD gene; later onset and milder clinical course
  - Distinction from DMD is clinical: Patients are usually wheelchair-dependent at age 16 years.
  - Collectively referred to as dystrophinopathies
- Myotonic muscular dystrophy (MMD)
  - Myotonia (slow relaxation after muscle contraction), distal and facial weakness
  - Second most common inherited muscle disease
- Facioscapulohumeral muscular dystrophy (FSHMD)
  - Facial and shoulder muscles most affected
  - Third most common inherited muscle disease
- Limb-girdle muscular dystrophy (LGMD)
  - Proximal weakness and atrophy, variable prognosis with many different identified mutations
- Oculopharyngeal muscular dystrophy (OPMD)
  - Usually adult-onset, affects extraocular and pharyngeal muscles; presents with ptosis and dysphagia
- Emery-Dreifuss muscular dystrophy (EDMD)
– Triad of early development of joint contractures, slowly progressive muscle wasting, and cardiomyopathy; can present as sudden death in apparently healthy, young adults

*Congenital muscular dystrophies (CMD)*
– Heterogeneous group of autosomal recessive myopathic diseases presenting in infancy, with generally poor prognosis
– Include Fukuyama CMD, Ullrich CMD, Walker-Warburg syndrome, muscle-eye-brain disease

**EPIDEMIOLOGY**

*Incidence*
– Duchenne: 1/3,600 male births (1)
– Myotonic dystrophy: 1/10,000 births
– CMD: 0.99 per 100,000
– Other muscular dystrophies vary widely by population but are generally rare.

**ETIOLOGY AND PATHOPHYSIOLOGY**

Mutations affect proteins connecting cytoskeleton to cell membrane and extracellular matrix, causing muscle fibers to become fragile and easily damaged; muscle weakness and atrophy result.

* DMD/BMD
  – Defective protein is dystrophin, product of the largest human gene, *DMD*; Duchenne phenotype results from mutations that cause profound loss of dystrophin, the protein involved in calcium transport in muscle cells and stabilizing fibers during contraction.
  – Becker phenotype results from less severe mutations in *DMD* gene; patients have low but detectable levels of functional dystrophin.

* MMD: Trinucleotide repeat expansion in the untranslated region of the gene *DMPK* on chromosome 19; encodes myotonin–protein kinase

* LGMD: mutations in genes encoding proteins associated with dystrophin: Calpain-, dysferlin-, and fukutin-related proteins are affected most commonly.

* EDMD: Dysfunctional proteins are associated with the nuclear membrane in muscle fibers; emerin in X-linked form, lamin A/C in autosomal forms

* OPMD: Trinucleotide repeat expansion in *PABPN1* results in nuclear inclusions in muscle cells by hampering normal transport of mRNA from the nucleus.

* FSHMD: deletion in untranslated region of chromosome 4; function of deleted genes is unclear, although the most accepted concept is that they likely affect
the expression of multiple genes by epigenetic effects.

**Genetics**

- **X-linked**
  - Duchenne and Becker muscular dystrophies
  - Gene located at Xp21
    - 30% of affected males have a de novo mutation (mother is not a carrier).
    - 20% of female carriers have some manifestation of the mutation (usually mild muscle weakness or cardiomyopathy).
- **Autosomal dominant**
  - Generally later onset and less severe than diseases with recessive or X-linked inheritance
  - FSHMD, OPMD, some forms of LGMD and EDMD
  - Myotonic dystrophy
    - Trinucleotide repeat expansion with more severe phenotype in subsequent generations due to accumulation of repeats
- **Autosomal recessive**
  - Most types of CMD

**GENERAL PREVENTION**

Genetic counseling for carriers and prenatal diagnosis

**COMMONLY ASSOCIATED CONDITIONS**

- Decreased IQ: on average, 1 SD below the mean in DMD; speech and language delay
- Dilated cardiomyopathy and conduction abnormalities
  - Can be severe in EDMD
  - Can affect otherwise asymptomatic female carriers of DMD
  - Progressive scoliosis

**DIAGNOSIS HISTORY**

- **DMD**: normal attainment of early motor milestones with subsequent abnormal gait and slowing gross motor development: clumsiness, waddling gait, frequent falls, difficulty running, or climbing stairs
- **BMD**: progressive difficulty with ambulation and frequent falls in later
childhood

- MMD: slurred speech, muscle wasting, difficulty with ambulation; often with family history
- LGMD: back pain, lordosis/inability to rise from a chair, climb stairs, and use arms overhead
- FSHMD: facial weakness, inability to close eyes completely
- EDMD: contractures of elbows and ankles, difficulty with ambulation in teenage years
- OPMD: ptosis and dysphagia; often with family history

PHYSICAL EXAM

- DMD/BMD
  - Proximal muscle weakness; Gower sign: use of arms to push upper body into standing posture from lying prone
  - Trendelenburg gait (hip waddling)
  - Hyporeflexia/areflexia
  - Winged scapulae and lordosis
  - Pseudohypertrophy of the calf (caused by replacement of muscle with fibroadipose tissue)
  - Contractures of lower extremity joints and elbows
- MMD
  - Characteristic facial appearance: narrow face, open triangular mouth, high-arched palate, concave temples, drooping eyelids, frontal balding in males
  - Myotonia: inability to relax muscles after contraction
  - Distal muscle weakness and wasting
- CMD
  - Arthrogryposis (multiple joint contractures); diffuse hypotonia and muscle wasting in an infant

DIFFERENTIAL DIAGNOSIS

- Glycogen storage diseases and other metabolic myopathies
- Mitochondrial myopathies: MELAS (Mitochondrial Encephalopathy, Lactic Acidosis, and Stroke-like episodes), MERRF (Myoclonus with Epilepsy and Ragged-Red Fibers)
- Inflammatory myopathies: polymyositis, dermato myositis, inclusion-body myositis
- Neuromuscular junction diseases: myasthenia gravis, Lambert-Eaton syndrome
- Motor neuron diseases: amyotrophic lateral sclerosis, spinal muscular atrophy
Charcot-Marie-Tooth disease
Friedreich ataxia

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Creatine kinase (CK): Initial screening test if MD is suspected (2)[A].
- Elevated in DMD (10 to 100 times); elevated at birth, peaks at time of presentation, and falls during illness
- Initial detected lab abnormality may be elevated aspartate transaminase/alanine transaminase (AST/ALT) originating from muscle.
- Genetic testing/molecular diagnosis
  - For definitive diagnosis in patient with characteristic presentation and elevated CK
  - Deletion and duplication analysis (MLPA or CGH) will identify most patients; followed by genomic sequencing of DMD gene for point mutations (3)[A]
  - Genetic testing is available clinically for most other muscular dystrophies.

**Diagnostic Procedures/Other**

- Muscle biopsy: rarely performed in DMD (dystrophin protein absent); may be helpful in other cases (4)[A]
- Electromyography and nerve conduction studies are not necessary unless considering alternative diagnoses.
- ECG: abnormalities found in >90% of males and up to 10% of female carriers of DMD; Q waves in anterolateral leads, tall R waves in V1, shortened PR interval, arrhythmias, resting sinus tachycardia

**Test Interpretation**

- Heterogenic muscle fibers: atrophy and hypertrophy of fibers with proliferation of connective tissue in muscle
- Immunohistochemical staining for dystrophin protein
  - DMD: no detectable dystrophin in most fibers; occasional revertant fibers with normal dystrophin
  - BMD: highly variable staining for dystrophin throughout muscle

**TREATMENT**

mebooksfree.com
Trials of agents that affect gene expression, such as antisense oligonucleotides, and small molecules that cause skipping of premature stop codons (ataluren) are ongoing; however, steroid treatment is the only clinically available therapy that affects disease progression.

GENERAL MEASURES
- Ambulation prolonged by knee-ankle-foot orthoses
- Serial casting to treat contractures
- Diagnose sleep apnea with polysomnography; treat with noninvasive ventilation.
- Adaptive devices to improve function
- Avoid overexertion and strenuous exercise.

MEDICATION
- Prednisone 0.75 mg/kg/day (4)[A]
  - Slows the decline in muscle function, progression to scoliosis and degradation of pulmonary function; prolongs functional ambulation; prolongs lifespan; improved cardiac outcomes
  - Therapy should be initiated when there is no longer progress in motor skills, but prior to decline (2).
  - Monitor adverse effects.
    - Bisphosphonates should be considered for preventing loss of bone density; annual exam for cataracts; hypertension should be monitored; no NSAIDs due to risk of peptic ulcer disease (PUD); stress-dose steroids during surgeries and illnesses due to adrenal suppression
    - Patients should be aware of immune suppression and notify emergency providers.
- Deflazacort (0.9 mg/kg) is a recently approved oral corticosteroid in DMD; it acts on muscle regeneration and differentiation (5).
- ACE inhibitors
  - Treatment of cardiomyopathy; may be used in conjunction with β-blockers

ISSUES FOR REFERRAL
- Refer to neuromuscular diseases center for definitive diagnosis and coordinated multidisciplinary care (4).
- Cardiology for management of cardiomyopathy
- Pulmonology for monitoring of pulmonary function and clearance regimen
- Physical medicine and rehabilitation for management of adaptive devices
Nutrition/swallowing: for normal weight gain, attention for dysphagia
Psychosocial: learning/behavior and coping assessment, social development (2)

ADDITIONAL THERAPIES
Novel medication: Ataluren interferes with premature stop codons, allowing expression of dystrophin protein. In the 15% of DMD patients with nonsense mutation; FDA approved orphan drug designation (3), completed ACT DMD trial

SURGERY/OTHER PROCEDURES
- Spinal surgery for scoliosis diminishes rate of deformity progression (5)[A].
- Scapular fixation for scapular winging may be beneficial; however, also lacking clinical trials.
- Consider surgical treatment of ankle/knee contractures.
- Surgical procedures should be performed at a center experienced in DMD; total IV anesthesia should be used.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Whole body vibration exercises

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Recognize and mitigate adrenal suppression resulting from corticosteroid dependence (5).

ONGOING CARE
- Individualized education plan and developmental evaluation for school accommodations
- Maintenance of current influenza and pneumococcal vaccination status

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Electrocardiogram (ECG), echocardiogram, and consultation with a
cardiologist at diagnosis and annually after age 10 years
– Female carriers of DMD mutation should be monitored every 5 years.
• Annual spinal radiography for scoliosis
• Dual-energy x-ray absorptiometry (DEXA) scanning and serum marker testing for osteoporosis
• Pulmonary function testing twice yearly if no longer ambulatory
• Psychosocial: coping, emotional adjustment, depression

DIET
• Obesity is common due to steroid treatment and wheelchair confinement: Weight control can improve quality of life.
• Diet may be limited by dysphagia; swallow evaluation can determine appropriate foods; may require gastrostomy
• Calcium and vitamin D supplementation for patients on steroids; monitor vitamin D levels.

PATIENT EDUCATION
• Muscular Dystrophy Association: http://www.mda.org

PROGNOSIS
• DMD/BMD
  – Progressive weakness, contractures, inability to walk
  – Kyphoscoliosis and progressive decline in respiratory vital capacity with recurrent pulmonary infections
  – Significantly shortened lifespan (DMD: 16 ± 4 years; BMD: 42 ± 16 years). Respiratory failure cause of death in 90%; remaining due to myocardial disease (heart failure and dysrhythmia) (6)
• Other types: slow progression and near-normal lifespan with functional limitations

COMPLICATIONS
• Cardiac arrhythmia, cardiomyopathy
• Dysphagia, gastroesophageal reflux disease (GERD), constipation
• Scoliosis, joint contractures
• Obstructive sleep apnea
• Malignant hyperthermia–like reaction to anesthesia
• Respiratory failure and early death
REFERENCES

ADDITIONAL READING

CODES
ICD10
- G71.0 Muscular dystrophy
- G71.11 Myotonic muscular dystrophy
- G71.2 Congenital myopathies

CLINICAL PEARLS
- Primary care providers should have a low threshold to obtain serum CK as a screening test in the face of gross motor delay/muscular weakness, especially in boys.
- Steroids should be initiated in patients with DMD when gross motor function ceases to progress.
- High-quality care of patients requires a medical home; a multidisciplinary team of physicians, therapists, and other providers; and extensive patient and family support.
MYASTHENIA GRAVIS
Melody A. Jordahl-Iafrato, MD, FAAFP

BASICS

DESCRIPTION
Primary disorder of neuromuscular transmission characterized by fluctuating muscle weakness:

- Ocular myasthenia gravis (MG) (15%): weakness limited to eyelids and extraocular muscles
- Generalized MG (85%): commonly affects ocular as well as a variable combination of bulbar, proximal limb, and respiratory muscles
- 50% of patients who present with ocular symptoms develop generalized MG within 2 years.
- Onset may be sudden and severe, but it is typically mild and intermittent over many years, maximum severity reached within 3 years for 85%.
- System(s) affected: neurologic, hematologic, lymphatic, immunologic, musculoskeletal

EPIDEMIOLOGY
Occurs at any age but a bimodal distribution to the age of onset:

- Female predominance: 20 to 40 years
- Male predominance: 60 to 80 years

Incidence
Estimated annual incidence 2 to 21/1 million

Prevalence
In the United States, 200/1 million; increasing over the past 5 decades

Pediatric Considerations
A transient form of neonatal MG seen in 10–20% of infants born to mothers with MG. It occurs as a result of the transplacental passage of maternal antibodies that interfere with function of the neuromuscular junction; resolves in weeks to months. Autoimmune juvenile MG makes up 10–15% of cases of MG in North America.
ETIOLOGY AND PATHOPHYSIOLOGY

- Reduction in the function of acetylcholine receptors (AChR) at muscle endplates, resulting in insufficient neuromuscular transmission
- Antibody-mediated autoimmune disorder
- Antibodies are present in most cases of MG.
  - Seropositive/antiacetylcholine receptor (anti-AChR): a humoral, antibody-mediated, T-cell–dependent attack of the AChRs or receptor-associated proteins at the postsynaptic membrane of the neuromuscular junction. Found in 85% of generalized MG and 50% of ocular MG. Thymic abnormalities common (1)
  - Muscle-specific kinase (MuSK). 5% of generalized MG patients. Typically females. Is a severe form, respiratory and bulbar muscles involved. Thymic abnormalities are rare (1).
  - In remainder of seronegative, 12–50% with anti-LRP4, a molecule that forms a complex with MuSK, mild generalized weakness most common (1)
  - Seronegative MG (SNMG): 5%; may have anti-AChR detectable by cell-based assay. Clinically similar to anti-AChR, thymic hyperplasia may be present (1).
- Also documented immediately after viral infections (measles, Epstein-Barr virus [EBV], HIV, and human T-lymphotropic virus [HTLV])

Genetics

- Congenital MG syndrome describes a collection of rare hereditary disorders. This condition is not immune-mediated but instead, results from the mutation of a component of the neuromuscular junction (autosomal recessive).
- Familial predisposition is seen in 5% of cases.

RISK FACTORS

- Familial MG
- D-penicillamine (drug-induced MG)
- Other autoimmune diseases

COMMONLY ASSOCIATED CONDITIONS

- Thymic hyperplasia (60–70%)
- Thymoma (10–15%)
- Autoimmune thyroid disease (3–8%)
DIAGNOSIS
Myasthenia Gravis Foundation of America Clinical Classification (2)[C]:

- Class I: any eye muscle weakness, possible ptosis, no other evidence of muscle weakness elsewhere
- Class II: eye muscle weakness of any severity; mild weakness of other muscles:
  - Class IIa: predominantly limb or axial muscles
  - Class IIb: predominantly bulbar and/or respiratory muscles
- Class III: eye muscle weakness of any severity; moderate weakness of other muscles:
  - Class IIIa: predominantly limb or axial muscles
  - Class IIIb: predominantly bulbar and/or respiratory muscles
- Class IV: eye muscle weakness of any severity; severe weakness of other muscles:
  - Class IVa: predominantly limb/axial muscles
  - Class IVb: predominantly bulbar and/or respiratory muscles (can also include feeding tube without intubation)
- Class V: intubation needed to maintain airway

HISTORY
The hallmark of MG is fatigability.

- Fluctuating weakness, often subtle, that worsens during the day and after prolonged use of affected muscles, may improve with rest
- Early symptoms are transient with asymptomatic periods lasting days or weeks.
- With progression, asymptomatic periods shorten, and symptoms fluctuate from mild to severe.
- >50% of patients present with ocular symptoms (ptosis and/or diplopia).
  Eventually, 90% of patients with MG develop ocular symptoms.
- Ptosis might be unilateral, bilateral, or shifting from eye to eye.
- 15% present with bulbar symptoms.
- <5% present with proximal limb weakness alone.

ALERT
Myasthenic crisis: respiratory muscle weakness producing respiratory insufficiency and pending respiratory failure
PHYSICAL EXAM
- Ptosis may worsen with propping of opposite eyelid (curtain sign) or sustained upward gaze.
- "Myasthenic sneer," in which the midlip rises but corners of mouth do not move.
- Muscle weakness is usually proximal and symmetric.
- Test for muscle fatigability by repetitive or prolonged use of individual muscles.
- Important to test and monitor respiratory function.

DIFFERENTIAL DIAGNOSIS
- Thyroid ophthalmopathy
- Oculopharyngeal muscular dystrophy
- Myotonic dystrophy
- Kearns-Sayre syndrome
- Chronic progressive external ophthalmoplegia
- Brainstem and motor cranial nerve lesions
- Botulism
- Motor neuron disease (e.g., amyotrophic lateral sclerosis [ALS])
- Lambert-Eaton myasthenic syndrome
- Drug-induced myasthenia
- Congenital myasthenic syndrome
- Dermatomyositis/polymyositis
- Neurosarcoidosis
- Tolosa-Hunt syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Anti-AChR antibody (74–85% are seropositive):
  - Generalized myasthenia: 75–85%
  - Ocular myasthenia: 50%
  - MG and thymoma: 98–100%
  - Poor correlation between antibody titer and disease severity (1)[C]
  - False-positive results in thymoma without MG, Lambert-Eaton myasthenic syndrome, small cell lung cancer, and rheumatoid arthritis treated with penicillamine
- Anti-MuSK antibody:
  - Used if MG is suspected, patient seronegative
- Strong correlation between titer and disease severity (1)[C]
- LRP4 and clustered anti-AChR:
  - Used if MG suspected, patient seronegative
- Thyroid and other autoimmune testing antistriated muscle (anti-SM) antibody:
  - Present in 84% of patients with thymoma who are <40 years of age
  - Can be present without thymoma in patients >40 years of age
- Chest radiographs or CT scans may identify a thymoma.
- MRI of brain and orbits to rule out other causes of cranial nerve deficit

**Diagnostic Procedures/Other**

- Tensilon (edrophonium) test:
  - Initial 2-mg IV dose, followed by another 2 mg every 60 seconds up to a maximum dose of 10 mg
  - A positive test shows improvement of strength within 30 seconds of administration.
  - Sensitivity 80–90% (3)[C]
  - Cardiac disease and bronchial asthma are relative contraindications, especially in elderly.
  - Atropine: 0.4 to 0.6 mg IV may rarely be required as antidote; must be available
  - Can also do trial of other cholinesterase inhibitors (neostigmine or oral) and monitor response

- Ice pack test:
  - Ice pack applied to closed eyelid for 60 seconds, then removed; extent of ptosis immediately assessed
  - Ice will decrease the ptosis induced by MG.
  - Sensitivity 80% in patients with prominent ptosis

- Electrophysiology testing:
  - Repetitive nerve stimulation (RNS):
    - Widely available, most frequently used
    - Moderately sensitive for both generalized MG (75%) and ocular MG (50%) (3)[C]
  - Single-fiber electromyogram (SFEMG):
    - Assesses temporal variability between two muscle fibers within same motor unit (jitter)
    - Sensitive (90–95%) but less specific
    - Technically difficult to perform; limited availability, use if suspected and negative RNS (3)[C]
Test Interpretation
- Lymphofollicular hyperplasia of thymic medulla occurs in 65% of patients with MG, thymoma in 15%.
- Immunofluorescence: IgG antibodies and complement on receptor membranes in seropositive patients

TREATMENT

GENERAL MEASURES
- Treatment based on age, gender, and disease severity and progression
- Three basic approaches: symptomatic, immunosuppressive, and supportive. Few should receive a single therapeutic modality.

MEDICATION

First Line
Symptomatic treatments (anticholinesterase agents)
- Pyridostigmine bromide (Mestinon):
  - Most commonly prescribed because available in oral tablet
  - Starting dose of 30 mg PO TID with food
  - Maximum dose: 120 mg q3–4h
  - Long-acting available but effect not consistent
- Neostigmine methylsulfate (Prostigmin):
  - Starting dose of 0.5 mg SC or IM q3h
  - Titrate dosage to clinical need.
- Patients with anti-MuSK may not respond well to these meds.

Second Line
- Immunosuppressants: Oral corticosteroids are the first choice of drugs when immunosuppression is necessary.
  - Prednisone: Start as inpatient with a 60 mg/day PO; taper the dosage every 3 days; switch to alternate-day regimen within 2 weeks. Taper very slowly to establish the minimum dosage necessary to maintain remission (4)[B].
  - Cyclophosphamide: adults: 1 to 5 mg/kg/day PO; children: 2 to 8 mg/kg/day PO (5)[B]
  - Cyclosporine: adults: 5 mg/kg/day PO (nephrotoxicity and drug interactions) (5)[B]
– Mycophenolate: 1 g PO or IV BID
– Azathioprine: 100 to 200 mg/day PO (5)[B]
  o Most frequently used for long-term immunomodulation, similar efficacy to steroids and IVIG
  o Benefit may not be apparent for up to 18 months after initiation of therapy.
  o Prednisolone + azathioprine may be effective when used as a corticosteroid-sparing agent.

● Acute immunomodulating treatments:
  – Plasmapheresis: bulk removal of 2 to 3 L of plasma 3 times per week, repeated until rate of improvement plateaus (6)[B]
    o Improves weakness in nearly all and can last up to 3 months
  – Immunoglobulin: 2 g/kg IV over 2 to 5 days (5)[B]
  – Plasmapheresis and immunoglobulin have comparable efficacy in treating moderate to severe MG (6)[C].
  – Rapid onset of effect but short duration of action
  – Used for acute worsening of MG to improve strength prior to surgery, prevent acute exacerbations induced by corticosteroids, and as a chronic intermittent treatment to provide relief in refractory MG

● Other immunosuppressant therapies:
  – Tacrolimus
  – Rituximab:
    o Seronegative MuSK-antibody positive MG patients may have better response to rituximab than conventional therapies.

**ALERT**
Use caution with drugs that can precipitate weakness: aminoglycosides, fluoroquinolones, β-blockers, calcium channel blockers, neuromuscular blockers, statins, diuretics, oral contraceptives, gabapentin, phenytoin, lithium, among others.

**SURGERY/OTHER PROCEDURES**
● Thymectomy recommended for patients with thymic abnormalities
● May be beneficial for patients without thymic abnormalities in those <60 years of age especially in patients with elevated anti-AChR

**Pediatric Considerations**
Infants with severe weakness from transient neonatal myasthenia may be treated
with oral pyridostigmine; general support is necessary until the condition clears.

- Corticosteroids limited only to severe disease
- Side effects of many medications must be closely monitored in juvenile patients especially as some may affect long-term fertility or are consider carcinogenic.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Management of pulmonary infections
- Myasthenic/cholinergic crises
- Plasmapheresis
- IV \( \gamma \)-globulin

**ONGOING CARE**

**PATIENT EDUCATION**

**PROGNOSIS**

- Overall good but highly variable
- Myasthenic crisis associated with substantial morbidity and 4% mortality
- Seronegative patients are more likely to have purely ocular disease, and those with generalized SNMG have a better outcome after treatment.

**COMPLICATIONS**

Acute respiratory arrest; chronic respiratory insufficiency

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- G70.00 Myasthenia gravis without (acute) exacerbation
- G70.01 Myasthenia gravis with (acute) exacerbation
- P94.0 Transient neonatal myasthenia gravis

**CLINICAL PEARLS**

- An autoimmune disease, marked by abnormal fatigability and weakness of selected muscles, which is relieved by rest
- Anticholinesterase medication and a thymectomy lessen symptom severity.
- Steroid therapy, plasma exchange, or immunoglobulin can be used in severely affected patients.
MYELODYSPLASTIC SYNDROMES (MDS)

Gabriela Sanchez Petitto, MD • Pedro Emilio Alcedo, MD • Guillermo Garcia-Manero, MD

BASICS

DESCRIPTION

- Myelodysplastic syndromes (MDS) are a heterogeneous group of clonal stem cell disorders characterized by peripheral blood cytopenias: anemia, thrombocytopenia, and/or neutropenia.
- Dysplasia refers to an abnormality of development or differentiation in specific cell lines. In MDS, these changes take place in the bone marrow, and confer a tendency for leukemic transformation.

EPIDEMIOLOGY

Incidence

The incidence in the United States is approximately 3 to 4 cases per 100,000 population per year, expanding to 30 cases per 100,000 population per year, for patients age >70 years.

Prevalence

In 2012, >60,000 people with MDS resided in the country.

ETIOLOGY AND PATHOPHYSIOLOGY

- MDS is clinically characterized by peripheral cytopenias, consequence of ineffective marrow hematopoiesis (premature cell death).
- Nongenetic mechanisms encompass apoptosis, pyroptosis, deregulated immunity, and inflammatory cytokine amplification (see “Genetics” for genetic mechanisms) (1,2).
- Low-risk MDS (LR-MDS) are characterized by deregulated immunity and apoptosis, whereas high-risk MDS (HR-MDS) are characterized by clonal expansion and transformation to acute myelogenous leukemia (AML).
- A changing interplay of proapoptotic versus antiapoptotic signals is central in
the progression of the disease.

- In LR-MDS, stem cell programmed death occurs by different mechanisms: apoptosis, pyroptosis, and potentially autophagy.
  - *Apoptosis*: Tumor necrosis factor (TNF)-α, TNF-related apoptosis-inducing ligand (TRAIL), Fas ligand, and proapoptotic cytokines (TNF-α and IL-6) play a major role in stem cell apoptosis in LR-MDS.
  - *Pyroptosis*: It is an inflammatory cell death different from apoptosis that is considered sterile in nature.
    - Activation of nod-like receptors leads to formation of the inflammasome complex and caspase 1 activation that leads to pore formation in the plasma membrane of the cells; creates ionic gradients, water influx, cell swelling, and cell death (3). This potentially also explains the morphologic changes seen in MDS (macrocytosis, enlarged cells).
- Evolution to AML has been associated with upregulation of NFκB, enhanced activity of the Bcl-2 and the inhibitors of apoptosis protein (IAP) families. This is thought to be a mechanism of bypassing the apoptotic phenomenon in the bone marrow micro environment.

**Genetics**
- Recurrent somatic mutations are observed in >90% of MDS patients.
- Mutated genes are involved in:
  - Epigenetic regulation: TET2, EZH2, IDH1, IDH2, DNMT3A, ASXL1
  - DNA repair: TP53
  - Transcriptional regulation: BCOR, ETV6, RUNX1
  - RNA splicing: U2AF35, ZRSR2, SF3B1, SRSF2
  - Cohesin complex: STAG2
  - Signal transduction: JAK2, CBL, NRAS
- Mutations in the epigenetic modifiers: The concept is that any gain of function mutations in the DNA methyltransferases (DNMT3A and DNMT3B) leads to hypermethylation (a gene silencing mechanism that contributes to clonal evolution).
- It is unclear how these different molecular and genetic mechanisms translate into the same phenotypic manifestation of myelodysplasia and cytopenias.

**RISK FACTORS**
- Age: increased risk in patients >60 years old
- Tobacco use
- Chronic exposure to chemicals: benzene, pesticides, insecticides, and
petroleum

- Prior chemotherapy or radiation therapy
- Inherited disorders: Fanconi anemia, Shwachman-Diamond syndromes, severe congenital neutropenia, and familial platelet disorder

**GENERAL PREVENTION**

Avoiding known cancer-causing industrial chemicals, such as benzene, and also tobacco, might lower the risk of developing MDS.

**COMMONLY ASSOCIATED CONDITIONS**

Myeloproliferative disorders and paroxysmal nocturnal hemoglobinuria

**DIAGNOSIS**

**HISTORY**

- The clinical course of MDS patients is driven by the type and degree of cytopenias.
- Recurrent infections, bleeding issues, fatigue, weight loss and exertional dyspnea, are common symptoms reported.

**PHYSICAL EXAM**

- Generalized pallor and ecchymosis as result of the anemia and thrombocytopenia respectively
- Rarely hepatosplenomegaly as consequence of extramedullary hemopoiesis is present, especially in MDS/MPN overlapping syndromes. Lymphadenopathies are infrequent.

**DIFFERENTIAL DIAGNOSIS**

- Acute leukemia: AML
- Vitamin B$_{12}$ and folate deficiencies can manifest as a hypoproliferative anemia.
- Infections of the bone marrow: human immunodeficiency virus, tuberculosis, atypical mycobacterium and Epstein-Barr virus
- Indolent myeloid hematopoietic disorders that do not fulfill diagnostic criteria for MDS: idiopathic cytopenia of unknown significance, idiopathic dysplasia of unknown significance, clonal hematopoiesis of indeterminate potential (CHIP) and clonal cytopenia of unknown significance
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- A complete blood count, chemistry, viral studies (HIV and hepatitis panel), and vitamin levels (B$_{12}$ and folate) should be evaluated.
- The International Working Group (IWG) recommended minimal diagnostic prerequisites:
  - Stable cytopenia for $\geq 6$ months, or for 2 months with karyotype or bilineage dysplasia
  - Exclusion of other potential reasons for dysplasia/cytopenia
- In addition, the diagnosis of MDS requires $\geq 1$ of 3 decisive criteria:
  - Dysplasia ($\geq 10\%$ in $\geq 1$ of the 3 major bone marrow lineages)
  - Blast cell count of 5–19%  
  - Specific MDS-associated karyotypes: del(5q), del(20q), +8, or −7/del(7q)

Diagnostic Procedures/Other
- Histopathology. A bone marrow is essential to distinguish MDS from AML and to perform karyotype studies, fluorescent in situ hybridization (FISH) and mutational studies.
  - Blast %: $<20\%$ is consistent with MDS, $\geq 20\%$ is diagnostic of AML.
- Cytogenetics. Clonal chromosome abnormalities are observed in 30–80% of MDS patients. In the rest of the patients, (20–70%) submicroscopic alterations (microdeletions, point mutations) provide diagnostic evidence.
- In cases of uncertainty, analysis of somatic mutations and flow cytometry of bone marrow can evidence clonal disease.

Test Interpretation
- Hematologic findings in the blood smear include macrocytic anemia, hyposegmented neutrophils (pseudo Pelger–Huet), and thrombocytopenia.
- A low reticulocyte index reflects the hypoproliferative nature of the disease.

TREATMENT

GENERAL MEASURES
- LR-MDS: observation until patients develop symptoms from anemia, neutropenia, and/or thrombocytopenia
  - Initial treatment is tailored based on the specific cytopenia.
In higher risk, the only curative therapy is allogeneic stem cell transplant (SCT).

An accurate assessment of prognosis becomes critical for therapeutic decision making. For this aim, multiple scoring system have been developed:
- The World Health Organization (WHO) guidelines identify six entities:
  - MDS with single lineage dysplasia;
  - MDS with ring sideroblasts;
  - MDS with excess blasts;
  - MDS with multilineage dysplasia;
  - MDS with isolated del(5q);
  - MDS unclassifiable.
- The International Prognostic Scoring System (IPSS) score assigns patients to four groups (low, intermediate 1, intermediate 2, high) on the basis of number of cytopenias, karyotype, and blast percentage in the bone marrow.
- The MDAS (Global MD Anderson) score refines prognostic precision as complementary to the IPSS.

**MEDICATION**

**First Line**
- MDS-related anemia
  - Blood transfusions and erythropoiesis-stimulating agents (ESA)
    - ESA have a 40–50% response rate in LR-MDS; indications: hemoglobin <10 g/dL and erythropoietin level <500; uncommon complications: worsening hypertension and thromboembolism
    - Lenalidomide; used in anemia in MDS with isolated del(5q) (4); acts via casein kinase, inhibiting the nuclear β-catenin accumulation, subsequently restoring normal erythropoiesis
- MDS-related thrombocytopenia and neutropenia
  - In selected cases, thrombopoietin receptor agonists (romiplostim, eltrombopag) may be used for thrombocytopenia (with close monitoring owing its potential for leukemic transformation). Neutropenia may be managed with G-CSF and antibiotics, if clinically indicated.
- Low-intensity chemotherapy
  - In LR-MDS patients who lost response to the first line, the use of hypomethylating agents (HMA) is approved by the Food and Drug administration.
    - HMA are disease-modifying agents. Examples are azacitidine and decitabine.
    - HMA cause DNA hypomethylation via DNMT1 sequestration.
- High-intensity chemotherapy
  - Induction chemotherapy or SCT
Comparative studies have not demonstrated benefit between different intensive chemotherapy regimens (cytarabine, idarubicin, topotecan-based regimens) (5).

- Stem cell transplantation
  - To date, allogenic SCT remains the only curative treatment option but is reserved for high-risk disease due to its own toxicity.
  - Patients <70 years of age with an available donor and reasonable comorbidity should be considered.
  - Mortality after the procedure is attributable to transplant-related complication or relapse.

**Second Line**
There are not well-established agents as second-line treatment. Clinical trials can be considered for patients depending on their severity (low vs. high risk), cytopenias, and potential for transplantation.

**ISSUES FOR REFERRAL**
- Patients with cytopenias should be evaluated by a hematologist-oncologist.
- Evaluation of bone marrow with a hemopathologist is recommended.
- Referral to a bone marrow transplant team should be done if patient is a candidate for SCT.

**ADDITIONAL THERAPIES**
- *Management of iron overload.* Iron chelation is often considered in patient with transfusion dependency.
- *Promising agents.* Clinical trials with novel HMA (SGI-110, E7727), ABT 199, drugs targeting the TGF-β/SMAD sign and toll-like receptor pathways are currently ongoing.

**SURGERY/OTHER PROCEDURES**
Allogenic SCT, as discussed previously

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Complications such as bleeding, neutropenic fever, and undergoing SCT, warrant a hospital admission.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Follow-up of MDS is based on regular complete blood counts, to detect the need for transfusions. Severe neutropenia may indicate antibiotic use if infection occurs.
- Bone marrow examination is generally triggered by worsening of cytopenias.

DIET
Alcohol consumption, meat, vegetable and fruit intake do not appear to have significant influence in the risk of developing disease.

PATIENT EDUCATION
- Regular follow-up and compliance with medications; smoking cessation
- Instruct about symptoms that should prompt the patient to receive blood transfusion or commence antibiotics.

PROGNOSIS
Overall, the outcome of MDS patients is variable, with medial survival ranging from 6 months to >5 years.

COMPICATIONS
Infection and bleeding are the leading causes of death, rather than AML conversion.

REFERENCES

**CODES**

**ICD10**
- D46.9 Myelodysplastic syndrome, unspecified
- D46.4 Refractory anemia, unspecified
- D46.B Refract cytopenia w multilin dysplasia and ring sideroblasts

**CLINICAL PEARLS**
- MDS are a heterogeneous group of clonal stem cell disorders characterized by blood cytopenias and tendency for leukemic transformation.
- Different molecular and genetic mechanisms of pathogenesis translate into the same phenotypic manifestation of the disease.
- Infection and bleeding are the leading causes of death.
- SCT is ultimately the only curative treatment.
MYELOPROLIFERATIVE NEOPLASMS

Tarsheen K. Sethi, MBBS • Sanjay Mohan, MD, MSCI

BASICS

DESCRIPTION

- Myeloproliferative neoplasms (MPNs) are a group of clonal disorders that share a common cell of origin in the pluripotent hematopoietic stem cell.
- MPNs are characterized by proliferation of cells of myeloid lineage—granulocytic, erythroid, megakaryocytic, or mast cell. They share common clinical features including risk of thrombosis, spleen and/or liver enlargement and constitutional symptoms related to a hypermetabolic state.
- The “classic” MPNs include chronic myelogenous leukemia (CML), polycythemia vera (PV), essential thrombocythemia (ET), and primary myelofibrosis (PMF). World Health Organization (WHO) MPN classification also includes chronic neutrophilic leukemia, chronic eosinophilic leukemia not otherwise specified (CEL-NOS), systemic mastocytosis, and MPN unclassifiable.
- This topic focuses on the classic MPNs.
- CML is characterized by the presence of Philadelphia chromosome (reciprocal translocation between chromosomes 9 and 22 resulting in a BCR-ABL fusion gene). This fusion gene mediates the uninhibited proliferation of myeloid precursor stem cells predominantly resulting in granulocytosis and excess granulocyte precursors.
- The following three MPNs are characterized by varying degree of presence of JAK2 V617F mutation and are negative for BCR-ABL fusion gene:
  - PMF: JAK2 in about 50%; MPN characterized by marrow fibrosis, extramedullary hematopoiesis, and splenomegaly
  - ET: JAK2 in about 50%; MPN characterized by a clonal proliferation of megakaryocytes, leading to thrombocytosis
  - PV: JAK2 in 95%; MPN characterized by trilineage growth of hematopoietic stem cells with erythroid precursors predominating, leading to erythrocytosis

EPIDEMIOLOGY

Incidence
CML: 0.6 to 2.0/100,000/year; median age at diagnosis 66 years; male > female (1.6:1)
PMF: 0.2 to 0.5/100,000/year; median age at diagnosis 65 years; male = female
ET: 0.6 to 2.5/100,000/year; median age at diagnosis 60 years, second peak in younger patients at ~30 years; female > male (2:1)
PV: 1 to 2/100,000/year; male > female (1.3:1)

ETIOLOGY AND PATHOPHYSIOLOGY

**CML:** BCR-ABL1 gene leads to increased and unrestrained activity of the ABL tyrosine kinase resulting in an unchecked activation of downstream signaling pathways which have an antiapoptotic effect on the hematopoietic cells.

**PMF:** Progenitor hematopoietic stem cells undergo a clonal proliferation independent of growth factors likely due to activation of downstream intracellular pathways. The fibroblasts are nonclonal, and the increased fibrosis is driven by growth factors released by hematopoietic cells especially megakaryocytes.

**ET:** Thrombopoietin-induced megakaryocyte proliferation is uncontrolled due to a combination of increased sensitivity to thrombopoietin and decreased feedback regulation of the thrombopoietin levels by platelets allowing the platelet mass to expand.

**PV:** Gain-of-function mutation (JAK2) leads to increased erythrocyte production due to a downstream activation of proteins involved in cell proliferation and resistance to apoptosis. The JAK2 tyrosine kinase is downstream of the erythropoietin receptor and thus its constitutive activation makes the hematopoietic progenitor cell independent of erythropoietin.

**Genetics**

- Philadelphia chromosome (BCR-ABL1 gene): translocation and fusion of the BCR gene on chromosome 22 and the ABL gene on chromosome 9; seen in all patients with CML
- JAK2 mutations: point mutations in the tyrosine kinase domain of JAK2, causing a substitution of phenylalanine for valine at position 617 (JAK2 V617F); leading to unrestrained JAK2 activation with a deactivation of typical feedback mechanism. Seen in >95% of PV cases; 50% of ET and PMF cases
- CALR mutation: Calreticulin (CALR) is an endoplasmic reticulum chaperone protein directing proper folding of proteins. This mutation may be seen in up to a third of patients of ET and PMF. These patients are seen to have a higher
platelet count but lower risk of thrombosis.

- Myeloproliferative leukemia virus (MPL) gene: mutations found in 5–10% of patients with PMF and in 3–5% of those with ET. This encodes the thrombopoietin receptor MPL.
- JAK2, CALR, and MPL mutations are mutually exclusive and together account for 85% of cases of ET and PMF.

**RISK FACTORS**

- Rare familial cases have been reported.
- CML: exposure to ionizing radiation

**COMMONLY ASSOCIATED CONDITIONS**

- Progression to acute myeloid leukemia; most common with CML
- Thrombosis/hemorrhage

**DIAGNOSIS**

**HISTORY**

- Many MPN cases are found incidentally on routine blood work.
- CML: Most patients are asymptomatic at time of diagnosis.
  - Fatigue, malaise, weight loss, excessive perspiration, abdominal fullness, early satiety, bleeding episodes
- PMF: Symptoms depend on the degree of anemia and splenomegaly.
  - Fatigue, shortness of breath, early satiety, constitutional symptoms, cachexia, Budd-Chiari syndrome, splenic infarcts, osteosclerosis resulting in bone pains
- ET: characterized by thrombotic and hemorrhagic events
  - Thrombotic events (deep vein thrombosis, pulmonary embolism, Budd-Chiari syndrome), microvascular occlusive events (digital ischemia, erythromelalgia), major/minor hemorrhagic events; headaches, dizziness, syncope, tingling, visual changes, transient ischemic attacks
- PV: Symptoms are due to level of erythrocytosis and the resultant increased blood viscosity.
  - Erythromelalgia, pruritus after hot baths, headaches, tinnitus, paresthesias, gout attacks

**PHYSICAL EXAM**
CML: splenomegaly, hepatomegaly
PMF: splenomegaly seen in nearly all patients, hepatomegaly, pallor
ET: possible petechiae, purpura, ecchymosis; splenomegaly
PV: cyanotic blush (lips, nose, ears, distal extremities), increased blood pressure, splenomegaly, epistaxis, ecchymosis

DIFFERENTIAL DIAGNOSIS
CML: leukemoid reaction (elevated LAP), juvenile myelomonocytic leukemia, chronic myelomonocytic leukemia (CMML), chronic eosinophilic leukemia, chronic neutrophilic leukemia
PMF: other MPNs, lymphoma, hairy cell leukemia; secondary myelofibrosis (malignant or nonmalignant)
ET: reactive thrombocytosis, CML, PV, PMF, and myelodysplastic syndromes
PV: hypoxic states (e.g., chronic obstructive pulmonary disease [COPD], anemia), renal cell carcinoma, Wilms tumor, hepatoma, polycystic kidney disease, exogenous androgens

DIAGNOSTIC TESTS & INTERPRETATION
CML: white blood cell (WBC) count >10,000 × 10^9/L with differential showing increased mature and immature neutrophils and an increased percentage of myelocytes, metamyelocytes, and band forms; neutrophils have decreased leukocyte alkaline phosphatase; platelet count >600,000 × 10^9/L and a normochromic, normocytic anemia. Basophilia is common.

PMF (1)[A] (WHO criteria): Diagnosis requires meeting all three major criteria and two or more minor criteria:
- **Major criteria**: (i) megakaryocyte proliferation and atypia accompanied by either reticulin or collagen fibrosis; (ii) not meeting WHO criteria for CML, PV, MDS, or other myeloid neoplasm; (iii) demonstration of JAK2 V617F or other clonal marker or absence of marker with no evidence of secondary marrow fibrosis
- **Minor criteria**: (i) leukoerythroblastosis, (ii) increased serum lactate dehydrogenase level, (iii) anemia, and (iv) palpable splenomegaly

ET (1)[A] (WHO criteria): Diagnosis requires meeting all four major criteria:
- **Major criteria**: (i) thrombocytosis with persistent platelet level ≥450 × 10^9/L; (ii) megakaryocyte proliferation with large and mature morphology; (iii) not meeting the WHO criteria for CML, PV, PMF, MDS, or other myeloid neoplasm; and (iv) demonstration of JAK2 V617F or other clonal marker or absence of clonal marker with no evidence of reactive
thrombocytosis

- PV (1)[A] (WHO criteria): Diagnosis requires either both major criteria and one minor criterion or the first major criterion and two of the minor criteria:
  - Major criteria: (i) hemoglobin >18.5 g/dL in men, >16.5 g/dL in women or other evidence of increased red cell volume and (ii) presence of JAK2 V617F or other functionally similar mutation (e.g., JAK2 exon 12 mutation) (1)[B]
  - Minor criteria: (i) bone marrow biopsy showing hypercellularity for age with trilineage myeloproliferation, (ii) low serum erythropoietin level, (iii) endogenous erythroid colony formation in vitro

**Initial Tests (lab, imaging)**
If clinical suspicion of MPN, obtain a CBC and peripheral blood smear; if suggestive, obtain bone marrow biopsy.
- PMF: radiographic osteosclerosis in 25–66%

**Diagnostic Procedures/Other**
- CML: Diagnosis with identification of Philadelphia chromosome:
  - Fluorescence in situ hybridization is more sensitive than karyotyping and is routinely used. Polymerase chain reaction (P210) is done at baseline to help monitor response to tyrosine kinase inhibitors (TKIs).
  - Bone marrow biopsy: increased cellularity and increased myeloid to erythroid ratio
- PMF, ET, and PV: genotypic analysis and bone marrow biopsy as described in earlier WHO criteria; “dry tap” is common in PMF.
- Risk stratification
  - CML: three phases of CML
    - (i) Chronic phase (85% patients at diagnosis; <5% blast counts), (ii) accelerated phase (poorly controlled splenomegaly regardless of treatment, 10–19% blast counts, worsening anemia, basophil ≥20%), (iii) blast crisis (resembles acute myeloid or lymphoid leukemia, >20% blast counts)
  - PMF: International Prognostic Scoring System (IPSS) at diagnosis and Dynamic IPSS (DIPSS-plus) throughout disease
    - IPSS: age >65 years, constitutional symptoms, hemoglobin <10 g/dL, leukocyte count >25 × 10⁹, circulating blasts >1%
      - Low risk = 0 of above; intermediate-1 risk = 1 of above; intermediate-2 risk = 2 of above; high risk = ≥3 of above
DIPSS-plus: same 5 risk factors in the IPSS + the need for red cell transfusion, platelets <100 × 10⁹/L and unfavorable karyotype

- Low risk = 0 of above; intermediate-1 risk = 1 of above; intermediate-2 risk = 2 to 3 of above; high risk = ≥4 of above
- ET: low risk = age <40 years, no prior thromboembolic events, no cardiovascular risk factors, platelet count <1,500 × 10⁹/L; intermediate risk = age 40 to 59 years, presence of cardiovascular risk factors, platelet count <1,500 × 10⁹/L; high risk = age ≥60 years and/or prior thromboembolic or hemorrhagic episode and/or platelet count >1,500 × 10⁹/L
- PV: low risk = age <60 years, no history of thrombosis/cardiovascular risk factors; intermediate risk = platelets >1,000 × 10⁹/L and cardiovascular risk factors; high risk = age >60 years or a history of thrombosis

**TREATMENT**

**GENERAL MEASURES**
Low-dose aspirin for ET and PV

**MEDICATION**

*First Line*
- CML
  - Chronic phase: imatinib mesylate (Gleevec): 400 mg/day, a TKI. Dasatinib and nilotinib are also approved for use in the first line (1).
  - Accelerated or blast phase: Increase imatinib to 800 mg/day or switch to 2nd- or 3rd-generation TKIs like nilotinib and dasatinib.
  - While awaiting confirmation of diagnosis, hydroxyurea can be used to lower the WBC count.
- PMF: Main goal is symptomatic relief:
  - Low risk: symptom-directed therapy
  - Intermediate and high risk: Consider allogeneic SCT.
  - JAK2 inhibitor ruxolitinib is approved for intermediate or high-risk myelofibrosis. It is also approved for post-PV and post-ET myelofibrosis (2).
  - Supportive treatment
    - Anemia: transfusions, erythropoiesis-stimulating agents, androgens, danazol, thalidomide, or lenalidomide
- **Splenomegaly:** ruxolitinib, hydroxyurea, splenectomy, or IV cladribine for refractory cases
  - **Thrombosis:** hydroxyurea and low-dose aspirin
- **ET** low and intermediate risk: “Watch and wait” + low-dose aspirin if microvascular disturbances are present and no contraindications; high risk: hydroxyurea 15 mg/kg/day in divided doses to reduce platelet count to \(<450 \times 10^9/L\) (2). Anagrelide is an additional cytoreductive option.
- **PV**
  - Low and intermediate risk: phlebotomy with goal hematocrit <45% and low-dose aspirin
  - High risk (or those who do not tolerate phlebotomy): hydroxyurea 500 to 1,000 mg/day (2); ruxolitinib if poor response to or intolerance of hydroxyurea

**Second Line**
- **CML:** Only curable treatment is aSCT; reserved for accelerated/blast phase due to high rates of morbidity and mortality with aSCT
  - 2nd-generation TKIs: dasatinib, nilotinib, and bosutinib; increasing evidence for improved, deeper responses with these medication resulting in use of 2nd-generation TKIs for first-line therapy. Ponatinib is a 3rd-generation TKI that has activity in cases of TKI resistance due to a T315I mutation for which all the other available TKIs are ineffective.
- **PMF:** Only curable treatment is allogeneic SCT; reserved for intermediate or high-risk patients
  - If unresponsive to hydroxyurea, use pegylated interferon-\(\alpha\); tolerance may be an issue.
- **ET:** If resistant/intolerant to hydroxyurea, use anagrelide.
  - If resistant/intolerant to hydroxyurea or anagrelide, pregnant or age <40 years: Use interferon-\(\alpha\).
- **PV:** if resistant or intolerant to hydroxyurea, can use ruxolitinib

**ISSUES FOR REFERRAL**
Patients with MPNs are usually referred to hematology/oncology.

**SURGERY/OTHER PROCEDURES**
May require splenectomy/palliative radiation for foci of extramedullary hematopoiesis
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Severe cachexia; renal failure and hepatomegaly secondary to extramedullary hematopoiesis; massive splenomegaly requiring treatment; severe thrombotic/hemorrhagic episodes; anemia; tumor lysis syndrome
- Optimal hydration to prevent tumor lysis syndrome

ONGOING CARE

PROGNOSIS

- CML: 10-year survival rate ~80% from time of diagnosis; 85% will die in blast crisis; 12- to 18-month median survival for accelerated phase; 3- to 6-month median survival for blast phase
- PMF: worst prognosis of the MPNs; drug therapy does not modify disease course but treats the symptoms; median survival for IPSS low risk = 135 months, intermediate-1 risk = 95 months; intermediate-2 risk = 48 months; high risk = 27 months
- PV: median survival often >10 years
- ET: near-normal life expectancy

COMPLICATIONS

- CML: blast crisis, transformation to acute leukemia, gout, or nephropathy due to hyperuricemia
- PMF: 10% develop acute myeloid leukemia; anemia, massive hepatosplenomegaly, thrombohemorrhagic events, osteosclerosis, secondary gout, splenic infarcts, paraspinal/epidural extramedullary hematopoiesis
- ET: <10% develop post-ET myelofibrosis, 2% develop acute myeloid leukemia; thrombohemorrhagic events
- PV: 15–20% develop post-PV myelofibrosis, 5% develop leukemia; erythromelalgia, pruritus, secondary gout, headaches, vascular occlusive events

REFERENCES

Leukemia, Chronic Myelogenous; Polycythemia Vera

**CODES**

**ICD10**

- D47.1 Chronic myeloproliferative disease
- C92.10 Chronic myeloid leukemia, BCR/ABL-positive, not having achieved remission
- D45 Polycythemia vera

**CLINICAL PEARLS**

- MPNs are a group of clonal disorders that share a common cell of origin in the pluripotent hematopoietic stem cell.
- MPNs are characterized by proliferation of cells of myeloid lineage—granulocytic, erythroid, megakaryocytic, or mast cell. They share common clinical features including risk of thrombosis, spleen and/or liver enlargement and constitutional symptoms related to a hypermetabolic state.
- Splenectomy as an option for symptom and cytopenia control is associated with high risk of postsplenectomy mortality and complications including
thrombosis.
NARCOLEPSY
Waiz Wasey, MD • Sharefi Saleh, MD • Megha Manek, MD

BASICS
DESCRIPTION
- Narcolepsy is an incurable rapid eye movement (REM) sleep disorder mainly characterized by excessive daytime sleepiness (EDS) and may be associated with cataplexy (sudden loss of muscle control), hypnagogic hallucinations (vivid perceptual experiences while falling asleep), or sleep paralysis (temporary inability to move or speak that happens during transition from sleeping to awake state).
- Mainly two types: type 1 (60–70%) (formerly narcolepsy with cataplexy) and type 2 (formerly narcolepsy without cataplexy) (1)
- Usually diagnosed 5 to 15 years late from onset of symptoms (2)
- No cure; however, symptoms can be improved with sleep hygiene, brief 15-minute naps during the day, and drug therapy.

EPIDEMIOLOGY
Incidence
- Affects 0.03 to 0.16% general population with incidence 1/2,000 worldwide (3)
- Bimodal distribution, age of onset peak at 15 years and again at 35 years of age
- Predominant sex: male > female (1.6:1)
- 5% familial cases (1)

Prevalence
- Narcolepsy type 1 (with cataplexy): 25 to 50/100,000 people
- Narcolepsy type 2 (without cataplexy): 20 to 34/100,000 people (1)
- Highest in Japan, lowest in Israel

ETIOLOGY AND PATHOPHYSIOLOGY
- Primarily caused by degeneration of hypothalamic neurons that produce
orexin (hypocretin). Postmortem studies show 85% loss of these neurons in type 1 (hence low levels of orexin in CSF) and about 33% loss in type 2 (1).

- Orexin is crucial to promote wakefulness; it stimulates the reticular activating system (RAS) and inhibits REM.
- Neurodegeneration may be caused by autoimmune process, probably stimulated by infections (such as influenza or streptococcus) or environmental factors (occurs commonly in late spring) (2).
- Alterations in the lipocalin-type prostaglandin D synthase (L-PGDS) level also seem to be involved in causing EDS in narcolepsy (1).
- On rare occasions, may be caused by insult to hypothalamus due to sarcoidosis, stroke, tumor, or paraneoplastic disorder (2).
- International Classification of Sleep Disorders 3rd edition (ISCD-3) classification:
  - Narcolepsy
  - Narcolepsy type 1 (with hypocretin deficiency)
  - Narcolepsy type 2 (without hypocretin deficiency)
  - Narcolepsy due to medical conditions

**Genetics**

- Usually sporadic but increased incidence in families with positive history: 1–2% in first-degree relative of index case (10 to 40 times the general population) (2).
- Twin concordance is 25–31% (suggests environmental contribution).
- 98% of patients with narcolepsy type 1 have human leukocyte antigen (HLA) DQB1*0602; 40–50% of patients with narcolepsy type 2 express this antigen. HLA DQB1*0602 is present in 12–30% of the general population (2).
- Heterozygous subjects have 7- to 25-fold increased risk, whereas homozygous have 2- to 4-fold increased risk (1).
- Presence of DQB1*0602 gene increased risk of narcolepsy by a factor of 200 (2).
- Autosomal-recessive inheritance pattern
- 12% of Asians, 25% of Whites, and 38% of African Americans are gene carriers.

**RISK FACTORS**

- Age (peaks at 15 and 35 years)
- Obesity
- Head trauma
- CNS infectious disease
Anesthesia
Psychological stress
Positive family history
Recent influenza A, streptococcal infection, or H1N1 vaccine

COMMONLY ASSOCIATED CONDITIONS
Obstructive sleep apnea (OSA) (up to 25%), obesity, anxiety

DIAGNOSIS

HISTORY

- Classic tetrad of EDS, cataplexy, sleep paralysis, and hypnagogic hallucinations (four most common symptoms): Only 10–20% of patients have all four symptoms.
- EDS and sleep attacks (cardinal symptom):
  - EDS is present in 100% of patients, usually the first symptom.
  - ICDS-3 classification for both type 1 and 2 requires EDS occurring almost daily for at least 3 months (1).
  - Report refreshing daytime naps, maybe associated with dreams. EDS may return in 1 to 2 hours (2).
  - Sudden sleep attacks (5 to 20 minutes) during stimulating situations such as driving, walking, etc. (4).
  - Sleep attacks are longer in children (up to 2 hours).
  - Patients may report nocturnal insomnia.
- Cataplexy (60–70% patients)
  - Mainly associated with type 1 narcolepsy (1)
  - Sudden transient (seconds to minutes) episode of total or partial loss of motor tone, triggered by strong emotions (such as laughing, anger or fright) (4)
  - Consciousness and memory are not impaired.
  - May affect all or segmental muscles (sparing diaphragm and extraocular)
  - If seen in type 2, suggests progression of disease (1)
  - Status cataplecticus is a rare, prolonged episode of cataplexy (lasting hours) that is more likely in children or those withdrawing off drugs.
- Sleep paralysis
  - Transient (seconds to minute) inability to move or speak either while falling asleep or on awakening (4)
– Patients are aware of their surroundings.
– Occurs in 50% of patients with type 1 narcolepsy

- Hypnagogic or hypnopompic hallucinations:
  – Vivid dreamlike experience in 30–60% patients of type 1 narcolepsy that
    occur during awakening (hypnopompic hallucinations) or at sleep onset
    (hypnagogic) (4)
  – Hallucination may either be visual, tactile, or auditory.
  – Characteristic hallucinations include being attacked by animals or feeling
    that someone else is in the room (2).
  – 15% of type 2 patients may experience these as well.

- Other reported history
  – Nocturnal insomnia
  – Normal total sleep with decreased sleep efficiency
  – Retrograde amnesic and automatic behavior lasting minutes to hours
  – Increased periodic leg movements
  – Depression
  – Panic attacks and social phobias
  – Gaining weight

**PHYSICAL EXAM**
- Unremarkable exam, but complete physical may help rule out other causes of
  EDS
- Deep tendon reflexes are either diminished or absent during an episode of
  cataplexy.

**Pediatric Considerations**
Narcolepsy is rare before the age of 5 years. EDS is more often attributable to
OSA, poor sleep hygiene, and the increased sleep requirements early in life.
Recommended amount of sleep decreases with age: newborns 16 to 18 hr/day;
preschool-aged children 11 to 12 hr/day; school-aged children and teens 10
hr/day; adults 7 to 8 hr/day. Children can gain excessive weight, from 20 to 40 lb
(2). Symptoms of EDS, sleep paralysis, and cataplexy might last longer
compared to adult population.

**DIAGNOSTIC TESTS & INTERPRETATION**
- Sleep log/actigraphy: First, ensure patient is getting 6 hours of sleep at night
  for at least 2 weeks, if not, narcolepsy cannot be diagnosed.
- Primary diagnostic tools
– Polysomnography (PSG): Once patient reports symptoms and narcolepsy is suspected, an overnight PSG is performed (for ages 6 and older), mainly to rule out other causes of EDS.
– Multiple Sleep Latency test (MSLT): performed the day after PSG if at least 6 hours of sleep and no sleep disorder explained by PSG (2)
  o Four to five 20-minute naps at 2-hour intervals
  o Positive if; rapid onset of REM (<15 min) at least twice during the test and shortened mean sleep latency (<8 mins)
  o If MSLT negative, but strong clinical suspicion, repeat the test.
  o Antidepressants and stimulants should be discontinued prior to the test (2).

- Scoring tools
  – Epworth Sleepiness Scale: Score ranges from 0 to 24, and >10 is suggestive of a sleep disorder rather than generalized fatigue; helpful for detecting response to medications (2)
  – Stanford Sleepiness Scale: Patients select 1 of 7 statements that best describe energy level, concentration, and sleepiness. Statements 4 to 7 may indicate excessive sleepiness.
  – Narcolepsy Severity Scale: A 15-item scale to assess the frequency, severity, and consequences of symptoms of narcolepsy type 1

**Laboratory/Special Considerations**
- Orexin: obtained via lumbar puncture, a level of 110 pg/ml or less in the CSF is indicative of narcolepsy; done when MSLT is not available
- HLA typing: particularly in children. It is supportive of diagnosis, lacks specificity.

**Diagnostic Procedures/Other**
- Narcolepsy type 1 (2)[C]
  – Excessive daytime sleepiness daily for ≥3 months
  – One of the following:
    o Cataplexy with positive MSLT
    o Low CSF orexin level <110 pg/mL or <1/3 of mean values in normal subjects
- Narcolepsy type 2 (2)[C]
  – All above without the cataplexy and normal orexin
- It is a diagnosis of exclusion.
DIFFERENTIAL DIAGNOSIS
EDS is present in 4% of the general population, although most individuals are not narcoleptic. Possible etiologies include the following:

- Sleep apnea syndromes
- Epileptic seizures and syncope
- Idiopathic hypersomnia (5–10% with EDS)
- Psychiatric (depression, substance abuse/withdrawal)
- Sleep-related movement disorders (restless leg syndrome, periodic limb movements of sleep)
- Iatrogenic/secondary to medication (benzodiazepines; opioids; antihistamines; β-blocking agents; and some antipsychotics, antidepressants, and anticonvulsants)
- Poor sleep hygiene and habits leading to sleep deficit and chronic sleep deprivation (1)
- Circadian rhythm disorders (jet lag, shift work, delayed or advanced sleep phase disorders)
- Cataplexy disorders (Niemann-Pick type C, Prader-Willi syndrome, Norrie disease) (1)
- Hypersomnia in Parkinson disease
- Kleine-Levin syndrome (recurrent hypersomnia that lasts days to weeks and recurs months later)
- Menstrual-associated hypersomnia
- Stroke (slurred speech and facial sagging seen in partial cataplexy) (2)

TREATMENT

GENERAL MEASURES
- Medications do not cure, but the goal is to minimize EDS and cataplectic episodes.
- First step is proper sleep hygiene and regular sleep schedule.
- Well-timed 15 to 20 minute naps may be helpful.
- Drug therapy if used should be supplemented by various behavioral strategies.
- Avoid stimulus (alcohol, heavy meals, caffeine, nicotine).
- Maneuvers such as trying to think something else, putting tension on muscles or pressing against a firm support might rapidly terminate cataplectic episodes.
- Maintaining warmer body temp and confusing warm meals/drinks may improve wakefulness (5).
Use safety precautions, particularly when driving. Untreated patients are at 10-fold risk of accidents.

MEDICATION

First Line

- EDS
  - Modafinil (Provigil) (5)[A]:
    - First-line treatment for mild-to-moderate EDS
    - Works on dopaminergic, adrenergic, and histaminergic receptors of hypothalamus
    - Dose: 200 mg/day, maybe divided BID. Start with 100 mg; max dose: 400 mg/day
    - Half-life of 14 hours
    - Fewer adverse effects (headache, GI upset, increased metabolism of oral contraceptives) with less rebound hypersomnia and does not affect BP; tolerance limited
    - Caution in patients with cardiac diseases
  - Armodafinil (Nuvigil):
    - Enantiomeric form of modafinil with slightly longer half-life of 15 hours
    - Dose: 150 to 250 mg every morning
  - Pitolisant: (Wakix): new promising drug for narcolepsy and cataplexy approved for treatment in the EU (5)[A]
    - Other emerging Rx: hypocretin agonists administered via intranasal route, atomoxetine and clarithromycin (1)

- Cataplexy:
  - Sodium oxybate (Xyrem):
    - Only medication proven effective and FDA-approved for both EDS and cataplexy (5)
    - Used for moderate-to-severe cases
    - Best option for improving nighttime sleep and FDA-approved for the same (5)
    - Dose: 6 to 9 g/day divided BID, start with 2.25 g and increase by 1.5 g/day qwk; max dose: 9 g/day
    - May take 8 to 12 weeks for full response
    - Date rape drug; abuse potential
    - May worsen sleep-disordered breathing in patients with OSA
    - Overdose may lead to coma.
  - Tricyclic antidepressants
Protriptyline: dose: 5 to 60 mg/day. Taper dose gradually.
Clomipramine: dose: 25 to 75 mg/day
- High side effect profile (anticholinergic): dry mouth, sedation, urinary retention, impotence
  - Serotonin-norepinephrine reuptake inhibitors
    o Venlafaxine: dose: 75 to 300 mg/day. Start at 37.5 mg, max dose 375 mg/day. Taper dose to D/C.
    o Fluoxetine: dose: 20 to 80 mg/day
    o Work by suppressing REM sleep
    o Not FDA-approved
  - The patient may develop a tolerance to the anticataplectic drugs and can have rebound cataplexy when a drug is withdrawn. Most require tapered dosing to discontinue.
- Auxiliary symptoms (e.g., hypnagogic hallucination, sleep paralysis) require treatment less often than EDS and cataplexy, but anticataplectics are useful when symptoms are problematic.

Second Line
- EDS
  - Amphetamines: used if first line fail or patient unable to tolerate
    o Methylphenidate (Ritalin): dose: initial dose 5 to 10 mg/day divided BID or TID; maximum dose 60 mg/day (5)[B], short-acting, most potent amphetamine available; can be used in combination with modafinil and armodafinil
    o Dextroamphetamine: dose: initial dose 10 mg/day; can increase by 10 mg weekly to a maximum dose 60 mg/day divided BID or TID (5)[B]
  - Contraindicated in patients with hypertension (HTN)
  - Adverse reactions: headaches, irritability, HTN, psychosis, anorexia, habituation, rebound hypersomnia
  - If the patient develops a tolerance to stimulants, switch drug or drug holidays rather than increasing dose.
  - Highly addictive; high doses have been associated with frequent hospitalizations, arrhythmias, and psych disturbances (5).
- Cataplexy
  - Selegiline: selective MAO-B inhibitor
    o Anticataplectic effective for EDS; 20 to 40 mg/day divided morning and noon
    o Doses >20 mg require a low-tyramine diet because the drug begins to lose selectivity.
ISSUES FOR REFERRAL
- Unresponsive to primary medications
- Patient support groups can be very beneficial.
- Severe case of cataplexy may need neurology referral.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Monitoring using scoring tools to gauge treatment effectiveness and symptom control
- Frequent BP checks and regular follow-ups (approximately every 6 months) are recommended for those on medication.

DIET
Selegiline: Doses >20 mg require a low-tyramine diet because the drug begins to lose selectivity.

PATIENT EDUCATION
- Narcolepsy information from the National Institute of Neurological Disorders and Stroke at www.ninds.nih.gov/disorders/narcolepsy/narcolepsy.htm
- Narcolepsy Network, Inc., North Kingstown, RI 02852; www.narcolepsynetwork.org

PROGNOSIS
Narcolepsy is a lifelong disease. Symptoms can worsen with aging. In women, symptoms can improve after menopause.

REFERENCES
4. Sateia MJ. International classification of sleep disorders-third edition:

CODES

ICD10
- G47.429 Narcolepsy in conditions classified elsewhere w/o cataplexy
- G47.411 Narcolepsy with cataplexy
- G47.419 Narcolepsy without cataplexy

CLINICAL PEARLS
- Narcolepsy is an incurable, REM disorder, with an average of 15 years of symptoms before a definitive diagnosis is made.
- The classic tetrad of symptoms includes EDS, cataplexy, sleep paralysis, and hypnagogic hallucinations, but only cataplexy is pathognomonic for the disorder.
- The International Classification of Sleep Disorders has specific diagnostic criteria for narcolepsy.
- Medications help minimize symptoms but not curative.
NASAL POLYPS

Andrew Dinh, DO • Monica Ramirez, MD • Tharani Ravi, MD

BASICS

- Chronic inflammatory lesion of nasal mucosa
- Arise from ethmoidal cells but can arise from maxillary sinus mucosa although less common
- Appearance of edematous pedunculated mass in the nasal cavity or within the paranasal sinus
- Often causes symptoms of blockage, discharge, or loss of smell
- Most commonly bilateral; suspect tumor, such as inverted papilloma, if unilateral.
- Prevalence ~4% in general population
- Much rarer in children: ~0.1% and associated with cystic fibrosis
- Increases with age
- Predominant sex: female > male (2:1)
- Asthma is present in 65% of patients; 25% of patients have undiagnosed asthma.
- No clearly delineated pathway; research has demonstrated separate TH1- and TH2-driven pathways (1)[B].
- Development of condition remains unclear; multiple inflammatory and infectious pathways resulting from chronic rhinosinusitis is most common.

GENERAL PREVENTION

Use of intranasal corticosteroids after polyp removal surgery has shown effectiveness against recurrence.

COMMONLY ASSOCIATED CONDITIONS

- Bronchial asthma
- Bronchiectasis
- Aspirin hypersensitivity
- Allergic rhinitis
- Cigarette smoking promotes eosinophilic inflammation.
- Chronic sinusitis
- Allergic fungal sinusitis
- Aspirin sensitivity
- Cystic fibrosis
- Primary ciliary dyskinesia (Kartagener syndrome)
- Laryngopharyngeal reflux

**DIAGNOSIS**

- Symptoms present >12 weeks (2).
- Two or more symptoms, one of which is either nasal blockage/obstruction/congestion OR nasal discharge
- Nasal obstruction/restricted nasal airflow: persistent mouth breathing
- Nasal discharge:
  - Anterior discharge—rhinorrhea
  - Postnasal drip
- Reduction/loss of smell (hyposmia)
- Dull headaches
- Facial pain/pressure over the middle third of the face
- Symptoms of acute, recurrent, or chronic rhinosinusitis
- Anterior rhinoscopy looking for a pale translucent mass of tissue
  - Most commonly from lateral wall of middle meatus
  - Otoscope with nasal speculum or even otologic speculum is typically used.
- Flexible/rigid endoscopy is required to assess the nasal cavity fully.
  - Endoscopy is the gold standard for diagnosis.
  - Topical anesthesia nasal spray should be used prior to the endoscopy if patient is awake.
- Tympanic membrane examination for eustachian tube dysfunction secondary to large posterior nasal polyps
- Examine the posterior pharynx via oral cavity for large posterior polyps.
- Antrochoanal polyp (typically found in children)
- Benign or malignant tumor:
  - Papilloma
  - Fibroma
  - Hemangioma
  - Neurilemmoma
  - Osteoma
  - Adenoma
  - Chondroma
- Mycetoma
- Encephalocele
- Squamous cell carcinoma
- Malignant melanoma

**Allergy testing (3)[B]:**
- Skin prick test
- ImmunoCAP testing
- Radioallergosorbent test (RAST)

**Testing for cystic fibrosis in children with multiple benign polyps: sweat test:**
- Often requires repeat tests (3)[B]

**CT scanning (3)[B]:**
- May be helpful to corroborate history and endoscopic findings
- Unable to differentiate polyp from other soft tissue masses

**MRI (3)[B]:**
- May aid in diagnosis if concern for neoplasia, mycetoma, or encephalocele
- Histologic exam to exclude malignancy if unilateral polyp
- Diagnosis is made by the combination of rhinoscopy, endoscopy, and CT scanning.

**CT reveals extent of disease and is necessary to formulate a plan for surgical intervention (3)[B].**

- Ciliated pseudostratified columnar epithelium: with areas of transitional or squamous epithelium
- Chronic infiltration of inflammatory cells
- Eosinophils are the predominant cells in most patients.

---

**TREATMENT**

- Intranasal corticosteroid use has been demonstrated to reduce polyp size and recurrence as well as improvement in nasal congestion based on controlled studies (1)[A].
- Treat for a minimum of 12 weeks; minimal systemic absorption, side effects rare—minor nose bleeding is most common (1)[A].
  - Budesonide 256 μg/day
  - Beclomethasone dipropionate 320 μg/day
  - Fluticasone propionate 400 μg/day
  - Mometasone furoate 200 μg BID
- For children, mometasone furoate is preferred:
  - 100 μg BID ages 6 to 12 years
200 μg BID for ages 12 to 17 years

- Oral systemic corticosteroids: only temporary and less definitive benefit; more systemic adverse effects; use with caution in patients with diabetes mellitus, hypertension, or peptic ulcer disease (1)[A].
- Prednisolone
  - Weight-based dosing burst with taper
- Perioperative use oral prednisone 30 mg daily 5 to 7 days prior to surgery (1)[A]
  - Decrease nasal mucosa inflammation
  - Improves surgical field
  - Shorter surgical time
  - Improves postop results
  - Weight-based dosing burst with taper
- There is very limited information and data about the efficacy of using oral steroids as an adjunct to other treatments (4)[A].

ISSUES FOR REFERRAL
- Patients with severe obstruction symptoms should be referred for surgery (2).
- Referral to otorhinolaryngologist warranted, if patient has several polyps or 3 months of ineffective conservative management.

ADDITIONAL THERAPIES

Antileukotrienes: clinical improvement without aspirin hypersensitivity (1)[A], (3)[B]:
- Aspirin desensitization may have a role in reducing recurrence of nasal polyposis.
- Anti–interleukin-5 immunomodulators: may benefit those with TH2 eosinophilic disease process
- Oral antibiotics: Doxycycline for 3 to 4 weeks or oral macrolide for 12 weeks is an option for disease unresponsive to steroids alone with mixed results of therapy (5)[A].
- Indicated for patients with four or more episodes in 1 year of acute rhinosinusitis refractory to medical therapy (2)
  - Disease must be documented endoscopically or on CT during symptomatic period prior to surgical intervention.
- Surgical therapy reserved for refractory cases
  - Recurrence ~5–10% (2)
- Most surgeries are approached endonasally.
– Endoscopic sinus surgery has become the mainstay of treatment.
– The external (Caldwell-Luc) approach is used for more difficult cases but carries higher risk of complications.
- Functional endonasal sinus surgery has slightly lower revision rate than intranasal polypectomy. Both modalities provide effective symptom relief.
- Postoperative use of nasal corticosteroids delay the recurrence of nasal polyps and hence the timing of revision surgery (1,6)[A].
- Postoperative use of steroid-releasing stents to prevent polyp recurrence by decreasing mucosal inflammation (1,6)[A].
- Intrapolyp steroid injection may be considered in cases refractory to other interventions but has risk of visual loss.

**ONGOING CARE**
- Acute/chronic sinus infection
- Heterotopic bone formation within the sinus cavity
- Recurrence:
  – Twice as likely in those with asthma

**REFERENCES**

ADDITIONAL READING

CODES

ICD10

- J33.9 Nasal polyp, unspecified
- J33.0 Polyp of nasal cavity
- J33.8 Other polyp of sinus

CLINICAL PEARLS

- Intranasal corticosteroid use has been demonstrated to reduce polyp size and recurrence as well as to improve nasal congestion.
- Asthma is a common concomitant diagnosis and is often previously undiagnosed.
- Aggressive medical and surgical treatment improves asthma outcomes.
- Treat for a minimum of 12 weeks.
- Allergy testing can be helpful.
- Nasal polyposis associated with asthma and aspirin hypersensitivity known as Samter triad or aspirin exacerbated respiratory disease (AERD)
- Patients with severe obstruction should be referred for surgery.
• Unilateral nasal polyp needs malignancy workup (MRI).
NEPHROTIC SYNDROME
Hanadi Abou Dargham, MD • Nandhini Veeraraghavan, MD, CAQSM, FAAFP

BASICS
DESCRIPTION
- A clinical syndrome of proteinuria (>3.5 g/1.73 m²/24 hr), hypoalbuminemia (<3 g/dL), severe hyperlipidemia (total cholesterol often >10 mmol/l) (380 mg/dL), clinical evidence of peripheral edema, with risk for thrombotic disease
- Includes both primary (idiopathic) and secondary forms
- Associated with many types of kidney disease

EPIDEMIOLOGY
Based on definitive diagnosis
- Diabetic nephropathy: most common cause of secondary nephrotic syndrome (1)
- Minimal change disease (MCD)
  - Most common cause of nephrotic syndrome in children <10 years (90%)
  - Peaks at 2 to 8 years of age
  - Associated with drugs (mainly NSAIDs) or lymphoma in adults
- Amyloidosis: 7–14% of idiopathic nephrotic syndrome—two renal types primary (AL) and secondary (AA)
- Lupus nephropathy (LN): Adult women are affected about 10 times more often than men.
- Focal segmental glomerulosclerosis (FSGS)
  - 35% of nephrotic syndrome in adults
  - Most common primary nephrotic syndrome in African Americans
  - Has both primary (idiopathic) and secondary forms (associated with HIV, morbid obesity, reflux nephropathy, previous glomerular injury)
- Membranous nephropathy
  - Most common cause of primary nephrotic syndrome in adults (40%)
  - May be primary or secondary associated with malignancy, Hep B, autoimmune diseases, thyroiditis, and certain drugs
Membranoproliferative glomerulonephritis (MGN)
– May be primary or secondary
– May present in the setting of a systemic viral or rheumatic illness

ETIOLOGY AND PATHOPHYSIOLOGY
• Increased glomerular permeability to protein macromolecules, especially albumin
• Podocytes injury is the most common finding in diseases that cause primary nephrotic syndrome.
• Edema results primarily from renal salt retention, with arterial underfilling from decreased plasma oncotic pressure playing an additional role.
• Hyperlipidemia is thought to be a consequence of increased hepatic synthesis resulting from low oncotic pressure and urinary loss of regulatory proteins.
• The hypercoagulable state that can occur in some nephrotic states is likely due to loss of antithrombin III in urine.
• Primary renal disease:
  – MCD
  – FSGS
  – MGN
  – IgA nephropathy
• Secondary renal disease (associated primary renal disease shown in parentheses):
  – Diabetic nephropathy
  – Amyloidosis
  – LN
  – FSGS
  – Infections (MGN)
  – Cancer (MCD or MGN)
  – Drugs (MCD or MGN)

Genetics
Genetic factors are likely to play a role in susceptibility to the various nephrotic syndromes, although these have not been sufficiently defined to be useful clinically.

RISK FACTORS
• Drug addiction (e.g., heroin [FSGS])
• Hepatitis B and C, HIV, other infections
- Immunosuppression
- Nephrotoxic drugs
- Vesicoureteral reflux (FSGS)
- Cancer (usually MGN, may be MCD)
- Chronic analgesic use/abuse (NSAIDs)
- Preeclampsia
- Diabetes mellitus

**GENERAL PREVENTION**
In general, there are few preventive measures, including avoidance of known causative medications including NSAIDs, gold, penicillamine, and captopril; avoidance of heroin abuse and tight glycemic control

**DIAGNOSIS**

**HISTORY**
The history is key in pinpointing the cause of nephrotic syndrome.
- Inquire about signs or symptoms of systemic disease: joint complaint, rash, edema, infectious complaint, fevers, anorexia, oliguria, foamy urine, acute flank pain, and hematuria.
- Obtain a recent drug history for medications that may be causative, especially NSAIDs.
- Assess for risk factors.

**PHYSICAL EXAM**
A complete physical exam may discover clues to systemic disease as a potential cause and/or may suggest the severity of disease.
- Fluid retention: abdominal distention, abdominal fluid shift, extremity edema, puffy eyelids, scrotal swelling, weight gain, shortness of breath. Pericardial rub and decreased breath sounds with pleural effusions may develop.
- Hypertension
- Orthostatic hypotension

**ALERT**
The potential for thromboembolic disease leading to pulmonary embolism is one of the most life-threatening aspects of a patient who is actively nephrotic.
DIFFERENTIAL DIAGNOSIS

- Edema and proteinuria: See “Etiology and Pathophysiology.”
- Edema alone: Other diseases to rule out in patients who have edema without proteinuria include congestive heart failure, cirrhosis, hypothyroidism, nutritional hypoalbuminemia, protein-losing enteropathy.

DIAGNOSTIC TESTS & INTERPRETATION

No guidelines are available for the investigation of nephrotic syndrome. Blood workup should be based on the clinical presentation.

Initial Tests (lab, imaging)

- Confirm proteinuria if present: by urine dipstick initially; and then quantitate by 24-hour urine or spot urine protein-to-creatinine ratio.
- Rule out urine infection with urine culture.
- Full blood count and coagulation screen
- Renal function tests: BUN, creatinine with estimated glomerular filtration rate (GFR)
- Glucose to rule out overt diabetes
- Consider blood cultures to rule out a postinfectious process.
- Lipid panel
- Liver function tests to exclude liver disease or infection
- Look for autoimmune disease.
  - Antinuclear antibody and/or antidouble-stranded DNA positivity suggest lupus.
  - Complement levels (C3/C4 and total hemolytic complement): A low C3 may suggest a postinfectious or membranoproliferative process, whereas both low C3 and C4 point to lupus.
- Serum protein electrophoresis/urine immune electrophoresis to rule in a paraproteinemia
- Hepatitis B and C screen
- Measurement of cryoglobulins
- HIV and syphilis serology
- Urinalysis to evaluate for the presence of cellular casts
- Renal US to verify the presence of two kidneys of normal shape and size
- Chest x-ray to detect presence of pleural effusion or infection
- If thrombosis is suspected:
  - Doppler US of the legs
  - MRI or venography for renal vein thrombosis
– Ventilation/perfusion nuclear medicine lung scan and/or CT angiography may be required to rule out pulmonary embolism.

**Diagnostic Procedures/Other**

Renal biopsy is standard in determining the underlying cause of nephrotic syndrome.

- Rarely done in children with first episode of nephrotic syndrome, as MCD is common and empiric steroid therapy is the standard of care
- Required to confirm the clinical diagnosis in adults and assist with making a treatment plan (1)
- Contraindications to renal biopsy include small kidneys, renal tumor or bilateral renal cysts, active infection, severe malignant hypertension, hydronephrosis, bleeding diathesis, uncooperative patient.

**Test Interpretation**

- Light microscopy
  - May see nothing (e.g., MCD)
  - Sclerosis (e.g., FSGS or diabetic nodules in diabetes)
  - Diffuse hypercellularity suggests a proliferative disease such as IgA nephropathy, LN, or postinfectious glomerulonephritis (GN).
- Immunofluorescence: Mesangial IgA suggests IgA nephropathy, Henoch-Schönlein; other staining patterns are specific for other disease processes.
- Electron microscopy: The location of immunoglobulin deposits is useful in pointing to a particular diagnosis.

**TREATMENT**

**MEDICATION**

**First Line**

- Edema: salt restriction and salt-wasting diuretics (loop and thiazide diuretics) (2)[A]:
  - Salt restriction to <2 to 3 g sodium per day
  - Restrict fluid intake to <1.5 L/day if hyponatremic.
  - Target weight loss of 0.5 to 1.0 kg/day (1 to 2 lb/day)
- Edema should be corrected slowly to avoid acute hypovolemia, electrolyte disturbances, acute renal failure, and thromboembolism as a result of
hemoconcentration, and diuretic dose should be increased in comparison to the general population.

- Hyperlipidemia:
  - Is reversed with resolution of the disease
  - The role of dietary modification is unproven yet.

- Statins have been shown to improve endothelial function (2)[A] and may decrease proteinuria (3)[A], but effect on GFR and preservation of renal function is small. The major role for statin use is in cardiovascular risk reduction.

- ACE inhibitors or angiotensin II receptor blockers are thought to reduce proteinuria, hyperlipidemia, thrombotic tendencies, progression of renal failure, and to control hypertension, if present (4)[A].

- For steroid-responsive disease (MCD and FSGS), steroids dosed in consultation with nephrologist.

**Second Line**

- Many of the nephrotic diseases will require escalation in therapy above steroids. These include rapidly relapsing forms, as well as MGN, LN, and IgA nephropathy. Bolus steroids and other immunosuppressives are required in this circumstance (cyclophosphamide, mycophenolate mofetil, chlorambucil, cyclosporine) (5)[A].

- Rituximab, combined with steroids or other immunosuppressive agents, has demonstrated early promise in the treatment of refractory nephrotic syndrome (6)[B].

- Randomized controlled data have been insufficient to determine which patients require prophylactic anticoagulation (7)[A] and for how long. Common practice is to anticoagulate with heparin and then warfarin in patients who have persistent nephrotic-range proteinuria. This decision is made based on the patient’s history of edema, hypoalbuminemia, thromboembolism, or immobility.

- Hypocalcemia from vitamin D loss should be treated with oral vitamin D.

**ISSUES FOR REFERRAL**

Consultation with a nephrologist is often required to assist with renal biopsy to confirm diagnosis and to assist with management of edema. Cytotoxic medications may be called for, depending on the disease process, and this may best be handled by a nephrologist.
ADDITIONAL THERAPIES
Ambulation or range-of-motion exercises to lower risk of deep vein thrombosis (DVT)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization: respiratory distress, sepsis/severe infection, thrombosis, renal failure, hypertensive urgency/emergency, or other complications
- Discharge criteria: Hemodynamically stable patients without complications may be managed as outpatients.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Frequent monitoring is required for relapse, disease progression, and for detecting signs of toxicity of medical management.
- Reevaluate for azotemia, urine protein, hypertension, edema, loss of renal function, cholesterol, and weight.

DIET
Muscle wasting and malnutrition are major problems in severe nephrotic syndrome. Optimal diet includes:
- Normal protein (1 g/kg/day)
- Low fat (cholesterol)
- Reduced sodium (<2 g/day)
- Supplemental multivitamins and minerals, especially vitamin D and iron
- Fluid restriction if hyponatremic

PATIENT EDUCATION
- Printed material for patients: National Kidney Foundation, 30 E. 33rd Street, Suite 1100, New York, NY 10016; 800-622-9010
  – Childhood nephrotic syndrome
  – Diabetes and kidney disease
– Focal glomerulosclerosis

- Web site: National Institutes of Health: nephrotic syndrome

**PROGNOSIS**

- Nephrotic syndrome in children (MCD) is typically self-limited and carries a good prognosis. In the adult, the prognosis is variable. Proteinuria is the most important adverse prognostic factor that leads to rapid progression to end-stage renal failure.
- Complete remission is expected if the basic disease is treatable (infection, malignancy, drug-induced); otherwise, a relapsing and remitting course is possible, with progression to dialysis seen in more aggressive forms (diabetic glomerulosclerosis).

**COMPLICATIONS**

- Thromboembolism:
  - Deep vein, renal vein, or central venous thrombosis may occur. Arterial thrombosis is very rare.
  - The risk appears to be greater the lower the serum albumin.
  - Pulmonary embolism is a known complication.

- Pleural effusion

- Symptomatic hypovolemia

- Ascites

- Hyperlipidemia, cardiovascular disease

- Acute renal failure, progressive renal failure

- Protein malnutrition/muscle wasting

- Infection secondary to low serum IgG concentrations, reduced complement activity, and depressed T-cell function: peritonitis, pneumonia, or cellulitis

- Loss of vitamin D (vitamin D–binding protein loss in urine) leading to bone disease

- Proximal tubular dysfunction resulting in glucosuria, aminoaciduria, phosphaturia, bicarbonaturia, and vitamin D deficiency

**REFERENCES**

3. Fried LF, Orchard TJ, Kasiske BL. Effect of lipid reduction on the

**ADDITIONAL READING**

Acute Kidney Injury; Amyloidosis; Diabetes Mellitus, Type 1; Diabetes Mellitus, Type 2; Glomerulonephritis, Acute; HIV/AIDS; Lupus Erythematosus, Discoid; Multiple Myeloma

**CODES**

**ICD10**

- N04.9 Nephrotic syndrome with unspecified morphologic changes
- N04.1 Nephrotic syndrome w focal and segmental glomerular lesions
- N04.2 Nephrotic syndrome w diffuse membranous glomerulonephritis

**CLINICAL PEARLS**
- Nephrotic syndrome is a clinical syndrome of >3.5 g/day proteinuria, hypoalbuminemia, hyperlipidemia, and edema often associated with diabetes and NSAIDs use.
- Pediatric nephrotic syndrome typically carries a good prognosis and is more easily treated with steroids, although recurrences are common.
- Nondiabetic adults with nephrotic syndrome will require a renal biopsy to determine cause.
- Have a high index of suspicion for symptoms that may represent an embolic event in patients with nephrotic syndrome.
**NEUROFIBROMATOSIS TYPE 1**

*Michele Roberts, MD, PhD*

---

**BASICS**

**DESCRIPTION**

- Neurofibromatosis types 1 (NF1) and 2 (NF2) are neurocutaneous syndromes (phakomatoses). Although they share a name, they are unrelated.
  - NF1, the most common of the phakomatoses, is a multisystem disorder that may affect any organ: It is characterized by café au lait spots, axillary and inguinal freckling, neurofibromas, Lisch nodules, choroidal freckling.
  - NF2 is a rare condition that causes bilateral vestibular schwannomas.

- System(s) affected: musculoskeletal; nervous; skin/exocrine; cardiovascular; neuro-ophthalmologic
- Synonym(s): von Recklinghausen disease, formerly peripheral NF

**EPIDEMIOLOGY**

**Incidence**

- Predominant sex for NF1: male = female
- Birth incidence NF1: 1:2,500 to 3,000

**Prevalence**

1:3,000 to 1:4,000

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Neurofibromin is a guanosine triphosphatase–activating protein that acts as a tumor suppressor by downregulating a cellular proto-oncogene, *p21-ras*, which enhances cell growth and proliferation.
- Neurofibromata are benign tumors composed of Schwann cells, fibroblasts, mast cells, and vascular components that develop along nerves.
- The two-hit hypothesis has been invoked to explain malignant transformation in NF1.

**Genetics**

- Online Mendelian Inheritance in Man 162200
- Caused by a mutation in the *NF1* gene on chromosome 17q11.2; autosomal
dominant inheritance; protein product is called *neurofibromin*.

- 50% of cases are due to de novo mutations, mostly paternal; likelihood increases with paternal age.
- Prenatal diagnosis is possible if mutation is known.
- Penetrance is nearly 100%; expressivity is highly variable, even within a family.
- Gene is large, with a variety of mutations causing NF1. Molecular technology can detect 95% of clinically important *NF1* mutations, but clinical diagnosis frequently can be made in childhood.
- ~5% of individuals with NF1 have a large deletion of the *NF1* gene; usually a more severe phenotype
- *Segmental NF* is limited to a single body region and is caused by mosaicism for the *NF1* mutation.

**RISK FACTORS**

- Having an affected first-degree relative is a diagnostic criterion for NF1, although relatives may be unaware that they have NF1.
- Affected individuals with a positive family history (or a new mutation) have a 50% risk of transmitting NF1 to each offspring; 1 in 12 will be severely affected.
- Segmental NF1: may have gonadal mosaicism and may be at risk for transmission of the mutated gene

**COMMONLY ASSOCIATED CONDITIONS**

- Congenital heart disease, pulmonary stenosis, hypertension, renal artery stenosis
- Learning disabilities (50–75%)

**DIAGNOSIS**

- NF1 can be diagnosed by routine exam by age 4 years, with attention to skin stigmata; diagnostic criteria include ≥2 of the following (1):
  - ≥6 café au lait (light brown) macules, ≥5 mm in prepubertal individuals, or ≥15 mm in adults
  - ≥2 neurofibromata of any type or 1 plexiform (uncircumscribed) neurofibroma
  - Axillary or inguinal freckling
  - ≥2 Lisch nodules (benign iris hamartomas)
- Optic glioma by MRI
- Characteristic osseous lesions: sphenoid dysplasia, long-bone cortical thinning, ribbon ribs, angular scoliosis
- First-degree relative with NF1 by above criteria
- Prenatal diagnosis is possible with known mutation or by linkage testing (with positive family history), although not predictive of clinical course.
- With increasingly precise molecular analysis, and newly recognized clinical signs including nevus anemicus, unidentified bright objects, choroidal hamartomas, and a characteristic neuropsychological phenotype, 1988 clinical criteria may be due for revision (2).

HISTORY
- Family history of a first-degree relative with NF1
- Manifestations generally are not visible at birth, although plexiform neurofibromata are usually congenital, and tibial bowing is congenital.
- In addition to cutaneous lesions, NF1 may present with painful neurofibromata, pathologic fractures, or headaches secondary to hypertension caused by pheochromocytomas.
- Optic gliomata may present as involuntary eye movement, squinting, loss of vision, or as diencephalic syndrome.

PHYSICAL EXAM
- Skin
  - Café au lait macules, usually the presenting feature of NF1, develop before age 3 years. Evenly pigmented, irregularly shaped (coast of California), light brown macules seen in 97% of patients with NF1; many unaffected individuals have 1 to 3 such macules.
  - Neurofibromata: can be soft or firm, cutaneous, subcutaneous, or plexiform; buttonhole invagination is pathognomonic. Cutaneous neurofibromata usually appear during late childhood or adolescence.
  - Plexiform neurofibromata present in up to 50%
    - Usually congenital; may be subtle in infancy
    - Freckling or hypertrichosis may be present over plexiform neurofibromata; may affect underlying structures or focal hyperplasia
    - Many are internal, not obvious on exam.
    - Most grow slowly, but can have rapid growth, especially in early childhood.
  - Evaluate for new or progressive lesions. Rapidly growing cutaneous lesions should be evaluated.
- Axillary freckling (Crowe sign) or inguinal freckling (91%)

- Ophthalmologic
  - Lisch nodules in 30%: well-defined, dome-shaped, gelatinous hamartomatous lesions projecting from the iris, varying from clear yellow to brown
  - Essentially unique to NF, Lisch nodules are asymptomatic; significant only for diagnosis
  - Pallor or atrophy of optic disc, bulging of orbit, loss of vision may be signs of optic glioma.
  - Choroidal freckling (3)

- Skeletal
  - Scoliosis and vertebral angulation
  - Localized bone hypertrophy, especially of the face
  - Limb abnormalities:
    - Pseudoarthrosis of the tibia
    - Tibial dysplasia (anterolateral bowing of the tibia) is congenital.
    - Nonossifying fibromas of the long bones in adolescents and adults are uncommon but can increase risk of fracture.

- Pay particular attention to neurologic examination (asymmetry) or new focal pain.
- Measure BP yearly. Hypertension is more common in patients with NF1 and could be secondary to renal artery stenosis, aortic stenosis, pheochromocytoma.
- Evaluate neurodevelopmental progress in children. Learning disabilities occur in 50–75%.

**DIFFERENTIAL DIAGNOSIS**

Familial café au lait spots (autosomal dominant, no other NF1 features), Legius syndrome, constitutional mismatch repair deficiency syndrome (CMMRD), NF2, Watson syndrome, LEOPARD syndrome, McCune-Albright syndrome, neurocutaneous melanosis, proteus syndrome, lipomatosis, Jaffe–Campanacci syndrome

**Geriatric Considerations**

In NF1, cutaneous lesions and tumors increase in size and number with age.

**Pediatric Considerations**

- Children who have inherited the *NF1* gene of an affected parent usually are
identified by age 1 year, but external stigmata may be subtle.

- If no stigmata noted by age 2 years, NF is unlikely, but the child should be reexamined. Diagnosis usually can be made by age 4 years using NIH criteria (1), although young children may have multiple café au lait spots but no other stigmata.
- Molecular confirmation may be appropriate, especially with atypical presentation (4).

**DIAGNOSTIC TESTS & INTERPRETATION**

- Molecular genetic testing often not necessary for diagnosis:
  
  [https://www.genetests.org/](https://www.genetests.org/)

- Confirmatory genetic testing is appropriate in those suspected of having NF1 but do not fulfill diagnostic criteria or for prenatal diagnosis or preimplantation genetic diagnosis (PGD) (5).

- Molecular genetic testing of the *NF1* gene can identify mutations in ~95% of those with a clinical diagnosis.

- Multistep pathogenic variant detection with cDNA and gDNA sequence analysis recommended if molecular genetic testing is indicated (6). NF1 is caused by a wide variety of mutations in the *NF1* gene.

**Initial Tests (lab, imaging)**

- Characteristic radiographic findings: sphenoid dysplasia, long bone cortical thinning, ribbon ribs, angular scoliosis. Screening radiographs of the knees in adolescents is controversial. CT can demonstrate bony changes.

- MRI findings of the orbits, brain, or spine (86%). Routine head MRI scanning in asymptomatic individuals is controversial. Optic gliomata (on MRI, 11–15%) may lead to blindness. Although areas of increased T2 signal intensity (unidentified bright objects) are common on brain MRI, they are not diagnostic of NF1 and likely of no clinical significance.

- The NIH Consensus Development Conference does not recommend routine neuroimaging as a means of establishing a diagnosis, although modification of diagnostic criteria is discussed (1)[C].

**Diagnostic Procedures/Other**

- Ophthalmologic evaluation, including slit-lamp exam of the irides; visual field testing to evaluate optic gliomata

- Neuropsychological testing: intelligence usually normal but may have significant deficits in language, visuospatial skills, and neuromotor skills
TREATMENT

MEDICATION

First Line
No specific therapeutic agents; symptoms are treated as they arise (e.g., anticonvulsants for seizures, medications for ADHD, management of blood pressure).

Second Line
- In treating plexiform neurofibromas, tipifarnib, sirolimus, and pirfenidone have shown insufficient benefit. Small trials of imatinib have shown some tumor shrinkage. Selumetinib has shown promising results in a small study.
- Multiple clinical trials for NF1 are recruiting patients (see https://www.clinicaltrials.gov/).

ISSUES FOR REFERRAL
- Patients with more than minimal manifestations of NF1: Refer to a multidisciplinary NF clinic.
- Referral for psychosocial issues
- Educational intervention for children with learning disabilities or ADHD (40%)
- Early referral to orthopedics for congenital tibial bowing

ADDITIONAL THERAPIES
- Occupational therapy for children with NF1 who present with fine motor difficulties
- Laser therapy not recommended for café au lait spots
- The Children’s Tumor Foundation (CTF) has established the NF Clinical Trials Consortium and the CTF NF Clinic Network to facilitate clinical trials.

SURGERY/OTHER PROCEDURES
- Surgical treatment for dystrophic scoliosis or malignancy (especially malignant peripheral nerve sheath tumors [MPNST]). Surgery for plexiform neurofibromata is often unsatisfactory.
- Treatment of optic gliomata unnecessary unless symptomatic
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

NF1 health supervision 2008 guidelines:

- **Infancy to 1 year (7)[C]**
  - Growth and development: mild short stature, macrocephaly (increased brain volume); aqueductal stenosis/obstructive hydrocephalus
  - Check for focal neurologic signs or asymmetric neurologic exam.
  - Skeletal abnormalities, especially spine and legs
  - Neurodevelopmental progress

- **1 to 5 years (7)[C]**
  - Café au lait spots and axillary freckling have no clinical significance.
  - Annual ophthalmologic exam
  - Brain MRI for visual changes, persistent headaches, seizures, marked increase in head size, plexiform neurofibroma of the head
  - Assess speech and language: hypernasal speech due to velopharyngeal insufficiency and delayed expressive language development.
  - Developmental evaluation of learning and motor abilities; may benefit from speech/language and/or motor therapy, and special education
  - Monitor BP annually.

- **5 to 13 years (7)[C]**
  - Evaluate for skin tumors causing disfigurement, and obtain consultation if surgery is desired to improve appearance or function.
  - Evaluate for premature or delayed puberty. If sexual precocity is noted, evaluate for an optic glioma or hypothalamic lesion. Review the effects of puberty on NF.
  - Evaluate for learning disabilities and ADHD.
  - Evaluate social adjustment, development, and school placement.
  - Monitor ophthalmologic status yearly until age 8 years; complete eye exam every 2 years.
  - Monitor BP annually.
  - Refer patient to a clinical psychologist or child psychiatrist for problems with self-esteem.
  - Discuss growth of neurofibromata during adolescence and pregnancy.
  - Counsel parents about discussing diagnosis with child.

- **13 to 21 years (7)[C]**
  - Examine the adolescent for abnormal pubertal development.
– Skin examination for plexiform neurofibromata and neurologic exam for findings suggestive of deep plexiform neurofibromata; surgical consultation for signs of pressure on deep structures.
– Continue to monitor BP yearly.
– Ophthalmologic exam every 2 years until age 18 years.
– Discuss genetics of NF1 or refer for genetic counseling.
– Discuss sexuality, contraception, and reproductive options.
– Discuss effects of pregnancy on NF1, if appropriate. Neurofibromata may enlarge and new tumors may develop during pregnancy.
– Review prenatal diagnosis or refer to a geneticist.

PATIENT EDUCATION
- Genetic counseling and patient education regarding future complications about family planning.
- Support groups are important: [http://www.ctf.org/](http://www.ctf.org/).

PROGNOSIS
Variable; most patients have a mild expression of NF1 and lead normal lives.

COMPLICATIONS
- Disfigurement: Skin neurofibromata develop primarily on exposed areas. The number tends to increase with puberty or pregnancy.
- Scoliosis: 10–30% (most cases mild); bowing of long bones, 2%; osteopenia and osteoporosis.
- A large head is common but rarely associated with hydrocephalus.
- Increased risk of malignancy: MPNST (5–10%) usually in adults (1), especially within the field of previous radiotherapy for plexiform neurofibroma.
- CNS tumors (5–15%), optic pathway glioma most common, most often asymptomatic but usually presents before age 6 years if symptomatic; symptomatic lesions usually stable or slowly progressive.
- High relative risk (RR) for uncommon malignancies.
- Increased risk for pheochromocytoma, rhabdomyosarcoma, leukemia, Wilms tumor.
- RR for cancer of the esophagus (3.3), stomach (2.8), colon (2.0), liver (3.8), lung (3.0), bone (19.6), thyroid (4.9), malignant melanoma (3.6), non-Hodgkin lymphoma (3.3), chronic myeloid leukemia (6.7), female breast (2.3), and ovary (3.7).
- Learning disability: ~50%; may be associated with ADHD; cognitive impairment in 4–8%
- Neuropsychological phenotype
- GI neurofibromata may cause GI disturbances.
- Seizures: 6–7%
- Hypertension frequent in adults, may occur in childhood
- Disorders of puberty

**Pregnancy Considerations**
Increased risk of perinatal complications, stillbirth, intrauterine growth constriction; risk of cord compression and outlet obstruction by pelvic neurofibromata

**REFERENCES**

**SEE ALSO**
Tuberous Sclerosis Complex; Von Hippel-Lindau Syndrome

**CODES**
**ICD10**
Q85.01 Neurofibromatosis, type 1

**CLINICAL PEARLS**
- Marked clinical variability. External stigmata may be subtle or absent in young children. Minimally affected children may become severely affected adults.
- A single café au lait spot is of no concern in a child, but having ≥6 is a diagnostic criterion for NF1.
BASICS

DESCRIPTION
- Defined as pain caused by direct nerve injury \(^{(1)}\)
- Any injury to either the peripheral or central nervous system can lead to neuropathic pain.
- Can exist without ongoing disease
- Can arise from damage to nerve pathways at any point from the terminals of the peripheral nociceptors to the cortical neurons in the brain
- Causes include traumatic nerve injury, infection, metabolic injury, autoimmune disease, neoplasm, drugs, radiation, and neurovascular disorders.

EPIDEMIOLOGY

Prevalence
- Includes various chronic conditions that affect up to 7–10% of the population \(^{(2)}\)
- Approximately 20% of people with cancer have neuropathic pain as a result of either the disease or treatment.
- The lifetime incidence of herpes zoster (shingles) is ~25%. Between 2.6% and 10% will develop chronic postherpetic neuralgia \(^{(2)}\).
- 33 million people infected with HIV across the world; ~35% have neuropathic pain.
- 0.8% of population has painful diabetic neuropathy \(^{(2)}\).

ETIOLOGY AND PATHOPHYSIOLOGY
- Positive symptoms due to changes in peripheral nerves, loss of inhibitory mechanisms in CNS, and central sensitization
- Negative symptoms (sensory deficits) reflecting neural damage
- Associated with a predisposing factor, including:
  - Demyelinating disorders (multiple sclerosis, Guillain-Barré syndrome)
  - Neoplasm (primary/metastatic)
  - Neurovascular (central poststroke syndrome, diabetes, trigeminal neuralgia)
  - Autoimmune disease (Sjögren syndrome, polyarteritis nodosa)
– Structural disease (herniated disc disease) (3)

RISK FACTORS

- General risk factors include older age, female gender, physical inactivity, and manual occupation.
- There is growing evidence of genetic factors.
- Includes factors that cause nerve damage as well as those that increase pain when nerves damaged:
  - Diabetes
  - Herpes zoster
  - Trigeminal neuralgia
  - HIV
  - Lyme disease
  - Cancer and chemotherapy
  - Stroke
  - Multiple sclerosis
  - Trauma
  - Surgery
  - Limb amputation
  - Nutritional deficiencies
  - Medications

COMMONLY ASSOCIATED CONDITIONS

- Depression/anxiety
- Insomnia
- Substance abuse

DIAGNOSIS

Diagnosis is based primarily on history (e.g., underlying disorder and distinct pain qualities) and the findings on physical examination (e.g., pattern of sensory disturbance) (3,4)[A].

HISTORY

- History should include:
  - Onset and duration of symptoms: location, intensity, character, temporal profile, exacerbating factors, concomitant symptoms and effect on symptoms. Past medical and surgical history, psychosocial history,
substance use (especially alcohol) can highlight possible etiologies.

– Sensory descriptors: numbness, weakness, reduced sensation to touch, pinprick, temperature, or vibration; decreased proprioception

● Pain often described as burning, shock-like or tingling (3,4)

● No single feature is diagnostic (3).

PHYSICAL EXAM

● Positive symptoms and signs (3)
  – Hyperalgesia: (abnormally increased pain sensation to a stimulus) to pinprick, blunt pressure, heat, or cold
  – Allodynia: (pain from nonpainful stimulus) for example, pain evoked by light touch, clothing, bed sheets

● Negative symptoms - can be present in the same area as positive (3)
  – Hypoesthesia (abnormally reduced sensation of a tactile stimulus) to touch or cold

● Motor (3)
  – Symptoms may include weakness, fatigability, decreased range of motion, joint stiffness, and spontaneous muscle spasm.
  – Signs may include hypotonia, tremor, dystonia, ataxia, hypo-/hyperreflexia, motor neglect.

● Sensory examination (3,4)
  – Light touch, pinprick, vibration sense, and proprioception may be diminished or amplified in the involved nerve territory.
  – Sensory disturbance may extend beyond a discrete nerve territory.

● Skin examination
  – Alterations in temperature, color, sweating, and hair growth suggestive of sympathetic nervous system involvement, such as in CRPS (3)
  – Residual dermatomal scars can indicate previous herpes zoster (shingles) infection.
  – Acanthosis nigricans can indicate diabetes.

DIFFERENTIAL DIAGNOSIS

● Nociceptive pain: induced by transmission impulses along peripheral nociceptors due to tissue damage

● Differentiate by clinical signs and symptoms, mechanisms, and therapeutic management.

DIAGNOSTIC TESTS & INTERPRETATION
Lab tests may suggest etiology of pain. Neurologic testing establishes distribution but does not yet provide benefit in determining treatment (4).

**Initial Tests (lab, imaging)**
None specifically for neuropathic pain but can rule in or out a cause of symptoms
- Serum vitamin B₁₂
- 25-hydroxyvitamin D
- Thyroid-stimulating hormone (TSH)
- Rapid plasma reagin (RPR) or Venereal Disease Research Laboratory (VDRL) test
- Fasting glucose/hemoglobin A₁c, creatinine, Lyme serology

**Follow-Up Tests & Special Considerations**
- Neuroimaging of affected area—only useful for verifying pathology for procedure or surgery
- Nerve conduction study (NCS): Focus on large nerves limits utility for most neuropathic pain; exceptions include compression neuropathies such as carpal tunnel syndrome (4).
- Electromyography: also large nerve focus, results do not apply to Aδ and C fibers for pain (4)
- Quantitative Sensory Testing: measures patient perceptual response to quantified pain stimulus; being studied for types of neuropathic pain in hopes of better direction therapy for pain (4)
- Skin biopsy: used for population studies, decreased nerve fiber density seen in some neuropathic conditions (fibromyalgia, HIV neuropathy) (4)

**TREATMENT**

**GENERAL MEASURES**
- Due to multiple neuropathic pain pathways, all medications have limited efficacy and show significant benefit at tolerable doses for a small proportion of patients.
- Physical and occupational therapy can help with functional goals.
- Cognitive-behavioral therapy has proven benefit (5)[B].

**MEDICATION**
The efficacy of systemic drug treatments is generally not dependent on the etiology of the underlying disorder (3).
- Combined therapy (polypharmacy) likely more effective
- Treatment needs to be individualized.
- Thought to be resistant to acetaminophen or NSAIDs but often used with some benefit (1)

**First Line**
- Calcium channel alpha-2-delta ligands
  - Gabapentin: number needed to treat (NNT) = 7.2 for significant pain improvement (6)[A]
    - Dosing: up to 3,600 mg in 3 divided doses
    - Precautions: requires renal dosing
    - Common side effects: sedation, dizziness, peripheral edema, weight gain
  - Pregabalin NNT = 7.7 (6)[A]
    - Dosing: up to 600 mg in 2 doses
    - Precautions: requires renal dosing
    - Common side effects: sedation, dizziness, peripheral edema, weight gain

- Tricyclic antidepressants: NNT = 3.6 (6)[A]
  - Nortriptyline, desipramine, amitriptyline, clomipramine, imipramine
    - Dosing: Start 10 to 25 mg at bedtime and then increase by 10 to 25 mg every 4 to 7 days up to 150 mg/day to efficacy and side effects.
    - Precautions: cardiac disease, glaucoma, prostatic adenoma, seizure, tramadol use
    - Geriatric: falls; limit dose to <75 mg
    - Common side effects: somnolence, anticholinergic effects, weight gain

- Serotonin norepinephrine reuptake inhibitors (SNRIs): NNT = 6.4 (6)[A]
  - Duloxetine
    - Dosing: 20 mg once daily to 60 mg twice daily; effective doses 60 to 120 mg daily
    - Precautions: hepatic disorder, tramadol use, hypertension
    - Common side effects: nausea
  - Venlafaxine
    - Dosing: 37.5 mg to 225.0 mg daily
    - Effective doses: 150 to 225 mg daily
    - Precautions: cardiac disease, tramadol use, hypertension
    - Common side effects: nausea, hypertension at higher doses

- Lidocaine, 5% patches (5)[B]
– First line for elderly or frail patients only
– Only studied for postherpetic neuropathy
– Dosage: 1 to 3 patches for 12 hours daily to cover the painful area
– Precautions: none
– Common side effects: local erythema, itch, rash

**Second Line**

- Topical treatment
  - Lidocaine patches (See “Lidocaine” above.)
  - Capsaicin high-concentration patches (8%): NNT 10.6 (6)[B]
    - Dosing: 1 to 4 patches to cover the painful area; 30 minutes application to feet, 60 minutes application to remainder of body; avoid use on face; benefits for up to 3 months
    - Precautions: caution in progressive neuropathy
    - Common side effects: pain (initial increase), erythema, itching, rare hypertension

**Third Line**

- Opioids (including tramadol): No proven long-term benefit; utility for neuropathic pain questioned
  - Chronic opioids decrease number and sensitivity of μ-opioid receptors, increasing hyperalgesia.
  - Tests show chronic pain patients on chronic opioids have higher pain sensitivity.
- Botulinum toxin type A (6)[B]
  - Limited evidence for peripheral syndromes
    - Dosing: 50 to 200 units subcutaneously to the painful area; repeat every 3 months.
    - Precautions: local infection
    - Common side effects: pain at injection site, weakness

**ISSUES FOR REFERRAL**

- Physical or occupational therapy and psychology referrals part of standard multidisciplinary care
- Refer to pain clinic if refractory to initial treatment for trial of additional therapies.

**ADDITIONAL THERAPIES**
- Acupuncture: some evidence for diabetic neuropathy (5)[B]
- Interventional pain management (epidural or peripheral nerve injections) will provide partial, lasting relief in 40–60% of patients (5)[A].
- Cannabinoids (dronabinol and nabilone): few studies, but no evidence of benefit
- Spinal cord stimulation (SCS): Pain that is continuous and unchanging responds best. Best evidence for failed back surgery syndrome with leg pain. Less common indications are peripheral nerve injury, CRPS, and painful peripheral neuropathy (5)[B].
- Peripheral nerve stimulation (PNS): Indications include pain in the distribution of an accessible peripheral nerve.
- Intrathecal drug delivery: Reserved for refractory pain, ziconotide has demonstrated efficacy (5)[B].
- Transcutaneous electrical nerve stimulation is widely used; evidence of efficacy is poor (5).

**SURGERY/OTHER PROCEDURES**
Nerve destructive procedures haven’t shown effectiveness and may cause additional insult/injury (an exception is treatment of terminal cancer) (5)[B].
- Sympathectomy dorsal root entry zone lesion (dorsal rhizotomy)
- Lateral cordotomy
- Trigeminal nerve ganglion ablation

**ONGOING CARE**
**FOLLOW-UP RECOMMENDATIONS**
- Multidisciplinary team
- Periodic evaluation to rule out other treatable conditions

**Patient Monitoring**
- Pain management requires ongoing evaluation, patient education, and reassurance.
- Patient compliance and adequacy of analgesic drug titrations should be continually evaluated and documented, especially opioids.

**PROGNOSIS**
Chronic course of pain symptoms often requires management with numerous
medications and adjunctive therapies. Complete pain relief is rare.

**COMPLICATIONS**
Long-term disability and drug addiction are possible.

**REFERENCES**

**ADDITIONAL READING**

CODES

ICD10
- M79.2 Neuralgia and neuritis, unspecified
- E10.40 Type 1 diabetes mellitus with diabetic neuropathy, unsp
- E11.40 Type 2 diabetes mellitus with diabetic neuropathy, unsp

CLINICAL PEARLS
- Neuropathic pain is a common syndrome, affecting between 7% and 10% of the population with major impacts on quality of life.
- Due to numerous mechanisms of pain, any single treatment will likely have limited benefit.
- Narcotics are likely to have more harm than benefit, and chronic narcotics likely increase pain.
- Functional goals and realistic pain target are essential.
- Physical or occupational therapy and psychology should be standard elements of multidisciplinary care.
Peripheral neuropathy (PN) is a functional or structural disorder of the peripheral nervous system (PNS). PN affects any combination of motor, sensory, or autonomic nerves. The motor PNS comprises spinal cord motor neurons, their nerve roots that combine to form plexus, and branches that form individual nerves innervating skeletal muscles. Peripheral motor involvement causes muscle atrophy, weakness, cramps, and fasciculations.

The sensory PNS consists of sensory organs, which transmit touch, vibration, and position sensation in large-diameter myelinated fibers; pain and temperature in small-diameter, lightly myelinated and unmyelinated C fibers to the dorsal root ganglia. Sensory signals are relayed to the central nervous system (CNS) for integration. Disorders of sensory nerves produce negative phenomena (loss of sensibility, lack of balance) or heightened phenomena (tingling or pain). Large sensory fiber dysfunction impairs touch and vibration sensation, whereas small fiber sensory neuropathy (SFSN) affects pin and thermal sensation and causes neuropathic pain.

The autonomic nervous system (ANS) includes the sympathetic and parasympathetic systems. ANS dysfunction causes cardiovascular, gastrointestinal, and sudomotor symptoms. The PNS can be affected from the cell body (sensory ganglionopathy or motor neuronopathy), root (radiculopathy), or plexus (plexopathy) to the nerve (demyelinating or axonal neuropathy).

**EPIDEMIOLOGY**

**Prevalence**
Approximately 2.4% of general population, to an estimated 8% of people >55 years old, are affected by distal symmetric PN, the most common form of PN.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- PN can be acquired or hereditary.
The most common cause of acquired PN is diabetes mellitus.

Other categories of acquired PN with illustrative examples are the following:
- Vascular: ischemia, vasculitis
- Infectious: HIV, hepatitis C, cryoglobulinemia, Lyme disease
- Traumatic: compression, crush, or transection
- Autoimmune: rheumatoid arthritis, Sjögren, postinfectious Guillain-Barré syndrome (GBS), chronic inflammatory demyelinating polyneuropathy (CIDP), sarcoidosis
- Metabolic: diabetes, renal failure, hypothyroidism, vitamin B₁₂ deficiency, celiac disease
- Iatrogenic/toxic: chemotherapy, platinum, taxanes, metronidazole, colchicine, infliximab, alcoholism
- Idiopathic: 30% of PN
- Neoplastic/paraneoplastic: paraproteinemia, Waldenstrom macroglobulinemia, multiple myeloma, amyloidosis, neurofibromatosis

PN occurs due to demyelination or axonal degeneration.

Demyelination results from Schwann cell dysfunction, mutations in myelin protein genes, or direct damage to myelin sheaths.

Axonal degeneration occurs when injury/dysfunction occurs at the cell body or axon.

Genetics
- Approximately 50% of undiagnosed PN is hereditary.
- Currently, there are >70 known genetic causes of hereditary PN.
- Charcot-Marie-Tooth (CMT) neuropathies: the most common hereditary PN
  - CMT1A (duplication of the PMP22 gene) is the most common CMT.
  - A PMP22 deletion causes hereditary neuropathy with liability to pressure palsy (HNPP).

RISK FACTORS
Systemic disorders predispose to PN.

GENERAL PREVENTION
- Healthy nutrition and avoidance of alcoholism and of pressure at nerve entrapment sites
- Surveillance for glucose dysmetabolism and tight glycemic control may prevent diabetic PN.
DIAGNOSIS

HISTORY

- A detailed inquiry for symptoms of sensory, motor, or autonomic dysfunction:
  - Numbness, tingling, prickling, burning pain, a “tightly wrapped” sensation, and an “unsteady gait”
  - Distal weakness manifests as foot drop (tripping, foot slapping) or difficulty with grip; proximal weakness (e.g., difficulty arising from a chair) is less common.
  - Orthostatic dizziness, abnormal sweating, constipation, or voiding difficulties

- Symptom onset:
  - Acute: Consider infection (e.g., Lyme disease), postinfectious dysimmune process (e.g., GBS), ischemia (e.g., vasculitis), toxin, or trauma.
  - Subacute: Consider metabolic, neoplastic, paraneoplastic, or dysimmune processes.
  - Chronic: Consider dysimmune process (CIDP), idiopathic, or hereditary.

- Progression: stable or indolent; slowly or rapidly progressive; monophasic or relapsing or remitting

- Anatomic pattern: focal, multifocal, diffuse

PHYSICAL EXAM

- Based on exam, a functional (sensory: small-fiber vs. large-fiber vs. mixed, sensorimotor, motor, autonomic) and anatomic pattern of PN (distal symmetric, multifocal, or focal) should be established.
- Cognition preserved in isolated PN
- Cranial nerves may be involved with focal or multifocal PN (e.g., bifacial weakness may occur with GBS, Lyme disease, sarcoidosis, among other causes).
- Stocking/glove sensory loss is typical of distal symmetric sensory PN (e.g., diabetes).
- Isolated reduced pin or thermal sensation or allodynia suggests a pure SFN.
- Reduced vibration and proprioception suggests large-fiber sensory neuropathy; when severe, a Romberg sign is present, and gait is wide-based or ataxic.
- Distal muscle atrophy and weaknesses of toe extension and finger abduction are often present with distal symmetric axonal PN.
- In acquired demyelinating PN (e.g., GBS or CIDP), weakness is commonly
both proximal and distal.
- Deep tendon reflexes may be reduced or absent, distally at the ankles in large-fiber axonal PN, or diffusely in demyelinating PN.
- High arched or flat feet or hammer toes suggest hereditary PN.

**ALERT**
- Hemibody deficits or sensory loss below a spinal cord level suggest a CNS process.
- Hyperreflexia and spasticity are upper motor neuron signs not seen with isolated PN.

**DIFFERENTIAL DIAGNOSIS**
The following categories of PN can be identified (differential diagnosis [DDx] listed when applicable):
- Pure sensory neuropathy
  - DDx: SFN, sensory ganglionopathy, polyradiculopathy
- Distal symmetric sensorimotor axonal PN
  - Most common type of PN
  - DDx: distal acquired demyelinating symmetric (DADS) PN
- Motor predominant PN
  - DDx: motor neuron disease, polyradiculopathy, immune-mediated multifocal motor neuropathy (MMN)
- Mononeuropathy
  - Most likely due to compression, entrapment, or trauma
  - DDx: monoradiculopathy
- Mononeuropathy multiplex
  - DDx: plexopathy, polyradiculopathy

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (labs, imaging)**
- Blood tests
  - CBC, BUN, Cr, FBG, HgA1C, vitamin B<sub>12</sub> with methylmalonic acid, LFTs, serum protein immunofixation electrophoresis (SPIEP), TSH
- Nerve conduction studies and electromyography (NCS/EMG)
  - Delineate axonal versus demyelinating, anatomic pattern, chronicity, and severity of PN
- Test of small nerve fiber function
  - Autonomic reflex screen, testing of sweat function, quantitative sensory
testing, epidermal skin biopsy

- Specialized epidermal skin biopsy
  - In clinically suspected SFN if NCS/EMG is normal
  - Analysis of lower limb epidermal nerve fiber density (ENFD) (1)[A]

- Neuroimaging
  - Generally not indicated in evaluation of PN but useful in evaluation of brachial plexopathies, radiculopathies, or where findings are attributable to the CNS

**Follow-Up Tests & Special Considerations**

- Additional blood tests are done based on the medical history, the PN type, and NCS/EMG findings.
- For example: vitamin A, vitamin E, zinc, copper, ESR, CRP, ANA, Hep B/C, antitissue transglutaminase
- Genetic testing for diagnosis of hereditary PN should be ordered by neurologists with expertise in PN.
- Screen patients with distal symmetric PN for unhealthy alcohol use with CAGE-AID or AUDIT-C.

**ALERT**

Ordering of laboratory batteries (e.g., peripheral nerve antibody panels) without careful consideration of the clinical and NCS/EMG features should be avoided.

**Diagnostic Procedures/Other**

- Nerve biopsy (sural or superficial peroneal nerve): useful if vasculitis, amyloidosis, granulomatous disorders, or neoplastic infiltration is suspected; rarely helpful in late-onset chronic, slowly progressive distal symmetric PN
- Lumbar puncture
  - Cytoalbuminologic dissociation in GBS or CIDP
  - Infection, inflammation, or neoplasia in polyradiculopathies

**Test Interpretation**

- Demyelinating PN: disproportionate slowing of conduction velocities or prolonged distal latencies on NCS
- Axonal PN: reduced amplitude in sensory or motor responses, with relatively preserved conduction velocities on NCS
- Reduced ENFD on distal leg skin biopsies is supportive of SFN.
TREATMENT

GENERAL MEASURES

- Counsel on foot care and properly fitted footwear.
- Monitor feet for early signs of ulcer and injury.
- Targeted treatment for underlying systemic conditions:
  - Glycemic control, thyroid hormone supplementation, vitamin supplementation, antimicrobial therapy (e.g., Lyme disease, HIV), glucocorticoids for sarcoidosis, and cytotoxic therapy for vasculitis

MEDICATION

First Line

- Treatment of neuropathic pain: evidence of efficacy derived from clinical trials in diabetic painful neuropathy (DPN), postherpetic neuralgia (PHN), or trigeminal neuralgia:
  - Anticonvulsants: gabapentin, for PHN; gabapentin (off-label), for DPN; or pregabalin, for DPN and PHN
  - SNRI: duloxetine for DPN
  - Tricyclic antidepressants: amitriptyline or nortriptyline; carbamazepine, for trigeminal neuralgia
  - Patches: lidocaine 5%, capsaicin 8%
  - Supplements: alpha-lipoic acid, Acetyl-L-carnitine

Second Line

- Venlafaxine for DPN
- Tramadol: off-label for DPN

Third Line

- Tapentadol: for DPN

ISSUES FOR REFERRAL

- Rapidly progressive symptoms, suspected demyelinating PN, or hereditary PN should be referred to a neurologist with expertise in neuromuscular disorders.
- Patients with vasculitic PN should be referred to rheumatology.
- Patients with progressive painful PN, dysautonomia, and/or cardiomyopathy should be evaluated for transthyretin (TTR)-related familial amyloidosis.
- Patients with paraproteinemia should have a skeletal bone survey and be
referred to hematology.

- Patients with imbalance, ataxia, or falls should be referred to physical therapy for gait and balance training.

### ADDITIONAL THERAPIES

- Combination therapy (e.g., gabapentin with TCA or venlafaxine or tramadol) can be more effective than monotherapy for neuropathic pain.
- Long-acting opiates can be considered for refractory neuropathic pain.
- Additional immunosuppressant agents (e.g., cyclophosphamide) may be used in refractory chronic dysimmune PN.
- Immunotherapy for dysimmune PN
  - Intravenous immunoglobulin (IVIG): within the first 2 weeks of GBS to hasten recovery \((2)[A]\); as a first-line alternative to corticosteroids for treatment of CIDP \((3)[A]\); and for prevention of secondary axonal loss in MMN \((4)[A]\)
    - Loading dose 2 g/kg body weight divided into 2 to 5 days; maintenance regimen variable for CIDP and MMN
    - Adverse effects (AE): headache, fever, hypertension, and rarely pulmonary embolism
  - Plasma exchange: first agent shown to improve functional outcome for patients with GBS \((5)[A]\); short-term benefit in CIDP \((5)[A]\)
    - AE: catheter complication, hypotension, and others
  - Corticosteroids: a first-line option in treatment of CIDP \((5)[C]\); oral or pulsed IV regimen can induce remission.
- Treatment of autonomic symptoms
  - Compression stockings, hydration, midodrine, and fludrocortisone for orthostatic hypotension
  - Pyridostigmine for immune-mediated dysautonomia (off-label)

### ALERT

Opiates have significant side effects and may cause rebound headaches, tolerance, and dependence.

### SURGERY/OTHER PROCEDURES

- Decompressive surgery for entrapment neuropathy (e.g., carpal tunnel syndrome)
- Foot and ankle surgery to improve symptoms or function in hereditary PN
- Radiation, surgery, or bone marrow transplantation for plasmacytoma or osteosclerotic myeloma or POEMS syndrome
Liver transplantation for amyloidotic PN

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Low-intensity transcutaneous electrical nerve stimulation (TENS), acupuncture, meditation, supplements (G-agmatine, methylcobalamin, inositol)

**ALERT**

Vitamin B₆ supplementation may cause peripheral neurotoxicity and should be avoided except for a deficiency state.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Patients with suspected GBS should be admitted for diagnosis, monitoring (30–60% may develop cardiovascular or respiratory failure), and for acute treatment.
- Elective intubation may be required in GBS when forced vital capacity is <15 mL/kg body weight.
- Other rapidly progressive undiagnosed PNs that impair independent ambulation may require admission.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Physical therapy and gait assistive devices as needed
- Flu vaccination should be avoided in the 1st year following GBS.

**PROGNOSIS**

- Late-onset idiopathic distal symmetric axonal PNs are indolent.
- 80% of GBS have a near complete or good recovery. 80% of CIDP have moderate or good response with treatment but can be relapsing.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- G62.9 Polyneuropathy, unspecified
- G60.9 Hereditary and idiopathic neuropathy, unspecified
- G60.8 Other hereditary and idiopathic neuropathies

**CLINICAL PEARLS**

- There are many causes of PN. Diagnosis is made by history and physical exam, targeted laboratory testing, NCS/EMG, skin biopsy, or ANS testing.
- Consider hereditary neuropathy if patient has an early age of PN symptom onset, family history of PN, or foot deformity.
- GBS is monophasic and progresses for up to 4 weeks; CIDP progresses beyond 8 weeks, and if untreated, usually has a progressive course.
BASICS

DESCRIPTION
The compulsive use of nicotine products coupled with a lack of control over using, withdrawal symptoms, and/or continued use despite knowledge of or experiencing adverse consequences.

EPIDEMIOLOGY

Prevalence
Approximately 40 million people in the United States ≥18 years of age are current tobacco users. In the past year, 58.7 million smoked cigarettes, 13.3 million smoked cigars, 2.1 million smoked pipes, and 8.6 million used smokeless tobacco. An estimated 3 million middle and high school students are current smokers. About 80% of these individuals will continue smoking into adulthood. E-cigarette use among youth has been associated with nicotine addiction in adulthood.

Cost and Impact
Nearly 500,000 Americans die prematurely each year from smoking. The estimated economic costs attributable to smoking and secondhand exposure approach $300 billion annually, with direct medical costs of at least $130 billion.

ETIOLOGY AND PATHOPHYSIOLOGY

- Similar to other addictive drugs, nicotine affects neural pathways that control reward and pleasure.
- Nicotine exerts its biologic effects through nicotinic acetylcholine receptors (nAChRs), which modulate neurotransmission with acetylcholine and other chemical messengers including glutamate, GABA, dopamine, serotonin, acetylcholine, and norepinephrine. In this way it induces euphoria, assists in information processing, reduces anxiety, and mitigates fatigue.
- Up-regulation of these receptors occurs over time leading to tolerance and dependence.
- Polymorphisms in neuronal nAChR genes are associated with increased
susceptibility to dependence.
- Nicotine is metabolized by cytochrome P450 2A6 (CYP2A6). Individuals who are fast metabolizers tend to smoke more cigarettes, are more likely to suffer intense withdrawal symptoms, and have a lower probability of quitting than slow metabolizers.
- Nicotine withdrawal involves the release of corticotropin-releasing factor in the amygdala, which induces the perception of anxiety and stress.

**Pregnancy Considerations**
- Smoking is a risk factor associated with placenta previa, abruptio placentae, decreased maternal thyroid function, preterm premature rupture of membranes and ectopic pregnancy.
- Carbon monoxide and nicotine interfere with fetal oxygen supply, resulting in decreased birth weights and intrauterine growth restriction.
- Maternal smoking adversely affects fetal lung development, with lifelong decreases in pulmonary function and increased risk of asthma.
- Maternal smoking is associated with increased risk for sudden infant death syndrome, learning and behavioral problems, and obesity.

**RISK FACTORS**
- Mental illness (depression, posttraumatic stress disorder, bipolar disorder, and schizophrenia)
- Low socioeconomic status
- Low educational status
- Early first-hand nicotine experience
- Concurrent substance abuse
- Home and peer influence

**GENERAL PREVENTION**
- The U.S. Preventive Services Task Force (USPSTF) strongly recommends (1) [A]:
  - Screening all adults for tobacco use and provide cessation interventions for those who screen positive
  - Screening all pregnant women for tobacco use and provide pregnancy-tailored counseling to those who screen positive (1)
- The USPSTF recommends that clinicians provide interventions, including education or brief counseling to prevent initiation of tobacco use among school-aged children and adolescents (1)[B].
DIAGNOSIS

HISTORY
- Identify types, amount, and duration of nicotine products used.
- Review previous attempts to quit (methods used and duration of cessation).

PHYSICAL EXAM
- Pulmonary exam: wheezing, decreased breath sounds, prolonged expiration
- Cardiovascular exam: tachycardia, hypertension
- HEENT exam: epithelial dysplasia, squamous cell carcinoma, leukoplakia, stained teeth, hoarseness

DIAGNOSTIC TESTS & INTERPRETATION
- Low-dose CT: recommended annually by USPSTF for people ages 55 to 75 years with a history of 30+ pack years of tobacco use; those currently smoking or who have quit within the past 15 years (except those with life limiting comorbidities)
- Neither spirometry nor regular chest x-rays are recommended for routine screening.

TREATMENT

Counseling (2)[A]
- Counseling interventions (individual, telephone, or group format) improve quit rates compared to minimal support (relative risk [RR] of 1.76 [95% CI 1.58–1.96]) (1).
- Combined behavioral and pharmaceutical interventions increased cessation (RR, 1.82 [95% CI 1.66–2.00]) (1).
- More intensive interactions (i.e., motivational interviewing, close follow-up) may result in higher rates of quitting.

Brief strategies to help the patient willing to quit tobacco use—the “5 As” (2) [A]
- Ask patient if he or she uses nicotine.
- Advise him or her to quit.
- Assess willingness to make a quit attempt.
- Assist those willing to make a quit attempt.
- Arrange follow-up contact to prevent relapse.
Enhancing motivation to quit: the “5 Rs” (2)[A]

- Relevance: Encourage patient to indicate why quitting is personally relevant.
- Risks: Ask patient to identify potential negative consequences of use.
- Rewards: Ask patient to identify potential benefits of cessation.
- Roadblocks: Ask patient to identify barriers or impediments to quitting and provide treatment (e.g., problem-solving counseling or medication) that could address barriers.
- Repetition: This motivational intervention should be repeated each visit.

Users should be given a choice of methods to quit.

Quit rates are equivalent for tapering use versus abrupt cessation. Patient preference should dictate plan.

MEDICATION

There are currently seven FDA-approved medications: nicotine replacement therapy (NRT), both long-acting (i.e., patch) and short-acting (i.e., gum, inhaler, lozenge, nasal spray) types, and non-NRT meds, bupropion SR and varenicline.

With few exceptions, the choice of a first-line medication depends on patient preference.

NRT (RR, 1.60 [95% CI 1.53–1.68]) (1)[A] (Gum: pregnancy category C. All other formulations are category D).

- Patch: for >10 cigarettes per day, start with 21 mg patch per day for 6 weeks, then 14 mg patch/day for 2 weeks and then 7 mg patch per day for 2 weeks; for <10 cigarettes per day, start with 14 mg patch per day for 6 weeks, then 7 mg patch per day for 2 weeks. Extending use of the patch beyond 8 to 10 weeks may improve abstinence rates.
- Gum: for >25 cigarettes per day, use 4 mg gum q1–2h for 6 weeks; for <25 cigarettes per day, use 2 mg gum q1–2h for 6 weeks; chew then tuck between cheek and gingiva once nicotine flavor is released, repeat up to 30 minutes, then discard. Avoid using with acidic foods (e.g., coffee, soda) which decrease nicotine absorption.
- Lozenges: for patients who smoke their first cigarette within 30 minutes of waking, 4 mg lozenge PO q1–2h for 6 weeks; first cigarette >30 minutes after waking, 2 mg lozenge PO q1–2h for 6 weeks; decrease dosing by q1–2h for 3 weeks.
- Nasal spray: Start 1 to 2 sprays (0.5 mg/spray) each nostril q1hr for 8 weeks, then taper; max 10 sprays/hr and 80 sprays/day
- Inhaler: 6 to 16 cartridges inhaled (4 mg/cartridge) per day for 6 to 12
weeks and then taper; incorporates the behavioral and sensory aspects of smoking

- **Combination NRT:** All forms of NRT increase quit rate 50–70% (3)[A]. Combining long- and short-acting NRTs is more effective than using any single method alone. Heavier users may need higher doses. Starting NRT before planned quit date may increase success.

- **Bupropion SR** (RR, 1.62 [95% CI 1.49–1.76]) (1)[A] is an atypical antidepressant and norepinephrine-dopamine reuptake inhibitor (pregnancy category C). Contraindications: history of seizure, stroke, brain injury, brain tumors, anorexia/bulimia, recent use of MAOI (within 14 days)
  - Start 1 week before target quit date due to time needed to reach steady state.
  - Use 150 mg/day for 3 days and then 150 mg BID for 7 to 12 weeks.

- **Varenicline** (RR, 2.27 [95% CI 2.02–2.55]) is a nicotinic acetylcholine partial agonist (pregnancy Category C) (1)[A]. Contraindications: known history of skin reactions or hypersensitivity

**ALERT**

Associated neuropsychiatric symptoms may include vivid dreams, depression, suicidal ideation/attempts in patients with and without preexisting psychiatric conditions—close monitoring recommended.

- Starter pack: 0.5 mg/day for 3 days, 0.5 mg BID for 4 days, 1 mg/day starting day 7
- Maintenance pack of 1 mg BID for 12 weeks; if successful, may continue for another 12 weeks
- Varenicline + bupropion is not more effective than either alone and confers increased side effects.
- Varenicline + NRT is more effective at 6 months than varenicline alone (NNT 6).

- **Nortriptyline** (off-label use) is a tricyclic antidepressant (pregnancy category D). Contraindications: narrow-angle glaucoma, heart disease (CAD, heart block, long QT)
  - Start 25 mg/day, gradually increase to 75 to 100 mg/day and continue for 12 weeks.
  - Set quit date 2 to 4 weeks after initiation.

- **E-cigarette** is an electronic device that delivers aerosolized liquid with or without nicotine and includes various flavorings and other chemicals. Insufficient evidence exists regarding this product’s safety and efficacy. Low quality evidence suggests that e-cigarettes can help patients cut down on the
number of cigarettes smoked. Other research demonstrates poor efficacy of abstinence with long-term follow-up. Long-term safety has not been established (4).

**Pregnancy Considerations**
- Tobacco cessation prior to 15 weeks’ gestation provides the greatest benefit for both the woman and fetus, but quitting any time is beneficial.
- ACOG recommends that pregnant women be offered behavioral therapy and education as first-line treatment and that NRT and medications be reserved for patients in need of additional assistance.
- NRT is metabolized faster in pregnant women, which may lead to higher dose requirements.

**Pediatric Considerations**
- Behavioral therapy (including CBT) is recommended as first-line treatment.
- There are currently no FDA-approved pharmacologic treatments for children.
- AAP recommends using NRT only for patients with moderate to severe substance use disorder.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Acupuncture: no consistent evidence of efficacy
- Hypnotherapy: no consistent evidence of efficacy

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Consider NRT for all inpatients who use nicotine to decrease withdrawal symptoms (5)[A].
- Programs to stop nicotine use that begin during hospitalization and include follow-up support after discharge are effective for all hospitalized users, regardless of admission diagnosis (5)[A].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Patients who have initiated therapy should follow up after 1 to 2 weeks to
monitor response and side effects.

- Monitor for signs of nicotine withdrawal syndrome and start medication-assisted treatment or adjust dosage:
  - Increased appetite/weight gain (4 to 5 kg > 10 years)
  - Dysphoric, depressed mood, or anhedonia
  - Insomnia
  - Irritability, frustration, or anger
  - Anxiety
  - Difficulty concentrating
  - Restlessness

- Follow-up should continue periodically in-person or via telephone, especially during the first 3 months.

PATIENT EDUCATION

- http://smokefree.gov
- http://women.smokefree.gov/
- http://teen.smokefree.gov
- http://www.nicotine-anonymous.org
- http://quitnet.meyouhealth.com
- 1-877-44U-QUIT (1-877-448-7848)

PROGNOSIS

- Roughly 50% of all smokers will die from a tobacco-related illness.
- Former smokers have a 50% reduction in risk of CAD 1 year after quitting, a 50% reduction in head and neck cancers by 2 to 5 years, and a 50% reduction in mortality from lung cancer by 10 years. The risk of stroke is reduced to that of nonsmokers 2 to 5 years after quitting.
- 22% of smokers relapse within the 3 months of quitting. Multiple attempts are often required.
- Approximately 50–60% of women who quit smoking in pregnancy returned to smoking by 1-year postpartum.
- Individuals receiving support from significant others are more likely to quit.

COMPLICATIONS

- Chronic obstructive pulmonary disease (COPD) (emphysema and chronic bronchitis)
- Cancers (i.e., lung, oral/pharyngeal, kidney, bladder, cervical, anal, squamous cell)
- Atherosclerotic disease
- Insulin resistance
- Periodontal disease
- Osteoporosis and hip fracture (in women)
- Peptic ulcer disease
- Delayed wound healing
- Pregnancy and neonatal complications (discussed elsewhere)

- National Tobacco Cessation Collaborative: http://www.tobacco-cessation.org/resources/tools.html#clinicians
CODES

ICD10
- F17.200 Nicotine dependence, unspecified, uncomplicated
- F17.201 Nicotine dependence, unspecified, in remission
- F17.203 Nicotine dependence unspecified, with withdrawal

CLINICAL PEARLS
- Nicotine dependence is a chronic disease and will often require repeated interventions and multiple cessation attempts.
- Follow-up is key to continuing engagement and providing additional support as needed. Treatments, including but not limited to medications, can significantly increase rates of long-term abstinence.
- No single type of NRT/medication is best; thus, the choice should be based on patient preference and risk factors for side effects.
NONALCOHOLIC FATTY LIVER DISEASE (NAFLD)

Jill T. Wei, MD • Daniel T. Lee, MD, MA

BASICS

- A spectrum of fatty liver diseases not due to excess alcohol consumption ranging from nonalcoholic fatty liver (NAFL), to nonalcoholic steatohepatitis (NASH), to cirrhosis with hepatocyte injury with/without fibrosis
- Leading cause of chronic liver disease; implicated in up to 90% of patients with asymptomatic, mild aminotransferase elevation not caused by alcohol, viral hepatitis, or medications

DESCRIPTION

- NAFL (1)
  - Reversible condition in which large vacuoles of triglyceride fat accumulate in hepatocytes
  - Liver biopsy: fatty deposits in >30% of cells, no hepatocyte ballooning, no necrosis, no fibrosis
  - Alanine aminotransferase/aspartate aminotransferase (ALT/AST) enzymes usually normal but may be elevated, rarely >3 to 4 times ULN
  - Minimal risk of progressing to cirrhosis or liver failure
  - Synonym: steatosis
- NASH: progressive form of NAFL (1)
  - Liver biopsy: fatty deposits in >50% of cells with ballooning, acute/chronic inflammation, ± fibrosis
  - ALT and AST elevated, generally <3 to 4 times ULN
  - May progress to cirrhosis, liver failure, and rarely hepatocellular cancer; 30% with NASH may progress to fibrosis over 5 years.
- NASH cirrhosis (1)
  - Presence of cirrhosis with current or previous histologic evidence of steatosis or steatohepatitis

EPIDEMIOLOGY

- NAFLD: most common chronic liver disease globally; usually benign, asymptomatic
● Predicted to become the most frequent indication for liver transplantation by 2030 (2)
● NASH may be symptomatic with progressive inflammation and fibrosis.
  – Predominant age: 40s to 50s; can occur in children
  – Predominant sex: male > female (slight)

*Incidence*
Estimates vary widely from 31 to 86 cases of NAFLD per 10,000 person-years to 29/100,000 person-years (1)

*Prevalence*
● United States estimate: 30–40% (3)
● Worldwide: 6–33%, median 20–25% (1)
● Present in 58–74% of obese persons (BMI >30) and 90% of morbidly obese persons (BMI >39) (1)
● Among individuals with T2DM, rate of 69–87%; in patients with dyslipidemia, rate of 50% (1)

**ETIOLOGY AND PATHOPHYSIOLOGY**
Primary mechanism is *insulin resistance*, which leads to increased lipolysis, triglyceride synthesis, and increased hepatic uptake of fatty acids.
● NAFLD: excessive triglyceride accumulation in the liver and an impaired ability to remove fatty acids
● NASH: “2-hit” hypothesis: (i) macrovesicular steatosis due to increased hepatic lipid synthesis, reduced transfer of lipids, and increased insulin resistance with hepatic oxidative stress and (ii) mitochondrial damage leading to impaired restoration of ADT stores, lipid peroxidation, and resultant inflammatory injury (1)
● Other possible mechanism is lipotoxicity. Free-fatty acid metabolites cause endoplasmic reticular stress, hepatocyte apoptosis, necrosis, and inflammation. Hepatocellular injury triggers fibrogenesis and inflammation, hastening disease progression (3).

*Genetics*
Largely unknown: Some familial clustering and increased heritability. NAFL: more first-degree relatives with cirrhosis than matched controls; NASH: 18% with affected first-degree relative. Carriers of hemochromatosis gene are more likely to be affected. Patatin-like phospholipase domain-containing 3 (PNPLA3)
I148M polymorphism may play a role in NAFLD, hypertriglyceridemia, and insulin resistance (1,2).

**RISK FACTORS**
- Obesity (BMI >30), visceral obesity (waist circumference >102 cm for men or >88 cm for women), hypertension, dyslipidemia, high serum triglycerides and low serum high-density lipoprotein (HDL) levels, metabolic syndrome
- Type 2 diabetes, cardiovascular disease, and chronic kidney disease (2)
- Possible associations with hypothyroidism, hypopituitarism, hypogonadism, obstructive sleep apnea, pancreatoduodenal resection, osteoporosis, psoriasis, and polycystic ovary syndrome (2)
- Increasing age associated with increased prevalence, severity, advanced fibrosis, and mortality
- High fructose intake linked to intestinal dysbiosis and metabolic stress (4)
- Protein–calorie malnutrition; total parenteral nutrition (TPN) >6 weeks
- Severe weight loss (starvation, bariatric surgery)
- Organic solvent exposure (e.g., chlorinated hydrocarbons, toluene); vinyl chloride; hypoglycin A
- Gene for hemochromatosis/other conditions with increased iron stores
- Smoking
- Drugs: tetracycline, glucocorticoids, tamoxifen, methotrexate, valproic acid, fialuridine, many chemotherapy regimens, and nucleoside analogues

**Pregnancy Considerations**
Acute fatty liver of pregnancy: Rare but serious complication in 3rd trimester. 50% of cases are associated with preeclampsia.
- Symptoms: nausea, vomiting, headache, fatigue, right upper quadrant or epigastric pain, jaundice
- Elevated ALT and AST >300 IU/L but usually <1,000 IU/L; elevated bilirubin
- Liver biopsy confirms diagnosis (do not delay treatment for biopsy).
- Early recognition and prompt delivery is key.
- Recurrence is rare.

**Pediatric Considerations**
- Increasing prevalence of NAFLD among children parallels rise in pediatric obesity.
- Reports of NAFLD as early as age 2 years and NASH-related cirrhosis as early as age 8 years
Treat with intensive lifestyle modification. Vitamin E may be of possible benefit.
Reye syndrome: fatty liver syndrome with encephalopathy usually following viral illness
- Vomiting with dehydration
- Confusion, progressive CNS damage
- Hepatomegaly with extensive fatty vacuolization
- Hypoglycemia
Etiology unknown; viral URIs and drugs (especially salicylates) have been implicated.
Mortality rate: 50%
Treat with mannitol, IV glucose, and FFP.

GENERAL PREVENTION
- Avoid excess alcohol: ≤3 standard drinks/day (men); ≤2 standard drinks/day (women)
- Maintain appropriate BMI.
- Prevention and optimal management of diabetes
- Avoid hepatotoxic medications.
- HAV and HBV vaccination if not immune
- Pneumococcal and annual influenza vaccinations

COMMONLY ASSOCIATED CONDITIONS
Central obesity; HTN; type 2 diabetes; insulin resistance; hyperlipidemia; preeclampsia in pregnancy; CVD and arrhythmias; hypothyroidism; hypogonadism; OSA (2)

DIAGNOSIS
- Routine screening not recommended
- Consider NAFLD in patients with asymptomatic aminotransferase elevations (1)[A].
- Can occur with normal AST/ALT levels (1)[A]
- NAFLD has no distinguishing historical/lab features to distinguish from other chronic liver disorders.
- Index of suspicion is higher with risk factors such as metabolic syndrome, insulin resistance, or obesity.
- May present as cryptogenic cirrhosis
Noninvasive biomarkers of steatosis/fibrosis are not sufficiently reliable. There is currently no validated test available.
Liver biopsy is the definitive diagnostic test but should only be considered if results will change management.

**HISTORY**
- Typically asymptomatic
- Possible fatigue and/or abdominal fullness
- Vague right upper quadrant pain
- History of medications, alcohol use, family history

**PHYSICAL EXAM**
Most common signs (all are infrequent)
- Liver tenderness
- Mild to marked hepatomegaly
- Splenomegaly
- In advanced cases: cutaneous stigmata of chronic liver disease or portal hypertension, for example, palmar erythema, spider angiomata, ascites

**DIFFERENTIAL DIAGNOSIS**
- Viral hepatitis
- Alcoholic fatty liver
- Drug- or toxin-induced hepatitis
- Metabolic liver disease
- Autoimmune hepatitis
- Celiac disease
- Muscle disease, if nonhepatic cause of elevated enzymes are possible

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Both ALT and AST may be elevated.
  - Nonalcoholic, usually ALT:AST >1
  - If alcohol-induced, usually AST:ALT ≥2
  - Nonspecific enzyme abnormalities may exist or may be normal with advanced cirrhosis (1).
- Level of enzyme elevation does NOT correlate with degree of fibrosis (1).
- Serum ferritin (1.5 times normal), alkaline phosphatase (2 to 3 times normal), and total/direct bilirubin often elevated (1).
Severity and chronicity are characterized by defects in ability to produce plasma proteins (serum albumin, PT) and thrombocytopenia (1).

Lipids abnormalities are common and include elevated cholesterol, low-density lipoprotein (LDL), and triglyceride and decreased HDL (1).

Biomarkers of inflammation, increased oxidative stress, or hepatocyte apoptosis such as leptin, adiponectin, CRP, serum caspase, and cytokeratin 18 may help differentiate NASH from NAFLD (1)[B].

Serologic studies to exclude other etiologies of liver disease (celiac, α-1-antitrypsin, iron, copper, HepA IgG, HepB SAg, HepB SAb, HepB cAb, HepC Ab, anti-smooth muscle antibody, ANA, serum gammaglobulin (1)[B].

Ultrasound (US) is first-line imaging modality for assessing liver chemistry abnormalities: Fatty liver is hyperechoic on US. MRI/CT may also be used (1) [B].

Liver-derived microparticles released in response to free-fatty acid induced lipotoxicity and volatile organic compounds (VOCs) in exhaled breath (5)[C].

**Follow-Up Tests & Special Considerations**

- Imaging modalities help noninvasively quantify fibrosis by estimating liver stiffness (5)[B]; (i) vibration-controlled transient elastography (VCTE) or FibroScan, (ii) acoustic radiation force impulse (ARFI), (iii) magnetic resonance elastography (MRE)
- No imaging modality has been found to accurately distinguish and diagnose simple steatosis from steatohepatitis (6)[B].

**Diagnostic Procedures/Other**

- Liver biopsy is the gold standard for diagnosis—must have likelihood of changing management (1)[B].
- NAFLD fibrosis score age (>50 years), BMI (>30), platelet count, albumin, and AST/ALT ratio identify patients at risk of developing fibrosis/cirrhosis (7) [B].

**Test Interpretation**

- Liver biopsy is also the gold standard for prognosis (1).
- In NASH, steatosis, ballooning, and lobular inflammation are minimal criteria for diagnosis. Other common findings include mild to moderate portal inflammation, acidophil bodies, perisinusoidal zone 3 fibrosis, megamitochondria, and Mallory-Denk bodies (hyaline) in hepatocytes (1).
- Staging is based largely on the extent of fibrosis (1).
TREATMENT

- Sustained weight loss (3–5% body weight) through lifestyle modification is most successful treatment (1,7)[A]. Weight loss for those who are overweight or obese is the only therapy that has good evidence of benefits and safety.
- Foregut bariatric surgery not yet proven to specifically improve NASH (1)[B]
- Aerobic exercise 3 to 5 times per week for 20 to 45 minutes with reduced calorie intake/diet modifications (1)[B]
- Tight control of diabetes (1,7)[B]
- Treatment of metabolic syndrome—hypertension, dyslipidemia, and obesity (1,7)[B]
- Avoid or limit alcohol consumption (<21 drinks/week for men and <14 drinks/week for women) (7)[A].
- Avoid hepatotoxic medications (1)[B].

MEDICATION

- Currently no effective medication treatment (1,7)[A]
- Some promising agents include the following:
  - Thiazolidinediones (pioglitazone) (1)[B]
  - Vitamin E 400 to 800 IU daily, although long-term safety concerns at high doses (1,5)[B,C]
  - Other drugs studied in small studies (1,7)[B,C]
    - Statins (excluded with AST and AST >1.5 times ULN)
    - Gemfibrozil; omega-3 fatty acids; ezetimibe
    - Angiotensin receptor blockers
    - Probiotics
    - Obeticholic acid (bile acid derivative)
    - Ursodeoxycholic acid

ISSUES FOR REFERRAL

Patients with persistent AST/ALT elevations 2 to 3 times ULN or fibrosis on biopsy benefit from hepatology consult (1)[A].

SURGERY/OTHER PROCEDURES

Bariatric procedures: NAFLD is not a contraindication in otherwise eligible obese patients. There is a lack of data to definitively assess benefits and harms of surgery in treating patients with NASH (1)[B].
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Annual monitoring of LFTs (1,7)[B]
- Consider surveillance with US or CT scan to evaluate disease progression (7) [B]. Improvements provide motivation for lifestyle changes.
- Routine liver biopsy is not recommended but may be repeated 5 years after baseline biopsy if progression of fibrosis is suspected (1,7)[B].
- Hepatic fibrosis staging is the strongest predictor for all-cause and disease-specific mortality in patients with histologically confirmed NAFLD (2)[B].

DIET

Low in saturated and trans fat; low in simple carbohydrates; avoid excessive alcohol (protective or worsening effect of light/moderate consumption inconclusive).

PATIENT EDUCATION

Extensive counseling on sustained lifestyle changes in nutrition, exercise, and alcohol use.

PROGNOSIS

Within the spectrum of NAFLD, only NASH has been shown to be progressive, potentially leading to cirrhosis, hepatocellular carcinoma, cholangiocarcinoma, and/or liver failure:

- Cirrhosis develops in up to 15–20% of patients. Approximately 2–3% of patients with cirrhosis will develop HCC each year (3).
- Transplantation is effective, but NASH may recur after transplantation due to ongoing risk factors.

COMPLICATIONS

Progressive disease may lead to decompensated cirrhosis and portal hypertension with complications such as ascites, encephalopathy, bleeding varices, and hepatorenal or hepatopulmonary syndromes.

1. Chalasani N, Younossi Z, Lavine JE, et al. The diagnosis and management of non-alcoholic fatty liver disease: practice guideline by the American

**SEE ALSO**

*Alcohol Use Disorder (AUD); Cirrhosis of the Liver; Diabetes Mellitus, Type 2; Metabolic Syndrome*

**CODES**

**ICD10**

K76.0 Fatty (change of) liver, not elsewhere classified

**CLINICAL PEARLS**

- NAFLD is a major cause of liver disease. Spectrum ranges from NAFL to NASH, advanced fibrosis, and cirrhosis.
- NAFLD is the most common chronic liver disease in children; there has been a parallel rise in childhood obesity and NAFLD.
- Lifestyle changes with targeted weight loss are the cornerstones of therapy for NAFLD.
- NAFLD is a common cause of asymptomatic mild serum aminotransferase
elevation.
NONFATAL DROWNING

Joseph L. Steele, APA-C • Natasha J. Pyzocha, DO, FAWM

BASICS

DESCRIPTION

- Drowning defined as respiratory impairment from submersion/immersion in liquid (1)
- System(s) affected: cardiovascular, nervous, pulmonary, renal
- Synonym(s): submersion injury; terms such as “near-drowning,” “secondary drowning,” and “wet drowning” should be avoided.

EPIDEMIOLOGY

Incidence

- From 2005 to 2014, an average of 3,536 fatal unintentional drownings in the United States (2)
- Three age-related peaks: toddlers and young children (1 to 5 years), adolescents and young adults (15 to 25 years), and the elderly
- 80% of people who die from drowning are male (2).
- Greater incidence in minorities; African Americans age 5 to 19 years old are affected 5.5 times more frequently than Caucasians (2).

Prevalence

- Most common injury-related cause of death for children 1 to 4 years in the United States (3)
- For every child age <15 years who dies from drowning, five more children are seen in the emergency room for nonfatal submersion injuries.

ALERT

Proper water supervision and safety techniques are critical in avoiding morbidity and mortality from drowning.

ETIOLOGY AND PATHOPHYSIOLOGY

Hypoxemia via aspiration and/or reflex laryngospasm causing cerebral hypoxia
and multisystem organ involvement

- 10–20% of victims drown without aspiration; likely due to prolonged laryngospasm (previously termed “dry lungs”)
- Bathtub and bucket drowning in children <1 year
- Swimming pool drowning in children and young adults
- Motor vehicle accidents (vehicle submerged in water)
- Head trauma while swimming or diving
- Suicide
- Pulmonary: morbidity primarily caused by hypoxia. Aspiration causes dilution of surfactant with decreased gas transfer across alveoli, atelectasis, development of intrapulmonary right-to-left shunting; acute respiratory distress syndrome (ARDS); obstruction due to laryngospasm and bronchospasm
- Cardiac: hypoxic-ischemic injury and arrhythmia (primary or secondary)
- Renal: acute tubular injury from hypoxemia, shock, hemoglobinuria, myoglobinuria
- Neurologic: hypoxic-ischemic brain injury with damage especially to the hippocampus, insular cortex, and basal ganglia; cerebral edema
- Coagulation: hemolysis and coagulopathy

RISK FACTORS

- Risk-taking behaviors
- Inadequate physical barriers surrounding pools
- Alcohol ingestion; male sex
- Low socioeconomic status
- Use of illicit drugs
- Seizure disorder
- Inability to swim
- Hyperventilation prior to underwater swimming
- Boating mishaps and trauma during water sports, particularly when not wearing a life jacket
- Scuba diving
- Inadequate adult supervision of children; lack of appropriate instruction on how to swim
- Concomitant stroke or myocardial infarction (MI)
- Hypothermia
- Cardiac arrhythmias: familial long QT and polymorphic ventricular tachycardia (VT)
GENERAL PREVENTION
- Periodic education/reinforcement of supervision with an emphasis on drowning prevention for caretakers of young children
- Proper adult supervision of children, particularly around water; pool alarms
- Knowledge of water safety guidelines
- Mandatory physical barriers surrounding pools; four-sided fencing, self-closing gate 58 inches above the ground (2)
- Avoid alcohol or recreational drugs around water.
- Swimming instruction at an early age
- Cardiopulmonary resuscitation (CPR) instruction for pool owners and parents
- Boating safety knowledge
- Personal flotation device and rescue equipment (e.g., preserver, if necessary)

Pediatric Considerations
Children should never be left alone near water. Young children can drown in very small amounts of water (bathtubs, buckets, and toilets).

COMMONLY ASSOCIATED CONDITIONS
- Trauma
- Seizure disorder
- Alcohol or illicit drug use
- Hypothermia
- Concomitant stroke or MI
- Cardiac arrhythmias: familial long QT and familial polymorphic VT
- Hyperventilation

DIAGNOSIS
HISTORY
The Utstein approach to the evaluation of drowning victims standardizes reporting data and provides guidance for the history, physical exam, and appropriate management.
- Gender, age, birthdate, event date
- Time call received and emergency medical services (EMS) starts resuscitation.
- Precipitating event
- Location of drowning
- Duration of submersion
Loss of consciousness
Period of apnea
Artificial ventilation/CPR performed
History of associated trauma
Approximate water temperature (hypothermia)
Recent use of alcohol or drugs
Known seizure disorder, cardiac disease, syncopal event

PHYSICAL EXAM
Airway status and degree of respiratory effort and/or distress
Pulse: absent, weak, or normal
Vital signs, including pulse oximetry
Glasgow Coma Scale (GCS)
Wheezing
Evidence of trauma

DIFFERENTIAL DIAGNOSIS
Syncopal event, head trauma, arrhythmia, seizure, MI, stroke, alcohol or other substance overdose, nonaccidental trauma

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
May be unnecessary if initial GCS and pulse oximetry are normal and remain so for 6 to 8 hours

- CBC with differential
- Arterial blood gas (ABG) to assess hypoxia, hypercarbia, acidosis
- Electrolytes: hypokalemia, hyponatremia, hypernatremia
- Blood glucose: increased levels may impair neurologic recovery after ischemic brain injury.
- BUN, creatinine: acute tubular injury
- ECG, cardiac monitoring, and serial troponin: MI
- Creatine kinase (CK) and urine myoglobin: rhabdomyolysis
- Coagulation studies: coagulopathy
- Toxicology screen
- Blood alcohol level
- Chest x-ray (CXR) unnecessary if all of the following:
  - Normal initial GCS and pulse oximetry
  - No evidence of respiratory distress
– No change after 6 to 8 hours of observation
• CXR may show evidence of aspiration, atelectasis, pneumothorax, or ARDS in more severe cases
• Head CT and/or C-spine imaging for trauma

Follow-Up Tests & Special Considerations
• Observe patients with an initial GCS of 15 and pulse oximetry >95% for 6 to 8 hours in the emergency department (ED).
• CXR findings may be minimal or absent early on.

Diagnostic Procedures/Other
• Continuous cardiac monitoring and pulse oximetry
• Continuous core temperature monitoring if hypothermic
• 12-lead ECG
• Central venous pressure (CVP) monitoring for critically ill with hypotension refractory to IV fluids
• Electroencephalogram (EEG) if seizure suspected

TREATMENT
Early resuscitation and reversal of hypoxemia optimizes outcome.

GENERAL MEASURES
• Prehospital
  – Never approach a struggling victim alone.
  – Initial basic life support (BLS) and advanced cardiovascular life support (ACLS) evaluation (4)
  – Rescue breathing may be helpful if the victim is in the water and cannot be removed; chest compressions not as effective while in the water and may harm the rescuer and the victim (4)[C]
  – Remove the victim from the water and begin effective resuscitation as quickly as possible (5).
  – Immediate CPR (4)[A]
  – Start CPR if pulse is not definitely felt within 10 seconds, even in the hypothermic victim whose heart rate may be severely bradycardic (4)[C].
  – Routine cervical collar use and spinal precautions are not needed unless trauma suspected (5)[C].
  – Supplemental oxygen and early intubation with mechanical ventilation, if
needed (1)[A]

– Rapid crystalloid infusion if hypotension not corrected by oxygenation (1) [A]

– If patient is breathing on his or her own and does not need spinal precautions, consider placing in the right lateral decubitus position to prevent aspiration of vomit or gastric contents (1).

• ED

– Oxygen, as needed, to maintain saturation between 92% and 96% (1)

– Continuous positive airway pressure (CPAP), bilevel positive airway pressure (BiPAP), or intubation if supplemental oxygen alone is inadequate

– If intubation is indicated, employ lung-protective ventilator settings (lower end-inspiratory airway pressures, lower tidal volumes of 6 mL/kg, higher positive end-expiratory pressures of 6 to 12 cm H₂O) to avoid barotrauma (4)[A].

– Indications for intubation
  o Neurologic deterioration
  o Inability to protect the airway
  o Inability to maintain oxygen saturation >90% or PaO₂ >60 mm Hg on high-flow supplemental oxygen
  o PaCO₂ >50 mm Hg

– Remove wet clothing and initiate rewarming.

– Core temperature to rule out hypothermia

– If hypothermic, rewarmed with minimally invasive core techniques such as warm IV fluids, warm/humidified oxygen, and external blanket devices.

– Active core rewarming reserved for refractory cases

MEDICATION

First Line

• High-flow oxygen, as needed (1)[A]

• For bronchospasm: aerosolized bronchodilator (3)[C]: albuterol (Proventil, Ventolin), 3 mL of 0.083% solution or 0.5 mL of 0.5% solution diluted in 3 mL of saline

• Pressors, as needed, for hypotension refractory to IV fluid resuscitation

• Prophylactic antibiotics are not recommended (1)[B].

Second Line

For pneumonia: antibiotics based on sputum or endotracheal lavage culture (1)
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- All symptomatic patients
- Patients with abnormalities in vital signs, mental status, oxygenation, CXR, or laboratory analysis
- Continuous cardiac and pulse oximetry monitoring
- Frequent monitoring of vital signs and clinical reassessment including careful monitoring of neurologic status
- After initial resuscitation, induced hypothermia with core temp maintained between 32°C and 34°C for 24 hours may be neuroprotective for patients that remain comatose or have neurologic deterioration (1).
- Patients can be discharged from the ED after 6 to 8 hours of observation if the following criteria are met:
  - GCS = 15
  - Normal CXR, if indicated
  - Lack of clinical evidence of respiratory difficulty
  - Normal lung exam
  - Normal vital signs
  - Oxygen saturation ≥95% on room air (5)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Appropriate follow-up with primary care provider, orthopedic, neurologic, cardiac, pulmonary, and additional specialists as indicated

Patient Monitoring

- ABG monitoring, as indicated
- A pulmonary artery catheter may be needed for hemodynamic monitoring in unstable patients (3)[C].
- Intracranial pressure monitoring in selected patients (3)[C]
- Serum electrolyte determinations

DIET

NPO until mental status normalizes
PATIENT EDUCATION
Reemphasize preventive measures on discharge from hospital. Educate parents regarding supervision and preventive practices.

PROGNOSIS
- 75% of drowning victims survive; 6% will have residual neurologic deficits (1).
- Patients with an initial GCS ≥13 and an oxygen saturation ≥95% have a low risk of complications and an excellent chance for a full recovery (1).
- Patients who are comatose or receiving CPR at the time of presentation as well as those who have dilated and fixed pupils and no spontaneous respiratory activity have a more guarded and often poor prognosis, often secondary to neurologic sequelae.
- Neurogenic pulmonary edema may occur within 48 hours of initial presentation.

COMPLICATIONS
- Early
  - Bronchospasm, vomiting, aspiration
  - Hypoglycemia, hypothermia, seizures
  - Hypovolemia, electrolyte abnormalities
  - Arrhythmia from hypoxia or hypothermia (rarely from electrolyte imbalance)
  - Hypotension
- Late
  - ARDS, pneumonia, lung abscess, empyema
  - Anoxic encephalopathy, barotrauma, seizure
  - Renal failure, coagulopathy, sepsis

REFERENCES

**CODES**

**ICD10**
- T75.1XXA Unsp effects of drowning and nonfatal submersion, init
- T75.1XXD Unsp effects of drowning and nonfatal submersion, subs
- T75.1XXS Unsp effects of drowning and nonfatal submersion, sequel

**CLINICAL PEARLS**
- The single most important treatment for near-drowning victims is prompt reversal of any hypoxia.
- Water safety education combining physical and behavioral techniques has the greatest effect on drowning prevention.
- Encourage pool owners and parents with young children to become CPR certified.
- Patients remain at risk for ARDS for hours after submersion. Every resuscitated patient requires careful monitoring.
- Patients requiring intubation should be treated with lung-protective ventilator settings to prevent barotrauma.
- Patients with an initial GCS ≥13 and an oxygen saturation ≥95% have a low risk of complications and an excellent chance for a full recovery.
OBESITY
Kimberly Bombaci, MD

BASICS

DESCRIPTION
- Excess adipose tissue, typically quantified in adults by body mass index (BMI) ([kg] / [m²]), ≥30 kg/m²
- Obesity categorized into 3 classes:
  - Class 1 obesity is BMI 30 to 34.9 kg/m².
  - Class 2 obesity is BMI 35 to 39.9 kg/m².
  - Class 3 obesity (also called severe obesity) is BMI >40 kg/m².
- Obesity is associated with negative health outcomes. Abdominal obesity increases the risk of morbidity and mortality.
- System(s) affected: endocrine/metabolic, cardiac, respiratory, gastrointestinal, musculoskeletal, dermatologic, mental health
- Synonym(s): overweight; adiposity

Geriatric Considerations
Underweight BMI (≤18) is also associated with an increased risk of mortality.

EPIDEMIOLOGY
- Predominant age: Incidence rises in the early 20s.
- Predominant sex: female > male

Prevalence
- 35% of U.S. adults are obese (1,2).
- 40% of men and 25% of women are overweight.

Pediatric Considerations
- Pediatric obesity is defined as a BMI ≥95th percentile, by age and sex specific WHO or CDC growth curves.
- Obesity during adolescence and young adulthood is strongly associated with obesity in adulthood.

ETIOLOGY AND PATHOPHYSIOLOGY
Obesity is caused by an imbalance between food intake, absorption, and energy expenditure.

Underlying organic causes include psychiatric disturbances, hypothyroidism, hypothalamic disorders, insulinoma, and Cushing syndrome. It is likely that an individual’s gut microbiome may cause obesity and/or make it difficult to lose weight.

Medications that contribute to obesity include corticosteroids, neuroleptics (particularly atypical antipsychotics), and antidepressants.

**Genetics**
- Genetic syndromes such as Prader-Willi and Bardet-Biedl are found in a minority of people with obesity.
- Multiple genes are implicated in obesity.

**RISK FACTORS**
- Parental obesity
- Sedentary lifestyle
- Consumption of calorie-dense food
- Low socioeconomic status
- Stress and mental illness
- Medications

**GENERAL PREVENTION**
- Encourage at least 1 hour of daily exercise, limited television viewing, and moderation in portion size.
- Avoid calorie-dense and nutrient-poor foods such as sugar-sweetened beverages and processed foods.

**DIAGNOSIS**

**HISTORY**
- Diet and exercise habits
- Prior attempts at weight loss
- Reported readiness to change lifestyle
- Social support and resources
- Comorbidities: diabetes mellitus type 2, hypertension (HTN), hyperlipidemia, sleep apnea
Psychiatric history
Symptoms suggesting hypothyroidism, Cushing syndrome, and genetic syndromes

PHYSICAL EXAM
- Elevated BMI:
  - Overweight: BMI = 25 to 29.9 kg/m²
  - Obese: BMI 30 to 39.9 kg/m²
  - Morbid obesity: BMI ≥40 kg/m²
- Abdominal circumference:
  - Measure at the level of the umbilicus. Elevated:
    - Male: >40 inches (102 cm)
    - Female: >35 inches (88 cm)

DIAGNOSTIC TESTS & INTERPRETATION
- Screen for underlying physiologic causes as well as associated comorbid conditions.
- Labs should be done while fasting (nonfasting labs within normal limits are considered adequate).
- Glucose, total insulin, hemoglobin A1C, lipids
- Thyroid function tests
- LFTs (fatty liver)

TREATMENT

GENERAL MEASURES
- Assess:
  - Motivation to lose weight
  - Patient-specific goals of therapy
  - Need for intensive counseling to enhance adherence with diet, exercise, and behavior modification recommendations
- Goal is to achieve and sustain loss of at least 10% of body weight.
- Track nutritional intake and physical activity habits.
- Use of commercial weight loss programs (e.g., Weight Watchers) can be more effective than “standard of care” counseling (3)[B].
- Behavior therapy and cognitive behavioral methods result in modest weight loss and are most effective when combined with dietary and exercise
treatments.

**MEDICATION**
- Include diet, exercise, and behavior therapy for all patients without comorbid conditions who are considering pharmacologic treatment.
- NIH guidelines suggest at least 6 months nonpharmacologic treatment.
- Consider medication for unsatisfactory weight loss in those with:
  - BMI ≥30
  - BMI ≥27 combined with associated risk factors (e.g., coronary artery disease, diabetes, sleep apnea, HTN, hyperlipidemia)
- Relapse common after medications are discontinued
- Treat comorbidities (such as diabetes and hyperlipidemia).

**First Line**
- When compared to placebo, medications have been associated with at least 5% weight loss at 52 weeks (4)[A]. Orlistat (Xenical) is a lipase inhibitor that decreases the absorption of dietary fat. Dose: 120 mg PO TID with meals containing fat; omit dose if meal is skipped or does not contain fat. Patients must avoid taking fat-soluble vitamin supplements within 2 hours of taking orlistat. The FDA has approved orlistat (Alli) 60 mg PO TID to be sold over the counter as a weight loss aid; adverse effects mainly GI (cramps, flatus, fecal incontinence)
- Contraindications
  - Orlistat: chronic malabsorption syndromes, cholestasis, pregnancy

**Second Line**
- Appetite suppressants recommended for short-term treatment (≤6 months) (5) [A]
- Only beneficial in patients who exercise and eat reduced calorie diet
  - Naltrexone/bupropion (Contrave): 8 mg naltrexone/90 mg bupropion per tablet; slow titration up to 2 tablets PO BID by week 4; contraindicated if uncontrolled HTN, seizure disorder, chronic opioid use, pregnancy
  - Liraglutide (Saxenda): 1.203 mg SC once daily; GLP-1 agonist recently approved for obesity; discontinue if weight loss is <4% after 16 weeks.
  - Topiramate: Initiate with 25 mg BID and increase by 50 mg/week up to 100 mg PO BID; not FDA-approved for the treatment of obesity; tolerance is a concern (paresthesias, somnolence, difficulty concentrating).
- Schedule IV drugs:
– Lorcaserin (Belviq) 10 mg PO BID (D/C if weight loss is <5% after 12 weeks); works as serotonin agonist; avoid in those with CrCl <30 mL/min; contraindicated in pregnancy; avoid use with other serotonergic drugs.
– Phentermine: 15, 30, 37.5 mg PO every morning; discontinue if tolerance or no response after 4 weeks; contraindicated if history of CV disease, hyperthyroidism, history of substance abuse, pregnancy
– Phentermine/topiramate Qsymia (3.75 to 23.00 mg, 7.5 to 46.0 mg, 11.25 to 69.00 mg, 15 to 92 mg); initiate 3.75 to 23.00 mg PO once daily; requires enrollment into Risk Evaluation and Mitigation Strategy (REMS); women of childbearing age require negative pregnancy test prior to initiation and monthly thereafter.
– Diethylpropion: 25 mg PO before meals TID; discontinue if no response after 4 weeks; contraindicated if severe HTN, hyperthyroidism, history of substance abuse

**Pregnancy Considerations**
During pregnancy, obese women should gain fewer pounds than recommended for nonobese women.

**SURGERY/OTHER PROCEDURES**
Consider bariatric surgery if patients meet criteria.

- Requires complex presurgical evaluation, surgery, and follow-up in a skilled treatment center
- Surgical procedures include biliopancreatic diversion, Roux-en-Y gastric bypass, sleeve gastrectomy, adjustable gastric banding, vagal blocking therapy (Maestro Rechargeable system), and gastric aspiration (AspireAssist).

**Surgical treatment is the most effective long-term weight-loss treatment available for morbidly obese patients, but there is insufficient evidence on long-term outcomes (6)[A].**

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Physical activity is an integral part of any weight loss program, yet physical activity alone rarely results in significant weight loss.
- Combination of weight training and aerobic activity is preferred over aerobic activity alone.
Patient Monitoring
Long-term routine follow-up may prevent relapse after weight loss or further weight gain.

Diet
- Long-term studies suggest net calorie reduction (500 to 1,000 kcal/day) and ease of use are more important than the composition of the particular diet for long-term results:
  - A reduction of 500 kcal/day can result in ~1 lb (0.45 kg) weight loss per week.
  - Portion-control is essential.
- Very low calorie diet (400 to 800 kcal/day)
  - Can result in more rapid weight loss than higher calorie diets but is less effective in the long term
  - Complications include dehydration, orthostatic hypotension, fatigue, muscle cramps, constipation, headache, and cold intolerance.
  - Relapse common if diet discontinued
  - Contraindications: recent myocardial infarction or cerebrovascular accident, renal disease, cancer, pregnancy, insulin-dependent diabetes mellitus, and some psychiatric disturbances

Patient Education
- Healthy diet and physical activity patterns
- Focus on behaviors (not numbers).
- Recommended Web site:
  - https://www.nal.usda.gov/fnic/foodcomp/search for the FDA nutritional content in common foods

Prognosis
- Lowest mortality associated with a BMI of 22
- Long-term maintenance of weight loss is difficult.
- Patient motivation is associated with successful weight loss (7).

Complications
- Cardiovascular disease
- Stroke (in men)
- Thromboembolism
- Heart failure
HTN
Hypoventilation and sleep apnea syndromes
Higher death rates from cancer: colon, breast, prostate, endometrial, gallbladder, liver, kidney
Diabetes mellitus
Skin changes
Hyperlipidemia
Gallbladder disease
Osteoarthritis
Gout
Poor self-esteem
Discrimination
Increased sick leave

REFERENCES

CODES
ICD10
- E66.9 Obesity, unspecified
- E66.3 Overweight
- R63.5 Abnormal weight gain

CLINICAL PEARLS
- A majority of American adults are overweight or obese.
- Modification in dietary and physical activity patterns remain the cornerstone of therapy for obesity. Consider bariatric surgery in patients with a BMI >40 who have failed more conservative treatment, particularly if there are associated risk factors.
- Medication may be indicated when nonpharmacologic treatment for 6 months has been ineffective and the patient has a BMI >30 or a BMI >27 with associated risk factors.
OBSESSIVE-COMPULSIVE DISORDER (OCD)
Amar Kapur, DO

BASICS

DESCRIPTION
- An anxiety disorder characterized by pathologic obsessions (recurrent intrusive thoughts, ideas, or images) and compulsions (repetitive, ritualistic behaviors or mental acts) causing significant distress
- Not to be confused with obsessive-compulsive personality disorder

EPIDEMIOLOGY

Incidence
- Predominant age: mean age of onset 22 to 36 years
  - Male = female (males present at younger age)
  - Child/adolescent onset in 33% of cases 1/3 of cases present by age 15 years
  - 85% of cases present at <35 years of age
  - Diagnosis rarely made at >50 years of age
- Predominant gender: female > males but males more commonly affected in childhood

Pediatric Considerations
Insidious onset; consider brain insult in acute presentation of childhood OCD.

Geriatric Considerations
Consider neurologic disorders in new-onset OCD.

Prevalence
- 2.3% lifetime in adults
- 1–2.3% prevalence in children/adolescents (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Exact pathophysiology/etiology unknown
- Dysregulation of serotonergic pathways
Dysregulation of corticostriatal-thalamic-cortical (CSTC) path
Genetic and environmental factors
Pediatric autoimmune disorder associated with streptococcal infections

Genetics
Greater concordance in monozygotic twins
Positive family history: prevalence rates of 7–15% in first-degree relatives of children/adolescents with OCD

RISK FACTORS
Exact cause of OCD is not fully elucidated.
Combination of biologic and environmental factors likely involved the following:
– Link between low serotonin levels and development of OCD
– Link between brain insult and development of OCD (i.e., encephalitis, pediatric streptococcal infection, or head injury)

GENERAL PREVENTION
OCD cannot be prevented.
Early diagnosis and treatment can decrease patient’s distress and impairment.

COMMONLY ASSOCIATED CONDITIONS
Major depressive disorder
Panic disorder
Phobia/social phobia
Tourette syndrome/tic syndromes
Substance abuse
Eating disorder/body dysmorphic disorder

DIAGNOSIS
HISTORY
Patient presents with either obsessions or compulsions, which cause marked distress, are time-consuming (>1 hr/day) and cause significant occupational/social impairment.
Four criteria support diagnosis of obsessions:
– Patients are aware that they are thinking the obsessive thoughts; thoughts
are not imposed from outside (as in thought insertion).
– Thoughts are not just excessive worrying about real-life problems.
– Recurrent thoughts are persistent, intrusive, and inappropriate, causing significant anxiety and distress.
– Attempts to suppress intrusive thoughts are made with some other thought/activity.

Two criteria support a diagnosis of compulsions:
– The response to an obsession is to perform repetitive behaviors (e.g., hand washing) or mental acts (e.g., counting silently) rigidly.
– Although done to reduce stress, the responses are either not realistically connected with the obsession or they are excessive.
– In children, check for precedent streptococcal infection.

PHYSICAL EXAM
– Dermatologic problems caused by excessive hand washing may be observed.
– Hair loss caused by compulsive pulling/twisting of the hair (trichotillomania) may be observed.

DIFFERENTIAL DIAGNOSIS
– Obsessive-compulsive personality disorder
  – In personality disorder, traits are ego-syntonic and include perfectionism and preoccupation with detail, trivia, or procedure and regulation. Patients tend to be rigid, moralistic, and stingy. These traits are often rewarded in the patient’s job as desirable.
– Impulse-control disorders: compulsive gambling, sex, or substance abuse: The compulsive behavior is not in response to obsessive thoughts, and the patient derives pleasure from the activity.
– Major depressive disorder
– Eating disorder
– Tics (in tic disorder) and stereotyped movements
– Schizophrenia: Patient perceives thought to be true and coming from an external source.
– Generalized anxiety disorder, phobic disorders, separation anxiety: similar response on heightened anxiety, but presence of obsessions and rituals signifies OCD diagnosis
– Anxiety disorder due to a general medical condition: Obsessions/compulsions are assessed to be a direct physiologic consequence of a general medical condition.
DIAGNOSTIC TESTS & INTERPRETATION

According to DSM-5, diagnostic criteria for OCD are the following (2)[C]:

- Presence of obsessions, compulsions, or both
- Obsessions are defined by:
  - Recurrent or persistent thoughts, urges, or images that are experienced as intrusive and unwanted, and that cause marked anxiety or distress
  - The individual attempts to ignore or suppress such thoughts, urges, or images or to neutralize them with some other thought or actions (i.e., by performing compulsion).
- Compulsions are defined by the following:
  - Repetitive behavior (e.g., hand washing, ordering, checking) or mental acts (e.g., praying, counting, repeating words silently) that the individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly
  - The behavior or mental acts are aimed at preventing or reducing anxiety or distress or preventing some dreaded event or situation. However, these behavior or mental acts are not connected in a realistic way with what they are designed to neutralize or prevent or are clearly excessive.
- The obsessions or compulsions are time-consuming (e.g., take >1 hr/day) or cause clinically significant distress or impairment in social, occupational, or other important areas of functioning.
- The obsessive-compulsive symptoms are not attributable to the physiologic effects of a substance (e.g., a drug of abuse, a medication, or other medical condition).
- The disturbance is not better explained by the symptoms of another mental disorder (e.g., excessive worries, as in generalized anxiety disorder, preoccupation with appearance, as in body dysmorphic disorder or skin picking).
- Specify if:
  - With good or fair insight: The individual recognizes the OCD beliefs are definitely or probably not true or that they may or may not be true.
  - With poor insight: The individual thinks that OCD beliefs are probably true.
  - With absent insight/delusional beliefs: The individual is completely convinced that OCD beliefs are true.
- Specify if:
  - Tic related: The individual has a current or past history of tic disorder.

Diagnostic Procedures/Other
Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) or CY-BOCS for children (1)[C]
Maudsley Obsessive-Compulsive Inventory (MOCI) (3)[C]

**Test Interpretation**

- Compulsions are designed to relieve the anxiety of obsessions; they are not inherently enjoyable (ego-dynastic) and do not result in completion of a task.
- Common obsessive themes
  - Harm (i.e., being responsible for an accident)
  - Doubt (i.e., whether doors/windows are locked or the iron is turned off)
  - Blasphemous thoughts (i.e., in a devoutly religious person)
  - Contamination, dirt, or disease
  - Symmetry/orderliness
- Common rituals or compulsions
  - Hand washing, cleaning
  - Checking
  - Counting
  - Hoarding
  - Ordering, arranging
  - Repeating
- Neither obsessions nor compulsions are related to another mental disorder (i.e., thoughts of food and presence of eating disorder).
- 80–90% of patients with OCD have obsessions and compulsions.
- 10–19% of patients with OCD are pure obsessional.

**TREATMENT**

**GENERAL MEASURES**

- Cognitive-behavioral therapy (CBT) composed of exposure with response prevention and cognitive therapy is recommended as first-line treatment (1) [A].
- Five phases of treatment for CBT:
  - Family and individual psychoeducation
  - Cognitive training
  - Mapping OCD
  - Graded exposure and response training
  - Relapse prevention and generalization training
- Combined medications and CBT is most effective (1,2)[A].
- Brain modulation available for severe OCD includes electroconvulsive therapy and transcranial magnetic stimulation in small groups of patients.

**MEDICATION**

**First Line**
- Adequate trial at least 10 to 12 weeks
- Doses may exceed typical doses for depression.
- Optimal duration for pediatrics unknown but recommended minimum of maintenance treatment: 6 months
- Varying degrees of efficacy between agents (1)
- SSRIs recommended first-line agents (1,4,5)[A]
  - Fluoxetine (Prozac)
    - Adults: 20 mg/day; increase by 10 to 20 mg every 4 to 6 weeks until response; range: 20 to 80 mg/day
    - Children (7 to 17 years of age): 10 mg/day; increase 4 to 6 weeks until response; range: 20 to 60 mg/day
  - Sertraline (Zoloft)
    - Adults: 50 mg/day; increase by 50 mg every 4 to 7 days until response; range: 50 to 200 mg/day; may divide if above 100 mg/day
    - Children (6 to 17 years of age): 25 mg/day; increase by 25 mg every 7 days until response; range: 50 to 200 mg/day
  - Paroxetine (Paxil)
    - Adults: 20 mg/day; increase by 10 mg every 4 to 7 days until response; range: 40 to 60 mg/day
    - Children: Safety and effectiveness in patients <18 years have not been established.
  - Citalopram (Celexa)
    - Not approved by the FDA for use in OCD but used frequently due to good tolerability
    - Black box warning of no >40 mg/day due to arrhythmia risk
- Absolute SSRI contraindications
  - Hypersensitivity to SSRIs
  - Concomitant use within 14 days of monoamine oxidase inhibitor (MAOI)
- Relative SSRI contraindications
  - Severe liver impairment
  - Seizure disorders (lower seizure threshold)
- Precautions
– Watch for suicidal behavior/worsening depression during first few months of therapy/after dosage changes with antidepressants, particularly in children, adolescents, and young adults.
– Long half-life of fluoxetine (>7 days) may be troublesome if patient has an adverse reaction.
– May cause drowsiness and dizziness when therapy was initiated; warn patients about driving and heavy equipment hazards.

**Pregnancy Considerations**
All SSRIs are pregnancy Category C, except paroxetine, which is Category D.

**Second Line**
- Try switching to another SSRI.
- 40–60% of patients will remain refractory to SSRI.
- Tricyclic acid (TCA), clomipramine (Anafranil)
  - Adults: 25 mg/day; increase gradually over 2 weeks to 100 mg/day, and then to 250 mg/day (max dose) over next several weeks, as tolerated.
  - Children (10 to 17 years of age): 25 mg/day; titrate as needed and tolerated up to 3 mg/kg/day or 200 mg/day (whichever is less).
  - Absolute clomipramine contraindications
    - Within 6 months of a myocardial infarction (MI)
    - Hypersensitivity to clomipramine or other TCA
    - Concomitant use within 14 days of a MAOI
    - 3rd-degree atrioventricular (AV) block
  - Relative clomipramine contraindications
    - Narrow-angle glaucoma (increased intraocular pressure)
    - Prostatic hypertrophy (urinary retention)
    - 1st- or 2nd-degree AV block, bundle-branch block, and congestive heart failure (proarrhythmic effect)
    - Pregnancy Category C
  - Precautions
    - Dangerous in overdose
    - Pretreatment ECG for patients >40 years of age; potential arrhythmia
    - Watch for suicidal behavior/worsening depression during first few months of therapy or after dosage changes with antidepressants, particularly in children, adolescents, and young adults.
    - May cause drowsiness and dizziness when therapy is initiated; warn patients about driving and heavy equipment hazards.
    - Side effect profile worse than SSRIs as a whole.
ISSUES FOR REFERRAL
- Psychiatric referral for CBT (in vivo exposure and prevention of compulsions)
- Psychiatric evaluation if obsessions and compulsions significantly interfere with patient’s functioning in social, occupational, or educational situations

ADDITIONAL THERAPIES
Dopamine receptor antagonists (antipsychotic agents) alone are not effective in treatment of OCD. They can be used as augmentation to SSRI therapy for treatment-resistant OCD; they also can worsen OCD symptoms (4)[C]. Some evidence show that addition of quetiapine or risperidone to antidepressants will increase efficacy; data with olanzapine too limited to draw conclusions (4)[A].
- Risperidone (Risperdal): initial dose: 0.5 mg/day; target dose: 0.5 to 2 mg/day
- Quetiapine (Seroquel): initial dose: 25 mg/day; target dose: 600 mg/day

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Y-BCOS or MOCI surveys to track progress

Patient Monitoring
Monitor for decrease in obsessions and time spent performing compulsions.

DIET
No dietary modifications/restrictions recommended

PATIENT EDUCATION
- Importance of medication adherence
- Importance of psychotherapy (CBT)
- International OCD Foundation: https://iocdf.org/
- Obsessive Compulsive Anonymous: http://obsessivecompulsiveanonymous.org

PROGNOSIS
- Chronic waxing and waning course in most patients:
  - 24–33% fluctuating course
  - 11–14% phasic periods of remission
– 54–61% chronic progressive course
• Early onset a poor predictor
• Few studies address how long to continue therapy; poor results for those that do with high elapse rate (53% on placebo compared to 23% on stable escitalopram) (4)
• Patients who are classified as “responders” will continue to have symptoms, often significantly impacting their lives.

COMPLICATIONS
• Depression in 1/3 patients with OCD
• Avoidant behavior (phobic avoidance)
  – Children may drop out of education.
  – Adults may become homebound.
• Anxiety and panic-like episodes associated with obsessions

REFERENCES

ADDITIONAL READING
CODES

ICD10
- F42 Obsessive-compulsive disorder
- F63.9 Impulse disorder, unspecified
- F63.3 Trichotillomania

CLINICAL PEARLS
- CBT is the initial treatment of choice for mild OCD.
- CBT plus an SSRI or an SSRI alone is the treatment choice for more severe OCD.
- The majority of patients with OCD respond to first SSRI treatment.
- Improvement in symptoms however, is often incomplete, ranging from 25% to 60%.
OCULAR CHEMICAL BURNS

Robert J. Hyde, MD, MA, FACEP

BASICS

DESCRIPTION
- Chemical exposure to the eye can result in rapid, devastating, and permanent damage and is one of the true emergencies in ophthalmology.
- Separate alkaline from acid chemical exposure.
  - Alkali burns: more severe. Alkaline compounds are lipophilic, penetrating rapidly into eye tissue; saponification of cells leads to necrosis and may produce injury to lids, conjunctiva, cornea, sclera, iris, and lens (cataracts).
  - Acid burns: Acid usually does not damage internal structures because its associated anion causes protein denaturation, creating a barrier to further acid penetration (hydrofluoric acid is an exception to this rule; see below). Injury is often limited to lids, conjunctiva, and cornea.
- System(s) affected: nervous, skin/exocrine
- Synonym(s): chemical ocular injuries

EPIDEMIOLOGY
- Predominant age: can occur at any age, peak from 20 to 40 years of age
- Predominant sex: male > female

Incidence
- Estimated 300/100,000 per year
- Alkali burns twice as common as acid burns.

ETIOLOGY AND PATHOPHYSIOLOGY
- Acidic compounds
  - Anion leads to protein denaturing and protective barrier formation by coagulation necrosis forming an eschar. This more superficial mechanism of injury tends to have prominent scarring that may lead to vision loss:
    o Hydrofluoric acid is an exception. In its nonionized form, it behaves like an alkaline substance, capable of penetrating the corneal stroma and leading to extensive anterior segment lesions. When ionized, it may combine with intracellular calcium and magnesium to form insoluble
complexes, leading to potassium ion movements and cell death. Once systemically absorbed, severe hypocalcemia can occur.

- **Alkaline compounds**
  - Lipophilic compounds that penetrate into deep structures on disassociation into cations and hydroxide
  - Hydroxide causes saponification of fatty acids in cell membranes, leading to cell death.
  - Cation causes hydration of glycosaminoglycans, leading to corneal opacification and hydration of collagen, resulting in rapid shortening and thickening of collagen fibrils that leads to an acute elevation in intraocular pressure secondary to shrinking and contraction of the cornea and sclera.
  - Long-term elevation in intraocular pressure may occur from accumulation of inflammatory debris within the trabecular meshwork.
  - Penetration into deep structures may also affect perfusing vessels, leading to ischemia of affected area.

### Sources of Alkaline and Acidic Compounds

<table>
<thead>

<tr>
<td>Hydrofluoric acid</td>
<td>Glass polish</td>
</tr>
</tbody>
</table>

### RISK FACTORS

- Construction work (plaster, cement, whitewash)
- Use of cleaning agents (drain cleaners, ammonia)
- Automobile battery explosions (sulfuric acid)
- Industrial work, including work in industrial chemical laboratories
- Alcoholism
- Any risk factor for assault (~10% of injuries due to deliberate assault)
GENERAL PREVENTION
Safety glasses to safeguard eyes

COMMONLY ASSOCIATED CONDITIONS
Facial (including eyelids) cutaneous chemical or thermal burns

DIAGNOSIS

HISTORY
- Most often, complaints of pain, photophobia, blurred vision, and a foreign body sensation
- In alkali burns, can have initial pain that later diminishes
- Mild burns: pain and blurred vision
- Moderate to severe burns: severe pain and markedly reduced vision

PHYSICAL EXAM
- Acidic compound may present with a ground-glass appearance secondary to superficial scar formation.
- Alkaline compounds may present with corneal opacification secondary to glycosaminoglycan hydration; however, severe acid burns may also present with this finding.
- Mild burns
  - Blurry vision
  - Eyelid skin erythema and edema
  - Corneal epithelial defects or superficial punctate keratitis
  - Conjunctival chemosis, hyperemia, and hemorrhages without perilimbal ischemia
  - Mild anterior chamber reaction
- Moderate to severe burns
  - Reduced vision
  - 2nd- and 3rd-degree burns of eyelid skin
  - Corneal edema and opacification
  - Corneal epithelial defects
  - Marked conjunctival chemosis and perilimbal blanching
  - Moderate anterior chamber reaction
  - Increased intraocular pressure
  - Local necrotic retinopathy
DIFFERENTIAL DIAGNOSIS
- Thermal burns
- Ocular cicatricial pemphigoid
- Other causes of corneal opacification
- Ultraviolet radiation keratitis

DIAGNOSTIC TESTS & INTERPRETATION
Not necessary unless suspicion of intraocular or orbital foreign body is present. In this case, CT should be used and MRI is contraindicated.

Diagnostic Procedures/Other
- Measure pH of tear film with litmus paper or electronic probe:
  - Irrigating fluid with nonneutral pH (e.g., normal saline has pH of 4.5) may alter results.
- Careful slit-lamp exam, fundus ophthalmoscopy, tonometry, and measurement of visual acuity
- Full extent of damage from alkali burns may not be apparent until 48 to 72 hours after exposure.

Test Interpretation
- Corneal epithelial defects or superficial punctate keratitis, edema, opacification
- Conjunctival chemosis, hyperemia, and hemorrhages
- Perilimbal ischemia
- Anterior chamber reaction
- Increased intraocular pressure

TREATMENT
Copious irrigation and removal of corneal or conjunctival foreign bodies are always the initial treatment (1,2)[A]:
- Passively open patient’s eyelid and have patient look in all directions while irrigating.
- Be sure to remove all reservoirs of chemical from the eyes.
- Continue irrigation until the tear film and superior/inferior cul-de-sac is of neutral pH (7 ± 0.1) and pH is stable (1)[C]:
  - Severe burns should be irrigated for at least 15 minutes to as much as 2 to 4
hours; this irrigation should not be interrupted during transportation to hospital (1)[C].

- Irrigation via Morgan lens (polymethylmethacrylate scleral lens) is a good way to achieve continuous irrigation over a prolonged period of time.
- It is impossible to overirrigate.

- Initial pH testing should be done on both eyes even if the patient claims to only have unilateral ocular pain/irritation so that a contralateral injury is not neglected.

- Use whatever nontoxic fluid is available for irrigation on scene. In hospital, sterile water, normal saline, normal saline with bicarbonate, balanced salt solution (BSS), or lactated Ringer solution may be used.

- A topical anesthetic can be used to provide patient comfort (e.g., proparacaine, tetracaine).

- Sweep the conjunctival fornices every 12 to 24 hours to prevent adhesions (1)[C].

- Eye patching may relieve pain but has not been shown to improve outcomes (3)[C].

MEDICATION

First Line

- Further treatment (depending on severity and associated conditions)
  - Topical prophylactic antibiotics: any broad-spectrum agent (e.g., bacitracin–polymyxin B ointment q2–4h, ciprofloxicin drops q2–4h)
    - Some experts suggest that systemic tetracycline 250 mg PO q6h and especially derivatives such as doxycycline 100 mg PO BID may be beneficial to encourage healing of persistent corneal epithelial defects by inhibiting metalloproteinases (4)[C].
  - Tear substitutes: carboxymethylcellulose (Refresh Plus) drops q4h
    - Most beneficial in those with impaired tear production (elderly patients)
  - Cycloplegics for photophobia and/or uveitis: cyclopentolate 1% TID or scopolamine 1/4% BID (1)[C]
  - Antiglaucoma for elevated intraocular pressure: latanoprost (Xalatan) 0.005% q24h, timolol (Timoptic) 0.5% BID, or levobunolol (Betagan) 0.5% BID, and/or acetazolamide (Diamox) 125 to 250 mg PO q6h, or methazolamide (Neptazene) 25 to 50 mg PO BID (1)[C]
  - Corticosteroids for intraocular inflammation: prednisolone (Pred Forte) 1% or equivalent q1–4h for 7 to 10 days; if severe, prednisone 20 to 60 mg PO daily for 5 to 7 days. Taper rapidly if epithelium is intact by this time (1)
Use of corticosteroids >10 days may do harm by inhibiting repair and cause corneoscleral melt (5)[C].

- Vitamin C (ascorbic acid) 500 mg PO QID and topical 10% ascorbate solution in artificial tears reduces the incidence of corneal thinning and ulceration (1)[C].
- Acetylcysteine (Mucomyst) 10–20% topically q4h to promote wound healing (1)[C]

**Precautions**
- Timolol and levobunolol: history of heart failure (HF) or chronic obstructive pulmonary disease (COPD)
- Acetazolamide and methazolamide: history of nephrolithiasis or metabolic acidosis
- Mannitol: history of HF or renal failure
- Scopolamine: history of urinary retention
- Topical corticosteroids must be used with caution in the presence of damaged corneal epithelium because iatrogenic infection can occur. Daily follow-up or consultation with an ophthalmologist is recommended.

**SURGERY/OTHER PROCEDURES**
- Goal of subacute treatment is restoration of the normal ocular surface anatomy, control of glaucoma, and restoration of corneal clarity.
- Surgical options include the following:
  - Débridement of necrotic tissue
  - Conjunctival/tenon advancement (tenoplasty) to restore vascularity in severe burns
  - Tissue adhesive (e.g., isobutyl cyanoacrylate) for impending or actual corneal perforation of
  - Tectonic keratoplasty for acute perforation >1 mm
  - Limbal autograft transplantation for epithelial stem cell restoration
  - Amniotic membrane transplantation (5)[C] or umbilical cord serum drops to promote epithelial regeneration (5)[C]
  - Conjunctival or mucosal membrane transplant to restore ocular surface in severe injury

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Based on ophthalmologic consultation and concomitant burn injuries
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Depending on severity of ocular injury
  - From daily to weekly visits initially
- May be inpatient
- If on mannitol or prednisone, consider frequent serum electrolytes.

PATIENT EDUCATION
- Safety glasses
- Need for immediate ocular irrigation with any available water following chemical exposure to the eyes

PROGNOSIS
- Depends on severity of initial injury: Increased limbal involvement in clock hours and greater percentage of conjunctival involvement correlate with poorer prognosis (Dua classification system).
- For mildly injured eyes, complete recovery is the norm.
- For severely injured eyes, permanent loss of vision is not uncommon.

COMPLICATIONS
- Orbital compartment syndrome
- Persistent epitheliopathy
- Fibrovascular pannus
- Corneal ulcer/perforation
- Corneal scarring
- Progressive symblepharon
- Neurotrophic keratitis
- Lid malposition secondary to cicatricial ectropion and entropion
- Glaucoma
- Cataract
- Hypotony
- Phthisis bulbi
- Blindness

CLINICAL PEARLS

- Prompt irrigation of all chemical burns, even prior to arrival to the emergency department, is essential to ensure best outcomes. It is impossible to overirrigate.
- All patients with chemical injuries to their eyes should have urgent ophthalmology consultation and/or referral.
ONYCHOMYCOSIS
Lauren M. Simon, MD, MPH

BASICS
DESCRIPTION
- Fungal infection of fingernails/toenails
- Caused mostly by dermatophytes but also yeasts and nondermatophyte molds
- Toenails are more commonly affected than fingernails.
- System(s) affected: skin, exocrine
- Synonym(s): tinea unguium; ringworm of the nail

EPIDEMIOLOGY
Prevalence
- Occurs in 2–10% of general population
- Predominant age: 20% in adults >60 years of age
- Rare before puberty
- Prevalence 15–40% in persons with human immunodeficiency infection (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Dermatophytes: Trichophyton (Trichophyton rubrum most common), Epidermophyton, Microsporum
- Yeasts: Candida albicans (most common), Candida parapsilosis, Candida tropicalis, Candida krusei
- Molds: Scopulariopsis brevicaulis, Hendersonula toruloidea, Aspergillus sp., Alternaria tenuis, Cephalosporium, Scytalidium hyalinum
- Dermatophytes cause 90% of toenail and most of fingernail onychomycoses.
- Fingernail onychomycosis is more often caused by yeasts, especially Candida.
- Dermatophytes can invade normal keratin, whereas nondermatophyte molds invade altered keratin (dystrophic/injured nails).

RISK FACTORS
- Older age
- Tinea pedis
- Occlusive footwear
- Cancer/diabetes/psoriasis
Peripheral vascular disease
Cohabitation with others with onychomycosis
Immunodeficiency
Communal swimming pools
Smoking
Peripheral vascular disease
History of nail trauma
Autosomal dominant genetic predisposition

COMMONLY ASSOCIATED CONDITIONS
Immune deficiency/chronic metabolic disease (e.g., diabetes)
Tinea pedis/manuum

DIAGNOSIS

PHYSICAL EXAM
Dermatophytes: commonly preceded by dermatophyte infection at another site; 80% involve toenails, especially hallux; simultaneous infection of fingernails and toenails is rare. Five clinical forms occur.
- Distal/lateral subungual onychomycosis (most common): mainly due to *T. rubrum*. Spreads from distal/lateral margins to nail bed to nail plate; subungual hyperkeratosis; onycholysis; nail dystrophy; discoloration—yellow-white or brown-black, yellow streaking laterally; can progress proximally, *bois vermoulu* (“worm-eaten wood”); onychomadesis
- Proximal subungual onychomycosis (rare <1% of cases): hands/feet; leukonychia—begins at proximal part of nail plate, appearing to occur from the proximal underside of the nail (or direct invasion of the nail plate from above); spreads to nail plate and lunula; seen with immunosuppressive conditions
- Superficial (formerly known as superficial white onychomycosis) about 10% of cases: hallux is preferentially affected; infection of outer surface of nail plate; opaque white spots on nail plate eventually merge to involve entire surface of the nail; most commonly due to *Trichophyton mentagrophytes*
- Endonyx onychomycosis involves interior of nail plate, sparing nail bed. Nail develops milky white appearance with indentations. Subungual hyperkeratosis is absent.
– Totally dystrophic onychomycosis causes complete destruction of nail plate by fungus, resulting in thickened and ridged nail bed covered with keratotic debris.

- **Candidal**
  - Hands, 70%, especially for the dominant hand
  - Middle finger is most common.
  - Pain is mild, unless secondarily infected.
  - Increases on prolonged contact with water
  - Primarily affects tissue surrounding nail
  - Begins with cuticle detachment
  - White or white-yellow nail discoloration
  - Secondary ungual changes: convex, irregular, striated nail plate with dull, rough surface
  - Onycholysis, especially on hands
  - Distal subungual onychomycosis may occur.
  - Primary involvement of the nail plate is uncommon (thin, crumbly, opaque, brownish nail plate deformed by transverse grooves).
  - Periungual edema/erythema may occur (club-shaped, bulbous fingertips).

- **Molds (nondonematophyte)**
  - More common in those >60 years of age
  - More common in nails of hallux
  - Resembles distal and lateral onychomycosis

**Pediatric Considerations**
- Candidal infection presents more commonly as superficial onychomycosis.
- The U.S. Food and Drug Administration (FDA) has not approved any systemic antifungal agents for treatment of onychomycosis in children. Efficacy and safety profiles in children for some systemic antifungals are similar to those previously reported in adults (2).

**DIFFERENTIAL DIAGNOSIS**
- Psoriasis (most common alternate diagnosis)
- Traumatic dystrophy
- Lichen planus
- Onychogryphosis (“ram’s horn nails”)
- Eczematous conditions
- Hypothyroidism
- Drugs and chemicals
- Yellow nail syndrome
Neoplasms (0.7–3.5%) of all melanoma cases are subungual. In a brownish yellow nail, if dark pigment extends into periungual skin fold, consider subungual melanoma.

**DIAGNOSTIC TESTS & INTERPRETATION**

- Accurate diagnosis requires both laboratory and clinical evidence.
- About 50% of nail dystrophy seen on visual inspection is not fungal in origin, so laboratory assessment improves diagnostic accuracy.
- If onychomycosis is suspected clinically and initial diagnostic laboratory tests are negative, the tests should be repeated.
- A nail plate biopsy or partial/full removal of nail with culture is needed to diagnose proximal subungual onychomycosis.

**Initial Tests (lab, imaging)**

- Direct microscopy with potassium hydroxide (KOH) preparation (1)[C]
  - Clean nail with 70% isopropyl alcohol.
  - Using sterile clippers, remove diseased, discolored nail plate.
  - Collect debris from stratum corneum of most proximal area (beneath nail or crumbling nail itself) with 1-mm curette/scalpel.
  - Place sample on microscope slide with drop of 5–10% KOH. View after 5 minutes.
  - Gentle heat applied to slide can enhance keratin breakdown.
  - High sensitivity if >2 preparations were examined
  - Look for hyphae, pseudohyphae, or spores.
- Cultures: False-negative finding in 30% (secondary to loss of dermatophyte viability; improved by immediate culture on Sabouraud cell culture medium); results may take 3 to 6 weeks.
- In office dermatophyte test, medium culture indicates dermatophyte growth with yellow-to-red color change of the medium; results in 3 to 7 days; limited studies
- Histologic examination of nail clippings/nail plate punch biopsy: proximal lesions; stain both with periodic acid–Schiff (PAS) stain (1)[C].
- KOH-treated nail clipping stained with PAS: significantly higher rates of detection of onychomycosis as compared with standard methods of KOH preparation and fungal culture (3)[C]
- Polymerase chain reaction (PCR) increases sensitivity of detection of dermatophytes in nail specimen; results available within 3 days can be used as complementary to direct microscope exam and fungal culture; not widely available
Fluorescence microscopy can be used as a rapid screening tool for identification of fungi in nail specimens.

Commercial laboratories may use KOH with calcofluor white stain to improve view of fungal elements in fluorescent microscopy.

Discontinue all topical medication for at least 1 week before obtaining a sample.

**Test Interpretation**
Pathogens within the nail keratin

**TREATMENT**

**GENERAL MEASURES**
- Avoid factors that promote fungal growth (i.e., heat, moisture, occlusion, tight-fitting shoes).
- Treat underlying disease risk factors.
- Treat secondary infections.

**MEDICATION**

**Pregnancy Considerations**

Oral antifungals and ciclopirox are pregnancy Category B (terbinafine, ciclopirox) or C (itraconazole, fluconazole, and griseofulvin). Griseofulvin is not advised in pregnancy due to risks of teratogenicity and conjoined twins. Ideally postpone treatment of onychomycosis until after pregnancy.

**First Line**

- Oral antifungals are preferred due to higher rates of cure but have systemic adverse effects and many drug–drug interactions.

- **Terbinafine:** 250 mg/day PO for 6 weeks for fingernails and 12 weeks for toenails; most effective in cure and prevention of relapse compared with other antifungals and with itraconazole pulse in meta-analysis for toenail onychomycosis (4)[A]

- **Itraconazole pulse:** 200 mg PO BID for 1 week and then 3 weeks off, repeat for two cycles for fingernails and three to four cycles for toenails; does not need to monitor liver function tests (LFTs) with pulse dosing

- **Itraconazole continuous:** 200 mg/day PO for 6 weeks for fingernails and 12 weeks for toenails (less effective than itraconazole pulse for dermatophytes,
more effective than terbinafine for Candida and molds)

**Second Line**
- Fluconazole pulse: 150 to 300 mg PO weekly for 6 months (lower cure rate); not FDA-approved for onychomycosis
- Griseofulvin: 500 to 1,000 mg/day PO for up to 18 months (lower cure rate, continue until the diseased nail is replaced)
- Posaconazole: 100, 200, or 400 mg once daily for 24 weeks; 400 mg once daily for 12 weeks; higher cost
- Topical agents: Use limited to disease not involving the lunula (proximal nail plate). Topical therapy does not cause systemic toxicity but is less effective than oral therapy. Head-to-head comparison of efficacy of available agents is generally not available.
- Efinaconazole solution 10%, apply directly to affected nails once daily for 48 weeks; complete or almost-complete cure after 48 weeks in range of 15–18% (NNT compared to vehicle 7 to 10)
- Ciclopirox: 8% nail lacquer (available generically): Apply once daily to affected nails (if without lunula involvement) for up to 48 weeks; remove lacquer with alcohol every 7 days, and then file away loose nail material and trim nails (low-cure rate, avoids systemic adverse effects, less cost-effective). Application after PO treatment may reduce recurrences; systematic review >60% failure rate after 48 weeks of use (5)[A]
- Tavaborole 5% solution, a topical oxaborole antifungal is indicated for onychomycosis of the toenails due to T. rubrum or T. mentagrophytes; complete or almost-complete cure 15–18% after 48 weeks (NNT compared to vehicle approximately 7)
- Contraindications for oral antifungals
  - Hepatic disease
  - Pregnancy (see “Pregnancy Considerations”)
  - Current/history of congestive heart failure (CHF) (itraconazole)
  - Ventricular dysfunction (itraconazole)
  - Porphyria (griseofulvin)
- Precautions/adverse effects
  - Oral antifungals
    - Hepatotoxicity/neutropenia
    - Hypersensitivity
    - Photosensitivity, lupus-like symptoms, proteinuria (griseofulvin)
    - Chronic kidney disease (avoid terbinafine for patients with creatinine clearance [CrCl] <50 mL/min, decrease fluconazole dose)
CHF, peripheral edema, pulmonary edema (itraconazole)
- Rhinitis (itraconazole)

- Ciclopirox topical: side effects: rash, nail disorders; avoid contact with skin except along nail edge; caution with broken skin or vascular compromise
- Oral agents: numerous significant drug–drug interactions; need to check each medication:
  - Terbinafine (inhibits cytochrome P450 2D6 [CYP2D6] isoenzyme): for example, β-blockers, monoamine oxidase inhibitors (MAOIs), SSRIs, tricyclic antidepressants (TCAs), warfarin, oxycodone
  - Itraconazole (inhibit CYP3A4): for example, antiarrhythmics, benzodiazepines, ergot alkaloids, 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitors, calcium channel blockers, corticosteroids, hydrochlorothiazide, hypoglycemics, oral contraceptives (OCPs), warfarin, zolpidem
  - Griseofulvin: for example, OCPs, salicylates, warfarin

Surgery/Other Procedures
- Nail débridement to remove infected keratin (efficacy not well studied): Use for few nails involved or if not, for candidate of systemic therapy.
  - Mechanical: Soften with occlusive dressing with 40% urea gel; detach from nail bed with tweezers, file with abrasive stone or curette.
  - Chemical: Protect peripheral tissue with adhesive strips; apply ointment of 30% salicylic acid, 40% urea, or 50% potassium iodide under occlusive dressing.
  - Débridement may be combined with topical antifungal therapy.
  - Surgical avulsion if few nails are involved; for pain control

Laser treatment has shown some positive results but poor statistical power and limited efficacy or safety data (6)[A].

Photodynamic therapy using topical photosensitizing agents and irradiation with appropriate light source some success for treatment of superficial nail infections; limited data

Complementary & Alternative Medicine
- Melaleuca alternifolia (tea tree oil) Cochrane review found no evidence of benefit (5)[A].

Vicks VapoRub application to nails daily for 48 weeks has been found safe, but efficacy is uncertain.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Formation of a new fingernail takes 4 to 6 months, and a new toenail takes 12 to 18 months.
- Cure defined as:
  - Clinical cure, 100% absence of clinical signs, and/or
  - Mycotic cure, negative mycology with ≥1 of the following clinical signs:
    - Distal subungual hyperkeratosis/onycholysis leaving <10% of the nail plate affected
    - Nail plate thickening that does not improve with treatment because of comorbid condition

Patient Monitoring

- Topical agents: Slow response is expected; visits every 6 to 12 weeks
- Terbinafine, griseofulvin: baseline, and as needed, LFTs and CBC
- Itraconazole continuous: baseline, and as needed, LFTs

PATIENT EDUCATION

- Advise patient to:
  - Keep affected area clean and dry.
  - Avoid rubber/other occlusive, tight-fitting footwear.
  - Wear absorbent cotton socks.
  - Launder clothing and towels frequently in hot water.
  - Avoid sharing nail implements or use on both normal and abnormal nails.
- Cure of all toenails may not be attainable.
- Nails may not appear normal after cure.

PROGNOSIS

- Complete clinical cure in 25–50% (higher mycologic cure rates) with oral therapy
- Recurrence is 10–50% (relapse/reinfection).
- Poor prognostic factors
  - Areas of nail involvement >50%
  - Significant proximal/lateral disease
  - Subungual hyperkeratosis >2 mm
  - White/yellow or orange/brown streaks in the nail (includes
dermatophytoma)

- Total dystrophic onychomycosis (with matrix involvement)
- Nonresponsive organisms (e.g., Scytalidium mold)
- Patients with immunosuppression
- Diminished peripheral circulation

COMPLICATIONS

- Secondary infections with progression to soft tissue infection/osteomyelitis
- Toenail discomfort/pain that can limit physical mobility or activity
- Anxiety, negative self-image

REFERENCES

CODES

ICD10
- B35.1 Tinea unguium
- B37.2 Candidiasis of skin and nail

CLINICAL PEARLS

- Psoriasis and chronic nail trauma are commonly mistaken for fungal infection.
- Diagnosis should be based on both clinical and mycologic laboratory
evidence.
OPTIC NEURITIS

Olga Cerón, MD • Pablo Hernandez Itriago, MD, MHCM, FAAFP

BASICS

DESCRIPTION

- Inflammation of the optic nerve (cranial nerve II)
- Most common form is acute demyelinating optic neuritis (ON), but other causes include infectious disease and systemic autoimmune disorders.
- Optic disc may be normal in appearance at onset (retrobulbar ON, 67%) or swollen (papillitis, 33%).
- Key features:
  - Abrupt visual loss (typically monocular)
  - Periorbital pain with eye movement (90%)
  - Pain in the distribution of the first division of the trigeminal nerve
  - Dyschromatopsia: color vision deficits
  - Relative afferent pupillary defect (RAPD)
- Usually unilateral in adults; bilateral disease more common in children
- Presenting complaint in 25% of patients with multiple sclerosis (MS)
- In children, headaches are common.
- System(s) affected: nervous
- Synonym(s): papillitis, demyelinating optic neuropathy; retrobulbar ON

EPIDEMIOLOGY

Incidence

- 5/100,000 cases per year
- More common in northern latitudes
- More common in spring season
- More common in whites than in other races
- Predominant age: 18 to 45 years; mean age 30 years
- Predominant sex: female > male (3:1)

ETIOLOGY AND PATHOPHYSIOLOGY

- In both MS-associated and isolated monosymptomatic ON, the cause is
presumed to be a demyelinating autoimmune reaction.

- Possible mechanisms of inflammation in immune-mediated ON are the cross-reaction of viral epitopes and host epitopes and the persistence of a virus in CNS glial cells.
- Neuromyelitis optica (NMO) IgG autoantibody, which targets the water channel aquaporin-4
- Primarily idiopathic
- MS
- Viral infections: measles, mumps, varicella-zoster, coxsackievirus, adenovirus, hepatitis A and B, HIV, herpes simplex virus, cytomegalovirus
- Nonviral infections: syphilis, tuberculosis, meningococcus, cryptococcosis, cysticercosis, bacterial sinusitis, streptococcus B, Bartonella, typhoid fever, Lyme disease, fungus
- Systemic inflammatory disease: sarcoidosis, systemic lupus erythematosus, vasculitis
- Local inflammatory disease: intraocular or contiguous with the orbit, sinus, or meninges
- Toxic: lead, methanol, arsenic, radiation
- Vascular lesions affecting the optic nerve
- Posterior uveitis (i.e., birdshot retinochoroidopathy, toxoplasmosis, toxocariasis)
- Tumors
- Medications: ethambutol, chloroquine, isoniazid, chronic high-dose chloramphenicol, tumor necrosis factor α-antagonist, infliximab (Remicade), adalimumab (Humira), etanercept (Enbrel)

COMMONLY ASSOCIATED CONDITIONS

- MS (common): ON is associated with an increased risk of MS.
- Other demyelinating diseases: Guillain-Barré syndrome, Devic NMO, multifocal demyelinating neuropathy, acute disseminated encephalomyelitis

DIAGNOSIS

HISTORY

- Decreased visual acuity, deteriorating in hours to days, usually reaching lowest level after 1 week
- Usually unilateral but can also be bilateral
Brow ache, globe tenderness, deep orbital pain exacerbated by eye movement (92%)
Retro-orbital pain may precede visual loss.
Desaturation of color vision (dull or faded colors), especially red tones
Apparent dimness of light intensities
Impairment of depth perception (80%); worse with moving objects (Pulfrich phenomenon)
Transient increase in visual symptoms with increased body temperature and exercise (Uhthoff phenomenon)
Phosphenes: fleeting colors and flashes of light (30%)
May present with a recent flulike viral syndrome
Detailed history and review of systems, looking for a history of demyelinating, infectious, or systemic inflammatory disease

PHYSICAL EXAM
Complete general exam, full neurologic exam, and ophthalmologic exam looking for the following:
- Decreased visual acuity and color perception
- Central, cecocentral, arcuate, or altitudinal visual field deficits
- Papillitis: (1/3) swollen disc ± peripapillary flame-shape hemorrhage or often (2/3) normal disc exam
- Temporal disc pallor seen later at 4 to 6 weeks (1)[A]
- RAPD: The pupil of the affected eye dilates with a swinging light test unless disease is bilateral.

DIFFERENTIAL DIAGNOSIS
- Demyelinating disease, especially MS
- Infectious/systemic inflammatory disease
- Neuroretinitis: virus, toxoplasmosis, Bartonella
- Toxic or nutritional optic neuropathy
- Acute papilledema (bilateral disc edema)
- Compression:
  - Orbital tumor/abscess compressing the optic nerve
  - Intracranial tumor/abscess compressing the afferent visual pathway
  - Orbital pseudotumor
  - Carotid–ophthalmic artery aneurysm
- Temporal arteritis or other vasculitides
- Trauma or radiation
NMO (Devic disease)
Anterior ischemic optic neuropathy
Leber hereditary optic neuropathy
Kjer-type autosomal dominant optic atrophy
Severe systemic hypertension
Diabetic papillopathy

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- In typical presentations, erythrocyte sedimentation rate (ESR) is standard, but other labs are unnecessary. Antinuclear antibodies (ANAs), angiotensin-converting enzyme level (ACE), fluorescent treponemal antibody absorption (FTA-ABS), and chest radiograph (CXR) have been shown to have no value in typical cases (1)[A].
- In atypical presentations, including absence of pain, a very swollen optic nerve, >30 days without recovery, or retinal exudates, labs may be indicated to rule out underlying disorders:
  - CBC
  - ANA test
  - Rapid plasma reagin test
  - FTA-ABS test
- MRI of brain and orbits to evaluate risk of etiology of ON from MS: thin cuts (2 to 3 mm) gadolinium-enhanced and fat-suppression images to look for Dawson fingers of MS (periventricular white matter lesions oriented perpendicular to the ventricles) and also to look for enhancement of the optic nerve; baseline MRI provides prognostic information for MS and assists in stratifying risk of development of MS depending on absence or presence of white matter lesions in brain.
- CT scan of chest to rule out sarcoidosis if clinical suspicion is high
- Ocular coherence tomography (OCT) of the retinal nerve fiber layer (RNFL); a noninvasive imaging technique of the optic nerve; may serve as a diagnostic tool to quantify thickness of the nerve fiber layer objectively and thus, monitor structural change (axonal loss) of the optic nerve in the course of the disease

Follow-Up Tests & Special Considerations

- Visual field test (Humphrey 30–2) to evaluate for visual field loss: diffuse and central visual loss more predominant in the affected eye at baseline (2)[A]
OCT of the optic nerve RNFL to detect and monitor axonal loss in the anterior visual pathways
Low-contrast visual acuity (as a measure of disease progression)
A blood test serum marker: NMO-IgG checks for antibodies for NMO.

Diagnostic Procedures/Other
In atypical cases, including bilateral deficits, young age, or suspicion of infectious etiology, lumbar puncture (LP) with neurology consultation is indicated.
LP for suspected MS is a physician-dependent decision. Some studies indicate that it may not add value to MRI for MS detection (1)[A], but no consensus on the subject exists.

TREATMENT
Most persons with ON recover spontaneously.

MEDICATION
First Line
IV methylprednisolone has been shown to speed up the rate of visual recovery but without significant long-term benefit; consider for patients who require fast recovery (i.e., monocular patients or those whose occupation requires high-level visual acuity). For significant vision loss, parenteral corticosteroids may be considered on an individualized basis:ON treatment trial (ONTT):
– Observation and corticosteroid treatment are both acceptable courses of action.
  – High-dose IV methylprednisolone (250 mg q6h for 3 days) followed by oral corticosteroids (1 mg/kg/day PO for 11 days, taper over 1 to 2 weeks) (3)[A]
– Others use IV Solu-Medrol infusion (1 g in 250 mL D_\textsubscript{5} \textsubscript{1/2} normal saline infused over 1 hour daily for 3 to 5 days):
  – No evidence of long-term benefit (1)[A]
  – May decrease recovery time (3)[A]
  – May decrease risk of MS at 2 years but not 5 years (3)[A]
– Give antiulcer medications with steroids.
– Discuss benefits and potential side effects of corticosteroids with patient (i.e., weight gain, osteoporosis, mood changes, gastrointestinal disturbances,
hyperglycemia, insomnia).

**Second Line**
- Disease-modifying agents, such as interferon-β1a (IFN-β1a; Avonex, Rebif) and IFN-β1b (Betaseron), are used to prevent or delay the development of MS in people with ON who have ≥2 brain lesions evident on MRI.
  - These medications have been proposed for use in patients with one episode of ON (clinically isolated syndrome) at high risk of developing MS (1+ lesion on brain MRI).
- Decisions should be made individually with neurology consultation.

**ALERT**

NEVER use oral prednisone alone as the primary treatment because this may increase the risk for recurrent ON (3)[A].

**Pediatric Considerations**
- No systematic study defining high-dose corticosteroids in children with ON have been conducted.
  - Consensus recommends: 3 to 5 days of IV methylprednisolone (4 to 30 mg/kg/day), followed by a 2- to 4-week taper of oral steroids (4)[C]
- Optic disc swelling and bilateral disease are more common in children as is severe loss of visual acuity (20/200 or worse).
- Consider infectious and postinfectious causes of optic nerve impairment.

**ISSUES FOR REFERRAL**
Referral to a neurologist and/or ophthalmologist

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Monthly follow-up to monitor visual changes and steroid side effects

**PATIENT EDUCATION**
- Provide reassurance about recovery of vision.
- If the disease is believed to be secondary to demyelinating disease, patient
should be informed of the risk of developing MS.

- For patient education materials favorably reviewed on this topic, contact:
  - North American Neuro-Ophthalmology Society (NANOS), 5841 Cedar Lake Road, Suite 204, Minneapolis, MN 55416, 952-646-2037, Fax: 952-545-6073; [http://www.nanosweb.org](http://www.nanosweb.org) (click on section for patients);
  - [http://www.nanosweb.org/files/Patient%20Brochures/English/OpticNeuritis](http://www.nanosweb.org/files/Patient%20Brochures/English/OpticNeuritis) (available in other languages)

**PROGNOSIS**

- Orbital pain usually resolves within 1 week.
- Visual acuity
  - Rapid spontaneous improvement at 2 to 3 weeks and continues for several months (may be faster with IV corticosteroids)
  - Often returns to normal or near-normal levels (20/40 or better) within 1 year (90–95%), even after near blindness
- Other visual disturbances (e.g., contrast sensitivity, stereopsis) often persist after acuity returns to normal.
- Recurrence risk of 35% within 10 years: 14% affected eye, 12% contralateral, 9% bilateral; recurrence is higher in MS patients (48%).
- **ON is associated with an increased risk of developing MS; 35% risk at 7 years, 58% at 15 years (5)[A]**
  - Brain MRI helps to predict risk: (by number of lesions)
    - 0 lesions: 16%
    - 1 to 2 lesions: 37%
    - 3+ lesions: 51%
  - The presence of brain MRI abnormalities at the time of ON episode is a strong predictor of the 15-year risk of MS.
- Poor prognostic factors:
  - Absence of pain
  - Low initial visual acuity
  - Involvement of intracanalicular optic nerve
- Children with bilateral visual loss have a better prognosis than adults.

**COMPLICATIONS**

Permanent loss of vision

**REFERENCES**

Multiple Sclerosis

CODES

ICD10

- H46.9 Unspecified optic neuritis
- H46.00 Optic papillitis, unspecified eye
- H46.10 Retrobulbar neuritis, unspecified eye
CLINICAL PEARLS

- MRI is the procedure of choice for determining relative risk and possible therapy for MS prevention.

- The ONTT showed that high-dose IV methylprednisolone followed by oral prednisone accelerated visual recovery but did not improve the 6-month or 1-year visual outcome compared with placebo, whereas treatment with oral prednisone alone did not improve the outcome and was associated with an increased rate of recurrence of ON (1,2)[A],(6)[B],(7)[C].
BASICS

DESCRIPTION
- Osgood-Schlatter disease (OSD) is a syndrome associated with traction apophysitis and patellar tendinosis that is most common in adolescent boys and girls.
  - Patients present with pain and swelling of the anterior tibial tubercle
- System(s) affected: musculoskeletal
- Synonym: tibial tubercle apophysitis

EPIDEMIOLOGY

Incidence
In incidence in girls increasing with increased participation in organized youth sports; still more common in boys.

Prevalence
- A common apophysitis in childhood and adolescence affecting athletes (21%) and nonathletes (4.5%) (1)[B]
- Approximately 10% remain symptomatic as adults (2)[C].
- 10% of all adolescent knee pain is due to OSD.

ETIOLOGY AND PATHOPHYSIOLOGY
Traction apophysitis of the tibial tubercle due to repetitive strain on the secondary ossification center of the tibial tuberosity, concurrent patellar tendinosis, and disruption of the proximal tibial apophysitis
- Basic etiology unknown, exacerbated by exercise
  - Jumping and pivoting sports place highest strain on the tibial tubercle. Repetitive trauma is the most likely inciting factor.
- Possible association with tight hip flexors and tight quadriceps; increased quadriceps strength in adolescence relative to hamstring strength
- Early sports specialization increases the risk for OSD 4-fold (3)[B].
RISK FACTORS

- Affects children and adolescents most commonly from the ages of 8 to 18 years
  - Girls 8 to 14 years
  - Boys 10 to 18 years
- OSD is slightly more common in boys.
- Rapid skeletal growth
- Increased weight
- Quadriceps tightness
- Participation in repetitive-jumping sports and sports with heavy quadriceps activity (football, volleyball, basketball, hockey, soccer, skating, gymnastics)
- Ballet (2-fold risk compared with nonathletes)

GENERAL PREVENTION

- Avoid sports with heavy quadriceps loading (especially deceleration activities—eccentric loading).
- Patients may compete if pain is minimal.
- Increase hamstring and quadriceps flexibility.

COMMONLY ASSOCIATED CONDITIONS

- Shortened (tight) rectus femoris found in 75% with OSD
- Possible association with ADD/ADHD; adolescents with ADD/ADHD are at risk for other musculoskeletal injuries.
- Sinding-Larsen-Johansson apophysitis

DIAGNOSIS

HISTORY

- Unilateral or bilateral (30%) pain of the tibial tuberosity
- Pain exacerbated by exercise, especially jumping and landing after jumping
- Pain upon kneeling on the affected side(s)
- Antalgic or straight-legged gait

PHYSICAL EXAM

- Knee pain with squatting or crouching
- Absence of effusion or condyle tenderness
- Tibial tuberosity swelling and tenderness

mebooksfree.com
- Pain increased with resisted knee extension or kneeling
- Erythema over tibial tuberosity
- Functional testing: Single-leg squat (SLS) and standing broad jump reproduce pain (3)[C].

**DIFFERENTIAL DIAGNOSIS**

- Stress fracture of the proximal tibia
- Pes anserinus bursitis
- Quadriceps tendon avulsion
- Patellofemoral stress syndrome
- Chondromalacia patellae (retropatellar pain)
- Proximal tibial neoplasm
- Osteomyelitis of the proximal tibia
- Tibial plateau fracture
- Sinding-Larsen-Johansson syndrome (patellar apophysitis)—pain over inferior patellar tendon
- Patellar fracture
- Infrapatellar bursitis
- Patellar tendinitis—pain over inferior patellar tendon and inferior pole of patella
- Osteochondroma of the tibial tubercle
- Tibial tuberosity fracture
- Patellar tendon lipoma

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- Generally a clinical diagnosis. No tests are indicated unless other diagnoses are under consideration.
- Radiographic imaging of the proximal tibia and knee may show heterotopic calcification in the patellar tendon:
  - X-rays are rarely diagnostic, but appearance of a separate fragment at the tibial tuberosity identifies candidates for potential surgical intervention.
  - Calcified thickening of the tibial tuberosity with irregular ossification at tendon insertion on the tibial tubercle (4)[B]

*Diagnostic Procedures/Other*

- Bone scan may show increased uptake in the area of the tibial tuberosity:
  - Increased uptake in apophysitis is normal in children, but with OSD, there
Ultrasound is an excellent alternative, showing thickening of the distal patellar tendon and infrapatellar bursa effusion.

MRI shows fragmentation of the tibial tubercle and bone edema.

**Test Interpretation**

Biopsy is not necessary but would show osteolysis and fragmentation of the tibial tubercle.

**TREATMENT**

**GENERAL MEASURES**

- Frequent ice applications 2 to 3 times per day for 15 to 20 minutes
- Rest and activity modification—avoid activities that increase pain and/or swelling.
- Physical therapy helps with hamstring and quadriceps strengthening and stretching.
- Open- and closed-chain eccentric quadriceps strengthening
- Avoid aggressive stretching if pain is significant to avoid risk of tibial tubercle avulsion (1)[B].
- Consult orthopedic surgery for tibial tuberosity fracture or complete avulsion.
- Electrical stimulation and iontophoresis may be beneficial (1)[B].
- Patients with marked pronation may benefit from orthotics.
- A single study showed benefit from an infrapatellar strap and many experts recommend the use of a knee brace with an H- or U-shaped buttress (1)[C].

**MEDICATION**

**First Line**

- Any analgesic may be considered.
- NSAIDs may help control pain.
- Opioids are not recommended as first line.

**Second Line**

- More potent analgesics, such as opioids, may be considered for short-term use in extreme situations.
- Corticosteroid injections are not recommended.
- Hypertonic glucose and/or Xylocaine injections have shown recent benefit (5)
Acupuncture

ISSUES FOR REFERRAL
When conservative therapy is unsuccessful, consider surgical referral.

SURGERY/OTHER PROCEDURES
- Débridement of a thickened, cosmetically unsatisfactory tibial tubercle (rare) or removal of mobile heterotopic bone
- Surgical excision of a painful tibial tubercle is rarely needed (<5%) and may be successfully done with bursoscopy instead of an open procedure (4)[C].
- Recent report of successful pain elimination in OSD with percutaneous screw fixation of the tibial tuberosity (2)[C]
- Reduction wedge osteotomy has been recently reported as 100% successful in a small case series (6)[C].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Athletes may return to play if pain is controlled.
- Presence of pain does not preclude competition.

Patient Monitoring
With worsening of symptoms only

PATIENT EDUCATION
- Avoid jumping sports or reduce activities that increase pain and swelling.
- Assure family that symptoms and findings will diminish with time and rest.
- Patients can safely play sports with mild pain.
- Quadriceps stretching and strengthening are important.
- Surgical options are rarely needed, but good results can be expected.

PROGNOSIS
- Except in rare cases, this is a self-limiting illness that resolves within 2 years of full skeletal maturation.
- 10% of patients with OSD as adolescents will have symptoms in adulthood.
- Up to 60% of adults with prior OSD report occasional symptoms and pain
with kneeling.

- Most patients with OSD have residual “knots” of tibial tubercles that never completely resolve.

**COMPLICATIONS**

- Rarely, a heavily fragmented and inflamed tibial ossicle will avulse and require surgery.
- Rare complications in adulthood include pseudoarthrosis of the tibial tubercle, genu recurvatum, patella alta, and ossicle fragmentation possibly leading to osteoarthritis of the knee.

**REFERENCES**

**ADDITIONAL READING**

- Morris E. Acupuncture in Osgood-Schlatter disease [published online ahead

**CODES**

**ICD10**

- M92.50 Juvenile osteochondrosis of tibia and fibula, unsp leg
- M92.51 Juvenile osteochondrosis of tibia and fibula, right leg
- M92.52 Juvenile osteochondrosis of tibia and fibula, left leg

**CLINICAL PEARLS**

- Infrapatellar pain in an adolescent athlete undergoing a rapid growth spurt is OSD, patellar tendinosis, or Sinding-Larsen-Johansson syndrome.
- Always consider lumbar disc disease, osteogenic sarcoma, or hip pathology in the differential diagnosis of OSD.
- OSD is generally self-limited. Athletes should modify activity based on pain. Mild pain is not a contraindication to athletic participation.
- Treatment focuses on strengthening and stretching of the hamstrings and quadriceps.
- 10% of adolescents with OSD will be symptomatic as adults.
OSTEOARTHRITIS
Patrick Wakefield Joyner, MD, MS

BASICS

DESCRIPTION

- Progressive loss of articular cartilage with reactive changes at joint margins and in subchondral bone
- Primary osteoarthritis (OA)
  - Idiopathic: categorized by clinical features (localized, generalized, erosive)
- Secondary OA
  - Posttraumatic
  - Childhood anatomic abnormalities (e.g., congenital hip dysplasia, slipped capital femoral epiphysis [SCFE], Legg-Calvé-Perthes disease)
  - Inheritable metabolic disorders (e.g., Wilson disease, alkaptonuria, hemochromatosis)
  - Neuropathic arthropathy (Charcot joints)
  - Hemophilic arthropathy
  - Endocrinopathies: acromegalic arthropathy, hyperparathyroidism, hypothyroidism
  - Paget disease
  - Noninfectious inflammatory arthritis (e.g., rheumatoid arthritis [RA], spondyloarthropathies)
  - Gout, calcium pyrophosphate deposition disease (pseudogout)
  - Septic or tuberculous arthritis
  - Femoral acetabular impingement (FAI)
- System(s) affected: musculoskeletal
- Synonym(s): osteoarthrosis; degenerative joint disease (DJD)

EPIDEMIOLOGY

- Symptomatic OA most common in patients >40 years
- Leading cause of disability in patients >65 years
- Predominant sex: male = female
- 90% of hip OA is primary.
- Hip OA is more common in whites.
Prevalence
- ~60 million patients
- Increases with age; radiographic evidence of OA is present in many patients >65 years old.
- Moderate to severe hip OA in 3–6% of whites; <1% in East Indians, blacks, Chinese, and Native Americans

Etiology and Pathophysiology
- Failure of chondrocytes to maintain the balance between degradation and synthesis of extracellular collagen matrix. Collagen loss results in alteration of proteoglycan matrix and increased susceptibility to degenerative change.
- Biomechanical, biochemical, inflammatory, and immunologic factors contribute to cartilage loss. Attempts at repair most commonly manifest as osteophyte formation.

Genetics
- Up to 65% of OA may have a genetic component.
- The heritability of end-stage hip OA is up to 27%.
- Twin studies in women show 50% (hip, knee) to 65% (hip) heritability rates of OA.

Risk Factors
- Increasing age: >50 years
- Age as a risk factor is greatest for hip and knee OA.
- Hand OA is most common in postmenopausal women.
- Obesity (weight-bearing joints); BMI >35
- Small critical shoulder angle (<30°) can predispose to shoulder OA.
- Trauma, infection, or inflammatory arthritis
- Female gender (knee and hand)

Rx Diagnosis

History
- Distinguish OA from other types of arthritis by:
  - Absence of systemic findings
  - Minimal articular inflammation
  - Distribution of involved joints (e.g., distal and proximal interphalangeal
OA characterized by slowly developing joint pain. Pain often described as aching or burning in nature. Anecdotally, many patients describe pain changes with alterations in weather conditions.

Transient stiffness (especially after awakening in morning and after sitting) that tends to lessen 10 to 15 minutes after joint movement

OA more commonly affects hands, spine, and large weight-bearing joints (hip, knee).

PHYSICAL EXAM

- Joint bony enlargement (Heberden nodes of distal interphalangeal joints; Bouchard nodes of proximal interphalangeal joints)
- Decreased range of motion of affected joints
- Mechanical symptoms (clicking, locking) may be present, especially in knees with degenerative meniscal injury.
- Crepitation is a late sign.
- Local pain and stiffness with OA of spine; radicular pain (if compression of nerve roots)
- Changes in joint alignment (genu varum [bowlegs] and genu valgum [knock-knees])

DIFFERENTIAL DIAGNOSIS

- Crystalline arthropathies (gout; pseudogout): inflammatory arthritides (RA); spondyloarthropathies (reactive arthritis; psoriatic arthritis); septic arthritis
- Fibromyalgia; avascular necrosis; Lyme disease

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Routine chemistries are not helpful in diagnosis.
- X-rays are usually normal early in disease process.
- As OA progresses, plain films show:
  - Narrowed, asymmetric joint space
  - Osteophyte formation
  - Subchondral bony sclerosis
  - Subchondral cyst formation
- Erosions may occur on surface of distal and proximal interphalangeal joints (erosive OA).
- MRI may particularly demonstrate chondral degeneration and associated
meniscal tears. 5–10% weight loss is associated with slowing of arthritic changes and decreased chondral loss on follow-up studies (1).

**Follow-Up Tests & Special Considerations**
- May be useful in monitoring treatment with NSAIDs (renal insufficiency and GI bleeding)
- In secondary OA, underlying disorder may have abnormal lab results (e.g., hemochromatosis [abnormal iron studies]).

**Diagnostic Procedures/Other**
- Joint aspiration
  - Can help distinguish OA from other arthritides
  - OA: cell count usually <500 cells/mm³, predominantly mononuclear
  - Inflammatory: cell count usually >2,000 cells/mm³, predominantly neutrophils
  - Birefringent crystals in gout (−) and pseudogout (+)

**Test Interpretation**
- Macroscopic patchy cartilage damage and bony hypertrophy
- Histologic phases:
  - Extracellular matrix edema and cartilage microfissures
  - Subchondral fissuring and pitting
  - Erosion and formation of osteocartilaginous loose bodies
- Subchondral bone trabecular microfractures and sclerosis with osteophyte formation
- Degradation secondary to release of proteolytic and collagenolytic enzymes, prostaglandins, and associated immune response

**TREATMENT**

**GENERAL MEASURES**
- Weight management
- Heat (in the morning and prior to activity) or cold (in the afternoon or after activity) for symptomatic relief
- Physical therapy to maintain or regain joint motion and muscle strength
  - Quadriceps-strengthening exercises relieve knee pain and disability.
- Muscle strengthening improves pain in general.
• Transition to non–weight-bearing exercises (i.e., elliptical, stationary bike, swimming)
• Exercise must be maintained; benefits are lost 6 months after exercise cessation.
• Protect joints from overuse; ambulatory aids are beneficial as is proper fitting footwear.
• Bracing, joint supports, or insoles in patients with biomechanical instability:
  – Bracing is more beneficial in patients with unicompartmental disease of the knee.
• For knee OA in particular, several nonpharmacologic modalities are strongly recommended: aerobic, aquatic, and/or resistance exercise and weight loss.
• Nonpharmacologic modalities that are conditionally recommended for knee OA include medial wedge insoles for valgus knee OA, subtalar strapped lateral insoles for varus knee OA, medially directed patellar taping, manual therapy, walking aids, thermal agents, tai chi, self-management programs, and psychosocial intervention.

MEDICATION

First Line
• Manage pain and inflammation:
  – Acetaminophen up to 1,000 mg TID–QID: effective for pain relief in OA of knee and hip
  – Topical NSAID gels, creams have short-term (<4 weeks) benefits. Topical NSAIDs are a core treatment for knee and hand OA.
  – If acetaminophen or topical NSAIDs are insufficient, consider an oral NSAID/COX-2 inhibitor. Use the lowest effective dose for the shortest time possible.
  – May use nonacetylated salicylates (e.g., salsalate, choline-magnesium salicylate) or low-dose ibuprofen ≤1,600 mg/day
  – Topical NSAIDs and capsaicin as alternatives to oral analgesic/anti-inflammatory medications in knee OA
• NSAID contraindications:

  ALERT
  http://www.health.harvard.edu/blog/fda-strengthens-warning-that-nsaids-increase-heart-attack-and-stroke-risk-201507138138
  – All PO NSAIDs/COX-2 inhibitors have analgesic effects of a similar
magnitude but vary in their potential GI and cardiorenal toxicity.
- NSAIDs should be avoided in patients with renal disease, CHF, HTN, active peptic ulcer disease, and previous hypersensitivity to an NSAID or aspirin (asthma, nasal polyps, hypotension, urticaria/angioedema).
- Combination of NSAIDs and full-strength aspirin (325 mg) is contraindicated.
- In patients at high cardiovascular risk: Combination of a nonselective NSAID and low-dose aspirin (81 mg) is recommended.
- Oral or parenteral corticosteroids are contraindicated.

**Precautions:**
- If PO NSAID/COX-2 inhibitor use is necessary for a patient aged >65 years or a patient <65 years with increased GI-bleeding risk factors, proton-pump inhibitors are recommended.
- Significant possible interactions:
  - NSAIDs reduce effectiveness of ACE inhibitors and diuretics.
  - Aspirin and NSAIDs (except COX-2 inhibitors) may increase effects of anticoagulants.
  - Salicylates reduce effectiveness of spironolactone (Aldactone) and uricosurics.
  - Corticosteroids and some antacids increase salicylate excretion, whereas ascorbic acid and ammonium chloride reduce salicylate excretion and may cause toxicity.

**Pregnancy Considerations**
- ASA and NSAIDs have reported fetal risk during 1st and 3rd trimesters of pregnancy.
- Compatible with breastfeeding

**Second Line**
- Topical capsaicin is an adjunct therapy for knee and hand OA.
- Topical NSAIDs (e.g., diclofenac gel) can lower gastric and renal risks associated with oral NSAIDs.
- Rubefacients (e.g., oil of wintergreen) are not recommended.
- Physical therapy: Core strengthening for hip OA and knee muscle strengthening for knee OA decrease joint reactive forces and can relieve pain.
- Bracing; medial and lateral unloader braces are effective; long leg alignment x-rays can help determine the appropriate brace (2).
**Third Line**
- Intra-articular corticosteroid injections can be used for acute flares and for patients failing first- and second-line treatments. Minimize injections (<2/joint/year).
- The use of viscosupplementation injections for OA remains controversial. There is no clear evidence for benefit from hyaluronic acid (HA) injections.
- Platelet-rich plasma (PRP) is more effective than HA injections for early-stage knee OA (3).
- Bone marrow aspirate concentrate (BMAC) appears to demonstrate good to excellent outcomes for patient with mild to moderate knee OA; not recommended for patients with severe knee OA (4,5)
- No randomized trials have been performed with BMAC in knee OA, but it appears to be a safe and effective option for mild to moderate disease.
- TENS is effective for pain relief in large-joint OA.
- Ultrasound improves injection accuracy.

**ADDITIONAL THERAPIES**
Address psychosocial factors (i.e., self-efficacy, coping skills). Screen for and appropriately treat anxiety and depression. Improve social support.

**SURGERY/OTHER PROCEDURES**
- Total knee arthroplasty (TKA) may be necessary if conservative management fails.
- Knee arthroscopy is not routinely recommended for the treatment of OA in the absence of clear mechanical symptoms (i.e., locking, clicking, etc.).

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Nutritional supplements (glucosamine and chondroitin sulfate) may benefit some patients and have low toxicity. There is lack of standardized outcome assessments. Trial results using glucosamine and chondroitin have been mixed. If no response is apparent within 6 months, discontinue use.
- TENS, yoga, and acupuncture have shown benefit.

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Regularly assess range of motion and functional status.
- Monitor for GI blood loss, cardiac, renal, and mental status in older patients on NSAIDs or aspirin.
- Periodic CBC, renal function tests, stool for occult blood in patients on chronic NSAID therapy

PATIENT EDUCATION
- American College of Rheumatology:
- Arthritis Foundation: http://www.arthritis.org

PROGNOSIS
- Progressive disease: early in course, pain relieved by rest; later, pain may persist at rest and at night.
- Joint effusions and enlargement may occur (especially in knees) as disease progresses.
- Osteophyte (spur) formation, especially at joint margins
- Advanced stage with full-thickness loss of cartilage at which point joint replacement is a consideration

COMPLICATIONS
- Leading cause of musculoskeletal pain and disability
- Decompensated CHF, GI bleeding, decreased renal function on chronic NSAID or aspirin therapy

REFERENCES

### ADDITIONAL READING

### CODES

#### ICD10

- M19.90 Unspecified osteoarthritis, unspecified site
- M19.91 Primary osteoarthritis, unspecified site
- M19.93 Secondary osteoarthritis, unspecified site

### CLINICAL PEARLS

- Patients with OA typically have morning stiffness lasting for <15 minutes.
- OA most commonly affects the hips, knees, and hands (PIP and DIP joints).
- If used, intra-articular steroid injections should be limited to no more than 2 per joint per year.
- PRP and/or BMAC are (higher-cost) options for early-stage knee OA.
- Some professional organizations recommend against the use of HA injections for OA.
- Base long-term therapy on patient pain management and activity goals.
OSTEOMYELITIS

Thuy Le, DO • Obiefuna P. Okoye, MD, MPH

BASICS

DESCRIPTION

- An acute or chronic bone infection with associated inflammation; can occur as a result of hematogenous seeding, contiguous spread of infection, or direct inoculation into intact bone (trauma or surgery)
- Two major classification systems:
  - Lew and Waldvogel
    - Classified according to duration (acute or chronic) and mechanism of infection (hematogenous, contiguous)
  - Cierny-Mader classification
    - Based on the portion of bone affected, physiologic status of the host, and risk factors
    - Stage 1: medullary bone (often monomicrobial)
    - Stage 2: bony surface, involving only cortical bone (deep soft-tissue infection or ulcer)
    - Stage 3: advance local infection, often involves both cortical and medullary (polymicrobial); often associated with open fracture or infected orthopedic hardware
    - Stage 4: Extensive disease (multiple tissue layers) requires combination medical and surgical therapy.
    - Class A host: otherwise normal
    - Class B host: immunocompromised
    - Class C host: treatment risk benefit
- Special situations
  - Vertebral osteomyelitis
    - Acute, subacute, or chronic
    - May result from hematogenous seeding, direct inoculation, or contiguous spread
    - Back pain is most common initial symptom.
    - Lumbar spine is most commonly involved, followed by thoracic spine.
  - Infections of prosthetic joints
    - Easier to obtain specific diagnosis and targeted therapy (better access)
- X-ray and then three-phase bone scan, as MRI/CT is limited use with prostheses
- Treat with combination of antibiotics. Include rifampin (4 to 6 weeks) for higher success rate—penetrates biofilm.
  - Posttraumatic infections depend on type and severity of fracture; level of contamination
- Tibia is the most commonly involved.

**System(s) affected: musculoskeletal**

**EPIDEMIOLOGY**

- Predominant age: more common in older adults
- Predominant sex: male > female
- Hematogenous osteomyelitis
  - Adults (most >50 years of age): vertebral
  - Children: long bones
- Contiguous osteomyelitis: related to trauma and surgery in younger adults and decubitus ulcers and infected total joint arthroplasties in older adults

**Incidence**
Generally low; normal bone is resistant to infection.

**Prevalence**
Up to 66% of diabetics with foot ulcers

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Infection is caused by biofilm bacteria (protects from antimicrobial agents and host immune responses).
- Acute: suppurative infection of bone with edema and vascular compromise leading to sequestra
- Chronic: presence of necrotic bone or sequestra or recurrence of previous infection
- Hematogenous osteomyelitis (typically monomicrobial)
  - *Staphylococcus aureus* (most common)
  - Coagulase-negative staphylococci and aerobic gram-negative bacteria
  - *Pseudomonas aeruginosa* (intravenous drug user)
  - *Salmonella* sp. (sickle cell disease)
  - *Mycobacterium tuberculosis* and fungi (rare) in endemic areas or in immunocompromised hosts
Contiguous focus osteomyelitis (polymicrobial)
  - Diabetes or vascular insufficiency
    o Coagulase-positive and coagulase-negative staphylococci
    o Streptococci, gram-negative bacilli, anaerobes (Peptostreptococcus sp.)
  - Prosthetic device
    o Coagulase-negative staph and S. aureus

RISK FACTORS
- Diabetes mellitus
- Recent trauma/surgery
- Foreign body (e.g., prosthetic implant)
- Neuropathy and vascular insufficiency
- Immunosuppression
- Sickle cell disease
- Injection drug use
- Previous osteomyelitis

GENERAL PREVENTION
- Antibiotic prophylaxis
  - Clean bone surgery
    o Administer IV antibiotics within an hour of skin incision; continue ≤24 hours postprocedure.
  - Closed fractures
    o Cefazolin, cefuroxime, clindamycin (β-lactam allergy), or vancomycin (β-lactam allergy or MRSA infection)
  - Open fractures
    o In patients who can receive antibiotics within 3 hours of injury with prompt operative treatment, 1st-generation cephalosporins are preferred (clindamycin or vancomycin if allergy exists). Add aminoglycoside if type III fracture and penicillin for anaerobic coverage if farm injury or possible bowel contamination.
- Annual foot examination for diabetic patients

DIAGNOSIS

HISTORY
- Fever, chills, lethargy (particularly in children)
- Pain, swelling, erythema in affected area
- Hematogenous osteomyelitis
  - Elicit a history of conditions predisposing to bacteremia (diabetes, renal insufficiency, invasive procedures, IV drug use).
- Contiguous osteomyelitis and vascular insufficiency
  - Recent trauma/surgery within 1 to 2 months
  - Presence of prosthetic device
  - History of diabetes
- Chronic osteomyelitis
  - History of acute osteomyelitis
  - Draining sinus tract indicates chronic condition.

**PHYSICAL EXAM**
- Fever
- Restriction of movement of the involved extremity or refusal to bear weight
- Pain or tenderness in the infected area
- Signs of localized inflammation
- Motor and sensory deficits (vertebral infection)
- Visible defect: probe to bone
- Ulcer >2-cm wide and >2-cm deep increases likelihood in diabetic foot ulcers.
- Classic signs and symptoms of infection may be masked in diabetics due to vascular disease and neuropathy.

**DIFFERENTIAL DIAGNOSIS**
- Systemic infection from other source
- Aseptic bone infarction
- Localized inflammation or infection of overlying skin and soft tissues (e.g., gout)
- Brodie abscess (subacute osteomyelitis)
- Neuropathic joint disease (Charcot foot)
- Fractures/trauma
- Tumor

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

**Labs**
- WBC is not reliable (can be normal with infection).
- CRP is usually elevated (nonspecific).
- ESR is high in most cases:
  - ESR >70 mm/hr increases likelihood.
- Antibiotics given prior to culture may alter results.
- Other disorders that may alter lab results: immunosuppression (including diabetes), chronic inflammatory disease, other sites of infection (1)[C]
- Routine radiography is first-line imaging: Classic triad for osteomyelitis is demineralization, periosteal reaction, and bone destruction:
  - Bone destruction is not apparent on plain films until after 10 to 21 days of infection.
  - Bone must undergo 30–50% destruction before damage is evident on films.
  - Bone scan is first test after plain x-ray for evaluation of prosthesis-related infection.
- Radionuclide scanning (e.g., technetium, indium, or gallium) helps if diagnosis is ambiguous or unsure of extent of disease; limited by low sensitivity and specificity
- MRI
  - Best for visualization of septic arthritis, spinal infection, and diabetic foot infections (1)[C]
  - T1-weighted image: low signal intensity
  - T2-weighted image: high signal intensity
  - MRI with gadolinium: sensitivity and specificity range from 60–100% to 50–90%, respectively
  - MRI is not helpful in assessing the response to therapy due to persistence of bony edema.
- CT
  - Better than standard radiography to evaluate bony fragments and sequestration; inferior to MRI in soft tissue and bone marrow assessment
  - Helps define soft tissues and identify sequestration

**Follow-Up Tests & Special Considerations**
- A persistently elevated CRP (4 to 6 weeks) can be associated with osteomyelitis.
- Monitor patients receiving prolonged antimicrobial therapy with:
  - Weekly CBC
  - Liver and kidney function tests

**Diagnostic Procedures/Other**
- Cultures
  - Definitive diagnosis is made by blood culture (hematogenous) or by needle
aspiration/bone biopsy, with identification of the microorganism by culture and sensitivity or histology.
– Patients with positive blood cultures and with radiographic evidence of osteomyelitis may not need bone culture.
– Wound swabs and sinus tract cultures correlate well with presence of *S. aureus* in deep cultures.

- Image-guided bone biopsy for vertebral osteomyelitis (unless positive blood culture and positive radiographic evidence)

**Test Interpretation**
Inflammatory process of bone with pyogenic bacteria, necrosis

### TREATMENT

**GENERAL MEASURES**
- Adequate nutrition
- Smoking cessation
- Control diabetes

**MEDICATION**
- Direct empiric therapy toward probable organism and tailor according to culture results.
- Optimal antimicrobial concentration at infection site is essential (consider vascular perfusion to site).
- Adjust antibiotic dosing according to renal function.
- 4 to 6 weeks of therapy is appropriate for acute osteomyelitis; >8 weeks for chronic osteomyelitis or MRSA infection

- In children, early transition from IV to oral therapy, (after 3 to 4 days if responding well) followed by oral therapy for 3 weeks may be as effective as longer courses for uncomplicated acute osteomyelitis (2)[B].

**First Line**
- *S. aureus* or coagulase-negative staphylococci
  - MSSA: β-lactam at high dose (nafcillin or oxacillin 2 g IV q4h) *or* cefazolin 2 g IV q8h
  - MRSA: vancomycin 15 to 20 mg/kg IV q8–12h (use q8h interval if CrCl >70 mL/min) with target trough of 15 to 20 μg/mL, not to exceed 2 g/dose
**Streptococcus sp.**
- Ceftriaxone 2 g IV q24h or cefazolin 2 g IV q8h

**Enterobacter sp.**
- Fluoroquinolone (levofloxacin 750 mg IV/PO q24h) or ceftriaxone 2 g IV q24h

**P. aeruginosa**
- Ciprofloxacin 750 mg PO BID or levofloxacin 750 mg PO q24h

**Anaerobes**
- Clindamycin 600 mg IV q8h (300 to 450 mg PO q6–8h)

**Second Line**

**S. aureus**
- MSSA: fluoroquinolone plus rifampin (levofloxacin 750 mg IV/PO q24h plus rifampin 300 mg PO q12h or 600 mg PO q24h)
- MRSA: linezolid 600 mg PO/IV q12h or daptomycin 6 mg/kg IV q24h

**Streptococcus sp.**
- Penicillin G 4 million U q4–6h

**Enterobacter sp.** (quinolone-resistant, including extended-spectrum β-lactamase–producing *Escherichia coli*)
- Carbapenem (imipenem/cilastatin) 500 mg IV q6h

**P. aeruginosa**
- Cefepime or ceftazidime 2 g IV q8h (Consider adding aminoglycoside.)

**Anaerobes**
- Metronidazole 500 mg IV/PO q6–8h

**ADDITIONAL THERAPIES**
- Hyperbaric oxygen therapy may be a useful adjunct.
- Negative pressure wound therapy is another possible adjunctive treatment.

**SURGERY/OTHER PROCEDURES**
Surgical drainage, minimizing dead space, adequate soft tissue coverage, restoration of blood supply, and removal of necrotic tissues improve cure rates.

**Pediatric Considerations**
Medullary osteomyelitis (stage 1) in children may be treated without surgical intervention (2)[B].

**ADMISSION, INPATIENT, AND NURSING**
CONSIDERATIONS
- Correct electrolyte imbalances, hyperglycemia, azotemia, and acidosis; control pain.
- Bed rest and immobilization of the involved bone and/or joint
- Discharge criteria: clinical and laboratory evidence of resolving infection and appropriate outpatient therapy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Blood levels of antimicrobial agents, ESR, CRP, and repeat plain radiography as clinical course dictates

PATIENT EDUCATION
Diabetic glycemic control and foot care

PROGNOSIS
- Superficial and medullary osteomyelitis treated with antimicrobial and surgical therapy have a response rate of 90–100%.
- Up to 36% recurrence rate in diabetics
- Increased mortality after amputation

COMPLICATIONS
- Abscess formation
- Bacteremia
- Fracture/nonunion
- Loosening of prosthetic implant
- Postoperative infection
- Sinus tract formation can be associated with neoplasms, especially in presence of long-standing infection.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- M86.9 Osteomyelitis, unspecified
- M86.00 Acute hematogenous osteomyelitis, unspecified site
- M86.10 Other acute osteomyelitis, unspecified site
CLINICAL PEARLS

- Hematogenous osteomyelitis is usually monomicrobial. Osteomyelitis due to contiguous spread or direct inoculation is usually polymicrobial.
- Pain associated with acute osteomyelitis typically is gradual in onset.
- Treatment of chronic osteomyelitis often requires both surgical débridement and at least 6 weeks of antimicrobial therapy.
OSTEOPOROSIS AND OSTEOPENIA

Adam Lyons, MD • Rahul Kapur, MD

BASICS

DESCRIPTION
A skeletal disease characterized by low bone mass, deterioration of bone tissue, and disruption of bone architecture that leads to compromised bone strength and an increased risk of fracture.

EPIDEMIOLOGY

- Most common bone disease in humans
- Predominant age: elderly >60 years of age
- Predominant sex: female > male (80%/20%)

Incidence
There is poor data on incidence of osteoporosis and osteopenia; however, there is an estimated 9 million fractures annually attributed to osteoporosis worldwide.

Prevalence
- >10.2 million Americans have osteoporosis.
- >43.4 million Americans have osteopenia.
- Women >50 years of age: osteoporosis 15.4% and osteopenia 51.4%
- Men >50 years of age: osteoporosis 4.3% and osteopenia 35.2%
- One in three women and one in five men will experience an osteoporotic fracture.

ETIOLOGY AND PATHOPHYSIOLOGY

- Imbalance between bone resorption and bone formation
- Aging
- Hypoestrogenemia

Genetics
- Familial predisposition
- More common in Caucasians and Asians than in African Americans and Hispanics
**RISK FACTORS**

- **Nonmodifiable**
  - Advanced age (>65 years)
  - Female gender and menopause
  - Caucasian or Asian
  - Family history of osteoporosis
  - History of atraumatic fracture

- **Modifiable**
  - Low body weight (58 kg or body mass index [BMI] <21)
  - Calcium/vitamin D deficiency
  - Inadequate physical activity
  - Cigarette smoking
  - Excessive alcohol intake (>3 drinks/day)
  - Medications: See “Commonly Associated Conditions.”

**GENERAL PREVENTION**

The aim in the prevention and treatment of osteoporosis is to prevent fracture:

- Regularly perform weight-bearing exercise.
- Consume a diet that includes adequate calcium (1,000 mg/day for men aged 50 to 70 years; 1,200 mg/day for women aged 51+ years and men 70+ years) and vitamin D (800 to 1,000 IU/day).

  **The USPSTF has concluded that vitamin D supplementation is effective in preventing falls in community-dwelling adults aged 65 years or older who are at increased risk for falls (1)[B].**

  **Evidence is insufficient to assess the balance of the benefits and harms of daily supplementation with >400 IU of vitamin D₃ and >1,000 mg of calcium for the primary prevention of fractures in noninstitutionalized postmenopausal women (1)[B].**

  **USPSTF recommends against daily supplementation with 400 IU or less of vitamin D₃ and 1,000 mg or less of calcium for the primary prevention of fractures in noninstitutionalized postmenopausal women (1)[B].**

- Avoid smoking.
- Limit alcohol consumption (<3 drinks/day).
- Fall prevention (vitamin D supplementation, home safety assessment, correction of visual impairment)
- Screen (USPSTF recommendations):
  - All women ≥65 years of age (1)[B]
  - Women >50 years of age with ≤10-year fracture risk (using the WHO’s
Fracture Risk Assessment [FRAX Tool] >9.3%
– The current evidence is insufficient to recommend screening for osteoporosis in men; however, the National Osteoporosis Foundation recommends screening men age >70 years, especially if at increased risk.

COMMONLY ASSOCIATED CONDITIONS
- Malabsorption syndromes: gastrectomy, inflammatory bowel disease, celiac disease
- Hypoestrogenism: menopause, hypogonadism, eating disorders, female athlete triad
- Endocrinopathies: hyperparathyroidism, hyperthyroidism, hypercortisolism, diabetes mellitus
- Hematologic disorders: hemophilia, sickle cell disease, multiple myeloma, thalassemia, hemochromatosis
- Other disorders: multiple sclerosis, end-stage renal disease, rheumatoid arthritis, lupus, chronic obstructive pulmonary disease (COPD), HIV/AIDS
- Medications: antiepileptics, aromatase inhibitors (raloxifene), chronic corticosteroids (>5-mg prednisone or equivalent for >3 months), medroxyprogesterone acetate, heparin, SSRI, thyroid hormone (in supraphysiologic doses), PPI

DIAGNOSIS
HISTORY
- Review modifiable and nonmodifiable risk factors.
- Online risk factor assessment tools are available:
  - FRAX: http://www.shef.ac.uk/FRAX/
- Assess for any commonly associated conditions.

PHYSICAL EXAM
- Thoracic kyphosis, poor balance, deconditioning
- Historical height loss >1.5 cm (difference between current height and peak height at age 20 years)
- Prospective height loss >2 cm (difference between current height and previously documented height)

DIFFERENTIAL DIAGNOSIS
- Multiple myeloma/other neoplasms
- Osteomalacia
- Type I collagen mutations
- Osteogenesis imperfecta

**DIAGNOSTIC TESTS & INTERPRETATION**

Dual energy x-ray absorptiometry (DEXA) of the lumbar spine/hip is considered the gold standard for the diagnosis of osteoporosis.

**Initial Tests (lab, imaging)**

Consider screening for secondary osteoporosis:

- Serum 25-hydroxyvitamin D and parathyroid hormone
- CBC
- Serum chemistry including calcium, phosphorus, magnesium, total protein, albumin, liver enzymes, creatinine, alkaline phosphatase, and TSH
- Urinalysis (24-hour collection) for calcium, sodium, and creatinine to identify calcium malabsorption of hypercalciuria
- DEXA of the lumbar spine/hip is the gold standard for measuring bone mineral density (BMD).
- A BMD at the hip or lumbar spine that is ≤2.5 standard deviations (SDs) below the mean BMD of a young-adult reference population is diagnostic of osteoporosis.
- A minimum of 2 years may be needed to reliably measure a change in BMD.
- BMD is expressed in terms of T-scores and Z-scores:
  - T-score is the number of SDs a patient’s BMD deviates from the mean for young, normal (age 25 to 40 years) control individuals of the same sex.
  - WHO defines normal BMD as a T-score ≥−1, osteopenia as a T-score between −1 and −2.5, and osteoporosis as a T-score ≤−2.5.
  - WHO thresholds can be used for postmenopausal women and men >50 years of age.
  - The Z-score is a comparison of the patient’s BMD with an age-matched population.
  - A Z-score <−2 should prompt evaluation for causes of secondary osteoporosis.
- Plain radiographs lack sensitivity to diagnose osteoporosis, but an abnormality (e.g., widened intervertebral spaces, rib fractures, vertebral compression fractures) should prompt evaluation.
Follow-Up Tests & Special Considerations
Further labs depending on initial evaluation, Z-score $\leq -2.5$ or lower, or young age
- Iron and ferritin (hemochromatosis)
- Testosterone levels (hypogonadism in men)
- Serum protein electrophoresis and free $\kappa$ and $\lambda$ light chains (multiple myeloma)
- Urinary-free cortisol (Cushing disease)
- Tissue transglutaminase antibodies (celiac disease)

Diagnostic Procedures/Other
Bone biopsy may be recommended for patients with bone disease and renal failure to establish the correct diagnosis as it can assess the degree of mineralization and microarchitecture and specific bone loss mechanisms.

Test Interpretation
- In osteoporosis, can see reduced skeletal mass; trabecular bone thinned or lost more than cortical bone
- Can assess osteoclast and osteoblast relative activity
- Can rule out other metabolic bone diseases
- Can assess if bone marrow is normal or atrophic

TREATMENT
- Criteria for patients who benefit from treatment for their osteoporosis includes:
  - All patients with a T-score $\leq -2.5$ with no risk factors
  - All postmenopausal women and men $>50$ years old who have had an osteoporotic vertebral/hip fracture
  - All postmenopausal women who have BMD values consistent with osteoporosis (T-score $\leq -2.5$) at the lumbar spine, femoral neck, or total hip region
  - Postmenopausal women and men $>50$ years old with T-scores from $-1.0$ to $-2.5$ and a 10-year risk, based on FRAX calculator of an osteoporotic fracture (spine, hip, shoulder, and wrist) of at least 20% or hip of at least 3%
  - All men $>50$ years of age who present with a hip or vertebral fracture or a T-score $<-2.5$ after appropriate evaluation; however, evidence for the
effectiveness of treatment of osteoporosis in men is limited.
- For osteopenia, treatment should only focus on risk modification: weight-bearing exercise, vitamin D supplementation (2,000–4,000 IU/day), limiting alcohol, and smoking cessation

MEDICATION
Vitamin D 2,000–4,000 IU/day

First Line
- Bisphosphonates: Mechanism is to become incorporated into skeletal tissue where they inhibit the resorption of bone by osteoclasts reducing the incidence of vertebral and nonvertebral fractures.
  - Alendronate 10 mg PO daily or 70 mg PO weekly
  - Risedronate 5 mg PO daily, 35 mg PO weekly, or 150 mg PO monthly
  - Zoledronic acid 5 mg IV yearly
- Zoledronic acid appeared to be the most effective in preventing vertebral and nonvertebral fracture in a 2016 meta-analysis (2).
- The side effects are similar for all bisphosphonates and include gastrointestinal problems such as difficulty swallowing and inflammation of the esophagus and stomach.
- Osteonecrosis of the jaw has been associated with bisphosphonates, particularly in patients with cancer who receive high doses and those who receive IV treatment (3).
- There is a possible risk of midfemur fractures in patients receiving bisphosphonates for >5 years (4).
- Avoid oral bisphosphonates in patients with
  - Delayed esophageal emptying
  - Inability to stand/sit upright for at least 30 to 60 minutes after taking the bisphosphonates
  - Hypocalcemia (correct prior to initiating therapy)
  - Severe renal impairment (creatinine clearance [CrCl] ≤30 for risedronate, and ≤35 mL/min for alendronate and zoledronic acid)

Second Line
- Denosumab: 60 mg SQ every 6 months
  - Human monoclonal antibody receptor activator of nuclear factor kappa-B ligand (RANKL) receptor
  - Inhibits osteoclast formation
Teriparatide 20 mg SC daily
- Recombinant formulation of PTH
- Works anabolically to stimulate the growth of bone through osteoblastic activation
- Studies have shown a reduction in the incidence of vertebral fractures by 65% and nonvertebral fractures by 53%.
- No data exist on its safety and efficacy after >2 years of use.

Estrogen 0.625 mg PO daily (with progesterone if patient has a uterus): effective in prevention and treatment of osteoporosis (34% reduction in hip and vertebral fractures after 5 years of use), but the risks (e.g., increased rates of myocardial infarction, stroke, breast cancer, pulmonary embolus, and deep vein thrombosis) must be weighed against the benefits

Raloxifene 60 mg PO daily is a selective estrogen receptor modulator with positive effects on BMD and vertebral fracture risk but no stimulatory actions on breasts/uterus. It can be considered in the treatment and prevention of osteoporosis in postmenopausal women with high risk for invasive breast cancer. Due to the risk of DVT, PE, or stroke (especially in postmenopausal women at risk for coronary heart disease), it must be weighed against the benefits (4).

Strontium 2 g PO daily
- Appears to inhibit bone resorption and increase bone formation
- Available for use in Europe

Calcitonin
- PTH antagonist that reduces osteoclastic activity, therefore decreasing bone turnover
- FDA-approved for treatment of osteoporosis in women who are at least 5 years postmenopausal when alternative treatments are not suitable
- Calcitonin reduces vertebral fracture occurrence in those with prior vertebral fracture.
- Associated with an increased risk for malignancy

ISSUES FOR REFERRAL
Endocrinology for recurrent bone loss/fracture

ADDITIONAL THERAPIES
- Weight-bearing exercise 30 minutes 3 times per week
- Counseling on fall prevention
- Smoking cessation
- Physical therapy to help with muscle strengthening
SURGERY/OTHER PROCEDURES
Options for patients with painful vertebral compression fractures failing medical treatment:

- **Vertebroplasty**: Orthopedic cement is injected into the compressed vertebral body.
- **Kyphoplasty**: A balloon is expanded within the compressed vertebral body to reconstruct volume of vertebrae. Cement is injected into the space.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Isoflavones not better than placebo for fracture risk
- Beneficial effect of Chinese herbal medicines in improving BMD is still uncertain.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Inpatient care for pain control of acute back pain secondary to new vertebral fractures and for acute treatment of femoral and pelvic fractures
- Rehabilitation, nursing home, or home care may be needed following hospitalization for fractures.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

*Patient Monitoring*

- Weight-bearing exercises such as walking, jogging, stair climbing, and tai chi, have been shown to decrease falls and fracture risk.
- Yearly height measurement is essential to determination of osteoporosis treatment efficacy. Patients who lose >2 cm in height should have repeat vertebral imaging to determine if any new vertebral fractures have occurred (2).
- Although there is no consensus, most recommendations suggest BMD testing by DEXA scanning retesting 2 years after starting bisphosphonate therapy.
- For many women, 3 to 5 years of treatment with a bisphosphonate is as good as 10 years of treatment.
A comprehensive risk assessment should be performed after 3 to 5 years of treatment. Those at high risk for vertebral fracture or with very low BMD may benefit by continuing treatment beyond 5 years.

Physicians prescribing bisphosphonates should advise patients of the small risk of osteonecrosis and encourage dental examinations (5).

**DIET**
- Diet to maintain normal body weight
- Calcium and vitamin D (see “General Prevention”)

**PATIENT EDUCATION**

**PROGNOSIS**
- With treatment, 80% of patients stabilize skeletal manifestations, increase bone mass and mobility, and have reduced pain.
- 15% of vertebral and 20–40% of hip fractures may lead to chronic care and/or premature death.

**COMPLICATIONS**
Severe, disabling pain and recurrent fractures

**REFERENCES**
CODES

ICD10

- M85.80 Other specified disorders of bone density and structure, unspecified site
- M81.0 Age-related osteoporosis w/o current pathological fracture
- M80.00XA Age-rel osteopor w current path fracture, unsp site, init

CLINICAL PEARLS

- Regular weight-bearing exercise from adolescence onward is recommended for prevention.
- Screen all women ≥65 years of age with DEXA scans.
- Premenopausal women with osteoporosis should be screened for secondary causes such as malabsorption syndromes, hyperparathyroidism, hyperthyroidism, and medication sensitivity.
- Evaluate and treat all patients presenting with fractures from minimal trauma.
- Bisphosphonates are first line for treatment of osteoporosis in most patients.
- For osteopenia, treat with counseling on fall prevention, weight-bearing exercise, diet high in calcium, vitamin D, limiting alcohol, and smoking cessation.
- If the patient is not responding to treatment, consider screening for a secondary, treatable cause of osteoporosis.
OTITIS EXTERNA
Douglas S. Parks, MD

BASICS

DESCRIPTION
Inflammation of the external auditory canal:
- Acute diffuse otitis externa: the most common form; an infectious process; usually bacterial; occasionally fungal (10%)
- Acute circumscribed otitis externa: synonymous with furuncle; associated with infection of the hair follicle, a superficial cellulitic form of otitis externa
- Chronic otitis externa: same as acute diffuse but of longer duration (>6 weeks)
- Eczematous otitis externa: may accompany typical atopic eczema or other primary skin conditions
- Necrotizing malignant otitis externa: an infection that extends into the deeper tissues adjacent to the canal; may include osteomyelitis and cellulitis; rare in children
- System(s) affected: skin/exocrine
- Synonym(s): swimmer’s ear

EPIDEMIOLOGY

Incidence
- Unknown; higher in the summer months and in warm, wet climates
- Predominant age: all ages
- Predominant sex: male = female

Prevalence
- Acute, chronic, and eczematous: common
- Necrotizing: uncommon

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute diffuse otitis externa
  - Traumatized external canal (e.g., from use of cotton swab)
  - Bacterial infection (90%): Pseudomonas (67%), Staphylococcus, Streptococcus, gram-negative rods
– Fungal infection (10%): Aspergillus (90%), Candida, Phycomycetes, Rhizopus, Actinomyces, Penicillium

● Chronic otitis externa: bacterial infection: Pseudomonas

● Eczematous otitis externa (associated with primary skin disorder)
  – Eczema
  – Seborrhea
  – Psoriasis
  – Neurodermatitis
  – Contact dermatitis
  – Purulent otitis media
  – Sensitivity to topical medications

● Necrotizing otitis externa
  – Invasive bacterial infection: Pseudomonas, increasing incidence of methicillin-resistant Staphylococcus aureus (MRSA)
  – Associated with immunosuppression

RISK FACTORS

● Acute and chronic otitis externa
  – Traumatization of external canal
  – Swimming
  – Hot, humid weather
  – Hearing aid use

● Eczematous: primary skin disorder

● Necrotizing otitis externa in adults
  – Advanced age
  – Diabetes mellitus (DM)
  – Debilitating disease
  – AIDS
  – Immunosuppression

● Necrotizing otitis externa in children (rare)
  – Leukopenia
  – Malnutrition
  – DM
  – Diabetes insipidus

GENERAL PREVENTION

● Avoid prolonged exposure to moisture.

● Use preventive antiseptics (acidifying solutions with 2% acetic acid [white vinegar] diluted 50/50 with water or isopropyl alcohol, or 2% acetic acid with
aluminum acetate [less irritating]) after swimming and bathing.
- Treat predisposing skin conditions.
- Eliminate self-inflicted trauma to canal with cotton swabs and other foreign objects.
- Diagnose and treat underlying systemic conditions.
- Use ear plugs when swimming.

**DIAGNOSIS**

**HISTORY**
Variable-length history of itching, plugging of ear, ear pain, and discharge from ear

**PHYSICAL EXAM**
- Ear canal: red, containing purulent discharge and debris
- Pain on manipulation of the pinnae
- Possible periauricular adenitis
- Possible eczema of pinna
- Cranial nerve (VII, IX to XII) involvement (extremely rare)

**DIFFERENTIAL DIAGNOSIS**
- Idiopathic ear pain
- Otitis media with perforation
- Hearing loss
- Cranial nerve (VII, IX to XII) palsy with necrotizing otitis externa
- Wisdom tooth eruption
- Basal cell or squamous cell carcinoma

**DIAGNOSTIC TESTS & INTERPRETATION**
- Gram stain and culture of canal discharge (occasionally helpful)
- Antibiotic pretreatment may affect results.
- Radiologic evaluation of deep tissues in necrotizing otitis externa with high-resolution CT scan, MRI, gallium scan, and bone scan

**Test Interpretation**
- Acute and chronic otitis externa: desquamation of superficial epithelium of external canal with infection
- Eczematous otitis externa: pathologic findings consistent with primary skin disorder; secondary infection on occasion
- Necrotizing otitis externa: vasculitis, thrombosis, and necrosis of involved tissues; osteomyelitis

## TREATMENT

Outpatient treatment, except for resistant cases and necrotizing otitis externa

### GENERAL MEASURES

- Cleaning the external canal may facilitate recovery.
- Analgesics as appropriate for pain
- Antipruritic and antihistamines (eczematous form)
- Ear wick (Pope) for nearly occluded ear canal

### MEDICATION

- Trial data is of generally poor quality and may not be fully relevant to primary care settings (1)[A].
- Resistance is an increasing problem. *Pseudomonas* is the most common bacteria, and it is more susceptible to fluoroquinolones such as ciprofloxacin or ofloxacin, whereas *Staphylococcus* is equally susceptible to both fluoroquinolones and polymyxin B combinations (2)[B]. If a patient has recurring episodes or is not improved in 2 weeks, change the class of antibacterial and consider cultures and sensitivities.
- There is evidence that using of a topical antibiotic with a corticosteroid shortens time to symptom resolution, although there is no evidence that it increases overall cure rate. There is not enough evidence to demonstrate that any antibiotic regimen is clearly superior to any other (3)[B],(4)[A].
- Oral antibiotics are indicated only if there is associated otitis media. Oral antibiotics alone are not effective and markedly increase the risk of progressing to chronic otitis externa.
- Analgesics as needed; narcotics may be necessary. Recurrent otitis externa may be prevented by applying equal parts white vinegar and isopropyl alcohol (over-the-counter [OTC] rubbing alcohol) to external auditory canals after bathing and swimming.

### First Line

- Acute bacterial and chronic otitis externa
- Ciprofloxacin 0.3% and dexamethasone 0.1% suspension (expensive as brand): 4 drops BID for 7 days or ofloxacin 0.3% solution (inexpensive generic): 10 drops once a day for 7 days \( (1)[A] \); less ototoxicity and reported antibiotic resistance \( (5)[A] \)

- Neomycin/polymyxin B/hydrocortisone (Cortisporin, generics): 5 drops QID. If the tympanic membrane is ruptured, use the suspension; otherwise, the solution may be used; may be ototoxic and resistance-developing in \textit{Staphylococcus} and \textit{Streptococcus} sp.; not expensive

- Acetic acid 2% with hydrocortisone 1%: 3 to 5 drops q4–6h for 7 days; may cause minor local stinging. An inexpensive generic. This is as effective as neomycin–polymyxin B. It may take up to 2 days longer to achieve resolution of symptoms \( (3)[A] \). A wick may be helpful in severe cases by keeping the canal open and keeping antibiotic solution in contact with infected skin.

- \textbf{Fungal otitis externa}
  - Topical therapy, antiyeast for \textit{Candida} or yeast: 2% acetic acid 3 to 4 drops QID; clotrimazole 1% solution; itraconazole oral
  - Parenteral antifungal therapy: amphotericin B
  - Patients with Ramsay-Hunt syndrome: acyclovir IV

- \textbf{Eczematous otitis externa: topical therapy}
  - Acetic acid 2% in aluminum acetate
  - Aluminum acetate (5%; Burow solution)
  - Steroid cream, lotion, ointment (e.g., triamcinolone 0.1% solution)
  - Antibacterial, if superinfected

- \textbf{Necrotizing otitis externa}
  - Parenteral antibiotics: antistaphylococcal and antipseudomonal
  - 4 to 6 weeks of therapy
  - Fluoroquinolones PO for 2 to 4 weeks

\textbf{Second Line}

- \textbf{Acute bacterial and chronic otitis externa}
  - Betamethasone 0.05% solution may be as effective as a polymyxin B combination without the risk of ototoxicity or antibiotic resistance. However, the data are not very robust, and more study is needed \( (3)[A] \).

- Azole antifungals for fungal otitis externa

\textbf{ISSUES FOR REFERRAL}

Resistant cases or those requiring surgical intervention
SURGERY/OTHER PROCEDURES
For necrotizing otitis externa or furuncle

COMPLEMENTARY & ALTERNATIVE MEDICINE
- OTC white vinegar; 3 drops in affected ear for minor case
- Tea tree oil in various concentrations has been used as an antiseptic. Ototoxicity has been reported in animal studies at very high doses (6)[C].
- Grapefruit seed extract in various concentrations has been described as useful in the lay literature.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization: necrotizing otitis media requiring parenteral antipseudomonal antibiotics
- Discharge criteria: resolution of infection

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
No restrictions

Patient Monitoring
- Acute otitis externa
  - 48 hours after therapy instituted to assess improvement
  - At the end of treatment
- Chronic otitis externa
  - Every 2 to 3 weeks for repeated cleansing of canal
  - May require alterations in topical medication, including antibiotics and steroids
- Necrotizing otitis externa
  - Daily monitoring in hospital for extension of infection
  - Baseline auditory and vestibular testing at beginning and end of therapy

DIET
No restrictions
PROGNOSIS

- Acute otitis externa: rapid response to therapy with total resolution
- Chronic otitis externa: With repeated cleansing and antibiotic therapy, most cases will resolve. Occasionally, surgical intervention is required for resistant cases.
- Eczematous otitis externa: Resolution will occur with control of the primary skin condition.
- Necrotizing otitis externa: usually can be managed with débridement and antipseudomonal antibiotics; recurrence rate is 100% when treatment is inadequate. Surgical intervention may be necessary in resistant cases or if there is cranial nerve involvement. Mortality rate is significant, probably secondary to the underlying disease (7)[C].

COMPLICATIONS

- Mainly a problem with necrotizing otitis externa; may spread to infect contiguous bone and CNS structures
- Acute otitis externa may spread to pinna, causing chondritis.

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Ear Pain/Otalgia

**CODES**

**ICD10**

- H60.90 Unspecified otitis externa, unspecified ear
- H60.339 Swimmer’s ear, unspecified ear
- H60.509 Unsp acute noninfective otitis externa, unspecified ear

**CLINICAL PEARLS**

- Acute diffuse otitis externa is the most common form: bacterial (90%), occasionally fungal (10%).
- Acute circumscribed otitis externa is associated with infection of a hair follicle.
- Chronic otitis externa is the same as acute diffuse but of longer duration (>6 weeks).
- Eczematous otitis externa may accompany typical atopic eczema or other primary skin conditions.
- Necrotizing malignant otitis externa is an infection that extends into the deeper tissues adjacent to the canal. It may include osteomyelitis and cellulitis; it is rare in children.
OTITIS MEDIA
Paul George, MD

BASICS

DESCRIPTION

- Inflammation of the middle ear; usually accompanied by fluid collection
- Acute otitis media (AOM): inflammation of the middle ear. Rapid onset; cause may be infectious, either viral (AOM-v) or bacterial (AOM-b), but there is also a sterile etiology (AOM-s).
- Recurrent AOM: ≥3 episodes in 6 months or ≥4 episodes in 1 year with ≥1 in the past 6 months
- Otitis media with effusion (OME): fluid in the middle ear without signs or symptoms of infection
- Chronic otitis media with or without cholesteatoma
- System(s) affected: nervous, ENT
- Synonym(s): secretory or serous otitis media

EPIDEMIOLOGY

Incidence

- AOM
  - Predominant age: 6 to 24 months; declines >7 years; rare in adults
  - Predominant gender: male > female
  - By age 7 years, 93% of children have had ≥1 episodes of AOM; 39% have had ≥6.
  - Placement of tympanostomy tubes is second only to circumcision as the most frequent surgical procedure in infants.
  - Increased incidence in the fall and winter
- OME
  - By age 4 years, 90% of children have had at least one episode.

Prevalence

- Most common infection for which antibacterial agents are prescribed in the United States
- Diagnosed 5 million times per year in the United States
ETIOLOGY AND PATHOPHYSIOLOGY

- AOM-b (bacterial): Usually, a preceding viral upper respiratory infection (URI) produces eustachian tube dysfunction.
  - *Streptococcus pneumoniae*: 20–35%, *Haemophilus influenzae*: 20–30%, *Moraxella (B.) catarrhalis*: 15%, group A streptococci: 3%, *Staphylococcus aureus*: 12% produce β-lactamases that hydrolyze amoxicillin and some cephalosporins.
- AOM-v (viral): 15–44% of AOM infections are caused primarily by viruses (e.g., respiratory syncytial virus, parainfluenza, influenza, enteroviruses, adenovirus, human metapneumovirus, and parechovirus).
- AOM-s (sterile/nonpathogens): 25–30%
- OME: eustachian tube dysfunction; allergic causes are rarely substantiated.

Genetics

- Strong genetic component in twin studies for recurrent and prolonged AOM
- May be influenced by skull configuration or immunologic defects

RISK FACTORS

- Age
- Bottlefeeding while supine
- Routine daycare attendance
- Frequent pacifier use after 6 months of age
- Environmental smoke exposure
- Male gender
- Absence of breastfeeding
- Low socioeconomic status
- Family history of recurrent otitis
- AOM before age 1 year is a risk for recurrent AOM.
- Presence of siblings in the household
- Underlying ENT disease (e.g., cleft palate, Down syndrome, allergic rhinitis)

GENERAL PREVENTION

- Pneumococcal vaccine (PCV)-7 immunization reduces the number of cases of AOM by about 6–28% (however, evidence shows that this is offset by an increase in AOM caused by other bacteria). The effect of the introduction of the PCV-13 vaccine on the incidence of AOM has yet to be studied.
- Influenza vaccine reduces AOM.
- Breastfeeding for ≥6 months is protective.
Avoiding supine bottlefeeding, passive smoke, and pacifiers >6 months may be helpful.
Secondary prevention: Adenoidectomy and adenotonsillectomy for recurrent AOM have limited short-term efficacy and are associated with their own adverse risks.
Vitamin D supplementation (1,000 IU/day to maintain vitamin D levels >30) may be helpful in reducing recurrent AOM, but further trials are needed.

COMMONLY ASSOCIATED CONDITIONS

URI

DIAGNOSIS

HISTORY

- AOM: acute history, signs, and symptoms of middle ear inflammation and effusion
  - Earache
  - Preceding or accompanying URI symptoms
  - Decreased hearing
- In adults, earache without fever or hearing loss may be the only presenting feature.

ALERT

- AOM in infants and toddlers:
  - May cause few symptoms in the first few months of life
  - Irritability may be the only symptom.
- OME: usually asymptomatic
  - Decreased hearing

PHYSICAL EXAM

- Infectious AOM:
  - Fever (not required for diagnosis)
  - Decreased eardrum mobility (with pneumatic otoscopy)
  - Moderate to severe bulging of tympanic membrane
  - Otorrhea
  - Redness alone is not a reliable sign.
- OME:
– Eardrum often dull but not bulging
– Decreased eardrum mobility (pneumatic otoscopy)
– Presence of air-fluid level
– Weber test is positive to affected ear for an ear with effusion.

DIFFERENTIAL DIAGNOSIS

- Tympanosclerosis
- Trauma
- Referred pain from the jaw, teeth, or throat
- TMJ in adults
- Otitis externa
- Otitis-conjunctivitis syndrome
- Temporal arteritis in adults

DIAGNOSTIC TESTS & INTERPRETATION

**Initial Tests (lab, imaging)**

WBC count may be higher in bacterial AOM than in sterile AOM, but this is almost never useful.

**Diagnostic Procedures/Other**

- To document the presence of middle ear fluid, pneumatic otoscopy can be supplemented with tympanometry and acoustic reflex measurement.
- Hearing testing is recommended when hearing loss persists for ≥3 months or at any time suspecting language delay, significant hearing loss, or learning problems.
- Language testing should be performed for children with hearing loss.
- Tympanocentesis for microbiologic diagnosis is recommended for treatment failures; may be followed by myringotomy

**TREATMENT**

- Significant disagreement exists about the usefulness of antibiotic treatment for this often self-resolving condition. Studies suggest that ~15 children need to be treated with antibiotics to prevent one case of persisting AOM pain at 1 to 2 weeks; the number needed to treat to cause harm (primarily diarrhea) is 8 to 10.
- If antibiotics are not used, 81% of patients >2 years of age are better in 1 week
versus 94% if antibiotics are used.

- Delay of antibiotics found a modest increase in mastoiditis from 2/100,000 to 4/100,000.

American Academy of Pediatrics/American Academy of Family Physicians (AAP/AAFP) guidelines recommend the following for observation versus antibacterial therapy, although these guidelines are not rigorously evidence based:
- <6 months of age: no recommendation (2004 guidelines suggest treatment with antibiotic therapy to any child diagnosed with otitis media <6 months of age)
- >6 months: Antibacterial therapy is recommended when the diagnosis with severe otitis media (i.e., moderate to severe otalgia or fever ≥39°C in the previous 24 hours) or otorrhea or bilateral otitis media between 6 months and 2 years of age.
- Observation is an option with nonsevere otitis media.

OME: Watchful waiting for 3 months per AAP/AFPP guidelines for those not at risk (see “Complications”). Of these cases, 25–90% will recover spontaneously over this period; no benefit of antihistamines or decongestants or systemic steroids (1)[A], nor significant net benefit for antibiotics (2)[A]

**GENERAL MEASURES**

- Assess pain.
- Although unusual in adults, the treatment is the same.
- Acetaminophen, ibuprofen, benzocaine drops (additional but brief benefit over acetaminophen)

**MEDICATION**

**First Line**

- AOM: AAP/AAFP consensus guideline recommends amoxicillin, 80 to 90 mg/kg/day in 2 divided doses (3)[A] or
- Amoxicillin-clavulanate 90 mg/kg/day of amoxicillin, with 6.4 mg/kg/day of clavulanate in 2 divided doses; recommended in children who have taken amoxicillin in the previous 30 days and those with concurrent conjunctivitis or history of AOM unresponsive to amoxicillin
- Treatment duration: 10-day course for children <2 years; 7-day course for children 2 to 5 years; 5- to 7-day course for children 6 years and older
- If penicillin allergic:
  - Non–type 1 hypersensitivity reaction: cefdinir, 14 mg/kg/day in 1 to 2
doses; cefpodoxime, 10 mg/kg/day BID; or cefuroxime 30 mg/kg/day BID
- Type 1 hypersensitivity to penicillin: azithromycin (10 mg/kg/day [max
dose 500 mg/day] as a single dose on day 1 and 5 mg/kg/day [max dose 250
mg/day] for days 2 to 5)
- A single dose of parenteral ceftriaxone (50 mg/kg) is as effective as a full
course of antibiotics in uncomplicated AOM.
- A single dose of azithromycin has been approved by the FDA, but studies did
not include otitis-prone children or have criteria for AOM diagnosis.
- Consider treatment of children between ages 6 months and 2 years with
antibiotics to reduce duration of symptoms (4)[A].
- OME: See “General Measures”; no benefit to treatment. Medications promote
transitory resolution in 10–15%, but the effect is short-lived.

**Second Line**
- Alternative antibiotics are indicated for the following AOM patients:
  - Persistent symptoms after 48 to 72 hours of amoxicillin
  - AOM within 1 month of amoxicillin therapy
  - Severe earache
  - Age <6 months with high fever
  - Immunocompromised
    - Amoxicillin-clavulanate, 90 mg/kg to 6.4 mg/kg/day, divided BID
    - Ceftriaxone, 50 mg/kg IM or IV q24h for 3 consecutive days can be
      reserved for those who are too sick to take oral medications or who
      unsuccessfully took amoxicillin-clavulanate. Neither erythromycin-
sulfisoxazole nor trimethoprim-sulfamethoxazole should be used as a
second-line agent in treatment failures.
- Recurrent AOM: Antibiotic prophylaxis for recurrent AOM (>3 distinct, well-
documented episodes in 6 months) is not recommended.

**SURGERY/OTHER PROCEDURES**
- Recurrent AOM: Consider referral for surgery if ≥3 episodes of well-
documented AOM within 6 months, ≥4 episodes within 12 months with ≥ 1
episode in previous 6 months, or AOM episodes occur while on
chemoprophylaxis.
- Tympanostomy tubes may be effective in selective patients, particularly
children age <2 years with recurrent AOM (5)[A].
- Adenoidectomy has limited or no effect.
- Adenotonsillectomy reduced the rate of AOM by 0.7 episode per child only in
the 1st year after surgery and had a 15% complications rate.

- OME: Referral for surgery for tympanostomy should be individualized. It can be considered if >4 to 6 months of bilateral OME and/or >6 months of unilateral OME and/or hearing loss >25 dB or for high-risk individuals at any time.

- Tympanostomy tubes may reduce recurrence of AOM minimally, but it does not lower the risk of hearing loss (6)[A].

- Adenoidectomy is indicated in specific cases; tonsillectomy or myringotomy is never indicated.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- It is unclear whether alternative and homeopathic therapies are effective for AOM, including mixed evidence about the effectiveness of zinc supplementation of reducing AOM.

- Xylitol, probiotics, herbal ear drops, and homeopathic interventions may be beneficial in reducing pain duration, antibiotic use, and bacterial resistance.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Outpatient, except if surgery is indicated, or for AOM in febrile infants age <2 months or children requiring ceftriaxone who also require monitoring for 24 hours

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patients with otitis media who do not respond within 48 to 72 hours should be reevaluated:

- If therapy was delayed and diagnosis is confirmed, start therapy with high-dose amoxicillin.

- If therapy was initiated, consider changing the antibiotic; options are limited because macrolides have limited benefit against *H. influenzae* over amoxicillin, and most oral cephalosporins have no improved outcomes.

*Patient Monitoring*
- AOM: Up to 40% may have persistent middle ear effusion at 1 month, with 10–25% at 3 months.
- OME: Repeat otoscopic or tympanometric exams at 3 months, as indicated, as long as OME persists or sooner if there are red flags (see earlier discussion).

**PROGNOSIS**
- See “General Measures.”
- Recurrent AOM and OME: usually subsides in school-aged children; few have complications.

**COMPLICATIONS**
- AOM: Serious complications are rare: tympanic membrane perforation/otorrhea, acute mastoiditis, facial nerve paralysis, otitic hydrocephalus, meningitis, hearing impairment.
- OME: Speech and language disabilities may occur. Hearing loss is not caused by OME, but in children who are at risk for speech, language, or learning problems (e.g., autism spectrum, syndromes, craniofacial disorders, developmental delay, and children already with speech/language delay); it could lead to further problems because they are less tolerant of a hearing impairment.
- Recurrent AOM and OME: atrophy and scarring of eardrum, chronic perforation and otorrhea, cholesteatoma, permanent hearing loss, chronic mastoiditis, other intracranial suppurative complications
- For chronic suppurative otitis media with a perforated tympanic membrane, and acute otitis media in patients with tympanostomy tubes, topical quinolones (ciprofloxin, ofloxacin) are non-inferior to other treatments.

ADDITIONAL READING

SEE ALSO

Algorithm: Ear Pain/Otalgia

CODES

ICD10

- H66.90 Otitis media, unspecified, unspecified ear
- H66.40 Suppurative otitis media, unspecified, unspecified ear
- H65.199 Other acute nonsuppurative otitis media, unspecified ear

CLINICAL PEARLS

- Pneumatic otoscopy is the single most specific and clinically useful test for diagnosis.
- Consider a delay of antibiotics for 24 to 48 hours in uncomplicated presentations (>6 months of age) who do not have severe illness or otorhea.
- First-line treatment is amoxicillin, 80 to 90 mg/kg/day for 10 days for children age <2 years; consider a 5- to 7-day course in >2 years of age.
- Erythema and effusion can persist for weeks.
- Antibiotics, antihistamines, and steroids are not indicated for OME.
- OME rarely develops in adults. Persistent unilateral effusion should be investigated to rule out neoplasm, particularly if there is a cranial nerve palsy.
OTITIS MEDIA WITH EFFUSION
Hobart Lee, MD, FAAFP

BASICS

DESCRIPTION
- Also called serous otitis media, secretory otitis media, nonsuppurative otitis media, “ear fluid,” or “glue ear”
- Otitis media with effusion (OME) is defined as the presence of fluid in the middle ear in the absence of acute signs or symptoms of infection.
- More commonly, a pediatric disease
- May occur spontaneously from poor eustachian tube function or as an inflammatory response after acute otitis media (AOM)

EPIDEMIOLOGY

Incidence
Approximately 90% of children have OME before school age, mostly between the ages of 6 months and 4 years.

Prevalence
- Approximately 2.2 million new cases annually in the United States
- Less prevalent in adults and is usually associated with an underlying disorder

ETIOLOGY AND PATHOPHYSIOLOGY
- Chronic inflammatory condition where an underlying stimulus causes an inflammatory reaction with increased mucin production creating a functional blockage of the eustachian tube and thick accumulation of mucin-rich middle ear effusion
- Young children are more prone to OME due to shorter and more horizontal eustachian tubes, which become more vertical around 7 years of age.
- Biofilms, anatomic variations, and AOM caused by viruses or bacteria have been implicated as stimuli causing OME. The common pathogens causing AOM include nontypeable Haemophilus influenzae, Streptococcus pneumoniae, and Moraxella catarrhalis.
- In adults, OME is often associated with paranasal sinus disease (66%), smoking-induced nasopharyngeal lymphoid hyperplasia and adult onset
adenoidal hypertrophy (19%), or head and neck tumors (4.8%).

**RISK FACTORS**
- Risk factors include a family history of OME, early daycare, exposure to cigarette smoke, bottlefeeding, and low socioeconomic status (1).
- Eustachian tube dysfunction may be a predisposing factor, although the evidence is unclear (2).
- Gastroesophageal reflux is associated with OME (2).

**GENERAL PREVENTION**
OME is generally not preventable, although lowering smoke exposure, breastfeeding, and avoiding daycare centers at an early age may decrease the risk.

**DIAGNOSIS**

**HISTORY**
- OME is transient and asymptomatic in many pediatric patients.
- Most common reported symptom is hearing loss (2). There may be mild discomfort present in the ear, fullness, or “popping.”
- Infants may have ear rubbing, excessive irritability, sleep problems, or failure to respond appropriately to voices or sounds.
- Clinical features may include “a history of hearing difficulties, poor attention, behavioral problems, delayed speech and language development, clumsiness, and poor balance” (2).
- There may be a history of recent or recurrent episodes of AOM or a recent upper respiratory tract infection (2).

**PHYSICAL EXAM**
- Cloudy tympanic membrane (TM) with distinctly impaired mobility. Air-fluid level or bubble may be visible in the middle ear (1,2).
- Color may be abnormal (yellow, amber, or blue), and the TM may be retracted or concave (2).
- Distinct redness of the TM may be present in approximately 5% of OME cases (1).
- Clinical signs and symptoms of acute illness should be absent in patients with OME (1).
DIFFERENTIAL DIAGNOSIS
- AOM
- Bullous myringitis
- Tympanosclerosis (may cause decreased/absent motion of the TM)
- Sensorineural hearing loss

DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other
- The primary standard to make the diagnosis is pneumatic otoscopy, which demonstrates reduced/absent mobility of the TM secondary to fluid in the middle ear. Pneumatic otoscopy has 94% sensitivity and 80% specificity for diagnosing OME. Accuracy of diagnosis with an experienced examiner is between 70% and 79% (1)[C].
- Myringotomy is the gold standard but is not practical for clinical use (2)[C].
- Tympanometry may also be used to support or exclude the diagnosis in infants >4 months old, especially when the presence of middle ear effusion is difficult to determine (1)[C].
- Acoustic reflectometry (64% specificity and 80% sensitivity) may be considered instead of tympanometry (3)[B].
- Audiogram may show mild conductive hearing loss (2)[C].
- Hearing tests are recommended for OME lasting >3 months (1)[C].
- Language testing is recommended for children with abnormal hearing tests (1)[C].

TREATMENT
- OME improves or resolves without medical intervention in most patients within 3 months, especially if secondary to AOM (1)[C].
- Current guidelines support a 3-month period of observation with optional serial exams, tympanometry, and language assessment during that wait time (1,2)[C].
- Adults found to have OME should be screened for an underlying disorder and treated accordingly (2)[C].

MEDICATION
- The 2016 AAOHNS guideline and a 2012 Cochrane review recommend against routine use of antibiotics in treatment of OME. No long-term benefits
of antibiotics have been proven, and often, prescribed antibiotics have adverse side effects such as diarrhea, vomiting, rashes, and allergic reactions (1)[C], (4)[A].

The 2016 AAOHNS and a 2006 Cochrane review found that antihistamines and decongestants have no benefit over placebo in the treatment of OME with possible adverse side effects such as insomnia, hyperactivity, and drowsiness (4)[A].

The 2016 AAOHNS guideline recommends against administering oral or intranasal corticosteroids. No long-term benefit was shown and adverse side effects such as weight gain and behavioral changes are possible (1)[C].

In adults, eustachian tube dysfunction secondary to allergic rhinitis or recent upper respiratory infection can be the cause of OME. It is unknown whether decongestants, antihistamines, or nasal steroids improve outcomes in adults.

**ISSUES FOR REFERRAL**
The following are indications for referral to a surgeon for evaluation of tympanostomy tube placement (5)[C]:

- Chronic bilateral OME (≥3 months) with hearing difficulty
- Chronic OME with symptoms (e.g., vestibular problems, poor school performance, behavioral issues, ear discomfort, or reduced quality of life)
- At-risk children (speech, language, or learning problems due to baseline sensory, physical, cognitive, or behavioral factors) with chronic OME or type B (flat) tympanogram

**ADDITIONAL THERAPIES**

- Hearing aids may be an acceptable alternative to surgery (2)[C].
- Autoinflation, which refers to the process of opening the eustachian tube by raising intranasal pressure (e.g., by forced exhalation with closed mouth and nose), may be beneficial in improving patients’ tympanogram or audiometry and quality of life scores (5)[A].

**SURGERY/OTHER PROCEDURES**

- Tympanostomy tubes are recommended as initial surgery. Risks include purulent otorrhea, myringosclerosis, retraction pockets, and persistent TM perforations (1)[C].
- Adenoidectomy with myringotomy has similar efficacy to tympanostomy tubes in children >4 years of age but with added surgical and anesthetic risks (1)[C].
Adenoidectomy should not be performed in children with persistent OME alone unless there is a distinct indication for the procedure for another problem (e.g., adenoiditis/chronic sinusitis/nasal obstruction) (1,5)[C].

Adenoidectomy (and concurrent tube placement) may be considered when repeat surgery for OME is necessary (e.g., when effusion recurs after tubes have fallen out or are removed). In these cases, adenoidectomy has been shown to decrease the need for future procedures for OME (1,2)[C].

Tonsillectomy or myringotomy alone is not recommended for treatment (1)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Children who are at risk for developmental difficulties should be evaluated for OME at the time of diagnosis and at 12 to 18 months (if initial diagnosis occurred younger than 12 months). At-risk conditions include: permanent hearing loss independent of OME, suspected or confirmed speech and language delay, autism spectrum disorder or other pervasive developmental disorder, Down syndrome or other craniofacial disorder, blindness or other uncorrectable visual impairment, cleft palate, unspecified developmental delay (1)[C].
- For patients diagnosed with OME, reevaluation and repeat hearing tests should be performed every 3 to 6 months until the effusion has resolved or until the child develops an indication for surgical referral (1)[C].

**PROGNOSIS**

Approximately 50% of children >3 years of age have OME resolution within 3 months.

**COMPLICATIONS**

- The most significant complication of OME is permanent hearing loss, leading to possible language, speech, and developmental delays.
- Underventilation of the middle ear can cause a cholesteatoma (1)[C].

**REFERENCES**

mebooksfree.com

ADDITIONAL READING

CODES
ICD10
- H65.90 Unspecified nonsuppurative otitis media, unspecified ear
- H65.00 Acute serous otitis media, unspecified ear
- H65.20 Chronic serous otitis media, unspecified ear

CLINICAL PEARLS
- OME is defined as the presence of a middle ear effusion in the absence of acute signs of infection.
- In children, OME most often arises following an AOM. In adults, it often occurs in association with eustachian tube dysfunction.
- The primary standard for diagnosis is pneumatic otoscopy.
- There is no benefit to the routine use of antibiotics, antihistamines, decongestants, or corticosteroids for the treatment of OME in children.
- Management includes watchful waiting and surgery (when indicated); which strategy is chosen depends on many factors, including the risk/presence of any associated speech, language, or learning delays, and on the severity of any associated hearing loss.
OVARIAN CANCER

Nidha Mattappally, MD • Susan Zweizig, MD

BASICS

There are >22,000 new cases of ovarian cancer annually in the United States, and approximately 14,000 women will die of their disease, making this the most lethal of gynecologic cancers. This accounts for 2.3% of all cancer deaths nationally.

DESCRIPTION

Malignancy that arises from the epithelium (90–95%), sex cord-stroma, or germ cells of the ovary as well as tumors metastatic to the ovary. Histologic types include the following:

- **Epithelial**
  - High grade serous (most common, 70–80%)
  - Low grade serous
  - Mucinous
  - Endometrioid
  - Clear cell
  - Malignant Brenner tumor (transitional cell epithelium)
  - Carcinosarcoma (malignant mixed müllerian tumor)

- **Sex cord-stromal**
  - Granulosa cell tumor
  - Sertoli–Leydig cell tumors
  - Lipid (steroid) cell tumor
  - Fibrosarcoma

- **Germ cell**
  - Teratoma (immature)
  - Dysgerminoma
  - Embryonal carcinoma
  - Endodermal sinus tumor (yolk sac tumor)
  - Choriocarcinoma

- **Metastatic disease from the following:**
  - GI tract (Krukenberg tumor)
  - Breast
– Endometrium
– Lymphoma
• System(s) affected: GI, genitourinary, endocrine

EPIDEMIOLOGY

Incidence
• 22,440 new cases/year in the United States; 14,080 deaths/year
• Leading cause of gynecologic cancer death in women
• Majority of ovarian cancer is diagnosed at an advanced stage.
• Average age of diagnosis
  – Epithelial: 63 years
  – Sex cord-stromal: 50 years
  – Germ cell: 10 to 30 years

Prevalence
Lifetime risk for general population: 1 in 78 American women develop ovarian cancer.

ETIOLOGY AND PATHOPHYSIOLOGY

• Malignant transformation of the ovarian epithelium may result from repeated trauma and inflammation during ovulation.
• Ovarian, fallopian tube, and primary peritoneal carcinomas have identical histologic and morphologic features. A higher percentage of ovarian cancers are now known to originate in the fallopian tube and other components of the secondary müllerian system, including primary peritoneal cancers.

Genetics
• Hereditary breast/ovarian cancer syndrome: early-onset breast or ovarian cancer, autosomal dominant transmission with variable penetrance, usually associated with BRCA-1 or BRCA-2 (tumor suppressor gene) mutation
• Lynch syndrome: autosomal dominant inheritance; increased risk for colorectal, endometrial, stomach, small bowel, breast, pancreas, and ovarian cancers; defect in DNA mismatch repair genes

RISK FACTORS
• 90% of ovarian cancer is sporadic and not inherited, but family history is the most significant risk factor. Multiple relatives with breast or ovarian cancer increases risk: Refer these patients for genetic counseling. Individuals in
families with familial cancer syndromes have 20–60% risk of developing ovarian cancer.

- Risk factors: older age, white race, infertility, nulligravidity, early menarche or late menopause, endometriosis, postmenopausal estrogen replacement therapy, residence in an industrialized Western country (i.e., North America, Northern Europe)
- Association between fertility medications and risk of ovarian cancer is controversial, but women with infertility who have a successful live birth do not have an increased risk of ovarian cancer.

**GENERAL PREVENTION**

- Use of oral contraceptives: 5 years of use decreases risk by 20%; 15 years of use decreases risk by 50% (1)[A]
- Multiparity
- Breastfeeding
- Tubal ligation or hysterectomy
- Risk-reducing salpingo-oophorectomy
- Protective effect of aspirin and NSAIDs in ovarian cancer is controversial.

**Recommendations for high-risk (family history of a hereditary ovarian cancer syndrome) population (2)[A]**

- Women should undergo pelvic examinations, CA-125 level measurement, and transvaginal US every 6 to 12 months beginning at age 30 or 10 years prior to the earliest age of diagnosis of ovarian cancer in the family.
- Women with family histories of ovarian cancer or premenopausal breast cancer should be referred for genetic counseling.
- Prophylactic oophorectomy is advised for mutation carriers after childbearing is completed or by age 35 years.
  - Risk of primary peritoneal carcinoma remains 1–2% after prophylactic oophorectomy.

**Screening:** No effective screening exists for ovarian cancer in the general population (2)[A].

- Routine use of CA-125 and transvaginal US for screening in women of average risk is NOT recommended. Annual pelvic examinations may be performed, particularly in postmenopausal women. An adnexal mass in a premenarchal female or a palpable adnexa in a postmenopausal female warrants further evaluation.

**COMMONLY ASSOCIATED CONDITIONS**
DIAGNOSIS

HISTORY

- Acute presentation:
  - Shortness of breath (pleural effusion)
  - Nausea, vomiting, decreased oral intake (bowel obstruction)
  - Calf pain, shortness of breath (venous thromboembolism)
  - Severe abdominal or pelvic pain (ovarian torsion or rupture)

- Subacute presentation:
  - Bloating, sense of abdominal fullness, increased abdominal size
  - Early satiety, anorexia, dyspepsia
  - Abdominal or pelvic pain/cramping
  - Dyspareunia
  - Urinary frequency or urgency in absence of infection
  - Fatigue, weight loss
  - Precocious puberty (sex cord-stromal or germ cell tumors)

PHYSICAL EXAM

- Pelvic mass
- Cul-de-sac and/or pelvic nodularity (rectovaginal exam)
- Fluid wave (ascites)
- Decreased or absent breath sounds (pleural effusion)
- Abdominal mass (omental caking)
- Cachexia
- Lymphadenopathy
- Hirsutism in androgen-secreting tumors

DIFFERENTIAL DIAGNOSIS

- GI or endometrial malignancies
- Benign or borderline neoplasms
Tubo-ovarian abscess or hydrosalpinx
Uterine fibroids
Endometriomas
Physiologic cysts
Irritable bowel syndrome
Colitis
Hepatic failure with ascites
Diverticulitis
Pelvic kidney

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Obtain with confirmed or suspected disease.
  - CBC
  - Liver function tests (LFTs) to rule out hepatic disease
  - Urinalysis
  - Serum albumin
  - Tumor markers:
    - Epithelial tumors: CA125, CA19-9, CEA
      - CA125: levels are elevated in 90% of women with malignant nonmucinous tumors but 50% of stage I ovarian cancers will have a falsely negative CA125 and common benign gynecologic conditions (PID, endometriosis, fibroids, pregnancy, menstruation) can cause elevations. Additionally, CA125 levels can be elevated with ascites, pleural effusion, congestive heart failure, pancreatitis, systemic lupus erythematous, and liver disease.
      - CA19-9 and CEA: better indicators of disease in mucinous tumors, helpful if GI primary suspected
    - Nonepithelial tumors: inhibit A/B (granulosa cell tumor), HCG (dysgerminoma, choriocarcinoma, embryonal carcinoma), AFP (endodermal sinus tumor, embryonal carcinoma), LDH (dysgerminoma)
  - Pelvic US
  - CT abdomen and pelvis with contrast
  - CXR or CT chest to evaluate for pleural effusions or lung nodules

Follow-Up Tests & Special Considerations
- Patients with ovarian cancer should be up-to-date with screening recommendations—mammograms, pap smear, and colonoscopy.
Colonoscopy (or other test to evaluate the colon- barium enema, CT colonography) is needed if a colonic primary is suspected.

**Diagnostic Procedures/Other**
- Endometrial biopsy if abnormal uterine bleeding present to evaluate for dual primary
- Consider paracentesis or thoracentesis (or IR biopsy of pelvic mass) if patient not an operative candidate.
  - IR biopsy: Epithelial ovarian cancer commonly involves the peritoneal surfaces of the abdomen and pelvis.

**Test Interpretation**
Pathologic diagnosis (with surgery, IR biopsy, or cytology) is necessary for definitive diagnosis.

---

**TREATMENT**

**GENERAL MEASURES**
- Surgical exploration with staging and debulking is critical. Optimal cytoreduction of tumor burden enhances effectiveness of adjuvant therapy and is associated with longer survival.
- In patients with bulky advanced disease in epithelial ovarian cancer where optimal cytoreduction with primary surgery is unlikely, it is reasonable to consider neoadjuvant chemotherapy (NACT), preoperative chemotherapy, after consultation with a gynecologic oncologist (3)[A].

**SURGERY/OTHER PROCEDURES**
- For epithelial malignancies, staging and tumor excision/debulking includes the following:
  - Cytologic evaluation of peritoneal fluid (pelvic washings)
  - Bilateral salpingo-oophorectomy with total hysterectomy and tumor reductive surgery
  - Excision of omentum
  - Inspection and palpation of peritoneal surfaces
  - Cytologic smear of right hemidiaphragmatic surface
  - Biopsy of adhesions or any suspicious areas
  - Biopsies of paracolic recesses, pelvic sidewalls, posterior cul-de-sac, and
bladder peritoneum
– Bilateral pelvic and paraaortic lymph node biopsies
– Appendectomy for mucinous tumors or if appendix appears abnormal

- Goal of surgery is optimal cytoreduction (<1 cm of maximum tumor diameter remaining).
- Germ cell or sex cord-stromal cancers (less likely to be bilateral): salpingo-oophorectomy (unilateral if only one ovary involved) in young patient for fertility sparing management

**MEDICATION**

**First Line**

- After surgery, most patients will require chemotherapy or adjuvant therapy. Those with stage IA, grade 1, and most stage IB, grade 1, tumors who are optimally staged do not require adjuvant therapy (4)[A]. Patients with clear cell histology, grade 3 tumors, or tumors staged 1C or worse do require adjuvant therapy. Patients should be encouraged to participate in clinical trials whenever possible.

- Adjuvant chemotherapy in early stage epithelial ovarian cancer: carboplatin IV and paclitaxel (Taxol) IV every 3 weeks for 6 cycles
- Adjuvant chemo in advanced stage epithelial cancer for patients with optimal cytoreduction: Taxol IV on day 1, cisplatin intraperitoneal (IP) on day 2, and Taxol IP on day 8 to repeat every 21 days for 6 cycles
- Women with suboptimal cytoreduction are not candidates for IP chemotherapy. Instead, recommend carboplatin IV every 3 weeks with Taxol weekly (or every 3 weeks) for 6 cycles.

- IP chemotherapy in combination with IV chemotherapy improves survival in advanced ovarian cancer. IP chemotherapy is associated with more toxicity (5)[A].

- Germ cell or sex cord-stromal cancers: bleomycin, etoposide, and cisplatin IV
- Contraindications to chemo: poor functional status, excessive toxicity, hypersensitivity
- Precautions: All regimens cause bone marrow suppression. Cisplatin is associated with ototoxicity, renal toxicity, and peripheral neuropathy. Taxol can cause neuropathy and alopecia.
- Antiemetics: ondansetron (Zofran), dronabinol (Marinol), metoclopramide (Reglan), prochlorperazaine (Compazine), promethazine (Phenergan)

**Second Line**
- Liposomal doxorubicin (Doxil)
- Carboplatin/gemcitabine
- Topotecan
- Etoposide
- Bevacizumab
- Cyclophosphamide
- Tamoxifen

**ADDITIONAL THERAPIES**
Patients receiving NACT typically receive subsequent interval surgery for debulking of disease if there is a good response to treatment followed by additional cycles of chemotherapy after surgery.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Physical exam every 3 months for the first 2 years after diagnosis, every 6 months until 5 years, and then annually thereafter
- If CA-125 elevated at diagnosis, follow levels after treatment to detect recurrence.
- Germ cell/sex-cord stromal cancer: physical exam and tumor markers every 3 months for the first 2 years after diagnosis, and then annually
  - Tumor markers for sex-cord stromal cancers should be checked every 6 months for 10 years, as recurrences can occur remote from initial diagnosis.
- CT scan of chest, abdomen, and pelvis and/or PET scan when recurrence suspected
- Routine screening with imaging not recommended

**PROGNOSIS**
- Recurrence rates for epithelial cancer
  - Early-stage disease: 20%
  - Advanced disease: >80%
- 5-year survival rates for ovarian cancer based on International Federation of Gynecology and Obstetrics (FIGO) data

**COMPLICATIONS**
- Pleural effusion
- Pseudomyxoma peritonei
- Ascites
- Toxicity of chemotherapy
- Bowel obstruction
- Malnutrition
- Electrolyte disturbances
- Fistula formation

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- C56.9 Malignant neoplasm of unspecified ovary
- C56.1 Malignant neoplasm of right ovary
- C56.2 Malignant neoplasm of left ovary

**CLINICAL PEARLS**
- Family history of ovarian cancer or early-onset breast cancer is the most significant risk factor for the development of ovarian cancer, yet the vast majority of cases remain sporadic.
- The diagnosis of ovarian cancer should be suspected in women with persistent bloating, upper abdominal discomfort, or GI symptoms of unknown etiology.
- Surgery is the mainstay of diagnosis and treatment for ovarian cancer. Many patients benefit from adjuvant chemotherapy.
- The prognosis of advanced ovarian cancer is poor and requires close follow-up by physical exam, tumor markers, and imaging when indicated.
OVARIAN CYST, RUPTURED

Glency Sue Marie S. Corominas, MD • Adriana Arocha, MD • Marcy Wiemers, MD

BASICS

- Ovarian cysts are frequent in reproductive-aged women.
- Most ovarian cysts are benign physiologic follicles created by the ovary at the time of ovulation.
- Ovarian cysts can cause symptoms when they become enlarged and exert a mass effect on surrounding structures, or when they rupture and the cyst contents cause irritation of the peritoneum or nearby pelvic organs.
- Patients with a symptomatic ruptured cyst will usually complain of acute onset unilateral lower abdominal pain.
- Rupture can be caused by sexual intercourse, luteal phase, exercise, trauma, or pregnancy.
- Evaluation of the patient should include exclusion of other emergent causes: ectopic pregnancy, ovarian torsion, and nongynecologic sources of acute unilateral lower abdominal pain.
- Once the diagnosis of a ruptured cyst is confirmed, most patients can be managed conservatively as outpatients with adequate pain control. Surgical intervention is rarely indicated.
- OCPs are not an effective treatment for existing ovarian cysts.

DESCRIPTION

A suspected ruptured ovarian cyst should be treated as an unknown adnexal mass (mass of the ovary, fallopian tube, and surrounding tissue) until proven otherwise.

EPIDEMIOLOGY

- The actual incidence of ovarian cysts is difficult to calculate as many ruptured cysts are asymptomatic or found incidentally.
- Ovarian cysts can be seen on transvaginal ultrasounds in nearly all premenopausal women and in up to 18% of postmenopausal women. The vast majority of these cysts are benign or functional.
- Most ruptured ovarian cysts are physiologic events and self-limited, expectant
management with pain control is usually sufficient.

- About 13% of ovarian masses in reproductive-aged women are malignant, as opposed to 45% in postmenopausal women. About 70% of ovarian malignancies are diagnosed at a late stage.
- Ruptured ovarian cysts most commonly affect the right ovary, 63%.

**RISK FACTORS**
Medications or conditions associated with increased ovulation and/or increased risk of cyst rupture.

- Ovulation induction agents (i.e., Clomid, aromatase inhibitors, GnRH agonists)
- Tamoxifen increases the risk of ovarian cysts in reproductive-aged women.
- Polycystic ovarian syndrome (common)
- Fibrous dysplasia/McCune-Albright syndrome (rare)

**GENERAL PREVENTION**
Ovulation suppression with combined oral contraceptives is the mainstay therapy for prevention of recurrent ovarian cysts.

**DIAGNOSIS**
- When a ruptured ovarian cyst is suspected, a pregnancy test should be performed to rule out an ectopic pregnancy (1)[C].
- Sonographic imaging along with CT and MRI can aid in diagnosis of gynecologic emergencies (2)[C].
- CT is useful to confirm a hemoperitoneum and MRI can assist when the diagnosis remains unclear after CT and ultrasound (2)[C].
- Ultrasound and CT imaging for diagnosis has decreased the need for diagnostic surgical intervention (3)[B].
- Additionally, ultrasound is useful in confirming normal Doppler flow to the affected ovary and adnexa (1)[C].

**HISTORY**
- A general past medical and surgical history should be reviewed.
- Specific questions that should be addressed if you suspect a ruptured cyst include:
  - Onset and characteristics of pain
– Pain associated with timing of sexual intercourse, strenuous activity, or trauma
– Date of last menstrual period
– Vaginal bleeding
– Nausea or vomiting
– Shoulder or upper abdominal pain due to subphrenic extravasation

- Symptoms of circulatory collapse, including palpitations, shortness of breath, sensation of being hot or clammy, dizziness
- Additional information that will guide diagnosis should include patient age, known or previous ovarian cysts, and reproductive history.

**ALERT**
Patients with bleeding diathesis or undergoing anticoagulation therapy may experience significant bleeding from hemorrhagic cysts.

**PHYSICAL EXAM**
- Vital signs are usually normal unless significant blood loss has occurred.
- Rupture characterized by significant blood loss may be present in the form of pallor, pale mucosal membranes, and tachycardia.
- Patients will have significant tenderness to palpation or an acute abdomen if the peritoneum is irritated or inflamed.
- On some occasions, a palpable adnexal mass can be felt on bimanual exam. Care should be taken not to cause further injury with a forceful exam.

**DIFFERENTIAL DIAGNOSIS**
Includes all causes of acute abdominal pain, both gynecologic and nongynecologic

**ALERT**
- Ectopic pregnancy should always be excluded with a negative pregnancy test (1)[C].
- Benign gynecologic etiologies include:
  – Functional ovarian cysts
  – Ovarian torsion
  – Tubo-ovarian abscess
  – Teratomas
  – Fibroids
  – Endometrioma
  – Cystadenoma (mucinous or serous)
– Hydrosalpinx

Malignant gynecologic etiologies can usually be attributed to the various gynecologic cancers of the reproductive tract.

Benign nongynecologic causes of acute lower abdominal pain include:
– Appendicitis
– Diverticulitis
– Infections of the urinary tract
– Renal colic

Malignant nongynecologic causes of acute lower abdominal pain can be attributed to neoplastic processes of the lower GI tract.

DIAGNOSTIC TESTS & INTERPRETATION

- In all premenopausal women, pregnancy must be ruled out by a urine test. Serial quantitative β-hCG tests are helpful in evaluating an ectopic pregnancy (1)[C].
- Complete blood count will evaluate baseline levels to determine a significant drop in hematocrit if there is ongoing hemorrhage (3)[B]. Leukocytosis should raise the suspicion of an infectious process (1)[C].
- Urinalysis and STD testing should be obtained to evaluate for infectious causes, PID, or symptomatic renal stones (1)[A].
- A type and screen is indicated if surgical intervention is planned or blood products are being considered.
- Ultrasonography is the first-line imaging modality (1)[C].
- CA-125 may assist in evaluation but can be elevated in a number of conditions (1)[C].

TREATMENT

GENERAL MEASURES

- For many patients, pain associated with a ruptured cyst will be transient and self-limiting.
- Cyst rupture in a stable healthy patient can be managed conservatively in 80% of cases due to advances in imaging (3)[B].
- Patient with anticoagulation can also be managed conservatively with cyst rupture using a multidisciplinary team (4)[C].
- Scheduled NSAIDs or oral narcotics can be prescribed depending on pain severity.
For patients with multiple episodes or a single severe occurrence, OCPs can be considered for ovulation suppression and prevention. They are not effective for treatment of ovarian cysts which are already present (5)[A].

Unstable patients with hemodynamic compromise or patients with significant hemoperitoneum should be resuscitated, and laparoscopy or a laparotomy should be considered. Surgical exploration should also be considered if there is a concern for malignancy.

ISSUES FOR REFERRAL

• OB/GYN
  – Consider referral to an obstetrician if an adnexal mass is diagnosed during pregnancy. Such masses have a low risk of malignancy or acute complication for the pregnancy.
  – Most cysts resolve without intervention within 2 to 3 weeks; those that do not resolve in 12 weeks require prompt referral for surgical intervention (5) [A].

• Gynecologic oncology
  – Referral to a gynecologic oncologist should be considered for complex adnexal masses with an elevated CA-125 and associated symptoms concerning for malignancy such as ascites, early satiety, pleural effusion, enlarging abdominal mass, or bowel obstruction.

• General surgery
  – Acute lower abdominal pain that is nongynecologic and suspicious for bowel involvement should be referred to general surgery or a gastroenterologist.

SURGERY/OTHER PROCEDURES

• Although the need for surgical intervention is rare, it is usually of an emergent nature.

• Patients with a low diastolic blood pressure and a large amount of hemoperitoneum have an increased rate of surgical intervention (3)[B].

• In most cases, laparoscopy is diagnostic and therapeutic. The decision to proceed with cystectomy or oophorectomy should be made intraoperatively after a thorough evaluation of the intra-abdominal environment has been completed.

• The advantages of a laparoscopic approach include a shorter length of stay, faster recovery, small scar, and few adhesions. Postoperative recovery time as well as patient satisfaction is significantly improved with a minimally
invasive approach.

- Laparotomy should be performed in cases of critical hemodynamic instability or lack of laparoscopically trained surgeons. If there is concern for malignancy or metastases, laparotomy may be the preferred method of surgery.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Patients who require inpatient management should be managed with serial abdominal exams, analgesia, and intravenous resuscitation as indicated by their initial presentation.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Follow-up for patients managed conservatively should be scheduled in 72 hours from the initial onset of symptoms. Patients should present sooner for new or worsening symptoms.
- Patients with complete resolution of symptoms within a few days can follow up as needed. However, these patients should be counseled on risk of recurrence and options for prevention.
- Patient in whom surgical intervention was indicated, postop follow-up should be scheduled 2 weeks from the date of surgery.
- Patients in whom an ovarian cyst was diagnosed incidentally should follow-up based on the size of their cyst.

Pregnancy Considerations

Most adnexal masses in pregnancy can be managed expectantly because the risk of malignancy is low (1)[C]. There is a risk for ruptured endometriotic cyst and early surgical intervention can reduce the effects of endometriotic cyst fluid, and thus prevent adhesions and preserve fertility. MRI can help further characterize a mass safely in pregnancy (1)[C].

PATIENT EDUCATION

Reassurance of the benign nature of most ovarian cysts is an important cornerstone of patient education.
REFERENCES

ADDITIONAL READING

- Miller RW, Ueland FR. Risk of malignancy in sonographically confirmed

CODES

ICD10

- N83.20 Unspecified ovarian cysts
- N83.0 Follicular cyst of ovary
- N83.1 Corpus luteum cyst

CLINICAL PEARLS

- Functional ovarian cysts are very common in reproductive-age women and are usually self-limiting.
- Always exclude ectopic pregnancy.
- Management of symptomatic ruptured cysts is usually accomplished with outpatient pain control and follow-up.
- In cases where the patient with a ruptured cyst is unstable or presents with signs of an acute abdomen, surgical intervention is indicated.
PALLIATIVE CARE
Erika Oleson, DO, MS

BASICS
Palliative care is a specialty that focuses on preventing and alleviating suffering of patients (and their families) living with life-limiting illness at any stage of that illness.

DESCRIPTION
- The principal goal of palliative care is to prevent and alleviate suffering—whether physical (pain, breathlessness, nausea, etc.), emotional, social, or spiritual regardless of underlying diagnosis.
- Palliative care aims to improve or maintain quality of life for patients and families despite serious illness.
- Palliative care is available for patients with serious, life-limiting illness, at any stage of their disease, with or without concurrent curative care.
- Patients and their families may access palliative care services in the hospital, rehabilitation or skilled nursing facility, and ambulatory setting.
- Hospice: In the United States, hospice is available for patients whose average life expectancy is 6 months or less and whose principal goal is to stay home (including long-term care or assisted living facility), avoid hospitalizations, and forego disease-directed care with a curative intent. Unlike regular home nursing services, hospice does not require a patient to be homebound and offers backup support for patients 24 hours a day and 7 days per week.

COMMONLY ASSOCIATED CONDITIONS
Common symptoms/syndromes in palliative care:
- Pain
  - Chronic pain
  - Headache
  - Neuropathic pain
  - Pain from bone metastases
  - Pruritus
- GI symptoms (~60% incidence)
  - Ascites
– Anorexia/cachexia
– Nausea (and vomiting)
  ○ Consider underlying etiology and treat accordingly.
    ■ GI causes: constipation, bowel (full or partial) obstruction, ileus, heart burn, reflux, inflammation
    ■ Intrathoracic causes: cardiac, effusions (cardiac, pulmonary), mediastinal causes, esophageal
    ■ Autonomic dysfunction
    ■ Centrally mediated: intracranial pressure change, inflammation, cerebellar, vestibular, medication or metabolic cause stimulating vomiting center, and/or chemoreceptor trigger zone
– Bowel obstruction
– Constipation and impaction of stool
– Diarrhea
– Dysphagia
– Mucositis/stomatitis
– Sialorrhea
● General medical
  – Delirium (40–85%)
● Pulmonary symptoms
  – Cough, chronic
  – Breathlessness or dyspnea (60%): which may be due to heart failure, COPD, lung cancer, etc.
● Psychological symptoms
  – Anxiety
  – Depression
  – Insomnia
● Skin
  – Decubitus ulcer
  – Pruritus
  – Complex wounds (fungating tumors, etc.)

DIAGNOSIS
The PEACE tool evaluates (1):
● Physical symptoms
● Emotive and cognitive symptoms
● Autonomy and related issues
• Communication: contribution to others and closure of life affairs–related issues
• Economic burden and other practical issues, also transcendent and existential issues

HISTORY
A comprehensive palliative care assessment includes:
• Underlying medical conditions and associated physical symptoms
• Comprehensive pain assessment and review of systems (consider use of Edmonton Symptom Assessment Scale)
• Psychological symptom assessment
• Cultural, social, and practical concerns
• Spiritual and existential issues
  – FICA assessment (Faith, Importance and influence, Community, Address—how does the patient wish to be addressed?)
  – HOPE (sources of Hope/strength/comfort, Organized religion’s role, Personal spirituality and practices, Effects on medical care and end-of-life care) (2)
• Presence and sources of suffering (personhood concerns)
• Goals of care: posthospital care, practical needs, hopes, and fears
• Prognosis: functional status and interest in knowing prognosis

PHYSICAL EXAM
Comprehensive physician examination directed by underlying diagnosis, symptoms, and functional decline

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
Per diagnosis and symptoms

TREATMENT
GENERAL MEASURES
• Targeted interventions to maximize quality of life and minimize symptom burden while taking into consideration the patient’s values, goals, fears, and social setting
Treatment should involve an interdisciplinary team—addressing potential and realized suffering, whether physical, emotional, social, or spiritual.

MEDICATION
- Attempt to minimize polypharmacy (deprescription); consider discontinuing medications that offer little improvement in the quality of life.
- Medications should focus on symptom management.
- Continue to use appropriate disease-modifying medications especially if they lessen symptom burden and enhance immediate quality of life.
- Improve compliance by addressing patient/caregiver understanding of:
  - Pain (3)[A]
    - Use immediate-release opioids PO/IV/SC and titrate to control.
    - Once pain is controlled, convert to long-acting opioids with short-acting agents made available as tolerance develops and/or patient develops breakthrough pain.
  - Bone pain: NSAIDs added to narcotics are more effective than narcotics alone.
  - Neuropathic pain: may use adjuvant treatment, such as gabapentin or other anticonvulsants. Glucocorticoids may also help.

ALERT
Avoid morphine in patients with renal failure; can induce delirium, hyperalgesia, agitation, and seizures

Vomiting associated with a particular opioid may be relieved by substitution with an equianalgesic dose of another opioid or a sustained-release formulation (4).
- Dopamine receptor antagonists (metoclopramide, prochlorperazine, promethazine) are commonly used. Haloperidol may help with nausea.
- Droperidol: insufficient evidence to advise on the use for the management of nausea and vomiting

Constipation: Consider prophylactic stool Softeners (docusate) and stimulants (bisacodyl or senna) or osmotic laxatives.

ALERT
Consider laxatives with opioid treatment to avoid constipation.

- SC methylnaltrexone is effective in inducing bowel movements without inducing withdrawal with opioid-induced constipation.
- Dyspnea: Consider oxygen, if congestive heart failure (CHF); diuretics and/or
long-acting nitrates, benzodiazepines
– In addition to treating the underlying cause of breathlessness, as the disease advances, low-dose opioids may be beneficial to patients (3,5)[C]. Immediate-release opioids PO/IV treat dyspnea effectively and typically at doses lower than necessary for the relief of moderate pain.

- Delirium: lowest doses necessary of benzodiazepines or antipsychotics (haloperidol or risperidone, etc.)
  – Monitor patient safety and use nonpharmacologic strategies to assist orientation (clocks, calendars, environment, and redirection).
- Pruritus: no optimal therapy
- Anxiety: insufficient data for recommendations of specific medication, but anxiolytics and/or other agents may be tried
- Megestrol acetate improves appetite and slight weight gain in patients with anorexia-cachexia syndrome.

ISSUES FOR REFERRAL
- Referral to palliative care
  – Any patient with a serious, life-limiting illness who could benefit from help with burdensome symptoms or suffering and/or complex goals of care discussion
  – Early referral to palliative care may improve quality of life and longevity for patients with advanced cancer.
- Referral to hospice care
  – Any patient with an average life expectancy of 6 months or less
  – Consider the question, “Would you be surprised if the patient died within the next 6 months?” If the answer is no, they likely meet criteria for hospice.
    o Consider patients who have multiple hospitalizations and/or emergency department visits in the prior 6 months.
    o Refer to local hospice guidelines for additional disease-specific criteria.

REFERENCES

**CODES**

**ICD10**

Z51.5 Encounter for palliative care

**CLINICAL PEARLS**

- Early referral to palliative care helps enhance the quality of life of patients living with serious illness.
- Consider the type of pain: The addition of adjuvant treatments such as NSAIDs or gabapentin to narcotics may be more effective than narcotics alone.
- Laxatives should be started with opioid treatment to avoid constipation.
BASICS

DESCRIPTION

- Adenocarcinoma of the exocrine pancreas (90% of pancreatic cancers) is the fourth most common cause of cancer death in the United States and the ninth most common cancer in women.
- Rarely curable: overall 5-year relative survival rate of 7.7%
- 60–70% occur in the head, 20% in the body and tail, 20% diffusely involve the gland
- As few as 9% are localized at diagnosis. For localized, small cancers (<2 cm) with no lymph node metastases and no extension beyond the capsule, surgical resection has 5-year survival of about 29%.
- Majority of tumors have metastasized at diagnosis and are thus, largely incurable and have a 5-year survival rate of 2–3%.
- In apparently resectable disease, 20–40% have unresectable lesions at surgery.
- Ampullary, duodenal, or distal bile duct tumors may mimic pancreatic carcinoma and are more likely to be resectable and curable.
- For advanced or unresectable cancers, survival is <1% at 5 years; most patients die within 1 year.

EPIDEMIOLOGY

During 2003 to 2007, median age at diagnosis = 70 years; rare <40 years; after 45 years of age, occurrence rises.

Incidence

- According to the American Cancer Society, an estimated 53,670 diagnoses and 43,090 deaths in the United States in 2017
- About 3% of all cancers and about 7% of cancer deaths
- Lifetime risk is about 1 in 65 (1.5%).
- More common in black and white races, 16.7 and 10.3 in 100,000 men and 14.4 and 10.3 in 100,000 women, respectively. Among Hispanic and Asian/Pacific Islanders, there is an incidence of 10.9 and 8.3 in 100,000 men and 10.1 and 8.3 in 100,000 women, respectively.
**Prevalence**

In 2008, in the United States, ~34,600 men and women (16,811 men and 17,846 women) were alive who had a history of pancreatic cancer.

**RISK FACTORS**

- Smoking: relative risk (RR) 2 to 3; correlates with amount smoked
- Diabetes: RR 2.1 (95% CI 1.6–2.8); 1 in 6 become diabetic within 6 months before diagnosis.
- Prior partial gastrectomy or cholecystectomy: 2- to 5-fold increased risk 15 to 20 years after gastrectomy
- Familial aggregation/genetic factors: 5–10% of patients have a first-degree relative with the disease, which confers a 9-fold increase in risk versus the general population; subgroup may carry germline mutations of DNA repair genes (BRCA2).
- Hereditary chronic pancreatitis (autosomal dominant, highly penetrant): cumulative risk by ages 50 and 75 years is 10% and 54%, respectively.
- Peutz-Jeghers syndrome: RR 30 to 40
- Familial atypical multiple mole and melanoma syndrome (p16): RR 10 to 20
- Hereditary nonpolyposis colon cancer (Lynch syndrome: RR 4
- Sporadic chronic pancreatitis
- Non-O blood type: RR 1 to 2
- High dietary fat, red meat, obesity, *Helicobacter pylori*
- Alcohol: Recent data indicate a modest increase in risk confined to heavy alcohol consumers.
- Coffee intake and NSAID use *NOT* regarded as risk factors

**GENERAL PREVENTION**

No effective screening modality exists to detect early cancer. Even with a strong family history or predisposition syndromes, use and cost-effectiveness of screening are unclear.

**COMMONLY ASSOCIATED CONDITIONS**

- Chronic pancreatitis, diabetes mellitus, cystic fibrosis
- KRAS mutations are present in >90% of pancreatic ductal adenocarcinomas.
- Mutation inactivation of tumor suppressors (SMAD4, p53, CDKN2A) allows for tumor progression.
- Subsets of familial pancreatic cancer involve germline cationic trypsinogen or PRSS1 mutations (hereditary pancreatitis), BRCA2 mutations (usually with
hereditary breast–ovarian cancer syndrome), CDKN2 mutations (familial atypical mole, multiple melanoma), or DNA repair gene mutations (e.g., ATM and PALB2, apart from BRCA2).

- Majority of familial pancreatic cancers have no genetic underpinnings.
- Precursor lesions are potentially curable—pancreatic intraepithelial neoplasia, intraductal papillary mucinous neoplasm, and mucinous cystic neoplasms.

# DIAGNOSIS

## HISTORY

- Depends on tumor location; majority become symptomatic late in disease. About 60–70% of pancreatic cancers develop in the pancreatic head and block the periampullary bile duct, causing obstructive jaundice.
- Weight loss 90%; pain 75% (progressive midepigastic dull ache that often radiates to the back); malnutrition 75%; jaundice 70%; anorexia 60%; pruritus 40%; diabetes mellitus 50%; weakness, fatigue, malaise 30–40%; alcoholic stools, dark urine, steatorrhea; depression is common.
- Pancreatic cancer is a consideration in acute pancreatitis in the elderly and with new-onset diabetes, but most new-onset diabetes are not associated with cancer; thus, evaluation for cancer is warranted only in selected cases.
- Uncommon: unexplained thrombophlebitis; acute pancreatitis from tumor obstruction of pancreatic duct; duodenal obstruction or GI bleeding

## PHYSICAL EXAM

- Muscle wasting and malnutrition are common; skin lesions are indicative of pruritus. Exam can be normal.
- Palpable abdominal mass or ascites in 20%
- Jaundice: 70% if tumor obstructs bile duct; 10% with body or tail carcinoma
- Courvoisier sign (painless jaundice with a palpable gallbladder): uncommon; usually associated with pancreatic head tumors, periampullary or primary bile duct tumors; hepatomegaly in advanced disease
- Virchow node (left supraclavicular) and Sister Mary Joseph node (umbilical) in metastatic disease; palpable rectal shelf (nonspecific sign of carcinomatosis)
- Migratory thrombophlebitis (Trousseau sign) (uncommon) due to hypercoagulability in mucin-producing pancreatic cancer
- GI bleeding from tumor erosion into adjacent viscera (colon); portal
hypertension-related bleeding (uncommon)
- Pancreatic panniculitis: subcutaneous areas of nodular fat necrosis

**DIFFERENTIAL DIAGNOSIS**
- Chronic pancreatitis, duodenal cancer, cholangiocarcinoma, lymphoma, islet cell tumor, sarcoma, cystic neoplasms, tumor metastatic to pancreas (rare)
- Nonmalignant conditions: choledocholithiasis, acute or chronic pancreatitis, biliary tract stricture, adenoma; chronic mesenteric ischemia
- Tuberculosis or fungal abscess in AIDS
- Patients may present with back pain mimicking musculoskeletal disease.

**DIAGNOSTIC TESTS & INTERPRETATION**
- Cross-sectional imaging (usually CT scan as first-line choice) to evaluate symptoms or abnormal lab results (1)[B]
- Endoscopic ultrasound (EUS)-guided biopsy: best modality for tissue diagnosis; sensitivity 75–90%; specificity ~100% for diagnosis of a mass (1) [A]
- Routine laboratory tests may reveal elevated serum bilirubin and alkaline phosphatase (cholestasis), anemia, or decreased serum albumin (malnutrition).

**Initial Tests (lab, imaging)**
- Most patients do not require measurement of serum tumor markers (CA19-9) for diagnosis or management. Some evidence suggests use in predicting outcome and response to adjuvant chemotherapy.
- CEA and CA19-9 are not recommended as screening tests; useful in following patients with known disease (2)[A]
- Elevated CA19-9 antigen: 80% sensitivity; 90% specificity; individuals with Lewis-negative blood group antigen phenotype (5–10%) are unable to synthesize CA19-9; elevations can occur in benign pancreatic or biliary diseases and in nonpancreatic malignancy.
- MUC5AC helps in differentiation.

**Follow-Up Tests & Special Considerations**
- During therapy, increase in CA19-9 may identify progressive tumor growth. Normal CA19-9 does not exclude recurrence.
- CT scan (pancreatic protocol) using thin section, multiphase multidetector helical CT with a pancreatic protocol is the choice for diagnosis and staging: 85–90% sensitivity; 90–95% specificity; useful for evaluation of distant
metastasis and prediction of resectability

- Abdominal ultrasound: common initial test to assess jaundice and duct dilatation; less sensitive than CT for pancreatic masses
- EUS is accurate for tissue biopsy, local tumor and node staging, predicting vascular invasion (90% specificity; 73% sensitivity), and when no mass is identified on CT.
- Endoscopic retrograde cholangiopancreatography (ERCP): 90% sensitivity; 95% specificity for ductal cancer; useful if endoscopic stent is indicated for biliary obstruction; generally confined to high probability for therapeutic intervention on biliary or pancreatic ductal systems
- MRI: no advantage over contrast-enhanced CT
- MR cholangiopancreatography: 90% sensitivity; 95% specificity. Preferred in specific settings: gastric outlet or duodenal stenosis or after surgical rearrangement (Billroth II) or ductal disruption; to detect bile duct obstruction, after attempted ERCP is unsuccessful or provides incomplete information.
- Cystic pancreatic lesions may be benign or malignant; must be differentiated from pancreatic pseudocysts. Cystadenocarcinomas have better prognoses than typical pancreatic cancers.

**Diagnostic Procedures/Other**

- Percutaneous fine-needle biopsy with US or CT guidance: 80–90% sensitivity; 98–100% specificity
- EUS-guided biopsy: 85–90% sensitivity; virtually 100% specificity for pancreatic mass
- Staging laparoscopy and US: 92% sensitivity; 88% specificity; 89% accuracy
- Positive peritoneal cytology has a positive predictive value of 94%, specificity of 98%, and sensitivity of 25% for determining unresectability.
- PET scan: 90% sensitivity but 70% specificity; limited anatomic information

**Tumor staging**

- Stage Ia: T1 N0 M0 (tumor ≤2 cm)
- Stage Ib: T2 N0 M0 (tumor >2 cm and ≤4 cm)
- Stage IIa: T3 N0 M0 (tumor >4 cm)
- Stage IIb: T1–T3 N1 M0 (N1 is metastasis in 1 to 3 regional lymph nodes)
- Stage III: T1–T3 N2 M0 (N2 is metastasis in ≥4 regional lymph nodes), T4 Any N M0 (Tumor involves celiac axis, superior mesenteric artery, and/or common hepatic artery, regardless of size.)
- Stage IV: Any T Any N M1 (distant metastases)

**Test Interpretation**
Duct cell carcinoma: 90%
Other less common tumors: acinar, papillary mucinous, signet ring, adenosquamous, mucinous, giant or small cell, cystadenocarcinoma, undifferentiated, unclassified carcinoma

**ALERT**
Chronic pancreatitis can present with similar pain, weight loss, jaundice, and an inflammatory mass on imaging.

**TREATMENT**
- Surgical resection: only chance of cure; no role for pancreatic resection in metastatic disease. As few as 15–20% are candidates for resection.
- Criteria for unresectability: extrapancreatic spread, encasement or occlusion of major vessels, distant metastases
- New combination chemotherapy regimens may offer advantages over gemcitabine. Standard therapies remain unsatisfactory; thus, patients should be considered for clinical trials (2)[B].

**MEDICATION**
- Analgesics
- Stages I and II
  - Radical pancreatic resection plus chemotherapy
  - ESPAC-3 trial after resection: Compared with 5-fluorouracil (5-FU) and folinic acid, gemcitabine did not improve overall survival.
  - Currently, postoperative gemcitabine alone or in combination with 5-FU–based chemoradiation is the current standard of care; preoperative neoadjuvant treatment trials are in progress (1)[A].
- Stage III
  - Standard: 6 months of chemotherapy with gemcitabine-based regimens (1) [A]; added chemoradiation (capecitabine and radiotherapy) is controversial (1)[B].
  - FOLFIRINOX (leucovorin, fluorouracil, irinotecan, and oxaliplatin) or gemcitabine—nab-paclitaxel were recently shown to have a benefit in patients with metastatic disease; may be tried in patients with locally advanced disease. These regimens are used for patients with no or minimal performance restrictions (1,3)[A].
  - Palliation of biliary obstruction by endoscopic, surgical, or radiologic
methods
- Intraoperative radiation therapy and/or implantation of radioactive substances

Stage IV
- Chemotherapy: Gemcitabine ± erlotinib, or capecitabine may modestly prolong survival compared with gemcitabine alone. This regimen is used for patients with significant performance restrictions (1,3)[A].
- Oxaliplatin- and irinotecan-containing regimens (including fluoropyrimidines) have similar efficacy when used after first-line gemcitabine-based therapy in stage IV patients (4)[A].
- In gemcitabine-refractory pancreatic cancer, S-1 (a fluoropyrimidine not available in the United States) combination regimens has a higher response rate and longer progression-free survival (PFS) than oral S-1 monotherapy (5)[A].
- Pain-relieving procedures (celiac or intrapleural block); supportive care; palliative decompression
- Duodenal obstruction: endoscopic expandable metal stent placement rather than surgery (1)[C]
- Biliary obstruction: Endoscopic biliary stenting is safer than percutaneous insertion and is as successful as surgical hepaticojejunostomy (1)[A].

ADDITIONAL THERAPIES
- For resected tumors: postoperative radiation therapy with other chemotherapeutic agents
- Intraoperative radiation therapy and/or implantation of radioactive substances (ongoing trials)
- Biliary decompression with endoprosthesis or transhepatic drainage for bile duct obstruction
- Celiac axis and intrapleural nerve blocks can provide effective pain relief for some patients.
- Opiates may be needed for pain control.

SURGERY/OTHER PROCEDURES
- Standard treatment options
  - Pancreaticoduodenectomy, Whipple procedure, en bloc resection of the head of the pancreas, distal common bile duct, duodenum, jejunum, and gastric antrum
  - Total pancreatectomy
– Distal pancreatectomy for body and tail tumors
• Nonstandard surgeries
  – Pylorus-preserving pancreaticoduodenectomy, regional pancreatectomy
  – Palliative bypass
    o Biliary decompression; gastrojejunostomy for gastric outlet obstruction; duodenal endoprosthesis for obstruction

ONGOING CARE

DIET
• Anorexia, asthenia, pain, and depression may contribute to cachexia.
• Fat malabsorption due to exocrine pancreatic insufficiency may contribute to malnutrition; pancreatic enzyme replacement may help to alleviate symptoms.
• Fat-soluble vitamin deficiency may require replacement therapy.

PROGNOSIS
• 90% diagnosed with pancreatic cancer die from the disease, predominantly from metastatic disease (2).
• 5-year survival: ~30% if node-negative; 10% if node-positive. Median survival: 10 to 20 months
• Metastatic cancer: 1–2% 5-year survival
• For localized disease and small cancers (<2 cm) with no lymph node involvement and no extension beyond the capsule, complete surgical resection can yield a 5-year survival of 18–24%.
• Detection of curable precursor lesions is a focus of current efforts to improve diagnosis and prognosis.

COMPLICATIONS
• Diabetes mellitus, malabsorption, thrombophlebitis
• Duodenal or distal bile duct obstruction
• Surgical complications: intra-abdominal abscess, postgastrectomy syndromes, pancreaticojejunostomy, gastric and biliary anastomotic leaks; operative mortality varies.

REFERENCES

### ADDITIONAL READING

### CODES
#### ICD10
- C25.9 Malignant neoplasm of pancreas, unspecified
- C25.0 Malignant neoplasm of head of pancreas
- C25.1 Malignant neoplasm of body of pancreas

### CLINICAL PEARLS
- Sudden onset of diabetes mellitus in nonobese adults aged >40 years may warrant consideration of pancreatic cancer in selected cases.
- Presence of occult peritoneal tumor cells denotes a worse survival in resectable pancreatic cancer patients.
• Diagnostic laparoscopy may decrease the rate of unnecessary laparotomy in pancreatic cancer found to be resectable on CT.
PANCREATITIS, ACUTE

Robert L. Frachtman, MD, FACG • Marni L. Martinez, APRN

BASICS

DESCRIPTION
Acute inflammatory process of the pancreas with variable involvement of regional tissue or remote organ systems

- Inflammatory episode with symptoms related to intrapancreatic activation of enzymes with pain, nausea and vomiting, and associated intestinal ileus
- Varies widely in severity, complications, and prognosis, accounting for ~280,000 hospital admissions per year in the United States
- Complete structural and functional recovery if there is no necrosis or pancreatic ductal disruption

EPIDEMIOLOGY

Incidence
- 1 to 5/10,000
- Predominant age: none
- Predominant sex: male = female

Prevalence
- Acute: 19/10,000
- Acute pancreatitis is the most common gastrointestinal diagnosis for inpatient hospitalization.

ETIOLOGY AND PATHOPHYSIOLOGY

- Alcohol
- Gallstones (including microlithiasis)
- Trauma/surgery
- Acute discontinuation of medications for diabetes or hyperlipidemia
- Following endoscopic retrograde cholangiopancreatography (ERCP)
- Medications (most common, not an exhaustive list)
  - ACE inhibitors; angiotensin receptor blockers (ARBs); thiazide diuretics
and furosemide
– Antimetabolites (mercaptopurine and azathioprine)
– Corticosteroids; glyburide; exenatide
– Mesalamine; pentamidine
– Sulfamethoxazole/trimethoprim
– Valproic acid
– HMG-CoA reductase inhibitors
– Review all medications and continue only if benefit outweighs risk.

• Metabolic causes
  – Hypertriglyceridemia (classically >1,000 mg/dL); even nonfasting levels as low as \(\geq 177\) mg/dL have been associated with acute pancreatitis.
  – Hypercalcemia; acute renal failure
  – Diet with high glycemic load
  – Systemic lupus erythematosus/polyarteritis
  – Autoimmune; with/without elevated IgG4
  – Infections
    o Mumps, coxsackie, CMV, EBV, cryptosporidiosis, ascaris, clonorchis

• Penetrating peptic ulcer (rare)
• Cystic fibrosis and \(CFTR\) gene mutations
• Tumors (e.g., pancreatic, ampullary)
• Miscellaneous obstruction
  – Celiac disease
  – Crohn disease
  – Pancreas divisum
  – Sphincter of Oddi dysfunction
• Scorpion venom; vascular disease
• Acute fatty liver of pregnancy
• Idiopathic
• Associated coexisting risk factors
  – Obesity
  – Type II Diabetes
  – Smoking

• Pathophysiology—enzymatic “autodigestion” of the pancreas, interstitial edema with severe interstitial acute fluid accumulation (“3rd spacing”), hemorrhage, necrosis, release of vasoactive peptides (within 6 weeks), pseudocyst or acute necrotic collection (>6 weeks), pancreatic ductal disruption, injury to surrounding vascular structures-splenic vein (thrombosis) and splenic artery (pseudoaneurysm)
• The severity of the first episode of acute pancreatitis, alcohol abuse, and
smoking all increase the risk of acute recurrent pancreatitis, which, in turn, increases the risk of progression to chronic pancreatitis.

- Clinical features increasing severity of acute pancreatitis: age ≥ 60 years; obesity; long-term, heavy alcohol use

**Genetics**
- Hereditary pancreatitis is rare; autosomal dominant
- Polymorphisms and mutations in multiple genes

**GENERAL PREVENTION**
- Avoid excess alcohol consumption.
- Tobacco cessation
- Correct underlying metabolic processes (hypertriglyceridemia or hypercalcemia).
- Discontinue offending medications.
- Cholecystectomy (symptomatic cholelithiasis)
- Diet: There is an increased risk of gallstone pancreatitis with diets high in saturated fats, cholesterol, red meat, and eggs. Decreased risk of gallstone pancreatitis with diet high in fiber and vitamin D. There is a decreased risk of non-gallstone pancreatitis with diets high in fiber, coffee, and caffeine.

**COMMONLY ASSOCIATED CONDITIONS**
- Alcohol withdrawal, alcoholic hepatitis, diabetic ketoacidosis, and ascending cholangitis
- Morbid obesity, a pro-inflammatory state, increases severity and adverse outcomes (organ failure, mortality).

**DIAGNOSIS**
Symptoms don’t always correlate with objective findings.

**HISTORY**
- Acute onset of “boring” epigastric pain, which may radiate posteriorly toward the back
- Nausea/vomiting
- Alcohol use
- Personal or family history of gallstones
- Medication use
Abdominal trauma
Recent significant rapid weight loss

PHYSICAL EXAM
Vital signs—assess hemodynamic stability; fever
Abdominal findings: epigastric tenderness, loss of bowel sounds, peritoneal signs
Other findings, jaundice, rales/percussive dullness
Rare (with hemorrhagic pancreatitis)
  – Flank discoloration (Grey-Turner sign) or umbilical discoloration (Cullen sign)

DIAGNOSTIC TESTS & INTERPRETATION
Interpret laboratory and radiographic findings in the context of the clinical history—false-positive and false-negative findings are common.
Bedside index in severity in acute pancreatitis (BISAP) score
  – Patients receive 1 point for each element in the first 24 hours: BUN > 25 mg/dL, impaired mental status, systemic inflammatory response syndrome (SIRS)—a score of 0 predicts mortality of <1%, and a score of 5 correlates with a mortality rate of 22%.
Ranson criteria is an older model of predicting severity of pancreatitis. It includes 11 criteria, 5 of which are measured at admission and 6 are measured in the following 48 hours. A score of 3 or less represents mild pancreatitis, and as the score increases, the mortality rises sharply.
American College of Gastroenterology requires at least two of the three following elements to make a diagnosis of acute pancreatitis: characteristic abdominal pain, specific radiographic findings, and lipase level 3 times the upper limits of normal (ULN).
Elevated serum amylase >3 times ULN (Severity is not related to degree of elevation.)
Elevated serum lipase >3 times ULN (may stay elevated longer than amylase in mild cases)
Elevated total bilirubin. If >3 mg/dL, consider common bile duct obstruction.
A 3-fold elevation in the alanine aminotransferase (ALT) in the setting of acute pancreatitis has a 95% positive predictive value for gallstone pancreatitis. Triglyceride levels >1,000 mg/dL suggest hypertriglyceridemia as the cause.
Glucose and calcium increased in severe disease.
WBC elevation to 10,000 to 25,000/μL possible and not indicative of active
infection
- Elevated baseline hematocrit >44 or rising hematocrit is poor prognostic sign (severe 3rd spacing with associated hemoconcentration).
- Rising BUN and creatinine imply volume depletion or acute renal failure.

**DIFFERENTIAL DIAGNOSIS**
- Penetrating peptic ulcer
- Acute cholecystitis or cholangitis
- Macroamylasemia, macrolipasemia
- Mesenteric vascular occlusion and/or infarction
- Intestinal obstruction; perforated viscus
- Aortic aneurysm (dissecting or rupturing)
- Inferior wall myocardial infarction
- Lymphoma

**Initial Tests (lab, imaging)**
- Use follow-up labs to assess renal function, hydration, sepsis, biliary obstruction, and tissue oxygenation.
- Chest x-ray (CXR) to evaluate for early acute respiratory distress syndrome (ARDS) and pleural effusion; can also rule out subdiaphragmatic air (perforated viscus)
- Ultrasound to look for gallbladder/biliary stones
- CT scan
  - Confirms the diagnosis, assesses severity, establishes a baseline, and rules out most other pathologies (excluding noncalcified cholelithiasis)
  - IV contrast is not essential for the initial CT scan; avoid contrast in volume-depleted patients.
  - If not contraindicated, a CT scan with IV contrast on day 3 can assess the degree of necrosis if necrotizing pancreatitis is suspected.
- Magnetic resonance cholangiopancreatography (MRCP) helps assess choledocholithiasis, pancreas divisum, dilated pancreatic duct, and ductal changes.
- Esophagastroduodenoscopy (EGD) may be necessary to rule out a penetrating duodenal ulcer or an obstructing ampullary neoplasm.
- ERCP may be necessary to decompress common bile duct due to an impacted stone.
- Endoscopic ultrasonography (EUS) is useful if patients present with “idiopathic pancreatitis.”
- EUS-guided fine needle aspiration if autoimmune pancreatitis is suspected
Follow-Up Tests & Special Considerations
If renal function is stable, a contrast-enhanced CT scan at day 3 to assess for necrosis. CT guidance assists aspiration and drainage of abscess—mainly recommended if a fungal or drug-resistant infection is suspected.

TREATMENT

MEDICATION

First Line

- Analgesia: no consensus; guidelines vary Hydromorphone (Dilaudid) 0.5 to 1 mg IV q1–2h PRN
  - AVOID Demerol due to the potential of accumulation of a toxic metabolite.
- Antibiotics
  - In the clear absence of infection, the use of prophylactic antibiotics is no longer recommended (even with necrotizing pancreatitis).
  - In patients with ascending cholangitis or necrotizing pancreatitis, if there is a strong suspicion of active infection, consider empiric β-lactam/β-lactamase inhibitor (e.g., piperacillin/tazobactam 4.5 g IV q8h) for initial treatment before cultures (especially aspirates) return.
  - Levofloxacin 500 mg QD IV if cholangitis and there is an allergy to penicillin
  - Be vigilant for fungal superinfections when giving prophylactic antibiotics.

GENERAL MEASURES

Most cases of acute pancreatitis require hospitalization; ICU if multiorgan dysfunction or hypotension/respiratory failure; 15–20% of cases of acute pancreatitis progress from mild to severe (including persistent organ failure).

- Fluid resuscitation
  - Significant volume deficit due to 3rd spacing
  - Infuse bolus of 1,000 to 2,000 mL (lactated Ringers may be better than normal saline, unless hypercalcemic), followed by 250 to 300 mL/hr, adjusted on the basis of age, weight, hemodynamic response, and comorbid conditions.
  - Target urine output should be 0.5 to 1 mL/kg/hr. Lower infusion rate when this goal is achieved or once BUN decreases; 4 L should be the maximum fluid on day 1.
Fluid resuscitation is of limited value after 24 hours, and fluid overload results in significant complications (1)[A].

- Eliminate unnecessary medications, especially those implicated as causes of pancreatitis.
- Nasogastric (NG) tube for intractable emesis
- Follow renal function, volume status, calcium, and oxygenation. Organ failure is more important prognostic indicator than pancreatic necrosis.
- Intermittent pneumatic compression; DVT prophylaxis
- Begin oral alimentation after pain, tenderness, and ileus have resolved; small amounts of high-carbohydrate, low-fat, and low-protein foods; advance as tolerated; NPO or NG tube if vomiting persists. In cases of mild pancreatitis, a soft low-fat diet may be started even before enzymes elevation and pain have completely resolved (1)[A].
- Enteral nutrition at level of ligament of Treitz if oral feeding not possible within 5 to 7 days (preferable to total parenteral nutrition [TPN] due to decreased infection rate and decreased mortality). Discontinue with increases in pain, amylase/lipase levels, or fluid retention.
- TPN (without lipids if triglycerides are elevated) if oral or nasoenteric feedings are not tolerated (2)[A]

**ISSUES FOR REFERRAL**
Refer to a tertiary center if pancreatitis is severe or actively evolving and when advanced imaging or endoscopic therapy is being considered.

**SURGERY/OTHER PROCEDURES**
- Consider cholecystectomy before discharge in patients with cholelithiasis and nonnecrotizing pancreatitis to reduce risk of recurrence.
- Necrosectomy should be performed nonsurgically for either infected or noninfected necrosis. Walled-off necrosis should be observed for 4 weeks (treated with antibiotics if infected), followed by percutaneous or dual-modality drainage if available (3)[B]. Drainage may not be required if there are no signs of infection. Aspiration and culture are not absolutely essential if infection is suspected, and patient is responding to appropriate antibiotic therapy (1)[A].
- ERCP early if evidence of acute cholangitis or at 72 hours if evidence of ongoing biliary obstruction; ERCP with pancreatic ductal stent placement, if ductal disruption persists longer than 1 to 2 weeks
- Resection or embolization for bleeding pseudoaneurysms
Plasma exchange with insulin within 24 hours of presentation if severe necrotizing pancreatitis secondary to hypertriglyceridemia (4)[C]

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Discharge criteria
- Pain controlled
- Tolerating oral diet
- Alcohol rehabilitation and tobacco cessation
- Low-grade fever and mild leukocytosis do not necessarily indicate infection and may take weeks to resolve. Infections may occur even after 10 days (33% of patients with necrotizing pancreatitis) due to secondary infection of necrotic material, requiring surgical débridement.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Follow-up imaging in several weeks if the original CT scan showed a fluid collection or necrosis or if the amylase/lipase continues to be elevated.
  Follow-up findings may include:
  - Pseudocyst (occurs in 10%) or abscess (sudden onset of fever):
    Conservative management is an option for asymptomatic pseudocysts up 6 cm in diameter.
  - Splenic vein thrombosis (gastric variceal hemorrhage rarely occurs)
  - Pseudoaneurysm (splenic, gastroduodenal, intrapancreatic) hemorrhage can be life-threatening.
- Mild exocrine and endocrine dysfunction is usually subclinical. Patients with necrotizing pancreatitis, steatorrhea, or ductal obstruction, however, should receive enzyme supplementation.
- After the first episode of acute pancreatitis, the risk of lifetime diabetes doubles.
- After the first episode of acute pancreatitis, the risk of developing acute recurrent pancreatitis is ~17%. The risk for developing chronic pancreatitis is ~8%.

DIET
Advance diet as tolerated; reduce fat, alcohol, and added sugars.

**PROGNOSIS**

85–90% of cases of acute pancreatitis resolve spontaneously; 3–5% mortality (17% in necrotizing pancreatitis)

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- K85.9 Acute pancreatitis, unspecified
- K85.8 Other acute pancreatitis
- K85.2 Alcohol induced acute pancreatitis
CLINICAL PEARLS

- Pancreatitis is a common indication for hospitalization.
- Gallstones and alcohol misuse are the leading causes for pancreatitis.
- The BISAP score is easier to apply than Ranson criteria and just as accurate for predicting mortality in patients with acute pancreatitis.
- Review all medications and discontinue any that may cause (or contribute to) pancreatitis.
- Start oral feeding as soon as possible in the absence of severe pain, vomiting, or ileus.
- Patients with mild pancreatitis can progress to severe pancreatitis over the initial 48 hours, often due to inadequate fluid replacement.
- Refer to tertiary center if acute pancreatitis is severe or evolving/worsening.
PANIC DISORDER
Amal Shine, MD • Anub G. John, MD • Hugh Peterson, MD, FACP

BASICS
DESCRIPTION
- A classic panic attack that is characterized by rapid onset of a brief period of sympathetic nervous system hyperarousal accompanied by intense fear.
- In panic disorder, multiple panic attacks occur (including at least one without a recognizable trigger). Worried anticipation of additional attacks, which can be disabling, is present for at least 1 month, and often, maladaptive (e.g., avoidance) behaviors develop.

EPIDEMIOLOGY
Incidence
- Predominant age: All ages; in school-aged children, panic disorder can be confused with conduct disorder and school avoidance.
- Median age of onset 24 years. Prevalence significantly decreases after 60 years.
- Predominant sex: female > male (2:1)

Prevalence
- Lifetime prevalence: 4.7%
- 4–8% of patients in a primary care practice population have panic disorder.
- Of patients presenting with chest pain in the emergency room, 25% have panic disorder.
- Chest pain is more likely due to panic if atypical, younger age, female, and known problems with anxiety.

ETIOLOGY AND PATHOPHYSIOLOGY
Remain unproven
- Biologic theories focus on limbic system malfunction in dealing with anxiety-evoking stimuli.
- Psychological theories posit deficits in managing strong emotions such as fear.
and anger.
- Noradrenergic neurotransmission from the locus coeruleus causes increased sympathetic stimulation throughout the body.
- Current neurobiologic research focuses on abnormal responses to anxiety-producing stimuli in the hippocampus, amygdala, and prefrontal cortex; for example, there appears to be limbic kindling in which an original frightening experience dominates future responses even when subsequent exposures are not objectively threatening.
- Brain pH disturbances (e.g., excess lactic acid) from normal mentation in genetically vulnerable patients may activate the amygdala and generate unexpected fear responses.
- Long term systemic inflammation caused by psychiatric comorbidities, medical comorbidities, and psychosocial stresses also impacts panic disorder.
- Twin studies have suggested a heritability of approximately 40% with contributions of 10% from common familial environment and >50% from individual-specific environmental effects. Some monoamine-related genes, such as serotonin transporter and monoamine oxidase A genes, have been proven to play a role in panic disorder.

**RISK FACTORS**
- Life stressors of any kind can precipitate attacks.
- History of sexual or physical abuse; anxious, overprotective parents
- Substance abuse, bipolar disorder, major depression, obsessive-compulsive disorder (OCD), and simple phobia

**COMMONLY ASSOCIATED CONDITIONS**
- Of patients with panic disorder, >70% also have ≥1 other psychiatric diagnoses: PTSD (recalled trauma precedes panic attack), social phobia (fear of scrutiny precedes panic attack), simple phobia (fear of something specific precedes panic), major depression, bipolar disorder, substance abuse, OCD, separation anxiety disorder.
- Panic disorder is more common in patients with asthma, migraine headaches, hypertension, mitral valve prolapse, reflux esophagitis, interstitial cystitis, irritable bowel syndrome, fibromyalgia, nicotine dependence.
- Panic disorder increases the risk of suicide attempts and ideation.

**DIAGNOSIS**
• Panic attack: an abrupt surge of intense fear, reaching a peak within minutes in which ≥4 of the following symptoms develop abruptly: (i) palpitations, pounding heart, or accelerated heart rate; (ii) sweating; (iii) trembling or shaking; (iv) sensation of shortness of breath or smothering; (v) a choking sensation; (vi) chest pain or discomfort; (vii) nausea or abdominal distress; (viii) feeling dizzy, unsteady, lightheaded, or faint; (ix) derealization (feelings of unreality) or depersonalization (feeling detached from oneself); (x) fear of losing control or going crazy; (xi) fear of dying; (xii) paresthesias; (xiii) chills or hot flashes (1)[C]
• Panic disorder: recurrent unexpected panic attacks not better accounted for by another psychiatric condition (e.g., PTSD, OCD, separation anxiety disorder, social anxiety disorder, or specific phobia) and not induced by drugs of abuse, medical conditions, or prescribed drugs and with >1 month of at least one of the following: (i) worry about additional attacks or worry about the implications of the attack (e.g., losing control, having a heart attack, “going crazy”); (ii) a significant maladaptive change in behavior related to the attacks (1)[C]
• Unlike DSM IV, DSM-5 defines agoraphobia as separate from panic disorder (1)[C].

HISTORY
• The best way to get a good history is through tactful, nonjudgmental questioning. Information should be elicited about current life stress, separations, recent deaths, patient concerns and fears, interpersonal problems.
• A thorough medication and substance abuse history is important.
• Patients must have a month of fear of out-of-the-blue panic attacks to diagnose panic disorder. Ask for avoidance patterns that have developed since the onset of panic attacks.

PHYSICAL EXAM
• During an attack, there will be tachycardia, hyperventilation, and diaphoresis.
• Check the thyroid for fullness or nodules.
• Cardiac exam to check for a murmur or arrhythmias
• Lung exam to rule out asthma (limited airflow, wheezing)

DIFFERENTIAL DIAGNOSIS
• Medication use may mimic panic disorder and create anxiety: Paradoxically, antidepressants used to treat panic may, initially, worsen panic;
antidepressants in bipolar patients can cause anxiety/mania/panic; short-acting benzodiazepines (alprazolam), β-blockers (propranolol), and short-acting opioids can cause interdose rebound anxiety; benzodiazepine treatment causes panic when patients take too much and run out of these medicines early; bupropion, levodopa, amphetamines, steroids, albuterol, sympathomimetics, fluoroquinolones, and interferon can cause panic.

- Substances withdrawal or abuse: alcohol withdrawal, benzodiazepine withdrawal, opioid withdrawal, caffeine, marijuana (panic with paranoia), amphetamine abuse, MDMA, hallucinogens (PCP, LSD), dextromethorphan abuse, synthetic cathinones (bath salts) abuse
- Medical conditions: cardiovascular (tachyarrhythmias, myocardial infarction, mitral valve prolapse), pulmonary (asthma, COPD, reflux esophagitis with hyperventilation, hypoxia, pulmonary embolism), endocrine (hypothyroidism, hyperthyroidism, menopause, pregnancy, hypoglycemia in diabetes, carcinoid syndrome, pheochromocytoma, Cushing syndrome, hyperaldosteronism, Wilson disease), neurologic (transient ischemic attacks [TIAs], pre- and postictal states, e.g., in TLE), miscellaneous (autoimmune disease, e.g., SLE; inner ear disturbances, e.g., labyrinthitis, anaphylaxis, heavy metal poisoning, heavy metal poisoning)
- Psychiatric conditions that have overlapping symptomatology include mood, anxiety, and personality disorders such as major depression, bipolar disorder, PTSD, borderline personality disorder, social phobia, OCD, and generalized anxiety disorder. In PTSD, there is always a recollection or visual image that precedes the panic attack. In social phobia, fear of scrutiny precedes the panic attack. In bipolar disorder, major depression, borderline personality disorder, and particularly substance abuse, the patient often complains first of panic symptoms and anxiety and minimizes other potentially relevant symptoms and behaviors.
- Somatic symptom disorder is also an illness of multiple unexplained medical symptoms, but the presenting picture is usually one of chronic symptoms rather than the acute, dramatic onset of a panic attack. Somatic symptom disorder and panic disorder can be (and often are) diagnosed together.

**DIAGNOSTIC TESTS & INTERPRETATION**

Consider ECG and pulse oximetry to rule out certain serious causes of panic; consider Holter monitoring. No specific lab tests are indicated except to rule out conditions in the differential diagnosis.

- Fingerstick blood sugar in acute setting in a diabetic patient
Thyroid-stimulating hormone (TSH), electrolytes, CBC
Consider ordering echocardiogram if you suspect mitral valve prolapse.

**Diagnostic Procedures/Other**
- If a medical cause of anxiety is strongly suspected, do the workup appropriate for that condition.
- Panic Disorder Severity Scale (PDSS) is a physician or self-administered instrument for monitoring changes in severity of symptoms and response to treatment.
  - [https://www.outcometracker.org/library/PDSS.pdf](https://www.outcometracker.org/library/PDSS.pdf)

**TREATMENT**
The two options are cognitive-behavioral therapy (CBT) and medical therapy. Studies have shown that both have comparable results and neither has advantage over the other. Combined antidepressant therapy and psychotherapy is superior to either alone during initial treatment for panic disorder (2)[A]. CBT provides long-lasting treatment, often without subsequent need for medications.

**GENERAL MEASURES**
CBT, tailored for panic disorder, consists of several steps: education, changing cognitions about the attack and the illness, relaxation and controlled breathing techniques, and, if appropriate, exposure to anxiety-provoking conditions coupled with relaxation exercises.

**MEDICATION**
- Medication management is indicated if psychotherapy is not successful (or not available) and may be combined with psychotherapy.
- Antidepressants like serotonin selective reuptake inhibitor (SSRI), serotonin-norepinephrine reuptake inhibitor (SNRI), tricyclic antidepressant (TCA), monoamine oxidase inhibitor (MAOI), and benzodiazepines have shown efficacy in treating panic disorder.
- If medications are started, they should be maintained for at least 1 year after symptom control.

**First Line**
- SSRIs are first line given efficacy, benign side effect profile, and lack of abuse
potential.

- Start a low-dose SSRI, for example, fluoxetine 5 mg, paroxetine 10 mg, sertraline 25 mg, citalopram 10 mg, and escitalopram 5 mg once daily in the morning. Titrate up slowly every 1 to 2 weeks to therapeutic doses over a period of 6 weeks. Side effects include irritability, diarrhea, and sexual dysfunction. Suicidality can be seen in young patients. When stopping SSRI, taper over few months (3)[A].

- Patients with associated mental disorders may benefit from a combination of SSRI and CBT.

**Second Line**

- Among SNRIs, venlafaxine extended release (ER) is effective. Start at 37.5 mg/day and titrate up to 75 mg/day after 7 days (maximum dose of 225 mg/day). Taper slowly over weeks to discontinue; risk of hypertension at higher doses (4)[A]

- TCAs, particularly imipramine (start 25 mg/day in the evening and increase up to 25 mg every 3 days to a maximum of 200 mg/day); slower titration and lower doses are often as effective. Imipramine is as efficacious as SSRIs in the treatment of panic disorder. TCAs are considered second line because of difficulty in dosing, more side effects, and greater risk associated with overdose compared with SSRIs (5)[A]. Screen for cardiac conduction system in patients >40 years of age with an electrocardiogram.

- MAOIs like phenelzine and tranylcypromine are also efficacious compared to placebo. Avoid with serotonergic agents given risk for serotonin syndrome.

- Benzodiazepines like alprazolam (start 0.5 mg TID and up to 5 mg/day) and clonazepam (0.25 mg BID to target 1 mg/day) are FDA-approved for panic disorder. Clonazepam has a longer half-life, less interdose anxiety, and lower abuse potential than alprazolam.

**ISSUES FOR REFERRAL**

Consider referral to a psychiatrist for panic disorder that is comorbid with bipolar disorder, borderline personality disorder, schizophrenia, suicidality, alcohol, or substance abuse.

**ADDITIONAL THERAPIES**

Aerobic exercise may reduce symptoms.

**ADMISSION, INPATIENT, AND NURSING**
CONSIDERATIONS

- If certain life-threatening mimics of panic disorder have not been ruled out, such as an MI or PE, hospitalize the patient to complete the evaluation.
- If a panic disorder patient has concrete suicidal ideation, a psychiatric admission is indicated.

ONGOING CARE

PATIENT EDUCATION

PROGNOSIS

- Panic disorder is a chronic or intermittent disease. Remission occurs in 64.5% of patients with a mean time to remission of about 5.7 months. Recurrence does occur in 21.4% in those who achieved remission. Predictors of remission are female gender, absence of ongoing stressors, and a low initial frequency of attacks (6).

COMPLICATIONS

- Iatrogenic benzodiazepine dependence
- Iatrogenic mania in bipolar patients treated for panic with unopposed antidepressants
- Misdiagnosis of panic in patients with difficult-to-treat psychiatric conditions

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Anxiety

**CODES**

**ICD10**
- F41.0 Panic disorder without agoraphobia
- F40.01 Agoraphobia with panic disorder
- F43.0 Acute stress reaction

**CLINICAL PEARLS**

For medically able patients, 10 minutes of vigorous aerobic exercise at onset of a panic attack often helps patient to feel safe during an attack. Always evaluate a patient with panic for suicidality. Patients with panic disorder are at increased risk for suicide, particularly if depressed.
PARKINSON DISEASE
Donald M. Chaffee III, MD

BASICS

DESCRIPTION
- Parkinson disease (PD) is a progressive neurodegenerative disorder caused by degeneration of dopaminergic neurons in the substantia nigra pars compacta.
- Cardinal symptoms include resting tremor, rigidity, bradykinesia, and postural instability.
- Diagnosis is based primarily on history and examination.

EPIDEMIOLOGY

Incidence
- Average age of onset: ~60 years
- Slightly more common in men than women

Prevalence
- Second most common neurodegenerative disease after Alzheimer disease
- 0.3% of general population and 1–2% of those ≥60 years of age and up to 4% of those ≥80 years of age
- Affects approximately 1 million people in the United States and 5 million worldwide

ETIOLOGY AND PATHOPHYSIOLOGY
Dopamine depletion in the substantia nigra and the nigrostriatal pathways results in the major motor complications of PD.
- Pathologic hallmark: selective loss of dopamine-containing neurons in the pars compacta of the substantia nigra
- Loss of neurons accompanied by presence of Lewy bodies, pale bodies (predecessor of the Lewy body), and Lewy neuritis

Genetics
Mutations in multiple autosomal dominant and autosomal recessive genes have been linked to PD/parkinsonian syndrome particularly when the age at symptom
onset is <50 years. Genes investigated in PD include SNCA, Parkin, PINK1, DJ-1, and LRRK2.

**RISK FACTORS**
- Age and family history of PD or tremor are the greatest risk factors.
- History of smoking as well as coffee and caffeine intake may reduce risk.
- Weak association with exposure to toxins (herbicides and insecticides); however, relationship is not clear.

**COMMONLY ASSOCIATED CONDITIONS**
Non–motor-associated symptoms include cognitive abnormalities, autonomic dysfunction (e.g., constipation, urinary urgency), sleep disturbances, mental status changes (depression, psychosis, hallucinations, dementia), orthostatic hypotension, and pain.

**DIAGNOSIS**
- Diagnosis is based on clinical features of bradykinesia, resting tremor, asymmetry of symptoms, and response to dopaminergic therapy.
- Gold standard for diagnosis is neuropathologic exam.
- Generally, bradykinesia plus either tremor or rigidity must be present in order to make the diagnosis of idiopathic PD.

**HISTORY**
Symptoms often subtle or attributed to aging:
- Decreased emotion displayed in facial features
- General motor slowing and stiffness (one or both arms do not swing with walk)
- Resting tremor (often initially one hand)
- Speech soft/mumbling
- Falls/difficulty with balance (tends to occur with disease progression)

**PHYSICAL EXAM**
- Tremor
  - Resting tremor (4 to 6 Hz) that is often asymmetric
  - Disappears with voluntary movement
  - Frequently emerges in a hand while walking and may present as pill rolling
– May also present in jaw, chin, lips, tongue

- Bradykinesia
- Rigidity: cogwheel (catching and releasing) or lead pipe (continuously rigid)
- Postural instability

**DIFFERENTIAL DIAGNOSIS**

- Essential tremor: Bradykinesia is not present; often symmetric and occurs mostly during action or when holding hands outstretched
- SWEDD: scans without evidence of dopaminergic deficit; isolated upper extremity resting and postural tremor resembling PD but failing to progress to generalized PD; no akinesia
- Dementia with Lewy bodies: characterized clinically by visual hallucinations, fluctuating cognition, and parkinsonism; dementia occurs concomitantly with or before the development of parkinsonism.
- Corticobasal degeneration: asymmetric parkinsonism, absence of tremor, no response to levodopa
- Multiple system atrophy: presents with parkinsonism but with varying degrees of dysautonomia, cerebellar involvement, and pyramidal signs
- Progressive supranuclear palsy: impairment in vertical eye movements (particularly down gaze), hyperextension of neck, and early falling; pseudobulbar palsy
- Idiopathic basal ganglia calcification
- Associated neurodegenerative disorders: late stages of Alzheimer disease, Huntington disease, frontotemporal dementia, spinocerebellar ataxias
- Secondary parkinsonism
  - Drug induced: reversible; may take weeks/months after offending medication is stopped
    - Neuroleptics (most common cause)
    - Antiemetics (e.g., prochlorperazine and promethazine), metoclopramide
    - SSRIs
    - Calcium channel blockers (e.g., flunarizine and cinnarizine)
      metoclopramide
    - Amiodarone
    - Lithium
    - Cholinergics
    - Chemotherapeutics
    - Amphotericin B
    - Estrogens
    - Valproic acid
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Diagnosis is mainly clinical, and there are no physiologic or blood tests to confirm the diagnosis.
- Excellent response to an acute dopaminergic challenge test supports the diagnosis.
- MRI of brain is nondiagnostic but can be used to rule out structural abnormalities.
- DaTscan: Striatal dopamine transporter imaging can distinguish PD and other parkinsonian syndromes but cannot differentiate between them.
- PET and single-photon emission CT may be helpful with diagnosis but are not required.

TREATMENT

GENERAL MEASURES
- Multidisciplinary rehabilitation with standard physical and occupational therapy components to improve functional outcomes
- Physiotherapy to help with gait reeducation, enhancement of aerobic capacity, improvement in movement initiation, improvement in functional independence, and help with home safety

MEDICATION
- PD goal: Improve motor and nonmotor deficits.
- Agents are chosen based on patient age and symptoms present.
- No treatment shown to slow progression or offer neuroprotection

First Line
- First-line agents in early PD: levodopa, dopamine agonists, monoamine oxidase B (MAO-B) inhibitors (1)[A]
  - Levodopa combined with carbidopa is still the most effective treatment for symptoms of PD, particularly bradykinesia.
  - Levodopa versus dopamine agonist is controversial (2)[B]:
    - Most patients eventually will develop motor fluctuations with levodopa. Younger patients are more likely to develop motor fluctuations. Some recommend delaying initiation of levodopa to decrease drug-induced
motor fluctuations early in the disease.
- Older patients often are less able to tolerate the adverse events of dopamine agonists.
- All patients eventually will require levodopa.
  - MAO-B inhibitors (rasagiline) should be considered as initial monotherapy; currently being investigated for potential neuroprotective effects (2)[B]

- Carbidopa + levodopa (carbidopa inhibits peripheral conversion of levodopa)
  - Immediate release (Sinemet)
    - Tablets (mg): 10/100, 25/100, 25/250
    - Usual initial maintenance dose: 25/100 mg PO TID. Most patients require 25 mg of carbidopa to inhibit peripheral conversion of levodopa.
    - Watch for nausea/vomiting, orthostatic hypotension, sedation, and vivid dreams.
  - Orally disintegrating (Parcopa)
    - Tablets (mg): 10/100, 25/100, 25/25
  - Sustained release (Sinemet CR):
    - Tablets (mg): 25/100, 50/200
    - Dose agents initially BID

- Carbidopa + levodopa + entacapone (Stalevo)
  - Tablets (mg): 12.5/50/200, 18.75/75/200, 25/100/200, 31.25/125/200, 37.5/150/200, 50/200/200
  - Addition of entacapone as a single agent should be initiated prior to use of this combination:
    - Once daily dose of carbidopa/levodopa has been identified; may convert to Stalevo
    - Dose of levodopa may need to be decreased with the addition of entacapone.
  - Side effects are the same, plus diarrhea and brownish orange urine.

- Dopamine agonists (nonergot): side effects: nausea, vomiting, hypotension, sedation, edema, vivid dreaming, compulsive behavior, confusion, light-headedness, and hallucinations:
  - Pramipexole (Mirapex): tablets (mg): 0.125, 0.25, 0.5, 1, 1.5
    - Start with 0.125 mg TID; gradually increase every 5 to 7 days; usual maintenance of 0.5 to 1.5 mg TID
    - CrCl 30 to 59 mL/min 0.125 mg PO BID
    - CrCl 15 to 29 mL/min 0.125 mg PO daily
  - Pramipexole ER (Mirapex ER): tablets (mg): 0.375, 0.75, 1.5, 3, 4.5; start with 0.375 PO daily.
  - Ropinirole (Requip): tablets (mg): 0.25, 0.5, 1, 2, 3, 4, 5; start with 0.25 mg
TID; increase gradually to 3 to 8 mg TID.
- Requip XL: tablets (mg): 2, 4, 6, 8, 12; start at a 2-mg dose once daily; increase in 1 to 2 weeks.

- Selective MAO-B inhibitors: side effects: insomnia, jitteriness, hallucinations; mostly found with selegiline; rasagiline similar adverse events as placebo in clinical trials. Rasagiline is metabolized via CYP1A2; caution with other medications using this enzyme system (e.g., ciprofloxacin):
  - Both agents contraindicated with meperidine and numerous other agents metabolized via CYP1A2
  - At therapeutic doses, unlikely to induce a “cheese reaction” (tyramine storm)

- Selegiline (Eldepryl)
  - Tablets: 5 mg; initiate 5 mg PO BID.
  - Orally disintegrating tablet (Zelapar): 1.25 mg; 1.25 mg PO daily for 6 weeks; increase as needed to max of 2.5 mg daily.

- Rasagiline (Azilect): tablets: 0.5 mg, 1.0 mg; initiate 0.5 to 1.0 mg daily.

Second Line

- Second-line agents in early PD: β-adrenergic antagonists (postural tremor), amantadine, anticholinergics (young patients with tremor); there is lack of good evidence for symptom control (1)[A].

- Dopamine agonists (ergot): Increased adverse event profile makes these agents nonpreferred to nonergot dopamine agonists; bromocriptine (Parlodel)

- Treatment of levodopa-induced motor complications
  - End of dose wearing off
    - Entacapone (with each levodopa dose) or rasagiline preferred (3)[B]
    - May also consider dopamine agonist, apomorphine, selegiline (4)[B]
  - Dyskinesias
    - Typically occur at peak dopamine level
    - Amantadine may be considered; however, its efficacy is questionable (1)[B].

- Anticholinergic agents: usually avoided due to lack of efficacy (only useful for tremor) and increased adverse event profile, including blurred vision, confusion, constipation, dry mouth, memory difficulty, sedation, and urinary retention
  - Trihexyphenidyl
    - Tablets: 2 mg, 5 mg
    - Start with 1 to 2 mg daily; increase by 2 mg every 3 to 5 days until usual
dose is 6 to 10 mg in 3 to 4 divided doses.

- Benztropine (Cogentin)
  o Tablets: 0.5 mg, 1 mg, 2 mg
  o Start with 0.5 to 1.0 mg in 1 to 2 divided doses; increase by 0.5 mg every 5 to 6 days; usual dose is 1 to 2 mg/day in divided doses.

- N-methyl-D-aspartic acid antagonist: Exact mechanism is unknown and efficacy is questionable; however, it may be useful for dyskinesias. Side effects include confusion, dizziness, dry mouth, livedo reticularis, and hallucinations:
  - Amantadine (Symmetrel)
    o Tablets: 100 mg
    o Start with 100 mg BID; may increase to 300 mg daily in divided doses; renally adjusted

- Catechol O-methyltransferase (COMT) inhibitors: entacapone preferred due to hepatotoxicity associated with tolcapone. Adverse events include nausea and orthostatic hypotension:
  - Entacapone (Comtan)
    o Tablets: 200 mg
    o 200 mg with each dose of carbidopa/levodopa; max dose 1,600 mg/day
  - Tolcapone (Tasmar)
    o Tablets: 100 mg, 200 mg
    o Start 100 mg TID; max dose 600 mg/day; must be taken with carbidopa/levodopa
    o Requires LFT monitoring

- Apomorphine (Apokyn): nonergot-derived dopamine agonist given SC for off episodes in advanced disease; adverse events: nausea, vomiting, dizziness, hallucinations, orthostatic hypotension, somnolence
  - Only for “off” episodes with levodopa therapy
  - Requires initial “test” dose (2 mg); monitor for orthostatic hypotension after initial dose; this is a potent emetic, so initiate an antiemetic (e.g., trimethobenzamide) 3 days prior to start and continue for 2 months. Avoid ondansetron (combination contraindicated due to profound hypotension) and dopamine antagonists, such as prochlorperazine and metoclopramide.
  - Effective dose ranges from 2 to 6 mg per injection.

**ISSUES FOR REFERRAL**

Early specialty referral (neurology) for patients with suspected PD to receive a more thorough clinical assessment and for treatment recommendations
ADDITIONAL THERAPIES

- Emotional and psychological support of patient family
- Physical therapy and endurance exercise has been shown to improve balance, muscle strength, walking speed, and the score on various clinical evaluation tools.
- Speech therapy: may be helpful in improving speech volume and maintaining voice quality
- Treatment of nonmotor symptoms
  - Sildenafil to treat erectile dysfunction (5)[C]
    - Tablets: 25 mg, 50 mg, 100 mg
    - Take once daily 1 hour prior to sexual activity.
    - Caution with orthostatic hypotension; avoid with nitrates.
  - Polyethylene glycol to treat constipation (5)[C]
    - Mix 17 grams in 8 oz of water once daily.
    - May titrate to one soft bowel movement per day
  - Carbidopa + levodopa to treat periodic limb movements (5)[B]

SURGERY/OTHER PROCEDURES

Deep brain stimulation (bilateral subthalamic nucleus/globus pallidus interna) is an effective therapeutic option for patients with motor complications refractory to best medical treatment who are healthy, have no significant comorbidities, are responsive to levodopa, and do not have depression or dementia.

ONGOING CARE

DIET

- Increase dietary fluids and fiber and increase activity for constipation.
- For dysphagia, consider soft food, swallowing evaluation, and increased time for meals.
- Avoid large, high-fat meals that slow digestion and interfere with medication absorption.

PATIENT EDUCATION

- www.apdaparkinson.org
- www.parkinson.org
- www.michaeljfox.org
PROGNOSIS
- PD is a chronic progressive disease; prognosis varies based on patient-specific symptoms.
- Increased mortality in PD; on average, PD survival reduced by 5% every year of follow-up (4)

COMPLICATIONS
Most commonly, the result of adverse effects of medications used to treat

REFERENCES

ADDITIONAL READING

CODES
mebooksfree.com
ICD10

- G20 Parkinson’s disease
- G21.9 Secondary parkinsonism, unspecified
- G31.83 Dementia with Lewy bodies

CLINICAL PEARLS

- The classic description for PD is shaky, stiff, slow, and stumbling.
- Emphasize the importance of exercise and movement to help preserve function.
- Pharmacotherapeutic regimens need to be individualized based on patient-specific symptoms and age.
PARONYCHIA
Nancy V. Nguyen, DO

BASICS
DESCRIPTION

● Superficial inflammation of the lateral and posterior folds of skin surrounding the fingernail or toenail
  – Acute: characterized by pain, erythema, and swelling; usually a bacterial infection appears after trauma. It can progress to abscess formation.
  – Chronic: characterized by swelling, tenderness, cuticle elevation, and nail dystrophy and separation lasting at least 6 weeks, or recurrent episodes of acute eponychial inflammation and drainage
  – May be considered work-related among bartenders, waitresses, nurses, and others who often wash their hands

● System(s) affected: skin and nail bed
● Synonym(s): eponychia, perionychia

Pediatric Considerations
Less common in pediatric age groups. Thumb/finger-sucking is a risk factor (anaerobes and Escherichia coli may be present).

EPIDEMIOLOGY
Incidence
● Common in the United States
● Predominant age: all ages
● Predominant sex: female > male

ETIOLOGY AND PATHOPHYSIOLOGY

● Acute: Staphylococcus aureus (1) most common and Streptococcus pyogenes (1); less frequently, Pseudomonas pyocyanea and Proteus vulgaris. In digits exposed to oral flora especially in pediatric age group, consider Eikenella corrodens, Fusobacterium, and Peptostreptococcus.
● Chronic: eczematous reaction with secondary Candida albicans (~95%)
● A paronychial infection commonly starts in the lateral nail fold.
● Recurrent inflammation, persistent edema, and fibrosis of nail folds cause nail
folds to round up and retract, exposing nail grooves to irritants, allergens, and pathogens.

- Inflammation compromises ability of proximal nail fold to regenerate cuticle leading to decreased vascular supply. This can cause decrease efficacy of topical medications.
- Early in the course, cellulitis alone may be present. An abscess can form if the infection does not resolve quickly.

**RISK FACTORS**

- Acute: direct or indirect trauma to cuticle or nail fold, manicure/sculptured nails, nail biting, and thumb sucking and predisposing conditions such as diabetes mellitus (DM)
- Chronic: frequent immersion of hands in water with excoriation of the lateral nail fold (e.g., chefs, bartenders, housekeepers, swimmers, dishwashers, nurses), DM, immunosuppression (reported association with antiretroviral therapy for HIV and with use of epidermal growth factor inhibitors)

**GENERAL PREVENTION**

- Acute: Avoid trauma such as nail biting; prevent thumb sucking.
- Chronic: Avoid allergens; keep fingers/hands dry; wear rubber gloves with a cotton liner. Prevent excoriation of the skin.
- Keep nails short. Avoid manicures. Apply moisturizer after washing hands.
- Good glycemic control in diabetic patients

**COMMONLY ASSOCIATED CONDITIONS**

- DM
- Eczema or atopic dermatitis
- Certain medications: antiretroviral therapy (especially protease inhibitors, indinavir, and lamivudine, in which toes more commonly involved) (2)
- Immunosuppression (3)

**DIAGNOSIS**

**HISTORY**

- Localized pain or tenderness, swelling, and erythema of posterior or lateral nail folds
  - Acute: fairly rapid onset
– Chronic: at least 6 weeks’ duration
● Previous trauma (bitten nails, ingrown nails, manicured nails)
● Contact with herpes infections
● Contact with allergens or irritants (frequent water immersion, latex) (3)

PHYSICAL EXAM
● Acute: red, warm, tender, tense posterior or lateral nail fold ± abscess
● Chronic: swollen, tender, boggy nail fold ± abscess
● Occasional elevation of nail bed
● Separation of nail fold from nail plate
● Red, painful swelling of skin around nail plate
● Fluctuance, purulence at the nail margin, or purulent drainage
● Secondary changes of nail platelike discoloration
● Suspect *Pseudomonas* if with green changes in nail (chloronychia).
● Positive fluctuation when mild pressure over the area causes blanching and
demarcation of the abscess.
● Chronic: retraction of nail fold and absence of adjacent healthy cuticle,
thickening of nail plate with prominent transverse ridges known as Beau lines
and discoloration; multiple digits typically involved

DIFFERENTIAL DIAGNOSIS
● Felon (abscess of fingertip pulp; urgent diagnosis required)
● Eczema
● Herpetic whitlow (similar in appearance, very painful, often associated with
vesicles)
● Allergic contact dermatitis (latex, acrylic)
● Psoriasis especially acute flare
● Proximal/lateral onychomycosis (nail folds not predominantly involved)
● Pemphigus vulgaris
● Acute osteomyelitis of the distal phalanx
● Reiter disease
● Pustular psoriasis
● Dermatomyositis
● Malignancy: squamous cell carcinoma of the nail, malignant melanoma,
metastatic disease

DIAGNOSTIC TESTS & INTERPRETATION
None required unless condition is severe; resistant to treatment or if recurrence
or methicillin-resistant *S. aureus* (MRSA) is suspected, then

- Gram stain
- Culture and sensitivity
- Potassium hydroxide wet mount plus fungal culture especially in chronic
- Drugs that may alter lab results: use of over-the-counter antimicrobials or antifungals

**Diagnostic Procedures/Other**

- Incision and drainage recommended for suppurative cases or cases not responding to conservative management or empiric antibiotics
- Tzanck testing or viral culture in suspected viral cases
- Biopsy in cases not responding to conservative management or when malignancy suspected

**TREATMENT**

**GENERAL MEASURES**

- Acute: warm compresses/soaks, elevation, splint protection if pain severe
- Abscesses should be opened to promote drainage.
- Insert nail elevator or hypodermic needle at junction of the affected nail fold and nail to facilitate drainage. If no drainage occurs, use a needle or scalpel to open skin directly above abscess.
- Chronic: Keep fingers dry; apply moisturizing lotion after hand washing; avoid exposure to irritants; improved diabetic control

**MEDICATION**

**First Line**

- Tetanus booster when indicated
  - Acute (mild cases, no abscess formation) Burow solution (aluminum acetate solution) and vinegar (acetic acid) combined with warm soaks
  - Topical antibiotic cream alone or in combination with a topical steroid
  - Antibiotic cream applied TID–QID after warm soak (e.g., mupirocin or gentamicin or a topical fluoroquinolone) for 5 to 10 days
  - If eczematous: low potent topical steroid applied BID (e.g., betamethasone 0.05% cream) for 7 to 14 days
- Acute (no exposure to oral flora). Treat for 7 days.
– Dicloxacillin 250 mg QID
– Cephalexin 500 mg TID–QID

**Acute (exposure to oral flora).** Treat for 7 days. Cover for Eikenella.
– Amoxicillin clavulanate: 875 mg/125 mg BID; pediatric, 45 mg/kg q12h (for <40 kg) doxycycline 100 mg BID or trimethoprim/sulfamethoxazole BID or ciprofloxacin 500 to 750 mg BID; plus clindamycin 300 to 450 mg TID–QID; pediatric, 10 mg/kg q8h, or metronidazole 500 mg TID

**Acute (suspected MRSA).** Treat for 7 days.
– Trimethoprim/sulfamethoxazole 160 mg/800 mg BID
– Doxycycline 100 mg BID
– Clindamycin 300 to 450 mg TID–QID

**Chronic**
– Topical steroids: betamethasone 0.05%; applied BID for 7 to 14 days (4)[B]
– Topical antifungal: clotrimazole or nystatin; applied topically TID for up to 30 days
– Other topical: Tacrolimus 0.1% ointment BID for up to 21 days has been shown to be effective but is more expensive.
– Doxycycline 100 mg BID for paronychia caused by antiepidermal growth factor receptor antibodies

**Second Line**

– Systemic antifungals (rarely needed, use if topical fails)
  – Itraconazole 200 mg for 90 days (may have longer action because it is incorporated into nail plate); pulse therapy may be useful (i.e., 200 mg BID for 7 days, repeated monthly for 2 months) (1)[C].
  – Terbinafine 250 mg/day for 6 weeks (fingernails) or 12 weeks (toenails)
  – Fluconazole 100 mg daily for 7 to 14 days
  – Ciclopinox 0.77% topical suspension BID for 2 to 4 weeks along with strict irritant avoidance (5)[B]

– Antipseudomonal drugs (e.g., ceftazidime, aminoglycosides) when pseudomonas is suspected

**ISSUES FOR REFERRAL**
Chronic: In treatment failure, consider biopsy and/or, in cases of chronic paronychia, referral for possible partial excision of the nail fold or eponychial marsupialization with or without complete nail removal or Swiss roll technique.

**SURGERY/OTHER PROCEDURES**
- Incision and drainage of abscess, if present
- A subungual abscess or ingrown nail requires partial or complete removal of nail with phenolization of germinal matrix.
- Swiss roll technique for chronic and severe acute paronychia with runaround abscess involving both nail folds (4)[A]
- Recalcitrant cases may also need nail removal.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Acute: Postdrainage care consists of warm soaks or soaking with Burow solution or acetic acid BID–TID × 2 to 3 days unless Swiss roll technique used (1)[C].
- Chronic: Avoid frequent immersion, triggers, allergens, or nail biting and finger sucking.

**DIET**

If patient is diabetic, consider appropriate dietary and medication changes for better control.

**PATIENT EDUCATION**

- Avoid trimming cuticles; avoid nail trauma; and stress importance of good diabetic control and diabetic education.
- Avoid contact irritants; use rubber gloves with cotton liners to avoid exposure to excess moisture.
- Use moisturizing lotion after washing hands; do not bite nails/suck on fingers.

**PROGNOSIS**

- With adequate treatment and prevention, healing can be expected in 1 to 2 weeks.
- Chronic paronychia may respond slowly to treatment, taking weeks to months.
- If no response in chronic lesions, rarely benign or malignant neoplasm may be present and referral should be considered.

**COMPLICATIONS**

- Acute: subungual abscess
- Chronic: nail thickening, discoloration of nail, and nail loss

SEE ALSO

Onychomycosis

CODES

ICD10

- L03.019 Cellulitis of unspecified finger
- L03.039 Cellulitis of unspecified toe
- L03.011 Cellulitis of right finger

CLINICAL PEARLS

- Consider tetanus booster when indicated.
- Consider incision and drainage when appropriate. Send culture.
- For chronic paronychia, topical steroid is first-line treatment. Consider other differentials in nonresponders (e.g., rare causes: Raynaud, metastatic cancer, psoriasis, drug toxicity).
- For suspected pseudomonal infections, use a topical fluoroquinolone and acetic acid.
- For chronic nonhealing lesion, consider dermatology referral.
- Consider possibility of cancer if chronic inflammatory process is unresponsive to treatment.
- Consider presence of more than one nail disease at the same time (e.g., paronychia and onychomycosis).
PAROTITIS, ACUTE AND CHRONIC

Alyson Weiner, MD • Kathy Ferrer, MD, AAHIVS

BASICS

DESCRIPTION

- Parotitis is inflammation of the parotid gland caused by infection, noninfectious systemic illnesses, mechanical obstruction, or medications.
- Can be unilateral or bilateral, acute or chronic
- The parotid gland is the largest of the salivary glands, located lateral to the masseter muscle anteriorly and extending posteriorly over the sternocleidomastoid muscle behind the angle of the mandible. It produces exclusively serous secretions, which lack the bacteriostatic properties of mucinous secretions, making the parotid gland more susceptible to infection than other salivary glands.
- The parotid duct, also called the Stensen duct, pierces the buccinator muscle to enter the buccal mucosa just opposite the 2nd maxillary molar.
- The branches of the 7th cranial nerve or “facial nerve” divide the gland into lobes.
- The parotid gland also contains lymph nodes.

EPIDEMIOLOGY

- Viral parotitis is the most common cause of parotitis in children; exact incidence is unknown and has decreased since the advent of the mumps vaccine.
- Acute bacterial parotitis occurs more frequently in elderly patients, neonates (especially preterm infants), and postoperative patients.
- Juvenile recurrent parotitis (JRP) is the second most common inflammatory cause of parotitis in children in the United States; first episode usually occurs between the ages of 3 and 6 years.
- Chronic parotitis mainly affects adults, more often females. The average age of presentation is between 40 and 60 years.
- Chronic bilateral parotid enlargement is a common manifestation of HIV infection; for perinatally HIV-infected children, the average age of onset for parotid enlargement is 5 years.
RISK FACTORS

- Acute viral parotitis: lack of mumps, measles, rubella (MMR) vaccination
- Acute bacterial parotitis
  - Conditions that predispose to salivary stasis, such as dehydration, debilitation, poor oral hygiene, Sjögren syndrome, cystic fibrosis, bulimia/anorexia, sialolithiasis (stones), ductal stenosis, trauma
  - Immunosuppression, HIV, chemotherapy, radiation, malnutrition, alcoholism
- Neonatal parotitis: prematurity, low birth weight, ductal obstruction, oral trauma, structural abnormalities, immunosuppression
- JRP: dental malocclusion, congenital duct malformation, genetic factors, immunologic anomalies
- Drug-induced parotitis: medications such as anticholinergics, ACE inhibitors (captopril), antihistamines, tricyclic antidepressants, antipsychotics (phenylbutazone, thioridazine, clozapine), iodine (contrast media), and L-asparaginase
- Chronic parotitis: ductal stenosis, HIV, tuberculosis, Sjögren syndrome, sarcoidosis, uremia, diabetes, gout, and atopy

GENERAL PREVENTION

- MMR vaccination with the 1st dose between 12 and 15 months and 2nd dose between 4 and 6 years of age; childhood mumps vaccination does not guarantee prevention, possibly due to waning immunity in adolescence.
  - Students in post-high school education without documented mumps immunity should also receive 2 doses of the MMR vaccine, 28 days apart.
  - Pregnant women should not receive the mumps vaccine, and pregnancy should be avoided for 4 weeks after vaccination.
- Maintain adequate hydration and good dental hygiene; smoking cessation, abstinence from alcohol, and avoidance of chronic purging

ETIOLOGY AND PATHOPHYSIOLOGY

- Acute viral parotitis begins as a systemic infection that localizes to the parotid gland, resulting in inflammation and swelling of the gland.
  - Mumps, or paramyxovirus, has a predilection for the parotid gland and classically has been linked to parotitis. The virus replicates in the upper respiratory tract and spreads by direct contact or airborne transmission.
  - Symptoms usually begin 16 to 18 days after infection.
- Acute bacterial parotitis results from stasis of salivary flow that allows
retrograde introduction of bacterial pathogens into the gland, resulting in localized infection.

**Pediatric Considerations**

There have been case reports of acute parotitis as a symptom of Kawasaki disease.

- **Acute parotitis pathogens**
  - **Viral**
    - Paramyxovirus (mumps), parainfluenza virus types 1 and 3, influenza A, coxsackievirus, Epstein-Barr virus (EBV)
    - Cytomegalovirus (CMV) and adenovirus have been seen in patients with HIV.
  - **Bacterial**
    - *Staphylococcus aureus* and anaerobes (oral flora) most commonly
    - *Streptococcus pneumoniae*, viridans streptococci, *Escherichia coli*, and *Haemophilus influenzae* (less common)
    - Other gram-negative rods, such as *Klebsiella*, *Enterobacter*, and *Pseudomonas*, can be seen in chronically ill or hospitalized patients.
    - *Bartonella henselae* in patients with cat exposure (rare)
  - **Fungal**
    - *Candida* has been isolated in chronically ill or hospitalized patients.
    - *Actinomyces* in patients with a history of trauma or dental caries

- **Acute, recurrent parotitis**
  - JRPs may be secondary to chronic inflammation; etiology is unknown, but a genetic predisposition may exist.
  - Mechanical: Repeated sialolith formation leads to ductal wall damage, fibrosis, and stricture formation.
  - Pneumoparotitis may occur when air is trapped in the ducts of the parotid gland; seen in wind instrument players, glass blowers, scuba divers, and with dental cleaning.
  - Certain medications and chronic diseases (see “Risk Factors”) predispose to chronic parotitis.
  - “Anesthesia mumps”: Possible mechanisms include transient mechanical compression of the Stensen duct by airway devices, loss of muscle tone around the Stensen orifice after neuromuscular relaxants, increased salivary secretion, and increased flexion or rotation of the head during general anesthesia.

- **Chronic parotitis** in HIV-infected patients can be due to presence of benign
lymphoepithelial cysts, follicular hyperplasia of parotid lymph nodes, or diffuse infiltrative lymphocytosis syndrome (DILS), causing infiltration of the parotid gland by CD8 cells.

Parotitis may be secondary to immune reconstitution after initiation of antiretroviral therapy.

COMMONLY ASSOCIATED CONDITIONS
Mumps, HIV, Sjögren syndrome, sarcoidosis, sialolithiasis

DIAGNOSIS

HISTORY

- Acute parotitis presents with sudden-onset pain and swelling of the cheek typically extending to and obscuring the angle of the mandible.
  - Viral parotitis is usually bilateral and accompanied by a prodrome of malaise, anorexia, headaches, myalgias, arthralgias, and fever; typically, overlying skin is not warm or erythematous, and no pus is reported at the opening of Stensen duct.
  - Bacterial parotitis is typically unilateral with induration, warmth, and erythema over the affected cheek; fever is often present.
  - JRP is usually unilateral; pain and swelling resolve within 2 weeks, and exacerbations occur until puberty; purulent exudate not typical unless superinfection occurs
  - Sialolithiasis is characterized by recurrent acute swelling and pain, exacerbated by eating; sialolithiasis affects the submandibular gland more frequently.
  - Other reported symptoms include trismus (inability to open mouth), pain exacerbated by chewing or worsened by foods that stimulate production of saliva, dry mouth with abnormal taste, difficulty with drinking/eating, anorexia, or dehydration.

- Chronic parotitis presents with recurrent or chronic nontender swelling of one or both parotid glands; can have periods of remission lasting weeks to years
  - Sjögren syndrome, sarcoidosis, HIV, tuberculosis
  - May predispose to superinfection, which would present similarly to acute parotitis

PHYSICAL EXAM
Parotitis is characterized by swelling or enlargement of the parotid gland(s)
overlying the masseter muscle; may obscure the angle of the mandible or
cause the ear to protrude upward and outward.

Palpation of the parotid gland is best done by using one hand to start at the
attachment of the earlobe and palpating anteriorly and inferiorly along the
mandibular ramus while the other hand simultaneously palpates the Stensen
duct orifice.

- Tender and bilateral suggest viral etiology, whereas tender, erythematous,
  warm, and unilateral suggest bacterial etiology.
- Nontender in chronic parotitis (HIV, tuberculosis, Sjögren syndrome,
sarcoidosis)

Trismus, halitosis, and dental decay may be noted.

Pus from the Stensen duct is suggestive of bacterial parotitis or superinfection;
opening of duct may appear edematous and erythematous in both bacterial
and viral parotitis.

In JRP, the Stensen duct is often enlarged, dilated, erythematous, and swollen.

Facial nerve palsy can be seen in severe cases.

**DIFFERENTIAL DIAGNOSIS**

- Lymphoma, neoplasm, lymphangitis, cervical adenitis, otitis externa, dental
  abscess, odontogenic infections, Ludwig angina, and cellulitis
- Parotid swelling or enlargement typically obscures the angle of the mandible
  (unlike cervical adenitis).
- Involvement of the Stensen duct is unique to parotitis.

**DIAGNOSTIC TESTS & INTERPRETATION**

- History and physical exam are usually sufficient for diagnosis.
- Performing aerobic culture and Gram stain of purulent drainage from Stensen
duct or aerobic and anaerobic culture from needle aspiration of gland or
abscess can be helpful to identify causative organism.
  - Anaerobic culture from Stensen duct will likely contain oropharyngeal
    contamination; it is recommended to perform anaerobic cultures only from
    needle aspirate fluid.
- Acute bacterial parotitis often demonstrates an elevated white blood cell count
  and amylase.
- For suspected mumps, the CDC recommends collecting a buccal/oral swab for
  mumps RT-PCR and a blood specimen for IgM and IgG serologies. Mumps
  RT-PCR is best obtained from a buccal swab within 1 to 3 days of parotitis
  onset by massaging the parotid gland area for 30 seconds prior to collection.
In areas of high vaccination rates, IgM may be falsely negative. A 4-fold increase of mumps IgG antibody indicates infection; normal <1:20

- Consider sending EBV titers and respiratory virus PCR panel if suspected viral parotitis; CMV titers should be sent in immunocompromised patients.
- For chronic, recurrent, or nontender parotitis, obtain HIV test, PPD, SS-A/SS-B antibodies, rheumatoid factor, and antinuclear antibodies to evaluate for underlying etiology.
- Consider obtaining ultrasound or CT scan of parotid area to assess for abscess, cystic masses, tumors, ductal stenosis, or sialolithiasis if no response to initial treatment. JRP patients have diffuse microcalcifications on US.
- Consider sialography for chronic parotitis to assess the anatomy and functional integrity of the gland; can be diagnostic and therapeutic

**Diagnostic Procedures/Other**
Consider performing a biopsy or fine-needle aspiration of gland if there is suspicion for tuberculosis, Sjögren syndrome, or sarcoidosis.

**Test Interpretation**
- Findings characteristic of HIV are described in the “Etiology and Pathophysiology” section.
- Noncaseating granulomas may be seen in sarcoidosis, and caseating granulomas may be found in tuberculosis and *B. henselae* infections.

**TREATMENT**

**GENERAL MEASURES**
- Usually a self-limiting course that requires supportive treatment with rest, adequate hydration, analgesia, and antipyretics
  - Can stimulate glands to produce saliva by sucking on hard candies or glycerin swabs
  - Local heat and gentle massage of gland
  - For chronic presentations, encourage good dental hygiene and treat underlying etiology of parotitis.
- Patients diagnosed with mumps should be isolated with standard and droplet precautions for 5 days after onset of parotid swelling. Mumps is a nationally reportable disease.
- MMR vaccine for postexposure prophylaxis (PEP) in fully vaccinated
individuals during a mumps outbreak results in an immune response but no statistically significant decrease in mumps spread. A third MMR vaccine may be used during an outbreak in which people are in close contact, transmission continues despite high two-dose MMR coverage, and standard control measures do not slow transmission (1)[C].

- Underimmunized individuals should get two doses of the MMR vaccine separated by at least 28 days. This will not help prevent disease if the person was already infected but will help prevent future infection.

**MEDICATION**

- Viral parotitis: There is no evidence for the role of immunoglobulin for PEP or treatment; may initiate the below antibiotics if patient is toxic appearing or has an unclear diagnosis
- Acute bacterial parotitis
  - Outpatient management: amoxicillin/clavulanate, 1st-generation cephalosporin, clindamycin
  - Chronically ill or hospitalized: ampicillin/sulbactam or clindamycin and nafcillin; if MRSA is probable, consider vancomycin or linezolid.
- Sjögren syndrome recurrent parotitis: Pilocarpine and cevimeline can stimulate saliva production and inhibit ascending infection as well as provide symptomatic relief. Alternatively, botulism toxin injection may be a consideration in these patients, as it limits production of saliva and sialectasis (2)[B].

**SURGERY/OTHER PROCEDURES**

- Consider needle aspiration for bacterial parotitis with abscess formation or clinical deterioration with increasing pain, erythema, and swelling not responding to medication.
- For sialolithiasis, ductal stenosis, or for patients with >1 recurrences per year, consult otolaryngologist for possible sialendoscopy, duct ligation, ductoplasty, or parotidectomy.
- Consider superficial parotidectomy for severe recurrent parotid infections in patients with underlying predisposing etiology.
- Pediatric considerations: sialendoscopy with irrigation (saline solution, steroids, antibiotics, or a combination of these solutions) is effective and safe for the treatment of JRP; irrigation alone may be just as effective; performing parotid ultrasound is recommended first to differentiate JRP from ductal stones (3)[A],(4)[C].
Sclerotherapy with methyl violet or tetracycline has been shown to be effective in the treatment of cysts in HIV parotitis and is also considered definitive treatment for chronic parotitis (5)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Admission is recommended for patients with comorbidities, systemic involvement, and inability to tolerate PO as well as neonates and patients for whom close outpatient follow-up is not feasible.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Antibiotic therapy for bacterial parotitis combined with adequate hydration should result in improvement within 48 hours; if not, patient should be reevaluated.

DIET
- Ensure adequate fluid intake.
- Hard or sour candies to promote salivary flow

PROGNOSIS
- Viral infection in immunocompetent individuals often resolves with excellent prognosis.
- Parotid cysts found in HIV-infected patients are usually benign lymphoepithelial lesions with infrequent malignant transformation.
- Increased incidence of malignant lymphoma or lymphoepithelial carcinoma may be seen in patients with Sjögren syndrome.

COMPLICATIONS
- For mumps, potential complications include orchitis, oophoritis, mastitis, aseptic meningitis, encephalitis, pancreatitis, myocarditis, sensorineural hearing loss, and nephritis.
- Untreated bacterial parotitis can lead to local extension, abscess formation, and facial paralysis.
REFERENCES

ADDITIONAL READING

CODES

ICD10

- K11.20 Sialoadenitis, unspecified
- K11.21 Acute sialoadenitis
- K11.23 Chronic sialoadenitis
CLINICAL PEARLS

- History and physical exam are usually sufficient for diagnosis (parotid swelling and tenderness with or without purulent drainage from the Stensen duct).
- In recurrent or chronic cases, consider other underlying etiologies, such as HIV.
- *S. aureus* and anaerobes are the most common organisms isolated in acute bacterial parotitis.
- Encouraging good oral hygiene and adequate hydration in chronically ill, debilitated, and hospitalized patients can reduce occurrence.
PARVOVIRUS B19 INFECTION

David L. Anderson, MD

BASICS

DESCRIPTION

- Human parvovirus B19 is the primary cause of acute erythema infectiosum (EI, or fifth disease).
- Individuals with increased RBC turnover (e.g., sickle cell anemia [SS]) are more susceptible to transient aplastic crisis (TAC). In immunocompromised individuals, pure red cell aplasia (PRCA) and chronic anemia are significant complications. In normal hosts, arthritis and arthralgias are common complications.
- System(s) affected: hematologic/lymphatic/immunologic, musculoskeletal, skin/exocrine, possibly central nervous system, cardiac, renal

Pregnancy Considerations

A documented acute infection during pregnancy should prompt referral to a maternal–fetal medicine specialist. Maternal parvovirus B19 infection between 9 and 20 weeks’ gestation has the highest fetal risk.

EPIDEMIOLOGY

- Parvovirus infection is common in childhood.
- EI has an extremely low mortality rate.
- Peak age for EI is 4 to 12 years.
- Males and females are equally affected.
- Women more likely to develop postinfectious arthritis
- No known racial predilection
- In temperate climates, infections often occur from late winter to early summer.
- Local outbreaks may occur every 2 to 4 years.

Prevalence

Extremely common in the United States. Based on IgG serology:
- 1 to 5 years of age: 2–15% seropositive
- 6 to 15 years of age: 20–40% seropositive
- 16 to 40 years of age: 50–60% seropositive
ETIOLOGY AND PATHOPHYSIOLOGY

- Small (20 to 25 mm), nonenveloped, single-stranded DNA virus in Parvoviridae family
  - Only known parvovirus to infect humans
- Natural host of B19 is human erythroid progenitor.
- Respiratory, hematogenous, and vertical transmission are sources of human spread.
- 4- to 14-day incubation. Rash and joint symptoms occur 2 to 3 weeks after initial infection.
- Most contagious 5 to 10 days after exposure
- EI rash thought to be autoimmune due to IgM complexes concurrent with viral clearance
- Cytotoxic infection of proerythroblasts reduces RBC production.

Genetics

Erythrocyte P antigen–negative individuals are resistant to infection.

RISK FACTORS

- School-related epidemic and nonimmune household contacts have a secondary attack rate of 20–50%.
- Highest secondary attack rates are for daycare providers and school personnel in contact with affected children.
- Increased cell turnover (e.g., hemoglobinopathy, SS, thalassemia) increases risk for TAC.
- Immunodeficiency (e.g., HIV, congenital) increases risk of PRAC and chronic anemia.
- As many as 40% of pregnant women are not immune; 1.5% seroconversion rate per year

GENERAL PREVENTION

- Respiratory spread; hand washing and barrier precautions
- Droplet precautions are recommended around patients with TAC, chronic infection, or anemia.
- Difficult to eliminate exposure because the period of maximal contagion occurs prior to the onset of clinical symptoms (rash)
- Pregnant health care workers should not care for patients with TAC.
No significant risk of infection based on occupational exposure. Exclusion from the workplace is neither necessary nor recommended.

No preventive vaccine is available.

COMMONLY ASSOCIATED CONDITIONS

- Nondegenerative arthritis
  - In adults, 80% of patients may manifest polyarthritis and/or arthralgia (female > male).
  - In children, joint symptoms are less common.
  - Knees, hands, wrists, and ankles (frequently symmetric) are most commonly involved.
  - Joint symptoms usually subside within 3 weeks but may persist for months. Routine radiography is not necessary.

- TAC
  - Involves patients with increased RBC turnover (SS, spherocytosis, thalassemia) or decreased RBC production (iron deficiency anemia)
  - Presents with fatigue, weakness, lethargy, and pallor (anemia)
  - Aplastic event may be life-threatening but is typically self-limited. Reticulocytes typically reappear in 7 to 10 days with full recovery in 2 to 3 weeks.
  - In children with sickle cell hemoglobinopathies and heredity spherocytosis, fever is the most common symptom (73%); rash uncommon in these patients

- Chronic anemia
  - Seen in immunocompromised individuals (HIV, cancer, transplant) with poor IgM response
  - Usually no clinical manifestations (fever, rash, or joint symptoms)

- Fetal/neonatal infection
  - Risk of transplacental spread of virus is ~33% in infected mothers.
  - Test pregnant women with a rash or arthralgias consistent with parvovirus B19.
  - Clinical manifestations vary. Many patients seroconvert without symptoms and have a normal pregnancy. Other patients develop variable degrees of fetal hydrops. 2nd- and 3rd-trimester pregnancy loss can occur without hydrops.
  - Suspect B19 infection in cases of nonimmune fetal hydrops.
  - Fetal bone marrow is primarily impacted. RBC survival is shortened resulting in anemia and (potentially) high-output cardiac failure.

mebooksfree.com
– >95% of fetal complications (fetal hydrops and death) occur within 12 weeks of acute maternal parvovirus B19 infection.
– Risk of fetal loss is highest (2–5%) in the 1st trimester.
– Infants requiring intrauterine transfusions due to parvovirus B19 infection are at risk for long-term neurodevelopmental impairment.
• Papular purpuric gloves and socks syndrome (PPGSS) is an uncommon dermatosis associated with parvovirus B19 infection. It results in a petechial and ecchymotic rash of the hands and feet associated with febrile tonsillopharyngitis and oral ulcerations (2).

**DIAGNOSIS**

**HISTORY**

• Rash
• Headache
• Pharyngitis
• Coryza and rhinorrhea
• Arthralgias and arthritis
• Nausea and GI disturbances are more frequent and severe in adults (nonspecific flulike illness).
• Pruritus (especially soles of feet)
• Fever, myalgia, and malaise

**PHYSICAL EXAM**

• “Slapped cheek” appearance is a well-known facial rash that spares the nasolabial folds.
• A lacy, reticular rash on the trunk, buttocks, and limbs often follows 1 to 4 days later lasting 1 to 6 weeks.
• The rash may be pruritic and recurrent, exacerbated by bathing, exercise, sun exposure, heat, or emotional stress.
• B19 may manifest as painful pruritic papules and purpura on the hands and feet.

**DIFFERENTIAL DIAGNOSIS**

• Rubella
• Enteroviral disease
• Systemic lupus erythematosus
Drug reaction
Lyme disease
Rheumatoid arthritis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- No need for routine lab studies in typical cases. Diagnosis is clinical; illness is mild and self-limiting.
- IgG and IgM serology in immunocompetent patients
- B19-specific DNA polymerase chain reaction (PCR) testing for fetal infection (via cord blood or amniotic fluid) as well as for patients with chronic infection or those who are immunocompromised
- PCR increases diagnostic sensitivity and specificity to confirm infections in IgM-negative patients.
- For patients with TAC, anemia and reticulocytopenia are noted. IgM antibodies are present by day 3, and IgG antibodies are detectable at time of clinical recovery. PCR shows high levels of viremia.
- Pregnant women exposed to B19 require serial IgG and IgM serology to assess fetal risk.

Follow-Up Tests & Special Considerations
Fetal/neonatal infection (3)[C]

- To exclude congenital B19 in infants with negative B19 IgM, follow IgG serology over the 1st year of life.
- Maternal serum α-fetoprotein may be increased with hydrops fetalis.
- Serial fetal ultrasound to assess for hydrops in cases of documented acute maternal infection in the 1st trimester, looking for ascites, pericardial effusion, oligohydramnios, cardiomegaly, and placental thickening
- Weekly peak systolic velocity measurements of the middle cerebral artery by Doppler US is recommended to evaluate for heart failure, fetal anemia, and the potential need for intrauterine transfusion (>1.5 MoM).
- Cerebral MRI to assess for CNS damage in infected neonates with prolonged hydrops fetalis or hematocrit <15%

Diagnostic Procedures/Other

- Skin biopsy is usually normal but may show mild inflammation consisting of perivascular infiltrations of mononuclear cells.
- In stillbirths related to maternal B19 infection, virus can be detected in all
Tissues.
- In hydrops fetalis, nucleated RBCs may have intranuclear inclusion bodies.

**TREATMENT**

**GENERAL MEASURES**
- No therapy is usually needed (4)[C].
- Cessation of immunosuppressive therapy allows some patients to clear chronic infections.
- B19-associated anemia in HIV-positive patients may resolve with highly active antiretroviral therapy.

**MEDICATION**

**First Line**
- Anti-inflammatory agents for arthritic symptoms

**Second Line**
- RBC transfusions for aplastic crisis
- Intravenous immunoglobulin (IVIG) for B19-related refractory anemia or PRAC, especially in immunodeficient states (5)[C]
- Intrauterine RBC transfusions reduce mortality in cases of fetal hydrops.

**ISSUES FOR REFERRAL**
- Acute infection during pregnancy should prompt referral to a maternal–fetal medicine specialist.
- TAC patients require treatment by a hematologist.
- Patients with chronic or abnormal B19 infections may benefit from consultation with immunology or infectious disease specialists.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Outpatient management is typical for EI.
- Inpatient management for aplastic crisis, which may require RBC transfusions
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Periodic blood counts for anemic patients

PATIENT EDUCATION

- Pregnant women should avoid exposure to patients with active/chronic infections. Exclusion of pregnant women from the workplace where EI is occurring is not recommended because of likelihood of prior exposure.
- Children with typical rash are no longer infectious and may attend childcare or school.

PROGNOSIS

- Usually self-limited
- Joint symptoms subside in weeks (often by 2 weeks but may last months).
- ~20% of infections result in delayed virus elimination and viremia persisting for several months to years.
- Full recovery from aplastic crisis in 2 to 3 weeks

COMPLICATIONS

Conditions associated with B19 but where causality is unconfirmed

- Chronic fatigue syndrome
- Glomerulonephritis, nephrotic syndrome, and other renal diseases
- Hepatitis
- Neurologic manifestations/stroke/meningoencephalitis
- Henoch-Schönlein purpura, idiopathic thrombocytopenic purpura, and vasculitis
- Myocarditis and pericarditis
Hemophagocytic syndrome

REFERENCES

ADDITIONAL READING

CODES

ICD10
- B34.3 Parvovirus infection, unspecified
- B08.3 Erythema infectiosum [fifth disease]

CLINICAL PEARLS
- Parvovirus B19 infection is usually a benign, self-limited illness with no long-term effects.
- The rash of EI, a “slapped cheek” appearance, signifies that the patient is no longer infectious.
- Patients with increased RBC turnover (SS, thalassemia) are at risk for TAC.
- Immunocompromised patients are at risk for chronic anemia.
- Documentation of acute infection in pregnant women <20 weeks’ gestation merits maternal–fetal consultation.
PATELLOFEMORAL PAIN SYNDROME (PFPS)
Ugo S. Bitussi, DO • Robert J. Dimeff, MD

BASICS
DESCRIPTION
- Pain in or around the patella that increases after prolonged sitting, squatting, kneeling, or ascending/descending stairs (1)
- Synonyms: anterior knee or retropatellar pain syndrome, runner’s knee
- System(s) affected: musculoskeletal

EPIDEMIOLOGY
Prevalence
- Most frequent presenting condition in patients <50 years old with knee complaints (1)
- Women have higher incidence than men, with female adolescents having the highest incidence (1).

ETIOLOGY AND PATHOPHYSIOLOGY
- Multifactorial etiology (1)
- Direct relationship with hip abductor weakness and poor functional control of the femur during weight-bearing tasks (2)
- Increased contact forces between the retropatellar cartilage and the trochlear groove due to musculoskeletal imbalances (1)

Genetics
Unknown

RISK FACTORS
- Female gender (1)
- Q angle >20 degrees (1)
- Decreased quadriceps and abductor strength (1)
- Decreased hamstring, quadriceps, and gastrocnemius flexibility (1)
- Excessive increase in volume and intensity of exercise training, including
change in training surface (1)
- Tight iliotibial (IT) band with weak vastus medialis (1)

**GENERAL PREVENTION**
Strengthening and stretching exercises, particularly hip abductors and terminal extension of the quadriceps (1,2)

**COMMONLY ASSOCIATED CONDITIONS**
- Overuse
- Knee ligament injury/surgery
- Patellar tendinopathy
- Prolonged synovitis
- IT band friction syndrome

**DIAGNOSIS**

**HISTORY**
- An accurate history to differentiate between pain and instability (pain quality, location, swelling, giving way, locking, grinding, inciting events, overuse, and history of trauma)
- Most common symptom: diffuse anterior knee pain exacerbated during or after physical activity
- Pain with squatting, descending or ascending stairs, ambulating over uneven surfaces, or running (2)

**PHYSICAL EXAM**
- Strength testing of knee extensors, flexors, hip abductors and external rotators (2)
- Measure Q angle (particularly females).
- Single leg squat: Compare affected to nonaffected knee. Side trunk flexion to affected side and/or dynamic valgus deformity of affected knee is suggestive for weak lower extremity and core strength involved in knee pain (2).
- J sign: Have patient flex and extend knee from seated position and observe for lateral subluxation of the patella suggestive of patellofemoral instability which may contribute to anterior knee pain (2).
- Compression/patellar grind test: With patient supine, place one hand superior to the patella and push the patella inferiorly. Ask the patient to contract
quadriceps; pain upon contraction is consistent with patellofemoral pain syndrome; grinding may indicate chondromalacia of the patellofemoral joint (2).

**DIFFERENTIAL DIAGNOSIS**
- Prepatellar bursitis
- Patellar and quadriceps tendinitis/tendinopathy
- Chondromalacia patella
- Patellofemoral arthrosis
- Patellar subluxation and dislocation
- Knee ligamentous and meniscal pathology
- IT band syndrome
- Plica syndrome
- Osteochondral defect
- Osteochondritis dissecans
- Sinding-Larsen-Johansson syndrome
- Osgood-Schlatter disease
- Knee infection
- Neuroma or nerve entrapment
- Benign or malignant tumors
- Referred pain from hip or spine

**DIAGNOSTIC TESTS & INTERPRETATION**
- None indicated. In general, imaging is unnecessary and not helpful in diagnosis of patellofemoral pain syndrome. If imaging is indicated because of severity, atypical symptoms, or persistence of symptoms despite treatment, plain films with four views of the knee are recommended to view patellar tilt and to rule out other etiologies of anterior knee pain:
  - Lateral
  - Merchant (also called sunrise)
  - Standing anteroposterior
  - Posteroanterior tunnel views
- CT can be used to grade patellar malalignment.
- Radiographic findings may not correlate with symptoms.

**Follow-Up Tests & Special Considerations**
Radiographic images may be normal until late stages, when the posterior patellar surface becomes irregular and cartilage erosion is radiographically detectable.
TREATMENT

GENERAL MEASURES
- Conservative therapy is the gold standard (2,3).
- Initial goal of therapy is to increase strength, flexibility, and ROM to enable practice of correct motion (2).
- Supervised therapy should focus on hip abductors and external rotators, knee extensors, and core muscles (2,3).
- Stretching of the muscles surrounding the hip and knee, particularly proprioceptive neuromuscular facilitation stretches (3).

MEDICATION
- Acetaminophen or NSAIDs for pain management
- The evidence for oral glucosamine and chondroitin sulfate and hyaluronic acid injections is lacking and is not routinely recommended for treatment of patellofemoral pain.

ISSUES FOR REFERRAL
- Referral for surgery after all conservative measures fails. Surgery is rarely needed.
- Recalcitrant cases can be associated with psychosocial issues including depression and abuse. Referral to a mental health care professional is critical in these cases.

ADDITIONAL THERAPIES
- Ice packs after activity have been found to improve clinical symptoms.
- Ankle and foot orthoses may offer some relief, but there is lack of strong evidence to support its use (3).
- Although patellar taping alone does not improve knee pain, any kind of patellar taping may show added benefit when combined with an exercise program (4).
- There is low-quality evidence that using a knee orthosis may not reduce knee pain (5).

SURGERY/OTHER PROCEDURES
- No additional benefits of surgery compared to conservative treatment (2)
- Rarely indicated
ONGOING CARE

PATIENT EDUCATION

- Educate patient on importance of participation and compliance in a specialized exercise program with a physical therapist.
- Provide a list of physical therapy locations for the patient.

PROGNOSIS

- PFPS is not self-limiting and can become chronic (6).
- Patellofemoral pain for longer than 12 months duration is associated with long-term pain (6).
- Long term PFPS is not associated with structural patellofemoral joint OA (6).

REFERENCES

ADDITIONAL READING

Patellofemoral pain syndrome is the most common cause of anterior knee pain in active adults. The clinical diagnosis is made by an accurate history and physical exam. Well-designed exercises geared at core, hip, and lower extremity flexibility and strength are the most effective evidence-based treatments. PFPS is not self-limiting and needs to be treated.
PEDICULOSIS (LICE)
Kaelen C. Dunican, PharmD • Cynthia Jeremiah, MD

BASICS

DESCRIPTION

- A contagious parasitic infection caused by ectoparasitic blood-feeding insects (lice)
- Two species of lice infest humans:
  - *Pediculus humanus* has two subspecies: the head louse (var. *capitis*) and the body louse (var. *corporis*). Both species are 1-to 3-mm long, flat, and wingless and have three pairs of legs that attach closely behind the head.
  - *Pthirus pubis* (pubic or crab louse): resembles a sea crab and has widespread claws on the 2nd and 3rd legs
- System(s) affected: skin/exocrine
- Synonym(s): lice; crabs

EPIDEMIOLOGY

Incidence

- In the United States: 6 to 12 million new cases per year
- Predominant age
  - Head lice: most common in children 3 to 12 years of age; more common in girls than boys
  - Pubic lice: most common in adults

Prevalence

Head lice: 1–3% in industrialized countries

ETIOLOGY AND PATHOPHYSIOLOGY

- Infestation by lice: *P. humanus* (var. *capitis*), *P. humanus* (var. *corporis*), or *P. pubis*
- Characteristics of lice:
  - Adult louse is dark grayish and moves quickly but does not jump or fly.
  - Eggs (nits) camouflage with the individuals’ hair color and are cemented to the base of the hair shaft (within 4 mm of the scalp).
  - Nits (empty egg casings) appear white (opalenscent) and remain cemented to
the hair shaft.
– Lice feed solely on human blood by piercing the skin, injecting saliva (anticoagulant properties to allow for blood meal), and then ingesting blood.
– Itching is a hypersensitivity reaction to the saliva of the feeding louse.

Transmission: direct human-to-human contact
– Head lice: direct head-to-head contact or contact with infested fomite (less likely)
– Body lice: contact with contaminated clothing or bedding
– Pubic lice: typically transmitted sexually (fomite transmission much less likely)

RISK FACTORS
● General: overcrowding and close personal contact
● Head lice
  – School-aged children, gender (girls; longer hair)
  – Sharing combs, hats (including helmets), clothing, and bed linens
  – African Americans rarely have head lice; theories include twisted hair shaft and increased use of pomades
● Body lice: poor hygiene, homelessness
● Pubic lice: promiscuity (very high transmission rate)

GENERAL PREVENTION
● Environmental measures: Wash, dry-clean, or vacuum items that may have contacted infected individuals.
● Screen and treat affected household contacts.
● Head lice: Follow-up by school nurses may help to prevent recurrence and spread.
● Pubic lice: Limit the number of sexual partners (condoms do not prevent transmission nor does shaving pubic hair).
● Body lice: proper hygiene

COMMONLY ASSOCIATED CONDITIONS
Up to 1/3 of patients with pubic lice have at least one concomitant STI.

DIAGNOSIS
HISTORY

- Pruritus is common, often worse at night.
- Often associated with “outbreak” in school settings
- Investigate contacts of infected individuals.

PHYSICAL EXAM

- Diagnosis is confirmed by visualization of live lice.

  **P. capitis** (head lice)
  - Found most often on the back of the head and neck and behind the ears (warmer areas)
  - Eyelashes may be involved.
  - Eggs, found cemented on the base of a hair shaft, are difficult to remove.
  - Pruritus may be accompanied by local erythema and small papules.
  - May see excoriations around hairline
  - Scratching can cause inflammation and secondary bacterial infection.
  - Pyoderma and lymphadenopathy may occur in severe infestation.

  **P. corporis** (body lice)
  - Poor general hygiene
  - Adult lice and nits in the seams of clothing
  - Intense pruritus involving area covered by clothing (trunk, axillae, and groin)
  - Uninfected bites present as erythematous macules, papules, and wheals.
  - Pyoderma and excoriation may be seen.

  **P. pubis** (pubic lice)
  - Pubic hair is the most common site, but lice may spread to hair around anus, abdomen, axillae, chest, beard, eyebrows, and eyelashes.
  - Eggs are present at the base of hair shafts.
  - Anogenital pruritus
  - Blue macules may be seen in surrounding skin.
  - Delay in treatment may lead to development of groin infection and regional adenopathy.

DIFFERENTIAL DIAGNOSIS

- Scabies and other mite species that can cause cutaneous reactions in humans
- Dandruff and other hair debris sometimes look like head lice eggs and nits but are less adherent.

DIAGNOSTIC TESTS & INTERPRETATION
Diagnosis is based on visualization of live louse.

- Head lice: Comb hair thoroughly with a fine-toothed louse comb (0.2 to 0.3 mm between teeth) to identify live lice (1)[C]. Wet hair limits static electricity. Simple visual inspection has same sensitivity as wet combing but is only ~25% as effective as dry combing with a metal comb (2).
- Body lice: Examine the seams of clothing to locate lice and eggs (3).
- Lice and eggs are more easily visualized with a microscope.
- In contrast to dandruff, eggs, and nits cannot be removed easily from a hair shaft.

**Follow-Up Tests & Special Considerations**

- Empty nits remain on hair shafts for months after eradication of the live infestation. Wood lamp exam: live nits fluoresce white and empty nits fluoresce gray.
- Pubic lice: Evaluate for concurrent STIs.

---

**TREATMENT**

**MEDICATION**

Permethrin (over the counter [OTC]), synergized pyrethrin (OTC), spinosad (Rx), benzyl alcohol (Rx), malathion (Rx), and topical ivermectin (Rx) are all effective for head lice (1)[A],(2)[C]. Permethrin, synergized pyrethrin, and malathion are effective for pubic lice (2)[C]:

- Permethrin generally preferred because it may have residual activity for up to 3 weeks. However, use of newer shampoos and conditioners may reduce the residual effect (1)[C].
- Malathion and spinosad are considered second line for head lice but may not require a second application due to ovicidal activity (1)[B],(2)[C].
- Ivermectin 0.5% lotion and benzyl alcohol 5% lotion are also effective for head lice (1,2)[C].

**First Line**

- Head and pubic lice
- Pyrethrum insecticides: Permethrin 1% cream rinse (Nix) or pyrethrins 0.33% with piperonyl butoxide 4% (synergized pyrethrin, Rid, Pronto) are first line unless there is proven resistance in the community.
  - Apply for 10 minutes and then wash.
- Reapply synergized pyrethrin in 7 to 10 days (day 9 is optimal); also be necessary with permethrin, if live lice are observed
- Side effects: application-site erythema, ocular erythema, and application-site irritation

Body lice: best treated with synergized pyrethrin lotion applied once and left on for several hours

Eyelash infestation: Apply petroleum jelly BID for 10 days.

Precautions
- Pyrethrin: Avoid in patients with ragweed allergy (may cause respiratory symptoms).
- Pediculicides should never be used to treat eyelash infections.

**Second Line**
Head lice and pubic lice

- Malathion 0.5% lotion (Ovide)
  - Apply for 8 to 12 hours and then wash off.
  - Excipients isopropyl alcohol (78%) and terpineol (12%) may contribute to its efficacy:
    - Flammable and has a bad odor
    - Despite ovicidal activity, a second application may be necessary after 7 to 10 days (day 9 is optimal) if live lice are observed.

- Lindane 1% shampoo, no longer recommended
  - Apply for 4 minutes and then wash (do not repeat).
  - Side effects: neurotoxicity (seizures, muscle spasms), aplastic anemia
  - Contraindications: uncontrolled seizure disorder, premature infants
  - Precautions: Do not use on excoriated skin, in immunocompromised patients, conditions that increase seizure risk, or with medications that decrease seizure threshold.
  - Possible interactions: concomitant use with medications that lower the seizure threshold

- Head lice
  - Spinosad 0.9% lotion (Natroba)
    - Apply to dry hair and scalp for 10 minutes and then rinse with warm water. Repeat in 7 days if live lice are observed.
    - Side effects: application-site erythema, ocular erythema, and application-site irritation

- Benzyl alcohol 5% lotion (Ulesfia)
  - Apply to dry hair using enough to saturate scalp and hair (amount
depends on hair length), rinse after 10 minutes; repeat in 1 week.

- Side effects: pruritus, erythema, pyoderma, ocular irritation, application-site irritation
  - Ivermectin 0.5% lotion (Sklice)
    - Apply to dry hair by using enough to saturate the scalp and hair (max. 4 oz) and then rinse after 10 minutes.
    - Side effects: burning sensation at application site, dandruff, dry skin, eye irritation
  - Mechanical removal of lice and nits by wetting hair and then systematically combing with a fine-toothed comb every 3 to 4 days for 2 weeks to remove all lice as they hatch

**ALERT**

Lindane: FDA black box warning of severe neurologic toxicity (use only when first-line agents have failed). The National Pediculosis Association strongly advises against using lindane at all.

**GENERAL MEASURES**

- Head lice: Clean items that have been in contact with the head of the infected individual within 48 hours.
- Wash all bedding, towels, clothes, headgear, combs, brushes, and hair accessories in hot water (60°C).
- Vacuum furniture and carpets
- Seal any personal articles that cannot be washed in hot water, dry cleaned, or vacuumed in a plastic bag and store for at least 2 weeks.
- Examine and treat household members and close contacts concurrently.
- Insecticide sprays are not necessary.
- Pubic lice: Avoid sexual activity until all partners are successfully treated.
- Nit and egg removal
  - Remove eggs within 1 cm of the scalp to prevent reinfestation.
  - After treatment with shampoo or lotion, eggs and nits remain in the scalp or pubic hair until mechanically removed. Hair conditioner facilitates nit removal.
  - Eggs and nits best removed with a fine nit comb

**Pediatric Considerations**

- Avoid synergized pyrethrin and permethrin in infants <2 months of age. Avoid benzyl alcohol, topical ivermectin, and spinosad in children <6 months of age; and avoid malathion in children <2 years of age.
Lindane: not recommended in patients <50 kg

Pregnancy Considerations
Permethrin, synergized pyrethrin, malathion, spinosad, and benzyl alcohol are pregnancy Category B. Lindane and topical ivermectin are Category C.

ADDITIONAL THERAPIES
- For “difficult to treat” cases of head lice, oral ivermectin 400 μg/kg (not approved by the FDA for lice), given twice at a 7-day interval, is superior to topical 0.5% malathion lotion (4,5)[B].
- Ivermectin: 200 μg/kg PO repeated in 10 days or 300 μg/kg PO repeated in 7 days
  - Should not be used in children <15 kg; pregnancy Category C
  - Not approved by the FDA for lice
- Dual therapy with permethrin 1% and oral trimethoprim/sulfamethoxazole (TMP/SMX) only for cases of multiple treatment failures or suspected cases of lice-related resistance to therapy (TMP/SMX is not approved by the FDA for lice)
- Permethrin 5% cream (Rx) is not FDA-approved for lice and is unlikely to be effective for lice that are resistant to 1% cream rinse (1)[B].

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Dry-on, suffocation-based pediculicide: Cetaphil lotion
  - Apply thoroughly to hair, comb and then dry with hair dryer; shampoo after 8 hours.
  - Repeat once a week until cured, up to a maximum of three applications.
  - Not approved by the FDA for lice
- Dimethicone 4% lotion: Apply to hair for 8 hours; repeat in 1 week (not approved by the FDA for lice).
- No home remedies (e.g., vinegar, isopropyl alcohol, olive oil, ylang ylang oil, mayonnaise, melted butter, and petroleum jelly) are proven as effective.
- Herbal shampoos and pomades have not been evaluated in clinical trials.
- Lavender oil and tea tree oil have been implicated in triggering prepubertal gynecomastia in boys and should not be used to treat lice.
- Electronic louse combs have not proven effective and are not approved by the FDA.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Children may return to school after completing topical treatment, even if nits remain in place. No-nit policies are unnecessary.

Patient Monitoring
Drug resistance should be suspected if no dead lice are observed 8 to 12 hours after treatment.

PATIENT EDUCATION
- National Pediculosis Association: http://www.headlice.org/
- CDC: http://www.cdc.gov/parasites/lice/

PROGNOSIS
- With appropriate treatment, >90% cure rate
- Recurrence is common, mainly from reinfection or treatment nonadherence. Resistance to synthetic pyrethroids is increasing.

COMPLICATIONS
- Poor sleep due to pruritus
- Persistent itching may be caused by too frequent use of the pediculicide.
- Missed school; social stigma
- Secondary bacterial infections
- Body lice can transmit typhus and trench fever.

SEE ALSO

Arthropod Bites and Stings; Scabies

CODES

ICD10

- B85.0 Pediculosis due to Pediculus humanus capitis
- B85.1 Pediculosis due to Pediculus humanus corporis
- B85.3 Phthiriasis

CLINICAL PEARLS

- School-based no-nit policies are not necessary because empty nits may remain on hair shafts for months after successful eradication.
- Proper product application is essential; improper product application is a common cause of treatment failure.
- Prevalence of resistant infestations is increasing; if no dead lice are observed 8 to 12 hours after treatment, suspect resistance and use an alternative agent.
- Routine retreatment on day 9 is recommended for nonovicidal products (permethrin and synergized pyrethrin).
- With all treatment options, reinspect hair after 7 to 9 days and, if live lice are detected, repeat treatment on day 9.
PELVIC INFLAMMATORY DISEASE

Juliana Zamora Cubillos, MD • Miguel A. Palacios, MD

BASICS

DESCRIPTION

• Pelvic inflammatory disease (PID) is an infectious and inflammatory disorder of the upper female genital tract, including the uterus, fallopian tubes, ovaries, and adjacent pelvic structures. It is community acquired from sexually transmitted organisms (1).
• Salpingitis is the most important component due to its impact on future fertility.
• Mild to moderate PID is defined as the absence of a tubo-ovarian abscess (TOA). Severe disease is defined as severe systemic symptoms OR the presence of a TOA (2).
• Diagnosis may be challenging due to variation in signs and symptoms as many patients with PID have subtle or nonspecific symptoms (3).

EPIDEMIOLOGY

• Predominant age: 15 to 25 years; this number has remained constant since early 1900s.
• Predominant sex: female only

Incidence

PID is the most common gynecologic reason for admission in the United States accounting for 18 per 10,000 recorded hospital discharges (2). The estimated prevalence of self-reported lifetime PID was 4.4% in sexually experienced women ages 18 to 44 years (4).
• Lifetime prevalence has decreased steadily since 1995 across all races (4).
• Among those with no history of prior STI, lifetime PID prevalence was higher in black versus white women (6% vs. 2.7%). Among women with a prior STI, lifetime prevalence of PID was similar by race (10% vs. 10.3%) (4).

ETIOLOGY AND PATHOPHYSIOLOGY

Multiple organisms may be etiologic agents in PID. Most cases are polymicrobial. The proportion of PID cases due to Chlamydia trachomatis and
*Neisseria gonorrhoeae* appears to be declining. Fewer than 50% of women diagnosed with acute PID have a test positive for either of these organisms.

- *C. trachomatis, N. gonorrhoeae*, genital tract mycoplasmas (particularly *Mycoplasma genitalium*), aerobic and anaerobic (*Bacteroides fragilis*), and vaginal flora (e.g., *Prevotella, Peptostreptococci, Gardnerella vaginalis, Escherichia coli, Haemophilus influenzae*) are recognized as etiologic agents (1,5).
- Many nongonococcal, nonchlamydial microorganisms recovered from upper genital tract in acute PID are associated with bacterial vaginosis.
- The precise mechanism by which microorganisms ascend from the lower genital tract is unclear. Possible mechanisms include the following: (i) travel from cervix to endometrium to salpinx to peritoneal cavity; (ii) lymphatic spread via infection of the parametrium (from an IUD); and (iii) hematogenous route, although this is rare.
- Of cases, 75% occur within 7 days of menses, when cervical mucus favors ascent of organisms.

### RISK FACTORS
- Sexually active and age <25 years
- First sexual activity at young age (<15 years)
- New/multiple sexual partners
- Nonbarrier contraceptive methods (i.e., oral contraceptive pills)
- Previous history of PID; 20–25% will have a recurrence.
- Cervical ectopy
- History of *C. trachomatis*; 10–40% will develop PID.
- History of gonococcal cervicitis; 10–20% will develop PID.
- Gynecologic procedures such as endometrial biopsy, curettage, and hysteroscopy break the cervical barrier, predisposing women to ascending infections.

### GENERAL PREVENTION
- Educational programs about safer sex practices such as barrier contraceptives, especially condoms and spermicidal creams or sponges, provide some protection.
- The U.S. Preventive Services Task Force recommends screening for chlamydia in all sexually active women <25 years and in those 25 years and older at increased risk (new sex partner/multiple sex partners). Moderate-quality evidence suggests that chlamydia screening reduces cases of PID (3)
Routine STI screening in pregnancy
Early medical care with occurrence of genital lesions or abnormal discharge

COMMONLY ASSOCIATED CONDITIONS
If PID is suspected in a patient with an IUD and a pelvic abscess is present, an *Actinomyces* infection requiring penicillin treatment may be present.
Rupture of an adnexal abscess is rare but life-threatening. Early surgical exploration is mandatory (5).
Chlamydial or gonococcal perihepatitis may occur with PID. This combination is called Fitz-Hugh-Curtis (FHC) syndrome and is characterized by severe pleuritic right upper quadrant pain. FHC syndrome complicates 10% of PID cases.
Plasma cell endometritis has also been seen in the majority of females with PID; the density of plasma cell infiltration has been related to severity of symptoms (5).

DIAGNOSIS
The diagnosis of PID is based primarily on clinical evaluation.
The positive predictive value of clinical diagnosis is 65–90% compared with laparoscopy (2).
The CDC recommends empiric treatment for PID in sexually active female or other female at risk with pelvic or lower abdominal pain with no other cause identified and if one or more of the following is present:
– Cervical motion tenderness
– Uterine tenderness
– Adnexal tenderness
Additional criteria used to enhance specificity: fever >101°F, new/abnormal cervical mucopurulent discharge or cervical friability, presence of abundant numbers of WBCs on wet prep, elevated CRP, elevated ESR, and laboratory documentation of cervical infection with *N. gonorrhoeae* or *C. trachomatis* (1,6)
Most specific criteria for diagnosing PID: Endometrial biopsy reveals endometritis, transvaginal ultrasound showing thickened, fluid-filled salpinges, and laparoscopic abnormalities consistent with PID (1,3).

HISTORY
Lower abdominal or pelvic pain: typically described as dull, aching or crampy, bilateral, and constant; accentuated by motion, exercise, or coitus
New/abnormal vaginal discharge (~75% of cases)
Fever, chills, cramping, dyspareunia
Low back pain
Urinary discomfort
Unanticipated vaginal bleeding, often postcoital, is reported in about 40% of cases.
Recent hysterosalpingogram (HSG)
IUD insertion within the past 21 days (1)

**PHYSICAL EXAM**
- Fever
- Lower abdominal pain and particularly cervical motion tenderness
- Findings of cervicitis with/without vaginal discharge (1)

**DIFFERENTIAL DIAGNOSIS**
- Appendicitis
- Constipation
- Gastroenteritis
- Ectopic pregnancy
- Ovarian tumor/torsion
- Hemorrhagic/ruptured ovarian cyst
- Endometriosis/dysmenorrhea
- Functional pelvic pain
- Inflammatory bowel disease
- Diverticulitis
- UTI/pyelonephritis
- Nephrolithiasis (1)

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Pregnancy test must be performed to rule out ectopic pregnancy and complications of an intrauterine pregnancy.
- Specific testing for chlamydia and gonorrhea (usually nucleic acid amplification test [NAAT] and/or ligase chain reaction)
- Urinalysis
- Saline microscopy of vaginal fluid (for WBC)
- Consider CBC: WBC count ≥10,500/mm³, although ≤50% of PID cases present with leukocytosis.
- CRP (optional)
- Consider transvaginal ultrasound: not necessary for diagnosis; may show thickened, fluid-filled tubes (hydrosalpinges) ± free fluid, or TOA

**Follow-Up Tests & Special Considerations**
- ESR >15 mm/hr or elevated C-reactive protein used in some diagnostic criteria
- Consider HIV testing in patients with PID.
- Follow-up ultrasound as outpatient for resolution of adnexal abscess

**Diagnostic Procedures/Other**
- Culdocentesis with culture is rarely necessary.
- Laparoscopy is best used for confirming, as opposed to making, the diagnosis of PID and should be reserved for the following situations:  
  - Ill patient with competing diagnosis (e.g., appendicitis)
  - Ill patient who has failed outpatient treatment
  - Any patient not improving after 72 hours of inpatient treatment
- Endometrial biopsy (rarely indicated): reveals endometritis/plasma cells

**TREATMENT**
- Outpatient treatment, if appropriate
- Criteria for hospitalization and parenteral treatment are described below.

**GENERAL MEASURES**
- Avoid intercourse until treatment is completed. IUD removal is NOT required for mild PID.
- Treatment should cover principal pathogens, regardless of the test results.

**MEDICATION**

*First Line*
- Several antibiotic regimens are highly effective, with no single regimen of choice.
- Outpatient treatment regimen
  - Ceftriaxone 250 mg IM single dose *plus* doxycycline 100 mg PO BID for
14 days ± metronidazole 500 mg PO BID for 14 days

- On the basis of the recent emergence of fluoroquinolone-resistant gonococci, the CDC no longer recommends the use of fluoroquinolones for the treatment of gonococcal infections and associated conditions such as PID.
- Metronidazole should be considered in cases where risk of infection with anaerobic organisms is considered high.

**Second Line**

- Because of emerging resistance in gonococci, resistance testing and confirmation of treatment success is advisable (5).
- Outpatient treatment regimen
  - Cefoxitin 2 g IM single dose and probenecid 1 g PO administered concurrently in single dose plus doxycycline 100 mg PO BID for 14 days ± metronidazole 500 mg PO BID for 14 days
- In persons with documented severe allergic reactions to penicillin or cephalosporins, azithromycin or spectinomycin might be an option for therapy of uncomplicated gonococcal infections.
- Special consideration
  - Refer sex partners for appropriate evaluation and treatment if they had sexual contact with patient during preceding 60 days or most recent sexual contact. Partners should be treated, irrespective of evaluation, with regimens effective against chlamydia and gonorrhea (5).

**SURGERY/OTHER PROCEDURES**

Reserved for failures of medical treatment and for suspected ruptured adnexal abscess with resulting acute surgical abdomen

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Criteria for hospitalization if any of following (5)[C]:
  - Surgical emergencies (e.g., appendicitis) cannot be excluded.
  - Patient is pregnant.
  - Patient does not respond clinically within 72 hours of initiation with oral antimicrobial therapy.
  - Failure to either tolerate or respond to outpatient therapy; the patient has severe illness, nausea and vomiting, or high fever, or the patient has a TOA
- For inpatient treatment of PID, the CDC recommends following treatment regimens (6):
– Parenteral regimen A
  o Cefotetan 2 g IV every 12 hours or cefoxitin 2 g IV q6h + doxycycline 100 mg orally or IV every 12 hours
  o Parenteral therapy for 24 hours after clinical improvement. Doxycycline should be preferred orally when possible as oral and IV provides similar bioavailability. Continue doxycycline for a total of 14 days (3).

– Parenteral regimen B
  o Clindamycin 900 mg IV every 8 hours plus gentamicin loading dose IV or IM (2 mg/kg of body weight) followed by a maintenance dose (1.5 mg/kg) q8h or single daily dosing at 3 to 5 mg/kg can be substituted (3).  
  o Parenteral therapy may be discontinued 24 hours after clinical improvement, and oral therapy with doxycycline as aforementioned or clindamycin 450 mg PO QID for a total of 14 days should be continued.

– Parenteral regimen C
  o Ampicillin/sulbactam 3 g IV every 6 hours plus doxycycline 100 mg orally or IV every 12 hours

● PID is rare in pregnant patients; however, may appear prior to 12 weeks’ gestation before mucous plug appears. Change doxycycline to azithromycin + 2nd-generation cephalosporin (6).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
● Follow up in 72 hours after initiation of treatment is recommended particularly for patients with moderate or severe clinical presentation (3).
● Observe for clinical signs and symptoms particularly for fever, leukocytosis, abdominal, and cervical motion tenderness.
● Retest for gonorrhea and chlamydia in 3 to 6 months. The likelihood of reinfection is high.
● Follow adnexal abscess size and position with serial ultrasounds.

PATIENT EDUCATION
● Abstinence from any type of sexual contact until treatment of patient/partner (if necessary) is complete.
● Consistent and correct condom use should be enforced.
● Hepatitis B and human papilloma virus (HPV) vaccines should be given to
patients who meet criteria.
- Advise comprehensive STI screening (6).

PROGNOSIS
- PID has a high morbidity; about 20% of affected women become infertile, 40% develop chronic pelvic pain, and 1% of those who conceive have an ectopic pregnancy (1).
- Wide variation with good prognosis if early effective therapy is instituted and further infection is avoided.
- Poor prognosis related to late therapy and continued high-risk sexual behavior
- Nongonococcal, nonchlamydial PID is more often associated with severe PID and with worse prognosis for future fertility.

COMPLICATIONS
- TOA will develop in ~7–16% of patients with PID.
- Recurrent infection occurs in 20–25% of patients.
- Risk of ectopic pregnancy is increased 7- to 10-fold among women with a history of PID.
- Tubal infertility occurs in 8%, 19.5%, and 40% of women after 1, 2, and 3 episodes of PID, respectively.
- Chronic pelvic pain occurs in 20% of cases and is related to adhesion formation, chronic salpingitis, or recurrent infection (1,4).
- Hydrosalpinx: After PID resolves, fallopian tube may fill with sterile fluid and become blocked; it may be associated with pain and infertility related to negative outcomes with IVF.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**
- N73.9 Female pelvic inflammatory disease, unspecified
- N73.0 Acute parametritis and pelvic cellulitis
- N70.93 Salpingitis and oophoritis, unspecified

**CLINICAL PEARLS**
- Most often, PID starts with gonorrhea or chlamydia infection, but it is often polymicrobial.
- Physicians should treat on the basis of clinical judgment (pelvic pain with cervical motion tenderness or adnexal tenderness or uterine tenderness in a patient at risk) without waiting for confirmation from laboratory or imaging tests. PID is a common cause of infertility.
- Complications include hydrosalpinx, adhesions, pelvic pain, and 10-fold increased risk of ectopic pregnancy.
- Three major predictors of preserved post-PID fertility: (i) short duration of symptoms (<72 hours) prior to initiation of treatment, (ii) first episode of PID, and (iii) nongonococcal PID
PEPTIC ULCER DISEASE

Fozia Akhtar Ali, MD • Paula A. Shelton, MD • Anh V. Dinh, MD

BASICS

DESCRIPTION

- Duodenal ulcer
  - Most common form of peptic ulcer
  - Usually located in the proximal duodenum
  - Multiple ulcers or ulcers distal to the second portion of duodenum raise possibility of gastrinoma (Zollinger-Ellison syndrome).
- Gastric ulcer
  - Less common than duodenal ulcer in absence of NSAID use
  - Commonly located along lesser curvature of the antrum
- Esophageal ulcers
  - Located in the distal esophagus; usually secondary to gastroesophageal reflux disease (GERD); also seen with gastrinoma
- Ectopic gastric mucosal ulceration
  - May develop with Meckel diverticulum

GENERAL PREVENTION

- NSAID ulcers: Use acetaminophen instead of NSAIDs, when appropriate, and discontinue NSAID use (or add a proton pump inhibitor [PPI]) in patients with previous NSAID-related ulcer.
  - If NSAIDs are absolutely necessary, use lowest possible dose to decrease risk of ulcerogenesis and use in combination with a PPI or misoprostol.
  - To reduce ulcer risk, consider testing for and eradicating Helicobacter pylori, particularly before starting therapy with NSAIDs.
- Maintenance therapy with PPIs or H₂ blockers is indicated for patients with a history of ulcer complications, recurrences, refractory ulcers, or persistent H. pylori infection.
- Consider maintenance PPI treatment in patients with H. pylori–negative, non–NSAID-induced ulcer.
  - H. pylori infection: present in 95% of duodenal and 70% of gastric ulcers; annual risk of duodenal ulcer in those with H. pylori infection: ≤1%
EPIDEMIOLOGY

Incidence
- Predominant sex: male = female
- Predominant age
  - 70% of ulcers occur between ages 25 to 64 years.
  - Duodenal and gastric ulcer incidence increases with age.
- Peptic ulcer: 500,000 new cases/year
- Recurrence: 4 million/year
- Global incidence rate: 0.1–0.19%

Prevalence
- Peptic ulcer: 2% in the United States
- The lifetime prevalence is higher (10–20%) in H. pylori-positive patients, compared to the general population (5–10%).

Genetics
Increased incidence of PUD in families is likely due to familial clustering of H. pylori infection and inherited genetic factors reflecting response to the organism.

RISK FACTORS
- H. pylori infection (1)
- Chronic NSAID use (5–20%)
- Tobacco use
- Family history of ulcers
- Stress (after acute illness, ventilator support, extensive burns, head injury)
- Gastrinoma
- Alcohol use
- Medications: corticosteroids (high-dose and/or prolonged therapy), bisphosphonates, potassium chloride, chemotherapeutic agents

COMMONLY ASSOCIATED CONDITIONS
- Gastrinoma (Zollinger-Ellison syndrome)
- Multiple endocrine neoplasia type 1
- Carcinoid syndrome
- Chronic illness: Crohn disease, chronic obstructive pulmonary disease (COPD), chronic renal failure, hepatic cirrhosis, cystic fibrosis
- Hematopoietic disorders (rare): systemic mastocytosis, myeloproliferative
disease, hyperparathyroidism, polycythemia rubra vera

**DIAGNOSIS**

**HISTORY**

- Signs and symptoms:
  - Duodenal ulcer
    - Mid-epigastric pain
    - Gnawing or burning, nonradiating, recurring pain that is often episodic and relieved by food or antacids.
  - Gastric ulcer
    - Mid-epigastric pain
    - Aggravated by food, relieved by antacids
- Nonspecific dyspeptic symptoms: indigestion, nausea, vomiting, loss of appetite, heartburn, and epigastric fullness
- Red flag or alarm symptoms
  - Onset of symptoms after age 55 years
  - Progressive dysphagia
  - Recurrent vomiting
  - Blood in stool, melena, hematemesis, anemia
  - Progressive dysphagia
  - Persistent or recurrent vomiting
  - Severe abdominal pain
  - Weight loss, anorexia, or family history of gastric malignancy
- NSAID-induced ulcers are often silent; perforation or bleeding may be the initial presentation.

**PHYSICAL EXAM**

Physical exam for uncomplicated peptic ulcer may be nonspecific: Check vital signs for hemodynamic stability, conjunctival pallor (anemia); epigastric tenderness (absent in at least 30% of older patients); guaiac-positive stool from occult blood loss

**DIFFERENTIAL DIAGNOSIS**

Functional dyspepsia, gastritis, GERD, biliary colic, gastroenteritis, pancreatitis, cholecystitis, Crohn disease, intestinal ischemia, cardiac ischemia, GI malignancy
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Lab tests to consider:
  - CBC: Rule out anemia.
  - Fecal occult blood test
  - If multiple/refractory ulcers: Consider fasting serum gastrin to rule out gastrinoma.

- Indications for H. pylori testing: new-onset PUD, prior history of PUD, persistent symptoms after empiric antisecretory therapy, gastric mucosa–associated lymphoid tissue (MALT) lymphoma, noninvestigated dyspepsia in patients <50 years of age without alarm symptoms H. pylori diagnostic tests:
  - False-negative results may occur if patient was recently treated with antibiotics, bismuth, or PPIs, or in patients with active bleeding.
  - Diagnostic yield improved using two different tests:
    - Noninvasive tests:
      - Serology: H. pylori antibody: commonly used in primary care, slow to normalize after treatment, cannot be used to document successful eradication (sensitivity, 85%; specificity, 79%)
      - Urea breath test: identifies active H. pylori infection; also used for posttreatment testing (sensitivity, >95%; specificity, >90%)
      - Stool antigen: can be used for screening and posttreatment testing (sensitivity, 91%; specificity, 94%)
      - To prove eradication, use urea breath test or stool antigen. Stop antibiotics and bismuth for at least 4 weeks and PPIs for 1 week prior to testing.
    - Invasive tests:
      - Diagnostic upper endoscopy (sensitivity, >95%; specificity, >95%) is most accurate for diagnosing PUD and active H. pylori infection.
      - Endoscopy is costly and invasive and recommended only for patients with “red flag” symptoms (1)[B].
      - Rapid urease test: conducted on gastric biopsies (sensitivity, 93–97%; specificity, 95%)

Barium or Gastrografin contrast radiography (double-contrast hypotonic duodenography): indicated when endoscopy is unsuitable or not feasible

TREATMENT
**MEDICATION**

**First Line**

- Acid suppression: PPIs. PPIs have higher efficacy than H₂ blockers. 95% of duodenal ulcers heal on PPI therapy within 4 weeks.
  - Omeprazole 20 mg/day PO; lansoprazole 30 mg/day PO; rabeprazole 20 mg/day PO; esomeprazole 40 mg/day PO; pantoprazole 40 mg/day PO; dexlansoprazole 30 mg/day PO
  - Administer PPIs on an empty stomach and before breakfast.
  - Administer PPI for 4 weeks to treat duodenal ulcer and 8 weeks to treat gastric ulcer.
- H₂ blockers: ranitidine or nizatidine 150 mg PO BID or 300 mg PO at bedtime; cimetidine 400 mg PO BID or 800 mg PO at bedtime; famotidine 20 mg PO BID or 40 mg PO at bedtime
- Treat ulcers for 8 to 12 weeks or until healing is confirmed in patients with complicated ulcers.
- PPIs help heal peptic ulcers more rapidly.

**Precautions:**
- Renal insufficiency: Decrease H₂ blocker dosage by 50% if CrCl <50 mL/min cimetidine: Use caution with theophylline, warfarin, phenytoin, and lidocaine.
- PPIs may decrease bone density. Obtain interval bone densitometry with long-term PPI use (2).
- PPIs may cause hypomagnesemia. Consider baseline and interval levels in patients, especially for long-term use and in patients taking diuretics.
- PPIs may be associated with increased risk of *Clostridium difficile* infection (2). Short-term use associated with development of community-acquired pneumonia; long-term use does not appear to have an increased risk.
- Despite earlier concerns, PPIs do not appear to decrease the efficacy of clopidogrel (2).

**NSAID-induced ulcers**
- Discontinue NSAID use.
- Treat with PPIs for 8 to 12 weeks; may use as maintenance for patients with recurrent, complicated, or idiopathic ulcers; or in patients who require long-term aspirin or NSAID use.

**H. pylori-induced ulcers**
- *H. pylori* eradication regimens: Preferred duration of therapy is 14 days.
  - Triple therapy: standard dose PPI given BID plus clarithromycin 500 mg
PO BID plus amoxicillin 1 g PO BID or metronidazole 500 mg PO BID in patients with allergy to amoxicillin; bacterial resistance: clarithromycin 10%; amoxicillin 1.4%; metronidazole 37%; Culture-guided choice of triple therapy is preferred (3).

**Second Line**
- For *H. pylori* eradication: Use second-line therapy if first-line fails (3):
  - Bismuth quadruple therapy for 14 days
    - Bismuth subsalicylate 525 mg PO QID plus
    - Metronidazole 250 mg PO QID plus
    - Tetracycline 500 mg PO QID plus
    - Standard dose PPI PO twice daily
  - Sequential therapy
    - Standard-dose PPI PO twice daily plus amoxicillin 1,000 mg PO QID for 5 days followed by
    - Standard-dose PPI PO twice daily plus clarithromycin 500 mg PO BID plus tinidazole (or metronidazole) 500 mg PO BID for 5 days
      - Levofloxacin 250 mg PO BID may be substituted in those with PCN allergy or in areas of high clarithromycin resistance rates.
    - Another alternative salvage therapy:
      - Rifabutin 300 mg PO daily plus
      - Amoxicillin 1,000 mg PO BID plus
      - PPI orally BID
    - Alternative ulcer-healing drugs:
      - Sucralfate and antacids are additional options; however, antisecretory options are preferred.
  - Significant possible interactions:
    - Cimetidine inhibits cytochrome P450 isozymes (avoid with theophylline, warfarin, phenytoin, and lidocaine).
    - Omeprazole may prolong elimination of diazepam, warfarin, and phenytoin.
    - Sucralfate reduces absorption of tetracycline, norfloxacin, ciprofloxacin, and theophylline; it leads to subtherapeutic levels.

**Pregnancy Considerations**
PPIs are *not* associated with an increased risk for major birth defects, spontaneous abortions, or preterm delivery.
Breastfeeding
Both ranitidine and esomeprazole are secreted in breast milk; at considerably lower doses than used for treatment in infants with reflux disease. Use in breastfeeding women is generally safe.

SURGERY/OTHER PROCEDURES
- Endoscopy is indicated for patients age >55 years with new onset of dyspeptic symptoms, those who do not respond to treatment, and patients of any age with alarm/red flag symptoms (4)[B].
- During endoscopy:
  - Biopsy stomach for *H. pylori* testing (CLO test)
  - Biopsy ulcer margin to exclude malignancy
  - Interventions to stop active bleeding or prevent rebleeding in those with certain stigmata include injection with epinephrine, heater probe treatment, or placement of endoscopic clips (2).
- Indications for surgery: Ulcers that are refractory to treatment and patients at high risk for complications (e.g., transplant recipients, patients dependent on steroids/NSAIDs); surgery also may be needed acutely to treat perforation and bleeding refractory to endoscopic therapy (5).
- Surgical options:
  - Duodenal ulcers: truncal vagotomy and drainage (pyloroplasty/gastrojejunostomy), selective vagotomy (preserving the hepatic and/or celiac branches of the vagus) and drainage, or highly selective vagotomy (1)
  - Gastric ulcers: partial gastrectomy, Billroth I or II
  - Perforated ulcers: laparoscopy/open patching (1)
- Emerging options: Vonoprazan is a novel acid blocker that blocks the hydrogen-potassium ATPase.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Discontinue ulcerogenic agents (e.g., NSAIDs).
- Bleeding peptic ulcers
  - Stable: Give PPI to reduce transfusion requirements, need for surgery, and duration of hospitalization (6).
  - Unstable: Fluid/packed RBC resuscitation followed by emergent esophagastroduodenoscopy (EGD); use IV PPI.
  - Insufficient evidence for high-dose PPI treatment over lower doses in peptic
ulcer bleeding (2)[A]

- Oral PPI equivalent to IV after endoscopic treatment (6)
- Perforated peptic ulcers are a surgical emergency (1).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- *H. pylori* eradication: expected in >90% (with double antibiotic regimen):
  - Confirm eradication with urea breath test.
- Acute duodenal ulcer: Monitor clinically.
- Acute gastric ulcer: Confirm healing via endoscopy after 12 weeks. Biopsies (if not done initially) to confirm benign mucosa.
- Tobacco cessation

PROGNOSIS

After *H. pylori* eradication (4):

- Low ulcer relapse rate; if relapse, consider surreptitious use of NSAIDs.
- Reinfection rates <1% per year
- Low risk of rebleeding
- Decreased NSAID ulcer recurrence (4)

COMPLICATIONS

- Hemorrhage: up to 25% of patients (initial presentation in 10%)
- Perforation: <5% of patients
- Gastric outlet obstruction: up to 5% of duodenal or pyloric channel ulcers; male predilection found
- Risk of gastric adenocarcinoma is increased in *H. pylori*-infected patients.
- Refractory peptic ulcer disease (5–10% after eradication of *H. pylori*, or completion of 12 weeks of PPI)

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- K27.9 Peptic ulc, site unsp, unsp as ac or chr, w/o hemor or perf
- K26.9 Duodenal ulcer, unspecified as acute or chronic, without hemorrhage or perforation
- K25.9 Gastric ulcer, unspecified as acute or chronic, without hemorrhage or perforation

**CLINICAL PEARLS**

- In patients with PUD, eradicate *H. pylori* to assist healing and reduce the risk of recurrence.
- Upper endoscopy is indicated for patients with suspected peptic ulcers and red flag symptoms and for those who do not respond to treatment.
• PPIs have higher efficacy than H₂ blockers for healing duodenal ulcers.
PERICARDITIS
Veronica J. Ruston, DO

BASICS
DESCRIPTION
Inflammation of the pericardium, with or without associated pericardial effusion. Myopericarditis or perimyocarditis refers to cases that have myocardial involvement in addition to involvement of the pericardium.

EPIDEMIOLOGY
Incidence
Epidemiologic studies are lacking. Exact incidence is unknown but occurs in up to 5% of patients evaluated in the ER for chest pain without myocardial infarction (MI); appears to be a slightly increased prevalence in men.

ETIOLOGY AND PATHOPHYSIOLOGY
- Inflammation of the pericardial sac can be acute or chronic (recurrent). Chronic/recurrent inflammation may result in constrictive pericarditis.
- Can produce serous/purulent fluid/dense fibrinous material (depending on etiology), which may or may not lead to hemodynamic compromise.
- Idiopathic: 85–90% of cases; likely related to viral infection, which may trigger immune-related process.
- Infectious
  - Viral: coxsackievirus, echovirus, adenovirus, Epstein-Barr virus, cytomegalovirus, hepatitis viruses, influenza virus, HIV, measles, mumps, varicella
  - Bacterial: gram-positive and gram-negative organisms
  - Fungal (more common in immunocompromised populations): Blastomyces dermatitidis, Candida sp., Histoplasma capsulatum
  - Mycobacterial: Mycobacterium tuberculosis
  - Parasites: Echinococcus
- Noninfectious causes
  - Acute MI (2 to 4 days after MI), Dressler syndrome (weeks to months after MI)
  - Aortic dissection
– Renal failure, uremia, dialysis-associated
– Malignancy (e.g., breast cancer, lung cancer, Hodgkin disease, leukemia, lymphoma)
– Radiation therapy
– Trauma
– Postpericardiotomy
– After cardiac procedures (e.g., catheterization, pacemaker placement, ablation)
– Autoimmune disorders: connective tissue disorders, systemic lupus erythematosus (SLE), rheumatoid arthritis, scleroderma, hypothyroidism, inflammatory bowel disease, Wegener granulomatosis, spondyloarthropathies
– Sarcoidosis
  ● Medication-induced: dantrolene, doxorubicin, hydralazine, isoniazid, mesalamine, methysergide, penicillin, phenytoin, procainamide, rifampin

**Genetics**

No known factors

**COMMONLY ASSOCIATED CONDITIONS**

Depends on etiology

**DIAGNOSIS**

**HISTORY**

● Prodrome of fever, malaise, myalgias, viral upper respiratory
● Acute, sharp, stabbing chest pain
● Duration typically hours to days
● Pleuritic pain
● Pain reduced by leaning forward, worsened by lying supine
● Shortness of breath

**PHYSICAL EXAM**

● Heart rate is usually regular and may be rapid.
● Pericardial friction rub: coarse, high-pitched sound best heard during end expiration at left lower sternal border with patient leaning forward. Highly specific for diagnosis (but not sensitive); may be transient and mono-, bi-, or
triphasic
• New S₃ may suggest myopericarditis.
• Cardiac tamponade
• Diagnostic clinical criteria
  – Acute pericarditis (at least two of four criteria)
    o Typical (pleuritic) chest pain
    o Pericardial friction rub
    o ECG changes with widespread ST elevation
    o New/increasing pericardial effusion
  – Myopericarditis
    o Definite pericarditis plus
      o Symptoms (dyspnea, chest pain, or palpitations) and ECG changes not previously documented (ST/T wave abnormalities, supraventricular/ventricular tachycardia) or focal/diffuse depressed left ventricular (LV) function documented on imaging study
      o Absence of evidence of other cause
      o One of the following: elevated cardiac enzymes (creatinine kinase [CK]-MB, troponin I or T) or new focal/diffuse depressed LV function or abnormal imaging consistent with myocarditis (MRI with gadolinium, gallium-67 scanning, antimyosin antibody scanning)
  – Case definitions
    o Suspected myopericarditis: criteria 1, 2, and 3
    o Probable myopericarditis: criteria 1, 2, 3, and 4
    o Confirmed myopericarditis: histopathologic evidence of myocarditis by endomyocardial biopsy (EMB) or autopsy (Note: In the clinical setting, for self-limited cases with predominantly pericarditis, EMB is rarely indicated.)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• It is not necessary to order tests for uncomplicated cases or when the diagnosis is clear. Following labs may be helpful (1)[C]:
  – CBC: typically shows leukocytosis
  – Inflammatory markers: elevated erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and lactate dehydrogenase (LDH)
  – Cardiac biomarkers: typically elevated CK, troponins
    o Elevated troponins associated with younger age, male sex, pericardial effusion at presentation, and ST segment elevation on ECG
Adverse outcomes are not predicted by elevated troponin.

- **ECG**: Findings include widespread upward concave ST segment elevation (in all or most leads, a diffuse, nonregional process) and PR segment depression that may evolve through four stages. ECG may be normal/show nonspecific abnormalities:
  - **Stage 1**: diffuse ST segment elevation and PR segment depression
  - **Stage 2**: Normalization of the ST and PR segments and T waves begin to flatten and invert.
  - **Stage 3**: widespread T wave inversions
  - **Stage 4**: normalization of T waves; may have persistent inversions if chronic pericarditis
- ECG may demonstrate low voltage and electrical alternans with tamponade.
- Transthoracic echocardiogram is recommended to evaluate for the presence of pericardial effusion, tamponade, or myocardial disease (presence of effusion helps to confirm diagnosis of pericarditis) (1)[C].
- Chest x-ray (CXR) is performed to rule out pulmonary/mediastinal pathology. Enlarged cardiac silhouette suggests large pericardial effusion (at least 200 mL).
- CT and MRI allow visualization of pericardium to assess for complications or if initial workup is inconclusive (1)[C].
- Additional testing (if clinically appropriate based on history or atypical presentation or course) may include tuberculin skin test, sputum cultures, rheumatoid factor, antinuclear antibody, and HIV serology (1)[C].
- Viral cultures and antibody titers rarely clinically useful (1)[C]

### Diagnostic Procedures/Other

- Pericardiocentesis indicated for cardiac tamponade; for suspected purulent, tuberculous, or neoplastic pericarditis; and for effusions >20 mm on echocardiography (2)[C]
- Surgical drainage with pericardial biopsy recommended if recurrent tamponade, ineffective pericardiocentesis, or hemodynamic instability (2)[C]

### Test Interpretation

- Microscopic examination may reveal hyperemia, leukocyte accumulation, or fibrin deposition.
- Purulent fluid with neutrophilic predominance if bacterial etiology
- Lymphocytic predominance in viral, tuberculous, and neoplastic pericarditis
**TREATMENT**

- Goal of treatment is to relieve pain and reduce complications (e.g., recurrence, tamponade, chronic restrictive pericarditis).
- Outpatient therapy is reported to be successful in 85% patients with low-risk features.

**GENERAL MEASURES**

Specific therapy directed toward underlying disorder for patients with identified cause other than viral/idiopathic disease. Restrictions of physical activity are important part of treatment for recurrences.

**MEDICATION**

**First Line**

- NSAIDs are considered the mainstay of therapy for acute pericarditis:
  - Ibuprofen 400 to 800 mg TID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper (3)[C]
  - Aspirin 650 to 975 mg TID—QID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper; preferable for patients with recent MI because other NSAIDs impair scar formation in animal studies (4)[C]
  - Indomethacin 50 mg TID for 1 to 2 weeks (2 to 4 weeks for recurrence) then taper; should avoid in elderly due to flow restrictions to coronaries (3)[C]
  - Ketorolac 15 to 30 mg IV/IM q6h while inpatient; maximum duration of 5 days (3)[C]
  - GI protection should be provided (3)[C].
  - Tapering should be done only if the patient is asymptomatic and CRP/ESR are normal and are done every 1 to 2 weeks (3)[C].
  - Treatment duration using NSAIDs for initial attacks is 1 to 2 weeks, but for recurrences, consider 2 to 4 weeks of therapy (3)[C].
  - Monitoring: NSAIDs: CBC and CRP at baseline and weekly until CRP normalizes
  - Contraindications: hypersensitivity to aspirin or NSAIDs, active peptic ulcer/GI bleeding
  - Precautions: Use with caution in patients with asthma, 3rd-trimester pregnancy, coagulopathy, and renal/hepatic dysfunction.
- Colchicine: common practice to use in combination with NSAIDs; 0.6 mg
BID for up to 3 months (up to 6 months for recurrence); taper is not required. Efficacious as therapy for initial occurrence and if multiple recurrences. This is the only agent proven to prevent recurrences in RCTs. Adjunctive therapy can reduce rate of recurrence by 50% (2)[A]. Monitoring: Consider CBC, CRP, transaminases, CK, and creatinine at baseline and at least after 1 month.

- Pregnant: <20 weeks’ gestation: Aspirin is first choice, but NSAIDs and prednisone are also allowed; >20 weeks’ gestation: Prednisone is allowed with avoidance of NSAIDs, aspirin, and colchicine (1)[C].

**Second Line**
- Corticosteroid treatment is indicated in connective tissue disease, tuberculous pericarditis, or severe recurrent symptoms unresponsive to NSAIDs or colchicine; should be avoided in uncomplicated acute pericarditis. *Corticosteroid use alone has been found to be an independent risk factor for recurrence (4)[C].*
- If steroids are used, consider low dose (0.25 to 0.50 mg/kg/day for 2 weeks for first attack; 0.25 to 0.50 mg/kg/day for 2 to 4 weeks for recurrence); then slow taper (if >50 mg: 10 mg/day every 1 to 2 weeks; if 25 to 50 mg: 5 to 10 mg/day every 1 to 2 weeks; if 15 to 25 mg: 2.5 mg/day every 2 to 4 weeks; if <15 mg/day: 1.0 to 2.5 mg/day every 2 to 6 weeks) following remission. Remember adequate prophylaxis treatment for osteoporosis prevention (4)[C].
- If unable to taper from steroids, resume lowest steroid dose and begin slow taper of 1 to 2 mg every 2 to 4 weeks (3)[C].
- Intrapericardial administration of steroids may be effective and limits systemic side effects.
- Emerging alternative options include azathioprine, IV human immunoglobulins, and anakinra (4)[C].

**ISSUES FOR REFERRAL**
- Refractory cases include those on unacceptably high long-term steroid doses (>25 mg/day).
- Consider trial of aspirin and/or NSAIDs plus steroid and colchicine.
- Uremic or dialysis-related cases require more frequent or urgent dialysis without significant benefit from pharmacologics (1)[C].

**SURGERY/OTHER PROCEDURES**
- Pericardiocentesis is indicated in cases of cardiac tamponade, high likelihood of tuberculous/purulent/neoplastic pericarditis, and large symptomatic
effusions refractory to medical therapy.
- Pericardial biopsy may be considered for diagnosis in those with persistent worsening pericarditis without a definite diagnosis.
- Pericardioscopy for targeted diagnostic imaging may be performed at experienced tertiary referral centers in refractory and difficult cases.
- Pericardial window may be performed in cases of recurrent cardiac tamponade with large pericardial effusion despite medical therapy and severe symptoms.
- Pericardiectomy can be considered. The 2004 European Society of Cardiology guidelines recommend pericardiectomy (class IIa) for frequent and highly symptomatic recurrences of pericarditis refractory to medical therapy. However, this is rarely performed in the United States and has high morbidity and mortality (1)[C].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Inpatient therapy recommended for pericarditis associated with clinical predictors of poor prognosis:
  - Major predictors: fever >38°C, subacute onset, large pericardial effusion, cardiac tamponade, lack of response to NSAID/aspirin therapy after at least 1 week (5)[C]
  - Minor predictors: immunosuppressed state, trauma, oral anticoagulation therapy, myopericarditis (5)[C]
- IV fluids considered for hypotension or in the setting of pericardial tamponade
- Discharge criteria
  - Response to therapy with symptom improvement
  - Hemodynamic stability

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- 7 to 10 days to assess response to treatment
- 1 month to check CBC and CRP and thereafter if symptoms continue to be present
- Those with clinical predictors of poor prognosis may require closer follow-up based on lab data and echocardiographic findings.

Patient Monitoring
Myopericarditis

- Use lower doses of anti-inflammatory drugs to control symptoms for 1 to 2 weeks while minimizing deleterious effects on myocarditic process.
- Exercise restrictions for 4 to 6 weeks or until symptoms resolved and biomarkers normalized (2)[C].
- Echocardiographic monitoring at 1, 6, and 12 months (especially in those with LV dysfunction)

**DIET**

No restrictions

**PROGNOSIS**

Overall good prognosis; disease usually benign and self-limiting; purulent and tuberculosis pericarditis with high mortality

**COMPLICATIONS**

- Recurrent pericarditis: occurs in ~30% of patients, with most instances resulting from idiopathic, viral, or autoimmune pericarditis; inadequate treatment of the initial attack; and, less commonly, neoplastic etiologies. Recurrence usually within 1st week following initial episode but may occur months to years later; rarely associated with tamponade/constriction
- About 5% of patients develop corticosteroid dependence and colchicine resistance.
- Cardiac tamponade: rare complication with increased incidence in neoplastic, purulent, and tuberculous pericarditis
- Effusive-constrictive pericarditis: reported in 24% of patients undergoing surgery for constrictive pericarditis and in 8% of patients undergoing pericardiocentesis and cardiac catheterization for cardiac tamponade. Failure of right atrial pressure to fall by 50% or to a level below 10 mm Hg after pericardiocentesis is diagnostic.
- Constrictive pericarditis: rare complication in which rigid pericardium produces abnormal diastolic filling with elevated filling pressures. Pericardiectomy remains definitive therapy.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

- I31.9 Disease of pericardium, unspecified
- I30.9 Acute pericarditis, unspecified
- I30.1 Infective pericarditis

**CLINICAL PEARLS**

- Consider *major* and *minor* predictors in deciding which patients should be admitted.
- Therapy aimed at symptomatic relief and NSAIDs are first-line treatment.
Colchicine is recommended as an adjunct to NSAIDs.

- Pericardiocentesis is recommended in the setting of cardiac tamponade or possible purulent pericarditis.
PERIODIC LIMB MOVEMENT DISORDER (PLMD)

Denise Sharon, MD, PhD, FAASM • John R. Burk, MD

BASICS

DESCRIPTION

- Sleep-related movement disorder with episodes of periodic limb movements (PLMs) occurring during sleep (1)[A]
  - Periodic limb movements of sleep (PLMS) demonstrated during polysomnography combined with clinical symptoms
  - Clinical history of significant sleep disturbance or functional impairment is necessary for diagnosis.
  - PLMS are repetitive contractions of the tibialis anterior muscles occurring mainly in non-rapid eye movement (NREM) sleep.
  - Movements consist of unilateral or bilateral, simultaneous or not, rhythmical extension of the big toe and ankle dorsiflexion.
  - Sometimes, knee and hip flexion is noted.
  - Arm movements or more generalized movements occur less commonly.
  - Movements might be associated with cortical arousals from sleep unbeknownst to the patient (PLMs with Arousals—PLMA).
  - Complaints include insomnia, nonrestorative sleep, daytime fatigue, and/or somnolence.
  - Bed partner may complain of patient’s movements.
  - Another sleep disorders: Obstructive sleep apnea, narcolepsy, restless legs syndrome do not explain the PLMS (2)[A].

- No wakeful perception of the PLMS or associated restlessness
  - If there is wakeful perception, the diagnosis is not periodic limb movement disorder (PLMD) but possibly RLS.

- System(s) affected: musculoskeletal, nervous
- Synonym(s): nocturnal myoclonus; sleep myoclonus; periodic leg movements of sleep

EPIDEMIOLOGY

Incidence
PLMD is rare, reported in both children and adults (1).
PLMS occurs in at least 15% of insomnia patients.
PLMS is frequent in rapid eye movement (REM) sleep behavior disorder (RBD) occurring during REM sleep.
PLMS is frequent in narcolepsy, in OSA, and during initiation of continuous positive airway pressure (CPAP).

**Prevalence**
- No predominant sex preference; male = female
- PLMS >5/hr is uncommon before age 40 years.
- PLMS increases with age: 45% of patients >65 years exhibit PLMS >5/hr but not necessarily PLMD.
- PLMD is much less common: <5% of adults but is underdiagnosed (1)
- 85% of RLS patients have PLMS (3).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Understudied; most data pertain to PLMS in RLS.
- Brain iron deficiency
- Supra-segmental disinhibition at the brainstem and spinal cord levels
- Spinal cord excitability
- CNS dopamine dysregulation supported by increased incidence of PLMS in untreated Parkinson disease (PD) patients
- Decreased incidence of PLMS in schizophrenia patients
- Triggering and exacerbating factors:
  - Peripheral neuropathy
  - Arthritis
  - Renal failure
  - Synucleinopathies (multiple-system atrophy)
  - Spinal cord injury
  - Pregnancy
  - Medications:
    - Most antidepressants (except bupropion or desipramine) and lithium
    - Some antipsychotic and anti-dementia medications
    - Antiemetics (metoclopramide)
    - Antihistamines

**Genetics**
BTBD9 on chromosome 6p associated with PLMS in patients with or without
RLS, but not in RLS patients without PLMS

RISK FACTORS
- Family history of RLS
- Iron deficiency and associated conditions
- Peripheral neuropathy
- Arthritis, orthopedic problems
- Chronic limb pain or discomfort

GENERAL PREVENTION
- Adequate nightly sleep
- Avoid PLMS triggers such as iron deficiency, frequently observed in children.
- Awareness, including family history

COMMONLY ASSOCIATED CONDITIONS
- Narcolepsy
- Iron deficiency
- End-stage renal disease (ESRD)
- Cardiovascular disease; stroke
- Gastric surgery
- Pregnancy
- Arthritis
- Synucleinopathies (multiple-system atrophy)
- Lumbar spine disease; spinal cord injury
- Peripheral neuropathy
- Insomnia, insufficient sleep, parasomnias
- ADHD
- Mood disorders, anxiety, oppositional behaviors

Pediatric Considerations
- PLMD may precede overt RLS by years.
- Association with RLS is more common than in adults.
- Symptoms may be more consequential than in adults (4)[B].
- Association and differential diagnosis with ADHD, oppositional behaviors, mood disorders, growing pains

Pregnancy Considerations
- May be secondary to iron or folate deficiency
Most severe in the 3rd trimester
Usually subsides after delivery

Geriatric Considerations
- May become a significant source of sleep disturbance
- May cause or exacerbate circadian disruption and “sundowning”
- Many medications given to the elderly may trigger or exacerbate PLMs, which can lead to PLMD or RLS.

DIAGNOSIS

HISTORY
- Sleep disturbance:
  - Insomnia: difficulty maintaining sleep
  - Nonrestorative sleep
  - Daytime fatigue, tiredness, and/or somnolence
  - Oppositional behaviors
  - Memory impairment
  - Depression
  - ADHD, particularly in children
- The PLMS and the symptoms cannot be better explained by another current sleep disorder, medical, neurologic or mental disorder.

PHYSICAL EXAM
- No specific findings
- Polysomnography
  - PLMs differ from limb movements (LMs) by showing periodicity: series of at least four movements 5 to 90 seconds apart.
  - Indices of PLMS suggestive of disorder:
    - PLMS >5/hr in children
    - PLMS >5/hr in adults
    - Not associated with apneas or hypopneas

DIFFERENTIAL DIAGNOSIS
- When PLMs occur along with RLS, RBD, or narcolepsy, these disorders are diagnosed as with PLMs, and PLMD is not diagnosed separately.
- OSA: LMs occur during microarousals from apneas; treatment of sleep apnea
eliminates these LMs.
- Sleep starts: nonperiodic, generalized, occur only at wake–sleep transition, <0.2 seconds duration
- Sleep-related leg cramps: isolated and painful
- Fragmentary myoclonus: 75 to 150 ms of electromyographic (EMG) activity, minimal movement, no periodicity
- Nocturnal seizures: epileptiform EEG, motor pattern incongruent with PLMs
- Fasciculations, tremor: no sleep association
- Sleep-related rhythmic movement disorder: voluntary movement during wake–sleep transition; higher frequency than PLMs
- Growing pains in children: Pain is the major concern.

DIAGNOSTIC TESTS & INTERPRETATION
- Polysomnography with finding of repetitive, stereotyped PLMs:
  - Tibialis anterior EMG activation lasting 0.5 to 10.0 seconds
  - EMG amplitude increases >8μV from baseline.
  - Movements occur in a sequence of ≥4 at intervals of 5 to 90 seconds.
  - Associated with heart rate variability from autonomic-level arousals
  - Most PLM episodes occur in the 1st hours of non-REM sleep.
  - Night-to-night PLMS variability is common.
- Serum iron stores (ferritin, transferrin, iron-binding capacity, serum iron) to assess for iron deficiency (at least ferritin)

Diagnostic Procedures/Other
- Ankle actigraphy for in-home use
- EMG or nerve conduction studies for peripheral neuropathy/radiculopathy

Test Interpretation
- Serum ferritin should be >75 ng/mL.
- Transferrin saturation >16%

TREATMENT
Treatment paradigm similar to that for RLS, except that all medications are off-label for PLMD (2,3,5)[B]

GENERAL MEASURES
● Assess for and correct iron deficiency.
● Adequate nightly sleep
● Regular exercise, low impact and stretches in the evening
● Warm the legs (long socks, leg warmers, electric blanket, etc.).
● Hot bath before bedtime; leg baths
● Avoid caffeine and alcohol.

**MEDICATION**

● Use minimum effective dose.
● Goals of medication:
  – Improve subjective sleep quality.
  – Control PLMS and their effect on sleep.
● Consider risks, side effects, and interactions individually (e.g., benzodiazepines in elderly).
● Low bedtime (HS) dosing minimizes daytime sleepiness side effect. Treatment should decrease instead of increase daytime somnolence.

**First Line**

Historically, currently debated—use clinical judgment.

● Dopamine agonists reduce PLMS, increase sleep efficiency but has no effect on sleep instability; start low, titrate slow to optimal dose \((2,3,5)\)[C]:
  – Pramipexole (Mirapex): 0.125 to 0.500 mg; titrate by 0.125 mg; take 2 hours before bedtime.
  – Ropinirole (Requip): 0.25 to 4.00 mg; titrate by 0.25 mg; take 1/2 to 1 hour before bedtime; preferred in renal impairment
  – Transdermal rotigotine (Neupro): 1 to 3 mg/24hr patch; initiate with 1 mg/24hr; titrate up by 1 mg slowly to effectiveness.
● Avoid dopamine agonists in psychotic patients, especially if taking dopamine antagonists.
● Dopamine agonists may exert a stimulant effect, further disturbing sleep.

**Second Line**

● Voltage-gated calcium channel \(\alpha 2\delta\) subunit ligands: useful for associated neuropathy; decrease PLMS and improve sleep architecture \((2,3)\)[C]:
  – Gabapentin enacarbil (Horizant): 600 mg/day taken early evening; caution with liver disease and with renal impairment.
  – Gabapentin (Neurontin): 300 to 1,200 mg/day 1/2 dose before bedtime; caution with liver disease and renal impairment.
- Pregabalin (Lyrica): 75 to 300 mg/day before bedtime
- Benzodiazepines and agonists (2,3)[C]; most commonly used because of their effect on sleep; caution in the elderly
  - Clonazepam (Klonopin): 0.5 to 3.0 mg/day
  - Zaleplon, zolpidem, temazepam, triazolam, alprazolam, diazepam
- Opioids: low risk for tolerance with bedtime dose; most commonly used when other treatments fail; can decrease respiratory drive
  - Hydrocodone: 5 to 20 mg/day
  - Oxycodone: 2.5 to 20.0 mg/day

**ISSUES FOR REFERRAL**
To sleep medicine clinic, neurology and movement disorders clinic:
- High-dose medications
- Worsening of symptoms while on medications

**Pediatric Considerations**
- First-line treatment is nonpharmacologic.

  - Assess/correct iron deficiency (4)[B].
  - Consider low-dose clonidine 0.1 mg to 0.3 mg at bedtime; caution: orthostatic hypotension

**Pregnancy Considerations**
- Initial approach: iron supplementation, nonpharmacologic therapies (5)
- Avoid medications class C or D.
- In 3rd trimester, low-dose opioids may be considered. Monitor/address constipation.

**Geriatric Considerations**
In weak or frail patients, avoid medications that may cause dizziness or unsteadiness.

**ADDITIONAL THERAPIES**
- If iron deficient, iron supplementation:
  - 325-mg ferrous sulfate with 200 mg vitamin C between meals TID
  - Repletion may require months of treatment.
  - Symptoms continue without other treatment.
- Vitamin/mineral supplements, including calcium, magnesium, B₁₂, folate
- Clonidine 0.05 to 0.30 mg/day
Relaxis leg vibration device (http://myrelaxis.com); limited data

**SURGERY/OTHER PROCEDURES**
Correction of orthopedic, neuropathic, or peripheral vascular problems

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Control during recovery from orthopedic procedures
- Addition or withdrawal of medications that affect PLMD
- Changes in medical status may require medication changes (e.g., Mirapex contraindicated in renal failure; Requip contraindicated in liver disease).
- Consider iron infusion when oral supplementation is ineffective, not tolerated, or contraindicated.
- When NPO, consider IV opiates.
- Evening walks, hot baths, leg warming
- Sleep interruption risks prolonged wakefulness.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*
- At monthly intervals until stable
- Assess symptom severity, medication side effects, augmentation.
- Annual and PRN follow-up thereafter
- If iron deficient, remeasure ferritin to assess repletion.

**DIET**
Avoid caffeine and alcohol late in the day.

**PATIENT EDUCATION**
- National Sleep Foundation: http://sleepfoundation.org/
- American Academy of Sleep Medicine: http://www.sleepeducation.org/

**PROGNOSIS**
- Primary PLMD: lifelong condition with no current cure
- Secondary PLMD: may subside with resolution of cause(s)
• Current therapies usually control symptoms.
• PLMD often precedes the emergence of RLS.

COMPLICATIONS
Mostly based on RLS data
• Tolerance to medications requiring increased dose or alternatives
• Augmentation (increased PLMs and sleep disturbance, emergence of RLS) from prolonged use of dopamine agonists:
  – Higher doses increase risk.
  – Iron deficiency increases risk.
  – Add alternative medication and then detitrate dopaminergic agent.
• Iatrogenic PLMD (from antidepressants, etc.)

CODES

ICD10
G47.61 Periodic limb movement disorder

CLINICAL PEARLS

- Many patients with PLMs may not require treatment; however, when sleep disturbance from PLMs causes insomnia and/or daytime consequences, PLMD exists and should be treated.
- Assessing iron stores, at least ferritin supports the diagnosis and provides options for treatment.
- Many antidepressants and some antihistamines cause or exacerbate PLMs.
Peripheral arterial disease (PAD) is defined as atherosclerotic occlusive disease of the peripheral arteries, most commonly in the lower extremities. Following coronary artery disease and cerebrovascular disease, PAD is the third leading source of atherosclerotic vascular morbidity. PAD manifests as intermittent claudication (IC) or atypical leg pain and is commonly diagnosed with a resting ankle-brachial index (ABI) of <0.90.

**Epidemiology**

- **Age:** >50 years
- **Sex:** male > female (2:1)
- **Impacts** at least 8 million people in the United States
- **Globally,** an estimated >200 million people have PAD with increased prevalence in low- and middle-income countries.

**Incidence**

- Annual incidence is 7.1/1,000 men and 3.6/1,000 women among all ages, per Framingham Heart Study.
- Incidence increases with age and the presence of cardiovascular risk factors.

**Prevalence**

- **U.S. prevalence:** 5.9% in adults >40
- Prevalence approaches 30% in high-risk populations.
- **Higher prevalence and severity** in African Americans and Hispanics

**Etiology and Pathophysiology**

- In PAD, arterial occlusion most commonly occurs secondary to atherosclerotic disease.
- Other etiologies include phlebitis, trauma, or autoimmune/vasculitic diseases.
- Arterial narrowing impairs the ability to adequately oxygenate muscle during
periods of increased demand (i.e., exercise), causing claudication and exercise limitation.

- Reperfusion at rest following ischemia can result in multiple subsequent physiologic changes, including inflammation, oxidant stress, endothelial dysfunction, and mitochondrial injury.

**Genetics**
Although several of the risk factors for PAD (as noted below) are heritable, genome-wide association studies isolating PAD-specific single nucleotide polymorphisms have not been as successful. This has been attributed to the increased clinical and genetic heterogeneity of PAD.

**RISK FACTORS**
- Age >50 years
- Cigarette smoking
- Diabetes mellitus (DM)
- Obesity
- Hypertension
- Hyperlipidemia
- Chronic kidney disease (CKD)
- Hyperviscosity
- Heritable conditions: chylomicronemia, hypercholesterolemia, hyperhomocysteinemia, and pseudoxanthoma elasticum

**GENERAL PREVENTION**
- Regular aerobic exercise program
- Smoking cessation
- Blood pressure (BP) and diabetes control
- Statin therapy is indicated in those with clinical PAD for secondary prevention of atherosclerotic cardiovascular disease.

**COMMONLY ASSOCIATED CONDITIONS**
In addition to the aforementioned risk factors, PAD is associated with other forms of atherosclerotic disease including myocardial infarction (MI), transient ischemic attack (TIA), and cerebrovascular accident (CVA).
HISTORY
- Nearly 50% of patients will be asymptomatic
- IC seen in 10–30% of patients and is typically self-limiting with symptoms resolving within 2–5 minutes of rest
- Atypical or resting leg pain in 20–40% of patients.
- Critical limb ischemia (pain and/or tissue loss)
- Nonhealing wounds and ulceration
- Skin discoloration and gangrene
- Erectile dysfunction (in conjunction with IC and absent or diminished femoral pulses constitutes Leriche syndrome)

PHYSICAL EXAM
- Pallor with leg elevation
- Dependent rubor
- Dry, scaly skin
- Brittle or hypertrophic nails
- Hair loss
- Reduced/absent extremity pulses
- Ulcers (distal toes, lateral malleolus, metatarsal heads)

DIFFERENTIAL DIAGNOSIS
- Arterial aneurysm
- Arterial dissection
- Deep vein thrombosis (DVT)
- Thromboangiitis obliterans (Buerger disease)
- Peripheral neuropathy
- Spinal stenosis or nerve root compression (neurogenic claudication)
- Popliteal entrapment syndrome

DIAGNOSTIC TESTS & INTERPRETATION
Screening
- The association between PAD and cardiovascular morbidity and mortality has been well established, with a lower ABI being an independent predictor.
- Patients at increased risk (criteria below) should undergo thorough history, review of systems, and physical examination with focus on vasculature and BP measurement in both arms (1)[C].
  - Age ≥65 years
  - Age 50 to 64 years with risk factors for atherosclerosis (DM, smoking,
HTN, HLD)
– Age <50 years with DM and one additional risk factor
– Patients at any age with known atherosclerotic disease elsewhere

**Initial Tests (lab, imaging)**
- Risk factor identification with fasting lipid profile, basic metabolic profile
- Resting ABI should be performed in patients with suggestive history and physical findings or those at increased risk of PAD (1)[C].
- Exercise treadmill ABI is useful in patients who are symptomatic but have normal resting ABI.
- Imaging is reserved for patients who have lifestyle limiting symptoms (claudication) despite appropriate guideline-directed management and therapy.
  - Duplex ultrasound, magnetic resonance angiography (MRA), and computed tomography angiography (CTA) is recommended in symptomatic patients who are considered for revascularization (1)[C].
  - Invasive angiography is recommended in patients with critical limb ischemia (1)[B] and is reasonable in those with symptomatic PAD who are candidates for revascularization (1)[C].

**Diagnostic Procedures/Other**
- Doppler ABI: ratio of systolic BP at the ankle and brachial artery
  - Obtain BP at dorsalis pedis and posterior tibial arteries while patient is supine and limb is at level of heart as well as BP of both brachial arteries. Divide higher of the two ankle systolic pressures (dorsalis pedis or posterior tibial) by the higher brachial systolic pressure.
  - ABI ≥1.40 → noncompressible calcified vessel, seen in CKD, DM, and elderly patients
  - ABI 0.91 to 0.99 → borderline
  - ABI ≤0.90, abnormal, diagnostic for PAD
- Leg segmental pressures: obtained after abnormal ABI to localize occlusion and determine treatment plan. A ≤20-mm Hg reduction in pressure is considered significant.
- Toe-brachial index (TBI) is recommended when ABI suggests noncompressible vessel (≥1.40) (1)[B].
GENERAL MEASURES

- The treatment of PAD is multifactorial and includes a supervised exercise program, guideline-based medical therapy, and risk factor modification (2).
- Supervised exercise training, which takes place in a hospital or outpatient facility, is the initial treatment modality recommended in patients with IC (1)[A]. Patients are instructed to walk for a minimum of 30 to 45 minutes (with rest when symptomatic) 3 times per week for a minimum of 12 weeks.
  - A structured community or home-based exercise program can be beneficial and is recommended when a supervised program is not possible (1)[A].
- Risk factor modification, most importantly smoking cessation and management of DM, hypertension, and hyperlipidemia:
  - Ask about smoking at every visit, counsel on stopping, and offer pharmacologic agents when appropriate (varenicline, bupropion, nicotine replacement therapy) (1)[A].
  - Antiplatelet therapy with aspirin or clopidogrel is recommended for patients with PAD when there are no contraindications; however, support for aspirin monotherapy is weak (3)[A]. Studies with aspirin monotherapy have not demonstrated a consistent reduction in fatal or nonfatal cardiovascular events or revascularization rates. Clopidogrel was shown to have a small relative-risk reduction in ischemic stroke, MI or vascular death compared to aspirin monotherapy (CAPRIE trial). Benefit must be weighed against harms—particularly risk of GI bleeding.
  - High-intensity statin (lipid-lowering therapy) is recommended for all patients with PAD and has been shown to reduce all-cause mortality (1)[A].
  - Goal BP <140/90 mm Hg
  - ACE-inhibitors are associated with a significant reduction in major adverse cardiovascular events in patients with PAD (1)[A].

MEDICATION

First Line

- Antiplatelet therapy is recommended in symptomatic patients with PAD without bleeding risk contraindications (3)[A]. Aspirin (75 mg to 325 mg) or clopidogrel (75 mg) are acceptable first-line antiplatelet agents.
  - It is reasonable to prescribe antiplatelet therapy in asymptomatic patients who have an ABI diagnostic of PAD (1)[C].
  - In asymptomatic patients with borderline ABIs (0.91 to 0.99), the utility of antiplatelet therapy is not well established (1)[B].
– The effect of aspirin on the risk reduction of overall ischemic events remains inconclusive. The Prevention of Progression of Arterial Disease and Diabetes (POPADAD) and Aspirin for Asymptomatic Atherosclerosis (AAA) trials compared low-dose aspirin to placebo in patients with lower ABIs and failed to show a significant reduction in fatal and nonfatal cardiovascular events. However, some studies suggest that aspirin delays disease progression and reduces the need for surgical intervention.

- Dual antiplatelet therapy (DAPT; aspirin and clopidogrel) is only reasonable to prescribe following endovascular intervention (1)[C]; however, the data of its efficacy is not well established (1)[B].
- Cilostazol (100 mg orally twice daily) has been shown to improve walking distance and should be considered in all patients with claudication that impacts daily living (1)[C]. However, there is insufficient data on the effect of cilostazol on all-cause mortality or cardiovascular events.

**Second Line**

- Vorapaxar sulfate (Zontivity) reduces thrombin-mediated platelet aggregation by inhibiting protease-activated receptor-1 (PAR-1). Although it reduces rates of revascularization and acute limb ischemia, several studies indicate a major risk of bleeding including intracranial hemorrhage. Thus it is not recommended in patients at high risk of bleeding or those with a prior CVA, TIA, or intracranial hemorrhage.
- Ticlopidine is no longer available in the United States and is not recommended due to risk of life-threatening hematologic complications.
- Pentoxifylline (400 mg 3 times daily) was previously considered first line for symptomatic relief of claudication; however, evidence is of poor quality and benefit is uncertain (Cochrane, other reviews).
- Prostaglandins (beraprost, iloprost, cisaprost) are not recommended as they have shown no long-term benefit and are associated with increased adverse events such as headache, nausea, flushing, diarrhea.

**SURGERY/OTHER PROCEDURES**

Endovascular and surgical interventions to achieve revascularization should be considered in select patients who had an inadequate response to less invasive modalities (i.e., exercise and pharmacotherapy), suffer debilitating IC, ischemic rest pain, or tissue loss and have a favorable risk-benefit ratio.

- Prior to consideration of interventional therapy, functional assessment is done using the Fontaine or Rutherford classification systems. Anatomic
classification of complexity is determined via the Trans-Atlantic Inter-Society Consensus (TASC) (4).

- Endovascular therapy is rapidly involving and includes angioplasty and stent placement. Balloons and stents can be drug eluting.
  - Preferred for patients with aortoiliac disease (1)[A] and reasonable for femoropopliteal disease (1)[B]
  - Current data is insufficient regarding infrapopliteal lesions but ongoing studies are comparing efficacy between endovascular and surgical intervention.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Chelation therapy and B-complex vitamins are not recommended in patients with PAD (1)[B].
- Additional studies on Ginkgo biloba, L-arginine, propionyl-L-carnitine, omega-3 fatty acids, and vitamin E have been studied and in general, their efficacy is uncertain. Thus, currently they are not recommended in the primary care setting.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- At follow-up, patients should undergo thorough history and physical examinations. They should be asked about their progress with risk-factor modification (i.e., smoking, glucose control, hypertension), exercise endurance and compliance with training program, and effectiveness of pharmacotherapy.
- Patients who underwent endovascular or surgical intervention should receive regular assessment of symptoms and occlusion via resting and exercise ABIs.

DIET

A heart-healthy diet is recommended. Balanced diets consisting of vegetables, fruit, nuts, protein, and healthy fats (such as the Mediterranean diet) are likely best.

PROGNOSIS HEALTHY FATS
With regard to limb ischemia and IC, 15–20% of patients will have worsening claudication; 5–10% will require endovascular or surgical intervention; and 2–5% will undergo amputation (most commonly smokers and diabetics).

With regard to cardiovascular outcomes, at 5 years, 20% of patients with PAD will experience a nonfatal cardiovascular event, and 15–20% will die, most commonly of cardiovascular disease.

CODES

mebooksfree.com
ICD10
- I73.9 Peripheral vascular disease, unspecified
- I70.209 Unsp athscl native arteries of extremities, unsp extremity
- I70.219 Athscl native arteries of extrm w intrmt claud, unsp extrm

CLINICAL PEARLS

- Different societies and organizations offer varying viewpoints on screening for PAD. The United States Preventive Services Task Force (2013) finds that evidence is insufficient to weigh harms and benefits of screening for PAD. The 2016 AHA/ACC guidelines recommend a thorough history, physical exam, and subsequent resting ABI for patients considered at high risk (≥65 years, 50 to 64 years with a risk factor [HTN, HLD, DM, smoking], <50 years with DM and one additional risk factor, or patients at any age with known atherosclerotic disease).
- A patient who fails noninvasive therapy with a supervised exercise training program and appropriate pharmacotherapy should be referred to vascular surgery for evaluation of endovascular or surgical intervention. Additionally, patients in which diagnosis is difficult or those with critical limb ischemia (pain at rest, gangrene, ulceration) should be referred.
- Antiplatelet therapy (aspirin or clopidogrel) and cilostazol for symptomatic relief are at the cornerstone of pharmacotherapy.
- Current studies assessing appropriate screening, optimal pharmacotherapy, and the benefit of endovascular over surgery are underway, suggesting possible improvement of the evidence and guidelines in coming years.
PERITONITIS, ACUTE

Gregory M. Piech, MD, MPH • Marie L. Borum, MD, EdD, MPH

BASICS

DESCRIPTION

• Definition: inflammation of the peritoneum
• Classification:
  – Aseptic: chemical irritation or systemic inflammation of peritoneum
  – Bacterial: infection of peritoneal fluid
• Bacterial peritonitis types:
  – Primary/spontaneous bacterial peritonitis (SBP): infection of ascitic fluid in the absence of an intra-abdominal source; typically monomicrobial
  – Secondary bacterial peritonitis: infection of ascitic fluid from a detectable intra-abdominal source (i.e., perforation, abscess); typically polymicrobial
  – Tertiary bacterial peritonitis: persistent infection despite adequate therapy

EPIDEMIOLOGY

Incidence

• In patients with ascites, the incidence of SBP in a 1-year period is 10–25% (1).
• Secondary bacterial peritonitis correlates with incidence of the underlying pathology (e.g., colitis, appendicitis, diverticulitis, PUD).
• 57% of patients with secondary bacterial peritonitis progress to tertiary peritonitis (2).

Prevalence

• SBP: In asymptomatic patients with cirrhosis and ascites, the prevalence is <3% in outpatients and 8–36% in the nosocomial setting (3).
• In patients with cirrhosis and ascites, 5% of peritonitis is secondary rather than SBP (4).

ETIOLOGY AND PATHOPHYSIOLOGY

• Mechanism
  – SBP:
• Bacterial translocation via lymphatic spread through mesenteric lymph nodes
• Cirrhotic patients have secondary:
  ■ Alterations to gut microbiota with higher prevalence of pathogenic organisms
  ■ Small intestinal bacterial overgrowth (SIBO) and increased intestinal mucosal permeability to bacteria
  ■ Decreased cellular and humoral immunity limiting peritoneal bacterial clearance
    – Secondary bacterial peritonitis
      o Spillage/translocation of bacteria from inflamed or perforated intraperitoneal organs or introduction of bacterial through instrumentation—that is, peritoneal dialysis, intraperitoneal chemotherapy
    – Tertiary bacterial peritonitis
      o Evolves from secondary peritonitis if inadequate source control or altered host immunity
• Microbiology
  – SBP
    o *Escherichia coli* (33%), *Streptococcus* spp. (15%), *Staphylococcus* (13%), *Klebsiella* (8%); reflects increasing rate of gram-positive and resistant organisms (e.g., extended-spectrum β-lactamase–producing [ESBL] *E. coli*, MRSA, *Enterococcus*) in the nosocomial setting (5)
  – Secondary bacterial peritonitis:
    o *E. coli*, *Klebsiella*, *Proteus*, *Streptococcus*, *Enterococcus*, *Bacteroides*, *Clostridium*

**RISK FACTORS**
• SBP: advanced cirrhosis with ascites, malnutrition, upper GI bleed, PPI usage, prior SBP
  – Acid suppression with PPIs promotes SIBO increasing incidence of SBP. Patients hospitalized with cirrhosis who are receiving PPIs have increased risk of developing SBP (3,5).
  – 70% of SBP cases are seen in patients with Child-Pugh class C cirrhosis (1).
  – Low ascites protein level (<1.0 g/dL)
• Factors associated with perforation or fluid translocation (e.g., peritoneal dialysis, *Helicobacter pylori* and NSAIDs causing ulcers, vascular disease causing bowel ischemia, ETOH abuse causing pancreatitis) increase risk for SBP
GENERAL PREVENTION

- SBP prophylaxis beneficial when risk factors are present (e.g., ascitic fluid protein concentration <1.0 g/dL, esophageal varices, or history of previous SBP)
  - Prior SBP: prophylactic norfloxacin or Bactrim PO daily (6)[A]
  - Cirrhosis and GI bleed: 7-day course of ceftriaxone 2 g IV daily or norfloxacin BID; IV while bleeding, PO as tolerated (6)[A]
  - Cirrhotic ascites: low ascitic fluid protein (<1.5 g/dL) with renal impairment (creatinine ≥1.2, BUN ≥25, or serum Na ≤130) or liver failure (Child score ≥9, bilirubin ≥3): prophylactic norfloxacin PO daily (3,6)[A]
- Limit use of PPIs to only proven indications (6)[B].

DIAGNOSIS

HISTORY

- SBP: history of cirrhosis or ascites, fever, mental status changes, abdominal pain, chills, nausea/vomiting, GI bleed
- Secondary bacterial peritonitis: may be clinically indistinguishable from SBP unless history of perforation, abscess, or peritoneal dialysis is present
- Tertiary: persistent signs and symptoms despite initial treatment, or history of recurrent peritonitis

ALERT

30% of patients are asymptomatic (1).

PHYSICAL EXAM

- Tachycardia, fever, tachypnea, altered mental status
- Abdominal distention, ascites, abdominal wall guarding and rigidity, rebound tenderness, hypoactive/absent bowel sounds

DIFFERENTIAL DIAGNOSIS

- Liver disease: acute hepatitis, decompensated cirrhosis
- Luminal disease: abscess formation, ileus, volvulus, intussusception, mesenteric adenitis, pancreatitis, cholecystitis, malignancy, peritoneal carcinomatosis
- Extraluminal disease: ruptured ectopic pregnancy, tubo-ovarian abscess, PID, severe UTI, and/or pyelonephritis
Systemic disease: tuberculosis, pneumonia, MI, porphyria, SLE

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

**ALERT**
Early diagnosis is essential to reduce mortality. Perform paracentesis in patients with ascites who are admitted to the hospital (6)[B].

- Immediate evaluation
  - Paracentesis, blood, and urine cultures before administering antibiotics (1,6)[B]. A single dose of effective broad-spectrum antibiotics decreases ascitic culture yield.
  - Ascitic fluid studies include culture, Gram stain, cell count with differential, and albumin (1)[B]; if assessing for secondary peritonitis, include LDH, total protein, glucose, alkaline phosphatase (ALP), and CEA.
  - Bedside inoculation of ascitic fluid into blood culture bottles (aerobic, anaerobic) increases culture yield 80–90% (3,5)[B].

  - Appropriately sensitive urine dipstick (PMN >250 cells/mm³) analysis of ascitic fluid shows promise for bedside diagnosis if SBP but is not yet widely implemented (6).

  **ALERT**
  Ascitic fluid culture is negative in up to 50% of patients with SBP (1)[A].

- SBP: ascitic fluid PMN >250 cells/mm³
- Culture-negative neutrocytic ascites: negative ascites culture, ascitic fluid PMN >250 cells/mm³
- Nonneutrocytic bacterascites: positive ascites culture, ascitic fluid PMN <250 cells/mm³
- Secondary peritonitis: PMN >250 cells/mm³ on ascitic fluid analysis (usually thousands), with the following:
  - Polymicrobial culture or two of the following: ascitic fluid total protein >1 g/dL, glucose <50 mg/dL, or LDH >225 mU/mL; more sensitive for perforation (96%) than for nonperforation secondary peritonitis (50%) (6)[B]
  - Secondary peritonitis with perforation is likely with ALP >240 U/l or CEA >5 ng/mL, sensitivity 92% (6)[B]; not useful for detection of nonperforation secondary peritonitis
CT scan is often not diagnostic for secondary peritonitis (6)[B].
- Abdominal or chest x-ray may show free air in peritoneal cavity, large/small bowel dilatation, intestinal wall edema in secondary peritonitis.

**Follow-Up Tests & Special Considerations**
- If asymptomatic bacterascites, recent antibiotic exposure, nosocomial atypical organism, or no clinical improvement, repeat paracentesis in 48 hours to determine resolution (decrease in PMNs of 25% or negative cultures) (1)[C].
- In hemorrhagic ascites, PMN count is corrected by subtracting 1 PMN per 250 RBCs (3)[A].

**TREATMENT**

**GENERAL MEASURES**
- For SBP, control ascites with salt restriction, spironolactone +/- furosemide, albumin infusion after large volume paracentesis, and/or lactulose for encephalopathy (6)[A].
- Avoid nephrotoxic medications (5)[C].

**MEDICATION**
- **SBP**
  - Community-acquired SBP without recent β-lactam antibiotic use: 3rd-generation cephalosporins, preferably cefotaxime, 2 g IV q8h for 5 days (6) [A]
  - SBP in absence of previous quinolone use/prophylaxis, vomiting, shock, hepatic encephalopathy, or serum creatinine >3 mg/dL: Ofloxacin 400 mg PO can be substituted for cefotaxime (6)[B].
  - Nosocomial SBP or recent β-lactam antibiotic: empiric therapy based on local susceptibility of patients with cirrhosis for resistant bacteria (6)[B]
  - Symptomatic bacterascites with PMN count <250 cells/mm³: cefotaxime 2 g IV q8h while awaiting sensitivities (6)[B]
  - Second-line antibiotic regimens include fluoroquinolones (levofloxacin), piperacillin/tazobactam, or vancomycin (5)[B], (6)[C].
  - SBP with renal or hepatic impairment (serum creatinine >1 mg/dL, BUN >30 mg/dL, or total bilirubin >4 mg/dL): Add albumin 1.5 g/kg within 6 hours and 1 g/kg on day 3 (1)[A], (6)[B].
- Secondary bacterial peritonitis
– Empiric broad-spectrum antibiotic coverage for polymicrobial infection; IV cefotaxime or other 3rd- to 4th-generation cephalosporin plus metronidazole is an initial option.
– In peritoneal dialysis–associated infection, intraperitoneal route superior to IV

**Tertiary bacterial peritonitis**
– If no unrepaired perforations or leaks, then continue with medical management. This includes antibiotics (guided by prior susceptibilities) and early enteral nutrition to prevent atrophy and maintain immunocompetence (2)[B].
– Consider removing catheter if recurrent or persistent peritoneal dialysis-associated infection.

**SURGERY/OTHER PROCEDURES**

**SBP**
– Medical management

**Secondary bacterial peritonitis**
– Emergent surgical management, including source control with open laparotomy to repair any perforated viscus and eradicate infected material, is first-line treatment (2)[A],(6)[B].

**Tertiary bacterial peritonitis**
– If no unrepaired perforations or leaks, additional surgery for severe abdominal infection is correlated with deterioration and significant mortality (2).

**ALERT**
Mortality of secondary bacterial peritonitis approaches 100% if not treated surgically, whereas the mortality of SBP approaches 80% if the patient receives unnecessary exploratory laparotomy (1,3).

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

– Acute peritonitis typically warrants hospitalization.
– In patients with cardiogenic or septic shock, use invasive monitoring with goal-directed fluid therapy.
– Patients who present with peritonitis can be severely hypovolemic and volume resuscitation is critical. In patients with significant renal or hepatic dysfunction, albumin decreases mortality (1)[A],(6)[B].
Cirrhotic patients are often on β-blockers. During an episode of SBP, β-blockers increase mortality, hepatorenal syndrome, and hospital stay (6)[B].

Nasogastric tube placement helps prevent aspiration in patients with vomiting or GI bleeding.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Normalization of vital signs with resolution of leukocytosis is a sign of improvement.

- SBP: PMN decrease >25% is expected if follow-up paracentesis is performed after 48 hours.
- Leukopenia suggests immune exhaustion and is associated with a poor prognosis.

DIET
- NPO, total parental nutrition as necessary
- Resume enteral feeding after return of bowel function.
- Sodium restriction can reduce future ascites (3)[A].

PROGNOSIS

- SBP
  - For inpatients with first episode of SBP, mortality ranges from 10% to 50% (3).
  - Prognosis improves if antibiotics are started early, prior to onset of shock or renal failure.
  - Renal insufficiency is the strongest negative prognostic indicator.
  - Other poor prognostic factors include nosocomial acquisition, old age, high Child-Pugh-Turcotte or MELD score, malnutrition, malignancy, peripheral leukopenia, and antibiotic resistance (3).
  - Patients with prior SBP have 1-year recurrence rate of 40–70% and 1-year mortality of 31–93% (1,3).
- Secondary bacterial peritonitis:
  - In-hospital mortality of treated patients is 67% (4).
  - Mortality approaches 100% if not treated surgically, especially with
perforation (2,4).
- Prognosis is worse in perforated etiologies.

COMPLICATIONS
- Renal failure, liver failure, encephalopathy, coagulopathy
- Secondary infection, iatrogenic infection, abscess, fistula formation, abdominal compartment syndrome
- Sepsis/septic shock, cardiovascular collapse, adrenal insufficiency, respiratory failure, ARDS

SEE ALSO
Appendicitis, Acute; Cirrhosis of the Liver; Diverticular Disease; Peptic Ulcer Disease

CODES
ICD10
- K65.0 Generalized (acute) peritonitis
- K65.2 Spontaneous bacterial peritonitis
- K65.8 Other peritonitis

CLINICAL PEARLS
- Maintain a high index of suspicion for SBP in cirrhotic patients with ascites (up to 30% of cases may be asymptomatic).
- Paracentesis is necessary to diagnose SBP. Ascitic fluid cultures collected via bedside inoculation with blood culture bottles prior to antibiotic administration significantly increases culture yield.
- E. coli is the most common bacterial isolate from cases of SBP. 3rd-generation cephalosporins remain the first-line treatment. The incidence of gram-positive and resistant organisms is increasing.
- Ascitic fluid analysis stratifies patients at risk for secondary peritonitis who need additional imaging. CT scanning should be performed if there is suspicion based on history and/or ascitic fluid analysis.
- Renal function is an important prognostic indicator for SBP. Albumin administration decreases the incidence of renal failure and mortality in patients with renal or hepatic impairment or who have received large-volume paracentesis.
PERSONALITY DISORDERS
Moshe S. Torem, MD, DLFAPA

BASICS
DESCRIPTION
- Personality disorders (PDs) are a group of conditions, with onset at or before adolescence, characterized by enduring patterns of maladaptive and dysfunctional behavior that deviates markedly from one’s culture and social environment, leading to functional impairment and distress to the individual, coworkers, and family.
  - These behaviors are perceived by patients to be “normal” and “right,” and they have little insight as to their ownership, responsibility, and abnormal nature of these behaviors.
  - These conditions are classified based on the predominant symptoms and their severity.
- System(s) affected: nervous/psychiatric
- Synonym(s): character disorder; character pathology

Geriatric Considerations
Coping with the stresses of aging is challenging.

Pediatric Considerations
A history of childhood neglect, abuse, and trauma is not uncommon.

Pregnancy Considerations
Pregnancy adds pressures in coping with the activities of daily living (ADLs).

EPIDEMIOLOGY
Prevalence
- General population: 15% (1)
- Cluster A: 5.7%
- Cluster B: 6.0%
- Cluster C: 9.1%
- Outpatient psychiatric clinic: 3–30%
- In male prisoners, the prevalence of antisocial PD is ~60%.
• Predominant age: starts in adolescence and early 20s and persists throughout patient’s life
• Predominant sex: male = female; some PDs are more common in females, and others are more common in males.

**ETIOLOGY AND PATHOPHYSIOLOGY**
• Environmental and genetic factors (2)
• Criteria for a PD include an enduring pattern of the following:
  – Inner experience and behavior that deviates markedly from the expectations of one’s culture in ≥2 of the following areas: cognition, affectivity, interpersonal functioning, or impulse control
  – Inflexibility and pervasiveness across a broad range of personal and social situations
  – Significant distress or impairment in social or occupational functioning
  – The pattern is stable and of long duration.
  – The enduring pattern is not better explained as a manifestation of another psychiatric disorder.
  – The enduring pattern is not attributable to the effects of a drug or a medical condition.
• PDs are classified into three major clusters:
  – Cluster A: eccentricity and oddness
    o *Paranoid PD*: unwarranted suspiciousness and distrust of others
    o *Schizoid PD*: emotional, cold, or detached; socially isolated
    o *Schizotypal PD*: eccentric behavior, odd belief system/perceptions, social isolation, and general suspiciousness
  – Cluster B: dramatic, emotional, or erratic behavioral patterns
    o *Antisocial PD*: aggressive, impulsive, irritable, irresponsible, dishonest, deceitful
    o *Borderline PD*: unstable interpersonal relationships, high impulsivity from early adulthood, intense fear of abandonment, mood swings, poor self-esteem, chronic boredom, and feelings of inner emptiness
    o *Histrionic PD*: needs to be the center of attention, with self-dramatizing behaviors and attention seeking in a variety of contexts
    o *Narcissistic PD*: grandiose sense of self-importance and preoccupation with fantasies of success, power, brilliance, beauty, or ideal love; lack of empathy for other people’s pain or discomfort, demanding to get their way
  – Cluster C: anxiety, excessive worry, fear, and unhealthy patterns of coping with emotions
- Avoidant PD: social inhibition, feelings of inadequacy, hypersensitivity to negative evaluation, avoidance of occupational and interpersonal activities that involve the risk of criticism by others, views self as socially inept and personally unappealing or inferior to others
- Dependent PD: excessive need to be taken care of, leading to submissive and clinging behavior with fears of separation, avoids expressing disagreements with others due to fear of losing support and approval, usually seeks out strong and confident people as friends or spouses and feels more secure in such relationships
- Obsessive-compulsive PD: preoccupation with cleanliness, orderliness, perfectionism; preoccupation with excessive details, rules, lists, order, organization, and schedules to the extent that the major point of the activity is lost
- Personality change due to another medical condition. It is a persistent personality disturbance that is caused by the physiologic effects of a medical condition such as frontal lobe lesion, epilepsy, MS, Parkinson disease, lupus, head trauma, postencephalitis or meningitis, and so forth.
- Other specified PD and unspecified PD: A category provided for two situations: (i) the individual’s personality pattern meets the general criteria for PD and traits of several PDs are present, but the criteria for any specific PD are not met; (ii) the individual’s personality pattern meets the general criteria for PD, but the individual is considered to have a PD that is not included in DSM-5 classification such as passive–aggressive PD, depressive PD, masochistic PD, and dangerous and severe PD.

Genetics
Major character traits are inherited; others result from a combination of genetics and environment.

RISK FACTORS
- Positive family history
- Pregnancy risk factors
  - Nutritional deprivation
  - Use of alcohol or drugs
  - Viral and bacterial infections
- Dysfunctional family with child abuse/neglect

COMMONLY ASSOCIATED CONDITIONS
Depression; other psychiatric disorders in patient and family members

**DIAGNOSIS**

**HISTORY**
- Comprehensive interview and mental status examination
- Screen to rule out alcohol and drug abuse.
- Interview of relatives and friends is helpful in establishing an enduring pattern of behavior.

**DIAGNOSTIC TESTS & INTERPRETATION**

Psychological testing (e.g., MMPI-II)

*Initial Tests (lab, imaging)*
- CBC
- Comprehensive metabolic panel
- Thyroid-stimulating hormone
- HIV
- Toxicology screen for substance abuse

*Follow-Up Tests & Special Considerations*
- EEG to rule out a chronic seizure disorder
- CT and MRI of the brain may be necessary in newly developed symptoms to rule out organic brain disease (e.g., frontal lobe tumor).

**DIAGNOSTIC TESTS & INTERPRETATION**

- Medical disorders with behavioral changes
- Other psychiatric disorders with similar symptoms
  - In obsessive-compulsive disorder (OCD), symptoms are ego-dystonic (i.e., perceived as foreign and unwanted). In addition, OCD has a pattern of relapse and partial remission.
  - In obsessive-compulsive personality disorder (OCPD), symptoms are perceived as desirable behaviors (ego-syntonic) that the patient feels proud of and wants others to emulate. In addition, OCPD has a lifelong pattern (i.e., without significant relapse or remission).
TREATMENT

Psychotherapy with family involvement is the foundation of treatment. No specific drugs are indicated to treat PDs; some medications can reduce the intensity, frequency, and dysfunctional nature of certain behaviors (3)[B].

GENERAL MEASURES

- Long-term psychotherapy and cognitive-behavioral therapy (3)[B]
- Group therapy is helpful in the use of therapeutic confrontation and increasing one’s awareness of and insight regarding the damaging effects of dysfunctional behavior patterns (4)[B].

MEDICATION

Medications are effective in the treatment of comorbid conditions such as anxiety and depression.

First Line

- Symptom management (5)[B]
  - Minipsychosis (associated with paranoid, schizoid, borderline, and schizotypal PDs): atypical antipsychotics: risperidone (Risperdal), quetiapine (Seroquel), olanzapine (Zyprexa), ziprasidone (Geodon), aripiprazole (Abilify), asenapine (Saphris), lurasidone (Latuda); start with a low dose, gradually adjusting to the patient’s needs.
  - Anxiety: anxiolytics (benzodiazepines, buspirone [Buspar], and serotonin reuptake inhibitors)
  - Depressed mood: antidepressants
  - Many patients with borderline PD respond well to small doses of atypical neuroleptics and mood stabilizers (5)[B].
  - Precautions: Some atypical neuroleptic drugs may be associated with hyperglycemia and insulin-resistant metabolic syndrome.

Second Line

Mood stabilizers: lithium carbonate, lamotrigine (Lamictal), carbamazepine (Tegretol, Equetro), and valproate (Depacon, Depakene, Depakote) (6)[B]

ISSUES FOR REFERRAL

- When psychiatric comorbidity of other psychiatric disorders is present (e.g., mood disorders, anxiety disorders, substance abuse)
Suicidal ideation or attempts  
Presence of psychotic symptoms  
Thoughts and impulses for violent behavior  
Management of complex pharmacotherapy  
Presence of intense countertransference feelings  
When the patient or family requests it

ADDITIONAL THERAPIES  
- Cognitive-behavioral therapy  
- Dialectical behavior therapy  
- Psychoanalytic therapy  
- Interactive psychotherapy  
- Ego-state therapy  
- Mindfulness-based psychotherapy  
- Group therapy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS  
Disorders with complications of suicide attempts and other behaviors involving a risk to self or others

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS  
Continue outpatient treatment, potentially long term.

Patient Monitoring  
- Regular physical exercise (e.g., 30 to 60 min/day, helps with stress and improving the ADLs)  
- If substance abuse is suspected, check drug screens.  
- Infrequent sessions with relatives or friends are helpful in monitoring behavioral progress.

DIET  
Emphasize variety of healthy foods; avoid obesity.
PATIENT EDUCATION

- Bibliotherapy and writing therapy, specific assignments, and watching certain movies to better understand the nature and origin of one’s specific condition are helpful.
- The movie *As Good as It Gets* illustrates someone with obsessive-compulsive behaviors and their impact on ADLs and relationships with family and friends.
- The movie series *The Godfather* includes several characters with antisocial PD and shows how this affects their interpersonal relationships and their own physical and mental health.
- The movie *What About Bob?* illustrates the challenges involved in treating certain patients with a borderline PD, especially in the management of boundaries in the doctor–patient relationship.
- The movie *A Streetcar Named Desire* illustrates an example of a woman with a histrionic PD.
- The movie *Wall Street* illustrates an example of a person with a narcissistic PD.
- The movie *The Caine Mutiny* illustrates an example of a person with a paranoid PD.
- The movie *Four Weddings and a Funeral* illustrates an example of a person with an avoidant PD.

PROGNOSIS
PDs are enduring patterns of behavior throughout one’s lifetime and are not readily responsive to brief therapies.

COMPLICATIONS

- Disruptive family life with frequent divorces and separations, alcoholism, substance abuse, and drug addiction
- Disruptive behaviors in the workplace may cause absenteeism and loss of productivity.
- Violation of the law and disregard for the concerns and rights of others

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

*Obsessive-Compulsive Disorder (OCD)*

**CODES**

**ICD10**

- F60.9 Personality disorder, unspecified
F60.0 Paranoid personality disorder
F60.1 Schizoid personality disorder

CLINICAL PEARLS

- PDs are enduring patterns of behavior throughout one’s lifetime and are not readily responsive to brief treatments.
- In spite of the initial lack of self-awareness and accepting responsibility for one’s dysfunctional behaviors, many patients can benefit from long-term treatment.
- No specific drugs are effective to treat PDs; however, specific medications can reduce the intensity, frequency, and dysfunctional nature of certain behaviors, thoughts, and feelings.
- Patients with a PD frequently elicit intense feelings in others, such as anger, hostility, likability, or sexual attraction.
- Health care professionals must be alert to potential blurring of interpersonal boundaries in the clinical care of these patients.
- Most patients with a PD require a well-trained and experienced mental health professional.
- A stable, trustful alliance with the patient is the foundation for any therapeutic progress.
- Many PD patients begin treatment in a crisis involving symptoms of anxiety, fear of abandonment, depressed mood, and intense interpersonal conflict at home or work. The focus at this initial phase of treatment should be symptom control and behavioral stabilization with restoration of hope.
- Lifelong patterns of dysfunctional behaviors should not be confronted at the initial phase of treatment.
- Therapeutic confrontation of dysfunctional behavioral patterns is effective only after a working and therapeutic alliance has been established.
- Treatment in an atmosphere of compassion, optimism, and hope for improvement are valuable principles.
- Showing genuine interest in the patient as a whole person including the patient’s life history and current life circumstances may be helpful in establishing a therapeutic and working alliance that is necessary for continuing treatment of PD patients.
- Regular meetings with a spouse, another family member, or significant other are essential for receiving feedback on therapeutic progress.
PERTUSSIS

Mary Cataletto, MD, FAAP, FCCP • Margaret J. McCormick, MS, RN, CNE

BASICS

- Highly contagious
- Synonym: Whooping cough

DESCRIPTION

- Host: humans
- Most common reservoir: adults
- Ages: all
- Distribution: worldwide
- Pattern: endemic or epidemic with outbreaks every 3 to 5 years
- Seasonality: can occur year-round; peaks late summer–autumn
- Transmission: person to person via aerosolized respiratory droplets
- Effective vaccine: available
- Immunity: neither 100% nor lifelong immunity with either infection or vaccine
- System(s) affected: respiratory

EPIDEMIOLOGY

Incidence

- United States: most recent peak in 2012 reported 48,277 (1)
- Worldwide: estimated 16 million cases/year (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Toxin mediated
- Infectious process with predilection for ciliated respiratory epithelium
- Common organisms:
  - Bordetella pertussis (accounts for ~95% of cases)
  - Bordetella parapertussis

RISK FACTORS

- Exposure to a confirmed case
- Non- or underimmunized infants and children
- Premature birth
- Chronic lung disease
- Immunodeficiency (e.g., AIDS)
- Age <6 months (accounts for ~90% pediatric pertussis hospitalizations) (2)

**GENERAL PREVENTION**
- Public health measures
  - Surveillance
  - Outbreak management
  - Care of exposed persons
- Prevention programs
- Immunization
  - Primary childhood immunization series against pertussis followed by boosters (3)
  - Maternal immunization during each pregnancy (4–6)
  - Adults, including health care providers in close contact with infants <1 year of age should be immunized.

**Pediatric Considerations**
Strategies to reduce neonatal pertussis:
- Tdap with each pregnancy, preferably between 27 and 36 weeks gestation (4–6)
- Cocooning (6)
- Tdap recommended for all persons in close contact with infants <1 year of age

**Geriatric Considerations**
The incidence of pertussis in individuals age 50 years and older has increased between 2006 and 2010.

**COMMONLY ASSOCIATED CONDITIONS**
- Apnea in infants
- Secondary bacterial pneumonia
- Sinusitis
- Seizures
- Encephalopathy
- Urinary incontinence
DIAGNOSIS

HISTORY
- Exposure to pertussis
- Incubation period 7 to 10 days (range 5 to 21 days)

PHYSICAL EXAM
- Classic pertussis has three phases, which occur over 6 to 10 weeks:
  - Catarrhal phase: rhinorrhea, mild cough, low-grade fever
  - Paroxysmal phase: Cough occurs in bursts, with increased intensity and frequency, often followed by an inspiratory whoop and/or posttussive vomiting.
  - Convalescent phase: Coughing paroxysms decrease in frequency and intensity.
- In the absence of paroxysms or complications, the physical exam may be normal.
- Classic presentation more common in adults

ALERT
Infants <6 months of age may have atypical presentations.

DIFFERENTIAL DIAGNOSIS
- B. parapertussis
- Mycoplasma pneumoniae
- Chlamydia trachomatis
- Chlamydophila pneumoniae
- Bordetella bronchiseptica
- Respiratory syncytial virus
- Adenovirus

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Nasopharyngeal culture (gold standard): best results within 2 weeks of cough onset
- Polymerase chain reaction (PCR) assays: rapid turnaround time; good sensitivity but variable specificity. Interpret in clinical context and local epidemiology.
Serology:
- Commercially available assays
- Not FDA-approved for diagnosis

**Follow-Up Tests & Special Considerations**
- Evaluation and follow-up for associated conditions and complications
- Chest radiograph (two views) to evaluate for the presence of pneumonia
- EEG/neuroimaging may be considered in infant with seizures or apparent life-threatening events (ALTEs).
- Infants <1 month of age who are treated with macrolides should be monitored for the possible development of hypertrophic pyloric stenosis.

**TREATMENT**

**GENERAL MEASURES**
Waiting rooms, during transport and procedures: Patients with suspected pertussis should wear masks.

**MEDICATION**
- Start empiric antibiotic therapy once diagnostic testing is performed in cases with clinical suspicion.
- Antibiotic therapy after cough is established may help to limit spread but is not expected to change clinical symptoms.
- Preferred antibiotics:
  - For patients >6 months: Azithromycin, clarithromycin, or erythromycin
  - For infants <1 month of age azithromycin preferred but with caution

**First Line**
Azithromycin is the first line for treatment and for postexposure prophylaxis (5-day course).

**ALERT**
Infantile hypertrophic pyloric stenosis has been associated with the use of macrolides in infants <1 month of age. Consultation and monitoring are recommended.
**ALERT**

*Fatal cardiac dysrhythmias* have been reported with azithromycin.

**Second Line**

Trimethoprim/sulfamethoxazole (TMP/SMX) (for persons >2 months of age) if:
- Macrolide intolerance
- Macrolide resistance

**ALERT**

- TMP/SMX is *contraindicated* in infants <2 months of age.
- Clarithromycin is not recommended in infants <1 month of age.

**ISSUES FOR REFERRAL**

Evaluation and treatment of infants <6 months of age, especially those born prematurely, who are unimmunized and those who require hospitalization.

**ADDITIONAL THERAPIES**

Symptomatic treatment of the cough in pertussis (e.g., corticosteroids, \(\beta_2\)-adrenergic agonists, pertussis-specific immunoglobulin, antihistamine, and leukotriene receptor antagonist) has not shown consistent benefit.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Small, frequent meals may be necessary to ensure adequate nutrition.
- IV fluids indicated for dehydration and when oral fluids are either contraindicated or poorly tolerated.
- In addition to standard precautions, hospitalized patients should be isolated with respiratory precautions for 5 days after the initiation of effective antibiotic treatment and for 3 weeks after onset of paroxysms in older patients if antibiotics are not used.
- Gentle suctioning of nasal secretions
- Avoid stimuli that trigger paroxysms.
- Respiratory monitoring including pulse oximetry
- Educate each family about the importance of immunizations.
- Discuss chemoprophylaxis with each family.
- Discharge criteria
  - Clinically stable
– Able to tolerate oral feedings

ONGOING CARE
Supportive

FOLLOW-UP RECOMMENDATIONS
● Monitor infants who received EES or azithromycin for pyloric stenosis.
● Neurologic and/or pulmonary follow-up as necessary

Patient Monitoring
ICU care may be necessary for severely ill or compromised patients.

DIET
IV fluids/nutrition may be required to treat dehydration or supplement poor oral intake.

PATIENT EDUCATION
● American Academy of Pediatrics: http://www.aap.org
● Centers for Disease Control and Prevention: http://www.cdc.gov

PROGNOSIS
● Complete recovery in most cases
● Most severe morbidity and highest mortality in infants <6 months of age
● Overall mortality approximately 195,000/year (1)

COMPLICATIONS
● Highest and most severe in infants; may include apnea, cyanosis, and sudden death
● In children: may include conjunctival hemorrhage, inguinal hernia, pneumonia, and seizures
● More frequent in adults than adolescents: may include sinusitis, otitis media, pneumonia, weight loss, fainting, rib fracture, urinary incontinence, seizures, encephalopathy, and death

REFERENCES

**ADDITIONAL READING**

ICD10
- A37.90 Whooping cough, unspecified species without pneumonia
- A37.80 Whooping cough due to other Bordetella species w/o pneumonia
- A37.10 Whooping cough due to Bordetella parapertussis w/o pneumonia

CLINICAL PEARLS
- Hospitalizations for pertussis is highest in infants <6 months of age.
  - Maternal Tdap is effective in protecting young infants against pertussis, especially during first 2 months of life.
- Neither immunization nor active infection confers lifelong immunity.
PHARYNGITIS

Cristian Fernandez Falcon, MD, DABFM, CAQGM, CAQHPM, CMD • Maria F. Arbelaez, MD

BASICS

DESCRIPTION
- Acute or chronic inflammation of the pharyngeal mucosa and underlying structures of the throat
- Group A Streptococcus (GAS) pharyngitis is notable for preventable suppurative (e.g., retropharyngeal or peritonsillar abscess) and nonsuppurative (e.g., rheumatic sequelae) complications.
- Synonym(s): sore throat; tonsillitis; “strep throat”

EPIDEMIOLOGY
- ~15 million cases are diagnosed yearly.
- Accounts for 1–2% of all outpatient visits and 6% of all pediatric visits to primary care physicians
- Most commonly viral (40–60%)
- GAS is the most common bacterial cause of acute pharyngitis, accounting for 15–30% of pediatric and 5–15% of adult cases. The incubation period ranges from 24 to 72 hours.
- Rheumatic fever is rare in the United States (<1 per 100,000). Early antibiotic use has diminished occurrence.
- 3,000 to 4,000 patients with group A β-hemolytic streptococcal infection must be treated to prevent one case of acute rheumatic fever.
- All age groups, some etiologies more common with certain age groups

Pediatric Considerations
The highest incidence of rheumatic fever is in children 5 to 18 years as a rare sequela of streptococcal pharyngitis.

ETIOLOGY AND PATHOPHYSIOLOGY
- Acute, viral (lower grade fever)
  - Rhinovirus
  - Adenovirus (associated with conjunctivitis)
– Parainfluenza virus
– Coxsackievirus (hand-foot-mouth disease)
– Coronavirus
– Echovirus
– Herpes simplex virus (vesicular lesions)
– Epstein-Barr virus (EBV/mononucleosis)
– Cytomegalovirus (CMV)
– HIV

• Acute, bacterial (higher fevers)
  – Group A β-hemolytic streptococcus
  – *Neisseria gonorrhoeae*
  – *Corynebacterium diphtheriae* (diphtheria)
  – *Haemophilus influenzae*
  – *Moraxella catarrhalis*
  – *Chlamydia pneumonia*
  – *Fusobacterium necrophorum* (20% young adult cases)
  – Group C or G streptococcus
  – *Arcanobacterium haemolyticum*
  – *Mycoplasma pneumoniae*
  – *Francisella tularensis* (tularemia)

• Acute, noninfectious
  – Various caustic, mechanical, or trauma-related (including endotracheal intubation)

• Chronic
  – More likely noninfectious
  – Chemical irritation (GERD)
  – Smoking
  – Neoplasms
  – Vasculitis
  – Radiation changes

**Genetics**
Patients with a family history of rheumatic fever have a higher risk of rheumatic sequelae following an untreated group A β-hemolytic streptococcal infection.

**RISK FACTORS**
• Epidemics of group A β-hemolytic streptococcal disease
• Cold and flu season (late fall through early spring)
• Age (especially children/adolescents 5 to 15 years)
Family history of rheumatic fever
- Close contact with infected individuals (home, daycare, military barracks)
- Immunosuppression
- Smoking/secondhand smoke exposure
- Acid reflux
- Oral sex
- Diabetes mellitus
- Recent illness (secondary postviral bacterial infection)
- Chronic colonization of bacteria in tonsils/adenoids

**GENERAL PREVENTION**
- Avoid close contact with infectious patients.
- Wash hands frequently.
- Avoid first or secondhand smoke.
- Manage preventable causes (e.g., GERD).

**DIAGNOSIS**

**HISTORY**
- Sore throat
- Difficulty swallowing (dysphagia) or pain on swallowing (odynophagia)
- Cough (uncommon in GAS pharyngitis)
- Hoarseness; “hot potato” voice
- Fever
- Anorexia
- Chills
- Malaise; fatigue
- Headache
- Dysuria and arthralgias (suggest gonococcal etiology)
- Sick contacts with similar symptoms or confirmed diagnosis

**PHYSICAL EXAM**
- Enlarged tonsils with or without exudate
- Pharyngeal erythema
- Unilateral tonsillar swelling (“frog’s belly”) or uvular deviation (concern for peritonsillar abscess)
- Trismus; stridor; drooling (concern for peritonsillar or retropharyngeal
abscess)
- Cervical adenopathy (anterior suggestive of GAS, posterior most commonly associated with infectious mononucleosis)
- Fever (higher in bacterial infections)
- Pharyngeal ulcers (CMV, HIV, Crohn, other autoimmune vasculitides)
- Scarlet fever rash: Punctate erythematous macules with reddened flexor creases and circumoral pallor suggests streptococcal pharyngitis.
- Tonsillar/soft palate petechiae and hepatosplenomegaly suggest infectious mononucleosis (EBV/CMV).
- Gray oral pseudomembrane suggests diphtheria and occasionally infectious mononucleosis (EBV/CMV).
- Characteristic erythematous-based clear vesicles suggest HSV or coxsackie A virus infection (herpangina).
- Conjunctivitis suggests adenovirus.

**DIFFERENTIAL DIAGNOSIS**

- Viral syndrome
- Streptococcal infection
- Allergic rhinitis/postnasal drip
- GERD
- Malignancy (lymphoma or squamous cell carcinoma)
- Irritants/chemicals (detergent/caustic ingestion)
- Atypical bacterial (e.g., gonococcal, chlamydial, syphilis, pertussis, diphtheria)
- Oral candidiasis (patients typically complain mostly of dysphagia)
- Epiglottitis (associated with stridor, drooling, and progressive respiratory distress)

**DIAGNOSTIC TESTS & INTERPRETATION**

- Prediction rules determine further testing (see below).

  Additional testing generally not needed if viral-like clinical features (e.g., cough, rhinorrhea, hoarseness, oral ulcers, diarrhea, conjunctivitis, rash) (1)
  
  Avoid testing for GAS pharyngitis in children <3 years as acute rheumatic flare is rare, unless there is a close sick contact who is GAS-positive (1)[B].
  
  Modified Centor clinical prediction rule for group A streptococcal infection (2)[A]:
  
  - +1 point: tonsillar exudates
– +1 point: tender anterior chain cervical adenopathy
– +1 point: absence of cough
– +1 point: fever by history
– +1 point: age <15 years
– 0 point: age 15 to 45 years
– −1 point: age >45 years

Scoring:
– If 4 points, positive predictive value of ~80%; treat empirically.
– If 2 to 3 points, positive predictive value of ~50%, rapid strep antigen; treat if GAS-positive.
– If 0 or 1 point, positive predictive value <20%; do not test; treat empirically with follow-up as needed.

Initial Tests (lab, imaging)

Testing, if performed, is usually for GAS. Options include:
– Rapid antigen streptococcus test (RAST); quick adjunct to throat culture with 96% specificity and 86% sensitivity (although sensitivity varies by modality kit) (3)[A]
– Blood agar throat culture from swab; gold standard—90–95% sensitivity (3)[A]
  – Back up throat cultures are not needed for adults with negative RAST. They are recommended for children with negative RAST due to the higher likelihood of complications but can be omitted if a highly sensitive immunoassay or molecular test was used.
– Antistreptolysin O (suspect carrier state if positive culture, and unchanged ASO titers)

Special tests if history suggests a different diagnosis
– Warm Thayer-Martin plate or antigen testing for N. gonorrhoeae
– Viral cultures for HSV
– Monospot for EBV
– IgM serology for CMV

Test Interpretation
Bacitracin disk sensitivity of hemolytic colonies suggests group A β-hemolytic streptococcus.

TREATMENT
GENERAL MEASURES
Conservative therapy recommended for most cases (unless bacterial etiology suspected):

- Salt water gargles
- Viscous lidocaine (2%) 5 to 10 mL PO q4h swish/spit
- Acetaminophen 10 to 15 mg/kg/dose q4h PRN pain or fever (pediatric). In adults, do not exceed >3 g/day.
- NSAIDs for pain or fever (more effective than acetaminophen for GAS pharyngitis)
- Anesthetic lozenges
- Cool-mist humidifier
- Hydration (PO or IV)

Pediatric Considerations
Opioids not recommended due to black box warnings

MEDICATION
- Antibiotics (particularly penicillin) are chosen primarily to prevent complications.
  - 60–70% primary care visits by children with pharyngitis result in antibiotic prescriptions (4). Empiric therapy results in antibiotic overuse.
  - Treatment duration generally 10 days (1)[A]
  - Antibiotics do not reduce risk of poststreptococcal glomerulonephritis.
  - Antibiotics shorten duration of symptoms by approximately 16 hours (5).
  - Antibiotics may prevent pharyngitis/fever by day 3 (NNT 4 if GAS-positive, 6.5 if GAS-negative, 14.4 if untested) (5)[A].

- Ulcers related to autoimmune diseases usually require systemic or intralesional injectable steroids.
- HIV-related ulcers are due to decreasing counts of CD4 and respond when patients’ CD4 titers increase.
- Corticosteroids, when used concomitantly with antibiotics, may provide a small reduction in the duration of symptoms (24 hours). Routine use is not currently recommended (1,3)[B].

First Line
Recommended first-line therapies (1)[A]:

- Penicillin V: children (<27 kg): 250 mg PO TID (BID dosing sufficient if
good compliance); adolescents and adults (>27 kg): 250 mg PO QID or 500 mg PO BID

- Penicillin G benzathine: children <60 lb (27 kg): 600,000 units intramuscularly 1 dose; children ≥60 lb and adults: 1.2 million units intramuscularly 1 dose
- Amoxicillin: 50 mg/kg PO once daily (max 1,000 mg/dose or 25 mg/kg PO BID (max = 500 mg/dose)

**ALERT**
Use with caution if diagnosis is unclear because using amoxicillin with EBV infection may induce rash.

**Second Line**
- If type IV hypersensitivity but no history of anaphylactic penicillin allergy:
  - Cephalexin 20 mg/kg PO BID or (children) 25 to 50 mg/kg/day divided BID or (adults) 1,000 mg PO QID (max = 4 g/day)
  - Cefadroxil 30 mg/kg PO once daily (max = 1 g/day)
- If history of anaphylactic penicillin allergy (type I hypersensitivity):
  - Azithromycin 12 mg/kg PO once daily for 5 days (max = 500 mg/dose)
  - Clarithromycin 7.5 mg/kg PO BID (max = 250 mg/dose) or (adults) 250 to 500 mg PO BID
  - Clindamycin 7 mg/kg PO TID (max = 300 mg/dose) or (children) 10 to 30 mg/kg/day PO divided TID–QID or (adults) 150 to 450 mg PO TID–QID
- Penicillin is the most documented treatment to prevent rheumatic sequelae, but cephalosporins have a lower rate of antimicrobial failure against streptococcal pharyngitis.
- Newer macrolides, although effective against streptococcal pharyngitis, are more expensive and unproven at preventing rheumatic complications.
- Macrolide-resistant strains of GAS are currently <10% in the United States but more prevalent worldwide.

**ISSUES FOR REFERRAL**
- Document each GAS-confirmed episode to support the need for future tonsillectomy and adenoidectomy.
- Tonsillectomy is recommended for patients who have had seven or more throat infections (viral or bacterial) in 1 year, five or more infections per year for the past 2 years, or three or more infections per year for the past 3 years. Tonsillectomy is also recommended in patients who are difficult to treat medically, including those who are allergic to multiple antibiotics.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Patient should complete the full course of antibiotic therapy, regardless of symptom response.
- Patients are generally noninfectious after 24 hours of antibiotics.
- Follow-up culture for GAS is not recommended (1)[A].

DIET
As tolerated. Encourage the consumption of fluids.

PROGNOSIS
- Streptococcal pharyngitis runs a 5- to 7-day course with peak fever at 2 to 3 days.
- Symptoms will resolve spontaneously without treatment, but rheumatic complications are still possible.

COMPLICATIONS
- Rheumatic fever (e.g., carditis, valve disease, arthritis)
- Poststreptococcal glomerulonephritis
- Peritonsillar abscess (a.k.a. quinsy tonsillitis): considered a clinical diagnosis and does not warrant ultrasound/computed tomography. Will generally require percutaneous/transoral drainage. Surgery may also involve a quinsy (acute) tonsillectomy. Most sources recommend resolution of the acute infection before surgery.
- Acute airway compromise (rare) can typically be bypassed with nasal trumpets. Consult anesthesiologist/otolaryngologist.
- Repeated episodes of GAS pharyngitis may represent recurrent viral infections in a chronic pharyngeal GAS carrier (1)[B]. IDSA recommends against repeated diagnostic efforts/antibiotic therapy in a known chronic pharyngeal GAS carrier, as they are seldom contagious or at risk for serious complications.

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

- Herpes Simplex; Infectious Mononucleosis, Epstein-Barr Virus Infections; Rheumatic Fever
- Algorithm: Pharyngitis

**CODES**

**ICD10**

- J02.9 Acute pharyngitis, unspecified
- J02.0 Streptococcal pharyngitis
- J31.2 Chronic pharyngitis
CLINICAL PEARLS

- Most cases of pharyngitis are viral and do not require antibiotics.
- The risk associated with undiagnosed and untreated group A streptococcal infection is for rheumatic sequelae—a rare complication.
- Use of the Modified Centor Score helps to guide testing and treatment.
- Penicillin is the preferred first-line therapy for group A streptococcal infection.
PILONIDAL DISEASE
Tam T. Nguyen, MD

BASICS

DESCRIPTION
- Pilonidal disease results from an abscess, or sinus tract, in the upper part of the natal (gluteal) cleft.
- Synonym(s): jeep disease

EPIDEMIOLOGY

Incidence
- 16 to 26/100,000 per year
- Predominant sex: male > female (3 to 4:1)
- Predominant age: 2nd to 3rd decade, rare >45 years
- Ethnic consideration: whites > blacks > Asians

Prevalence
Surgical procedures show male:female ratio of 4:1, yet incidence data are 10:1.

ETIOLOGY AND PATHOPHYSIOLOGY
Pilonidal means “nest of hair”; hair in the natal cleft allows hair to be drawn into the deeper tissues via negative pressure caused by movement of the buttocks (50%); follicular occlusion from stretching, and blocking of pores with debris (50%)
- Inflammation of SC gluteal tissues with secondary infection and sinus tract formation
- Polymicrobial, likely from enteric pathogens given proximity to anorectal contamination

Genetics
- Congenital dimple in the natal cleft/spina bifida occulta
- Follicular-occluding tetrad: acne conglobata, dissecting cellulitis, hidradenitis suppurativa, pilonidal
RISK FACTORS
- Sedentary/prolonged sitting
- Excessive body hair
- Obesity/increased sacrocccygeal fold thickness
- Congenital natal dimple
- Trauma to coccyx

GENERAL PREVENTION
- Weight loss
- Trim hair in/around gluteal cleft weekly.
- Hygiene
- Ingrown hair prevention/follicle unblocking

DIAGNOSIS

HISTORY
Three distinct clinical presentations
- Asymptomatic: painless cyst or sinus at the top of the gluteal cleft
- Acute abscess: severe pain, swelling, discharge from the top of the gluteal cleft that may or may not have drained spontaneously
- Chronic abscess: persistent drainage from a sinus tract at the top of the gluteal cleft

PHYSICAL EXAM
- Common: inflamed cystic mass at the top of the gluteal cleft with limited surrounding erythema ± drainage or a sinus tract
- Less common: significant cellulitis of the surrounding tissues near the gluteal cleft

DIFFERENTIAL DIAGNOSIS
- Furunculosis
- Hidradenitis suppurativa
- Anal fistula
- Perirectal abscess
- Crohn disease

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Consider CBC and wound culture but generally not necessary for less severe infections.
- MRI might be considered to differentiate between perirectal abscess and pilonidal disease.

TREATMENT

GENERAL MEASURES
Shave area; remove hair from crypts weekly.

MEDICATION
- Antibiotics not indicated unless there is significant cellulitis (1)
- If antibiotics are needed, a culture to direct therapy might be useful.
- Cefazolin plus metronidazole or amoxicillin-clavulanate are often used empirically if cellulitis is suspected.

ISSUES FOR REFERRAL
- Patients who cannot comply with frequent dressing changes required after incision and drainage (I&D)
- Patients who have recurrence after I&D
- Patients who have complex disease with multiple sinus tracts

ADDITIONAL THERAPIES
- I&D with only enough packing to allow the cyst to drain; overpacking not indicated
- Antibiotics only if significant cellulitis; temporizing, not curative
- Negative pressure wound therapy
- Laser epilation of hair in the gluteal fold (2)[B]
- Phenol treatment can be used especially for recurring disease.

SURGERY/OTHER PROCEDURES
Six levels of care based on severity or recurrence of disease; recent innovations in technique are aimed at expediting healing and minimizing recurrence.
- I&D, remove hair, curette granulation tissue (3)[A]
- Excision of midline “pits” allows drainage of lateral sinus tracts (pit picking).
- Pilonidal cystotomy: Insert probe into sinus tract, excise overlying skin, and close wound (4) [B].
- Marsupialization: Excise overlying skin and roof of cyst, and suture skin edges to cyst floor (3, 5) [B].
- Excision: use of flap closure; no clear benefit for open healing over surgical closure
- Off-midline surgical excision (cleft lift or modified Karydakis procedure): A systematic review showed a clear benefit in favor of off-midline rather than midline wound closure. When closure of pilonidal sinuses is the desired surgical option, off-midline closure should be the standard management (3) [A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Severe cellulitis
- Large area excision

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Frequent dressing changes required after I&D
- Follow up wound checks to assess for recurrence.

**Patient Monitoring**
Monitor for fever; more extensive cellulitis

PATIENT EDUCATION
- Wash area briskly with washcloth daily.
- Shave the area weekly.
- Remove any embedded hair from the crypt.
- Avoid prolonged sitting.

PROGNOSIS
- Simple I&D has a 55% failure rate; median time to healing is 5 weeks.
- More extensive surgical excisions involve hospital stays and longer time to heal.
COMPLICATIONS
Malignant degeneration is a rare complication of untreated chronic pilonidal disease.

ADDITIONAL READING

CODES
mebooksfree.com
ICD10

- L05.91 Pilonidal cyst without abscess
- L05.92 Pilonidal sinus without abscess
- L05.01 Pilonidal cyst with abscess

**CLINICAL PEARLS**

- Avoid prolonged sitting.
- Lose weight.
- Trim hair in gluteal cleft weekly.
- Refer recurring infections for more definitive surgical management.
PINWORMS
Jonathan MacClements, MD, FAAFP

BASICS

DESCRIPTION
- Intestinal infection with Enterobius vermicularis
  - Characterized by perineal and perianal itching
  - Usually worse at night
- System(s) affected: gastrointestinal; skin/exocrine
- Synonym(s): enterobiasis

EPIDEMIOLOGY
Predominant age: 5 to 14 years

Prevalence
- Most common helminthic infection in the United States
  - 20 to 42 million people harbor the parasite.
- ~30% of children are infected worldwide.

Pediatric Considerations
More common in children, who are more likely to become reinfected

ETIOLOGY AND PATHOPHYSIOLOGY
- Small white worms (2 to 13 mm) inhabit the cecum, appendix, and adjacent portions of the ascending colon following ingestion.
- Female worms migrate to the perineal areas at night to deposit eggs; this causes local irritation and itching.
- Scratching leads to autoingestion of the eggs and continuation of pinworm’s life cycle within the host. Eggs incubate 1 to 2 months in the host small intestine. When mature, female pinworms migrate to the colon where they lay eggs around the anus at night, and the lifecycle continues.
- Infestation by the intestinal nematode E. vermicularis

RISK FACTORS
- Institutionalization
• Crowded living conditions
• Poor hygiene
• Warm climate
• Handling of infected children’s clothing or bedding

**GENERAL PREVENTION**
• Hand hygiene, especially after bowel movements
• Clip and maintain short fingernails.
• Wash anus and genitals at least once a day, preferably during shower.
• Avoid scratching anus and putting fingers near nose (pinworm eggs can also be inhaled) or mouth.

**COMMONLY ASSOCIATED CONDITIONS**
Pruritus ani

**DIAGNOSIS**

**HISTORY**
Many patients are asymptomatic. Common symptoms include the following:
• Perianal or perineal itching
• Vulvovaginitis
• Dysuria
• Abdominal pain (rare)
• Insomnia (typically due to pruritus)

**PHYSICAL EXAM**
Perineal and perianal exam; particularly in early morning to look for evidence of migrating worms

**DIFFERENTIAL DIAGNOSIS**
• Idiopathic pruritus ani (1)[A]
• Atopic dermatitis, contact dermatitis
• Psoriasis; lichen planus
• Human papillomavirus (HPV)
• Herpes simplex virus (HSV)
• Fungal infections; erythrasma
• Scabies
- Vaginitis; hemorrhoids

**DIAGNOSTIC TESTS & INTERPRETATION**
- Adhesive tape test
  - Place cellophane tape on the perianal skin in the early morning before bathing and affix to a microscope slide to look for pinworm eggs.
  - 90% sensitivity if performed on three consecutive mornings
  - Alternatively, use anal swabs or a pinworm paddle coated with adhesive material.
  - Scrapings from under fingernails of affected individuals can reveal pinworm eggs.
- Digital rectal exam with saline slide preparation of stool on gloved finger
- Stool samples are not helpful.
- *Routine stool examination for ova and parasites is positive in only 10–15% of infected patients.*

**Test Interpretation**
Identification of ova on low-power microscopy or direct visualization of the female worm (10-mm long); ova are asymmetric, flat on one side, and measure $56 \times 27 \mu m$.

**TREATMENT**

**MEDICATION**

**First Line**
- Treatment options include:
  - Albendazole (Albenza): 400 mg PO as a single dose in adults and children $>20$ kg; may repeat in 2 weeks; 200 mg PO as a single dose repeated in 2 weeks in children $\leq 20$ kg (2,3)[A]
  - Mebendazole (Emverm, Vermox): chewable 100-mg tablet as a single dose in adults and children $>2$ years of age; may repeat in 2 to 3 weeks; use with caution in children $<2$ years of age (2,3)[A].
  - Pyrantel pamoate (Pin-X, Reese Pinworm Medicine): oral liquid or tablet 11 mg/kg as a single dose in adults and children $>2$ years of age; maximum dose 1 g. Use with caution in children $<2$ years of age (2,3)[A].
- Repeat treatment after 2 weeks is often recommended due to the high frequency of reinfection. Refractory cases may (rarely) require retreatment.
every 2 weeks for 4 to 6 cycles.

- All symptomatic family members should be treated.

**Pregnancy Considerations**
Avoid drug therapy in pregnancy. Treat after delivery. Breastfeeding is OK during mebendazole therapy (2,3)[A].

---

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Unnecessary unless symptoms recur after initial therapy

**PATIENT EDUCATION**
- Take medicine with food.
- Practice good hygiene: hand washing and perianal hygiene; particularly after bowel movements
- Encourage frequent and careful hand washing.
- Clip fingernails.
- Wash clothing and bedding after diagnosis to prevent reinfection. Do not shake linen and clothing before laundering because this may spread the eggs.
- Do not share washcloths.
- Do not allow children to cobarth during treatment and for 2 weeks after treatment; showering is preferred.

**PROGNOSIS**
- Asymptomatic carriers are common.
- Drug therapy is 90% curative.
- Reinfection is common, especially among children.

**COMPLICATIONS**
- Perianal scratching may lead to bacterial superinfection.
- Females: vulvovaginitis, urethritis, endometritis, and salpingitis (3,4)[A]
- UTIs
- Rarely: ectopic disease with granulomas of the pelvis, genitourinary tract, and appendix; colonic intussusception (5)[A]

**REFERENCES**

mebooksfree.com

**SEE ALSO**

*Pruritus Ani*

**CODES**

**ICD10**

B80 Enterobiasis

**CLINICAL PEARLS**

- Nocturnal or early morning perianal itch with restless sleep or insomnia (particularly in children) is the hallmark of symptomatic pinworm infection.
- Treatment includes of mebendazole, albendazole, or pyrantel pamoate.
- Treat close contacts.
- Retreatment after 2 weeks is generally recommended.
PITUITARY ADENOMA

Anup K. Sabharwal, MD, MBA, FACE • Lewis S. Blevins Jr., MD

BASICS

DESCRIPTION

Typically benign, slow-growing tumors that arise from cells in the pituitary gland

- Pituitary adenomas have been identified as the third most frequent intracranial tumor; accounts for 10–25%
- Subtypes (hormonal): prolactinoma (PRL) 25–40%, nonfunctioning pituitary adenomas 30%, somatotroph adenoma (growth hormone [GH]) 15–20%, corticotroph adenoma (adrenocorticotropic hormone [ACTH]) 5–10%, thyrotroph adenoma (thyroid-stimulating hormone [TSH]) <1%, gonadotropinoma (luteinizing hormone/follicle-stimulating hormone [LH/FSH]), mixed (1)[A]
- Defined as microadenoma <10 mm and macroadenoma ≥10 mm
- May secrete hormones and/or cause mass effects

EPIDEMIOLOGY

- Predominant age: Age increases incidence.
- Predominant sex: female > male (3:2) for microadenomas (often delayed diagnosis in men)

Incidence

- Autopsy studies have found microadenomas in 3–27% and macroadenomas in <0.5% of people without any pituitary disorders.
- MRI scans illustrate abnormalities consistent with pituitary adenoma in 1/10 persons.
- Clinically apparent pituitary tumors are seen in 18/100,000 persons.

ETIOLOGY AND PATHOPHYSIOLOGY

- Monoclonal adenohypophysial cell growth
- Hormonal effects of functional microadenomas often prompt diagnosis before
mass effect.
- Prolactin increased by functional prolactinomas or inhibited dopaminergic suppression by stalk effect

**Genetics**
- Carney complex
- Familial isolated pituitary adenomas: ~15% have mutations in the aryl hydrocarbon receptor–interacting protein gene (AIP); present at a younger age and are larger in size (2)
- McCune-Albright syndrome
- Multiple endocrine neoplasia type 1 (MEN1)–like phenotype (MEN4): germline mutation in the cyclin-dependent kinase inhibitor 1B (CDKN1B) (2)

**RISK FACTORS**
Multiple endocrine neoplasias

**DIAGNOSIS**

**HISTORY**
- Common
  - Hyperprolactinemia: infertility, amenorrhea, galactorrhea, gynecomastia, impotence
  - Headache (sellar expansion)
  - Visual disturbances: bitemporal hemianopsia
- Less common
  - Hypersomatotropinemia: acromegaly (coarse facial features, hand/foot swelling, carpal tunnel syndrome, hyperhidrosis, left ventricular hypertrophy)
  - Hyposomatotropinemia: failure to thrive (FTT) (children), asymptomatic (adults)
  - Intracranial pressure (ICP) elevation: headache, nausea, seizures
  - Hypercorticotropinemia: Cushing disease (supraclavicular/dorsocervical fat pad thickening, moon face, hirsutism, acne, plethora, abdominal striae, centripetal obesity with thin limbs, easy bruising and bleeding, hyperglycemia)
- Rare
  - Apoplexy: headache, sudden collapse
– Secondary hyperthyroidism: palpitations, diaphoresis, heat intolerance, diarrhea
– Secondary adrenal insufficiency: weakness, irritability, anorexia, nausea/vomiting
– Hypothalamic compression: temperature, thirst/appetite disorders

**PHYSICAL EXAM**

- **Common**
  - Visual disturbances: bitemporal hemianopsia
  - Hyperprolactinemia: hypogonadism, galactorrhea, gynecomastia
  - Hypersomatotropinemia: acromegaly (coarse features, hand/foot swelling, diaphoresis)
  - Hyposomatotropinemia: FTT (children)
- **Less common**
  - ICP elevation: papilledema, dementia
  - Cushing disease: centripetal obesity, supraclavicular fat pad thickening, moon face, hirsutism, acne
- **Rare**
  - Apoplexy: hypotension, hypoglycemia, tachycardia, oliguria
  - Secondary hyperthyroidism: tachycardia, tachypnea, diaphoresis, warm/moist skin, tremor
  - Adrenal crisis: orthostatic hypotension
- Hypothalamic compression: temperature dysregulation, obesity, increased urination

**DIFFERENTIAL DIAGNOSIS**

Pituitary hyperplasia (e.g., pregnancy, primary hypothyroidism, menopause), Rathke cleft cyst, granulomatous disease (e.g., tuberculosis), lymphocytic hypophysitis, metastatic tumor, germinoma, craniopharyngioma

**DIAGNOSTIC TESTS & INTERPRETATION**

Select based on dysfunction(s) suspected

- Somatotrophic (GH secreting: 40 to 130/million)
  - Acromegaly/hypersomatotropinemia: serum IGF-1 elevated; oral glucose tolerance test with GH given at 0, 30, and 60 minutes (normally suppresses GH to <1 g/L)
  - Hyposomatotropinemia: low growth hormone–releasing hormone response
- Corticotropic
- Cushing disease/hypercorticotropinemia
- 24-hour urinary-free cortisol >50 μg
- Overnight low-dose dexamethasone suppression test (DMST): normal free plasma cortisol (FPC) >1.8 μg/dL at 8 AM (after 1 mg given at 11 PM on night prior)
- ACTH level assay (if DMST results abnormal): <20 pg/mL = adrenal tumor; ≥20 pg/mL = ectopic/pituitary source
- Hypocorticotropinemia/secondary glucocorticoid deficiency: high-dose corticotropin stimulation test: FPC <10 g/dL at baseline, with an increase of <25% 1 hour after 250 μg; metyrapone test: 11-deoxycortisol <150 ng/L after 2 g given (Prepare to give steroids because test may worsen insufficiency.)
- Gonadotrophic/hypogonadotropinism: gonadotropin-releasing hormone stimulation of LH/FSH blunted in pituitary hypergonadism but increased in primary hypogonadism
- Lactotrophic (prolactin secreting): hyperprolactinemia: serum PRL >20 ng/mL
- Thyrotrophic (TSH secreting): hyper-/hypothyroidism: TSH and free T₄ both increased for pituitary hyperthyroidism and both decreased for pituitary hypothyroidism

Initial Tests (lab, imaging)
- A typical panel for asymptomatic tumors: prolactin, GH, IGF-1, ACTH, 24-hour urinary-free cortisol or overnight DMST, β-HCG, FSH, LH, TSH, free T₄
- Maintain the same GH and IGF-1 through patient management (3)[C].
- Screening for AIP mutations may be offered to families of patients with pituitary adenoma, where available.
- MRI preferred (>90% sensitivity and specificity) after biochemically confirmed
- Octreotide scintigraphy is useful in identifying tumors with somatostatin receptors (3)[B].

Diagnostic Procedures/Other
Inferior petrosal sinus sampling: ACTH sampled from inferior petrosal sinuses to distinguish Cushing disease (pituitary source) from ectopic ACTH

Test Interpretation
- Cell types identified by immunohistochemistry
• Light microscope: eosinophilic (GH, PRL), basophilic (FSH/LH, TSH, ACTH), chromophobic

TREATMENT
Medical therapy is primary therapy for prolactinomas and adjunct for other tumors.

MEDICATION

First Line
• Hyperprolactinemia: Dopamine agonists increase dopaminergic suppression of PRL.
  – Cabergoline (Dostinex): D₂ receptor–specific
    o Initial dose: 0.25 mg PO once or twice weekly
    o Maintenance dose: Increase q4wk by 0.25 mg 2 times per week per PRL (max 2 mg/week).
    o Contraindications: hypersensitivity (ergots), uncontrolled hypertension (HTN), pregnancy
    o Precautions: caution with liver impairment
    o Interactions: may be inhibited by tricyclic antidepressants, phenothiazines, opiates
    o Adverse reactions: orthostatic hypotension, vertigo, dyspepsia, hot flashes
  – Bromocriptine (Parlodel): D₂ receptor–specific
    o Initial dose: 1.25 to 2.50 mg PO daily (give with food)
    o Maintenance dose: increase by 2.5 mg/day q2–7d (max 15 mg/day)
    o Contraindications: hypersensitivity (ergots), uncontrolled HTN, pregnancy; preferred over cabergoline if required
    o Precautions: caution with liver impairment
    o Interactions: may be inhibited by tricyclic antidepressants, phenothiazines, opiates
    o Adverse reactions: orthostatic hypotension, seizures, hallucinations, stroke, myocardial infarction

• Somatotropinoma
  – Long-acting analogues of somatostatin (Sandostatin LAR and lanreotide Autogel)
    o Sandostatin LAR: 20 mg q28d (3)[A]; lanreotide Autogel 90 mg q28d; titrate per package insert.
Contraindication: hypersensitivity
Precautions: caution with biliary, thyroid, cardiac, liver, or kidney disease
Interactions: pimozide increases risk of QT prolongation; variable effects with β-blockers, diuretics, oral glycemic agents
Adverse reactions: ascending cholangitis, arrhythmias, congestive heart failure, glycemic instability
More effective as adjuvant than as primary treatment for somatotropinomas
Consider use of somatostatin analogue or pegvisomant in patients with severe residual disease (3)[A].
Consider use of cabergoline in patients with mild residual disease (4)[B].

- Pegvisomant (Somavert): GH receptor antagonist
  Initial dose: 40 mg SC × 1, then 10 mg daily and titrate by 5 mg every 4 to 6 weeks based on IGF-1 levels (max 30 mg/day maintenance dose)
  Contraindication: hypersensitivity
  Precautions: caution if GH-secreting tumors, diabetes mellitus, impaired liver function
  Interactions: NSAIDs, opiates, insulins, oral glycemic agents
  Adverse reactions: hepatitis, tumor growth, GH secretion

Corticotropinemia: peripheral inhibitors
- Mitotane (Lysodren)
  Initial dose: 2 to 6 g/day divided PO TID (max 19 g/day)
  Maintenance dose: 2 to 16 g TID
  Contraindication: hypersensitivity
  Precautions: caution with liver dysfunction and brain damage
  Interactions: contraindicated with rotavirus vaccine; caution with other vaccines
  Adverse reactions: HTN, orthostatic hypotension, hemorrhagic cystitis, rash
- Ketoconazole
  Dosing: 200 mg PO TID (max 1,200 mg/day)
  Contraindications: hypersensitivity, achlorhydria, fungal meningitis, impaired liver function
  Precautions: caution with liver dysfunction
  Interactions: contraindicated with dronedarone, methadone, statins, pimozide, sirolimus; caution with other antifungals
  Adverse reactions: adrenal insufficiency, thrombocytopenia, hepatic failure, hepatotoxicity, anaphylaxis, leukopenia, hemolytic anemia
- Signifor (pasireotide)
- Dosing: initially, 0.6 to 0.9 mg twice daily and then 0.3 to 0.9 mg twice daily
- Contraindication: none
- Precautions: hypocortisolism, hyperglycemia, bradycardia or QT prolongation, liver test elevations, cholelithiasis, and other pituitary hormone deficiencies
  - Korlym (mifepristone):
    - Dosing: Administer PO once daily with a meal. The recommended starting dose is 300 mg once daily; not to exceed 600 mg daily in renal impairment
    - Contraindication: pregnancy, use of simvastatin or lovastatin and CYP3A substrates with narrow therapeutic range, concurrent long-term corticosteroid use, women with history of unexplained vaginal bleeding, women with endometrial hyperplasia with atypia or endometrial carcinoma
    - Precautions: adrenal insufficiency, hypokalemia, vaginal bleeding and endometrial changes, QT interval prolongation, use of strong CYP3A inhibitors
    - Interactions: potential interactions with drugs metabolized by CYP3A, CYP2C8/9, CYP2B6, and hormonal contraceptives. Nursing mothers should discontinue drug or discontinue nursing.
    - Adverse reactions: most common adverse reactions in Cushing syndrome (≥20%): nausea, fatigue, headache, decreased blood potassium, arthralgia, vomiting, peripheral edema, HTN, dizziness, decreased appetite, endometrial hypertrophy
- Gonadotropinemia
  - Bromocriptine: See earlier discussion.
- Thyrotropinemia
  - Somatostatin analogues: See earlier discussion.

**Second Line**
- Corticotropinemia: peripheral inhibitors
  - Metyrapone
    - Dose: 250 mg PO QID
    - Contraindication: porphyria
    - Precautions: caution in liver/thyroid disease
    - Interactions: Dilantin increases metabolism.
    - Adverse reactions: nausea, hypotension
- Gonadotropinemia
  - Octreotide: See earlier discussion.
ISSUES FOR REFERRAL
- Neurosurgery consultation for symptomatic tumors (except for prolactinoma)
- Ophthalmologist evaluation prior to surgery

ADDITIONAL THERAPIES
- Fractionated radiotherapy: often effective as adjunctive when surgery is inadequate (4)[B]
- Stereotactic radiosurgery: alternative to surgery in high-risk patients or as adjunct (4)[B]

SURGERY/OTHER PROCEDURES
- Most are now done endoscopically via translabial/transsphenoidal approach (5)[A].
- Indications: symptoms or treatment-resistant
- Follow-up: serial neurologic/hormonal evaluations to evaluate complications (e.g., diabetes insipidus, CNS damage) and need for more treatment
- Remission rates: 72–87% for microadenoma but only 50–56% for macroadenomas

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Outpatient management unless apoplexy or adrenal crisis
- Treat pituitary apoplexy immediately to prevent death (see “Complications”) (5)[A].
- Consider stress-dose steroids in frail or hemodynamically unstable patients.
- Maintain BP with fluids and/or pressor agents.
- Check serum sodium, serum osmolality, and urine specific gravity if polyuric or electrolytes are imbalanced.
- Contact neurosurgery.
- Diabetes insipidus: hyperosmolar IV fluids
- Adrenal crisis: normal saline
- Pituitary apoplexy: Monitor inputs/outputs (I/Os), central venous pressure, and ICP, and do frequent neurologic checks.
- Adrenal crisis: Monitor BP and I/Os.
- Keep as inpatient postoperatively until diabetes insipidus and/or adrenal insufficiency is managed.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Follow-up MRIs at 6 and 12 months after discharge
- Involved hormone(s) are followed postoperatively, especially after radiation because hypopituitarism may develop 10 to 15 years after treatment.

PROGNOSIS
 Depends on type, size, symptoms, therapy

COMPLICATIONS
- Postoperative diabetes insipidus and/or hypogonadism (usually transient/common)
- Pituitary apoplexy (acute/uncommon): acute hemorrhagic pituitary infarction; adrenal crisis with severe headache; surgical decompression required to prevent shock, coma, and death
- Nelson syndrome (subacute/uncommon): rapid adenoma growth postadrenalectomy
- Pituitary hormone insufficiency (chronic/uncommon): often years after treatment
- Optic nerve neuropathy and brain necrosis after >60 Gy radiotherapy (chronic/rare)

REFERENCES
SEE ALSO
Cushing Disease and Cushing Syndrome; Galactorrhea

CODES

ICD10
D35.2 Benign neoplasm of pituitary gland

CLINICAL PEARLS

- An incidentaloma is an asymptomatic microadenoma found on imaging. General labs include PRL, GH, IGF-1, ACTH, 24-hour urinary-free cortisol/overnight DMST, β-subunit FSH, LH, TSH, and free T₄. Obtain follow-up MRIs at 6 and 12 months if normal, but consult endocrinology if not.
- Initial treatment selected for symptomatic pituitary adenoma includes a dopamine agonist for prolactinomas and surgical resection for all others.
- Pituitary apoplexy is a rapid hemorrhagic pituitary infarction due to compression of the blood supply. It is fatal within hours unless surgically decompressed.
PLANTAR FASCIITIS

Renu Gautam, MD, MSc • Thomas A. Waller, MD

BASICS

DESCRIPTION

- Degenerative change of plantar fascia at origin on medial tuberosity of calcaneus
- Pain on plantar surface, usually at calcaneal insertion of plantar fascia upon weight bearing, especially in morning or on initiation of walking after prolonged rest
- Also referred to as: plantar heel pain syndrome, heel spur syndrome, plantar fasciopathy, painful heel syndrome

EPIDEMIOLOGY

Prevalence

- Most common cause of plantar heel pain
- Lifetime: 10–15% of population
- Peak incidence between ages 40 and 60 years
- Data suggest persistence with BMI >30.
- Condition is typically self-limiting, resolving within 12 months.

ETIOLOGY AND PATHOPHYSIOLOGY

- Repetitive microtrauma and collagen degeneration of plantar fascia
- Chronic degenerative change (-osis/-opathy rather than -itis) of plantar fascia generally at insertion on medial tuberosity of calcaneus

RISK FACTORS

- Intrinsic
  - Age (>40 to 60 years)
  - Female, pregnancy
  - Obesity (BMI >30)
  - Pes planus (flat feet), pes cavus (high arch), overpronation, leg length discrepancy
  - Hamstring, calf, and Achilles tightness
  - Calf and intrinsic foot muscle weakness
– Decreased ankle range of motion with dorsiflexion (equinus or tight heel cord; <15 degrees of dorsiflexion)
– Systemic connective tissue disorders
  • Extrinsic
    – Dancers, runners, court sport athletes
    – Occupations with prolonged standing, especially on hard surfaces (nurses, letter carriers, warehouse/factory workers)
    – Overuse and rapid increase in activities involving repetitive loading

GENERAL PREVENTION
  • Maintain normal body weight.
  • Avoid prolonged standing on bare feet, sandals, or slippers.
  • Avoid training errors (increasing intensity, distance, duration, and frequency of high-impact activities too rapidly); avoid overtraining.
  • Proper footwear (appropriate cushion/arch support)
  • Runners should replace footwear every 250 to 500 miles.

COMMONLY ASSOCIATED CONDITIONS
  • Usually isolated
  • Heel spurs common but not a marker of severity
  • Posterior tibial neuropathy

DIAGNOSIS

HISTORY
  • Pain on plantar surface of foot, usually at fascial insertion at calcaneus (medial calcaneal tubercle), but can have pain anywhere along length of plantar fascia
  • Pain is typically worse with first few steps in the morning or after prolonged rest or standing (poststatic dyskinesia).
  • Pain typically improves after first few steps only to recur toward the end of the day or after prolonged ambulation.
  • Pain commonly unilateral but can be bilateral
  • Pain can be dull and constant in chronic cases.
  • Limp with excessive toe walking
  • Numbness and burning of medial hindfoot when associated with posterior tibial nerve compression
PHYSICAL EXAM
- Point tenderness on medial tuberosity of calcaneus at insertion of plantar fascia
- Pain along plantar fascia with dorsiflexion of foot
- Windlass test: Extend MTP while allowing passive flexion of IP joint of hallux—pain indicates a positive test; high specificity, low sensitivity; sensitivity improves (13.5 → 31.8%) if performed while standing.
- Dorsiflexion-eversion test: pain with dorsiflexion plus eversion of the subtalar joint
- Decreased passive range of motion with dorsiflexion
- Evaluate for pes planus, pes cavus, and overpronation.
- Loss of heel fat pad suggests heel fat pad syndrome.
- Point tenderness on posterosuperior aspect of heel suggests Achilles tendinopathy.

DIFFERENTIAL DIAGNOSIS
- Calcaneal stress fracture
- Heel fat pad syndrome (painful or atrophic heel pad)
- Longitudinal arch strain
- Nerve entrapment (posterior tibial nerve—tarsal tunnel syndrome, medial calcaneal branch of posterior tibial nerve, abductor digiti quinti)
- Achilles tendinopathy
- Calcaneal contusion
- Plantar calcaneal bursitis
- Tendonitis of posterior tibialis
- Plantar fascia tear
- Adolescents: calcaneal apophysitis (Sever disease)

DIAGNOSTIC TESTS & INTERPRETATION
- None necessary; typically a clinical diagnosis
- Consider further imaging only to rule out other causes, uncertain diagnosis, or persistent heel pain after 4 to 6 months of conservative therapy.
- Radiographs: Two views of foot can rule out fracture, tumor, cyst, periostitis, bony erosions; weight-bearing films preferred
- Ultrasound: hypoechoic at insertion, thickened plantar fascia (≥4 mm); diagnostic and even therapeutic when used as an adjunct to treatment; can improve delivery accuracy of injections and extracorporeal shock wave therapy (ESWT); can objectively evaluate change in plantar fascia thickness
to monitor effects of an intervention
- MRI can evaluate for other soft tissue etiologies.
- CT or technetium-99m bone scan can rule out calcaneal stress fracture and evaluate for infection.
- Nerve conduction studies can rule out nerve entrapment.
- Inflammatory markers: if bilateral heel pain or young patients

**TREATMENT**

Nonoperative management is mainstay of treatment.

**GENERAL MEASURES**
- Supportive footwear with stable midfoot; avoid sandals or walking barefoot.
- Relative rest/activity modification
- Stretching: plantar fascia stretches more effective than Achilles tendon/gastrocnemius-soleus stretches, and non-weight-bearing stretches may be preferable
- Strengthen calf and interosseous muscles, using the towel drag/pick-up exercise.
- Ice (frozen water bottle roll)
- Massage (golf or tennis ball roll)
- Weight reduction if BMI >25
- Orthotics
  - Custom orthotics show no benefit over prefabricated orthotics and are more costly.
  - Arch support straps are inexpensive and may be used in place or in addition to orthotics.
  - Improved effectiveness of night splints when used in association with orthotics
- Night splints: can be uncomfortable for the first few nights but generally become less bothersome with time; especially effective with calf and Achilles tightness; should be considered an adjunct therapy
- Surgical treatment of “heel spurs” is not indicated.

**MEDICATION**

*First Line*
- NSAIDs: naproxen 500 mg PO BID or ibuprofen 600 to 800 mg PO TID PRN
for pain
- Acetaminophen 1,000 mg PO TID PRN for pain

**Second Line**
None

**ISSUES FOR REFERRAL**
- Physical therapy for massage, manipulative treatments and patient instruction on proper stretching and strengthening techniques
- Podiatry: Consider if conservative measures fail after 3 to 6 months.
- Surgery: Consider if conservative measures fail after 6 to 12 months.

**ADDITIONAL THERAPIES**
- **Corticosteroid injections (1)[B]**
  - Short-term pain relief for up to 1 month, but not subsequently
  - Recommend ultrasound guidance when possible.
  - Risk for plantar fascia rupture and calcaneal fat pad atrophy with resultant permanent heel pain
  - Can cause injection and postinjection pain for up to 5 to 7 days
- **ESWT (2)[B]**
  - Uncomfortable to patients but less risk than injection or surgery;
  - Consider prior to surgery and (possibly) prior to steroid injection.
  - ESWT may be superior to corticosteroid injection for long-term improvement in those unresponsive to conservative therapy.
  - Delivery not yet standardized
- **Low-dye and calcaneal taping**
  - Limited, short-term evidence
  - Less effective in severe cases
- **Promising therapies with inconsistent evidence**
  - Radiofrequency nerve ablation (3)[B]: prospective, RCT with sham demonstrated efficacy; retrospective case series demonstrated benefit 1 to 2 years after treatment.
  - Plantar iontophoresis appears more effective with 5% acetic acid solution than with a corticosteroid.
  - Intralesional autologous blood injection
  - Low-level laser therapy
  - Myofascial trigger point dry needling (4)[B]: may significantly reduce heel pain, long-term effectiveness through 12 months
– Dehydrated amniotic membrane injection (5)[B]: can provide effective short term pain relief 0 to 2 months, but no data beyond; possibly superior to corticosteroids
– Platelet-rich plasma (PRP) injections (6)[B]:
  o Systematic reviews have demonstrated PRP improved symptoms until 12 months post injection.
  o PRP comparable to prolotherapy and better than corticosteroid injections in the short and long term
  o PRP preparation, characteristics, protocol not standardized
– Botulinum toxin (BT) A injection (5)[B]
  o Meta-analysis reveals significant pain improvement from 0 to 6 months with BT injection.
  o RCT comparing steroid injection to BT injection showed similar results in pain reduction and other measures of foot function at 1 month; improvements persisted at 6 months—more so with BT than with steroid injection.

SURGERY/OTHER PROCEDURES
- Necessary in <10% of patients; more likely beneficial in severely obese
- Recommended if conservative treatment fails after 6 to 12 months and pain is unrelenting
- Open/endoscopic plantar fasciotomy (less risk and complications with endoscopic technique but requires specialized equipment and skills; is not widely used)
- Cryosurgery
- Calcaneal spur resection
- No RCTs support surgery as a primary treatment.

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Heel cup with magnet has proven ineffective.
- Acupuncture may reduce pain in short term, but insufficient evidence for long term.

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
- Ensure patient adherence to proper stretching technique.
- Following 3 to 6 months of unsuccessful conservative treatment, consider additional therapies or referrals.

PATIENT EDUCATION
- Weight reduction if BMI >25
- Proper footwear (adequate cushion and arch support)
- Stretch plantar fascia: Pull toes into dorsiflexion prior to walking after prolonged sitting or sleep.
- Ice the foot using a frozen water bottle: Roll foot over bottle for 10 minutes in the morning and after work.
- Massage plantar fascia: Roll foot over a golf ball.
- Strengthen foot muscles: Grab cloth or carpet by plantar flexing the toes.
- Decrease repetitive stress.

PROGNOSIS
- Generally good
- Self-limited (resolves within 2 years) in up to 85–90% of patients

COMPLICATIONS
- Rupture of plantar fascia (more common with repeated corticosteroid injections)
- Chronic pain
- Gait abnormality

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Heel Pain

**CODES**

**ICD10**

M72.2 Plantar fascial fibromatosis
CLINICAL PEARLS

- Plantar fasciitis occurs due to degeneration of plantar fascia at origin (medial calcaneal tuberosity) with characteristic pattern of pain.
- Plantar medial heel pain with weight bearing (most noticeable with initial steps in the morning or after period of inactivity) is hallmark presentation.
- Generally, self-limited and conservative treatment is preferred. 85–90% of patients can be treated with conservative therapies.
- Supportive footwear helps avoid excess pronation and provides adequate cushion and arch support. Modify activity, stretch plantar fascia, strengthen intrinsic foot muscles, ice (water bottle roll), and massage (golf ball roll).
- Weight loss helps control symptoms, particularly for BMI ≥25.
PLEURAL EFFUSION
Felix B. Chang, MD, DABMA, FAAMA

BASICS
Abnormal accumulation of fluid in the pleural space

DESCRIPTION
Types: transudate, exudate
- Congestive heart failure: 40%: transudate
- Pneumonia 25%, malignancy 15%, and pulmonary embolism (PE) 10% account for exudative effusions
- Malignant: lung cancer and metastases of breast, ovary, and lymphoma

EPIDEMIOLOGY

Incidence
Estimated 1.5 million cases per year in the United States; CHF: 500,000; pneumonia: 300,000; malignancy: 150,000; PE: 150,000; cirrhosis: 150,000; TB: 2,500; pancreatitis: 20,000; collagen vascular disease: 6,000

Prevalence
- Estimated 320 cases per 100,000 people in industrialized countries; in hospitalized patients with AIDS, prevalence is 7–27%.
- No gender predilection: ~2/3 of malignant pleural effusions occur in women.

ETIOLOGY AND PATHOPHYSIOLOGY
- Pleural fluid formation exceeds pleural fluid absorption.
- Transudates result from imbalances in hydrostatic and oncotic forces.
  - Increase in hydrostatic and/or low oncotic pressures; increase in pleural capillary permeability; lymphatic obstruction or impaired drainage; movement of fluid from the peritoneal or retroperitoneal space
- Transudates
  - CHF: 40% of transudative effusions; 80% bilateral; constrictive pericarditis, atelectasis; superior vena cava syndrome
  - Cirrhosis (hepatic hydrothorax); nephrotic syndrome, hypoalbuminemia; myxedema
– Urinothorax, central line misplacement; peritoneal dialysis
– Dressler syndrome (postmyocardial infarction syndrome)
– Yellow nail syndrome: yellow nails, lymphedema and pleural effusion
• Exudates
  – Lung parenchyma infection, bacterial (parapneumonic, tuberculous pleurisy), fungal, viral, parasitic (amebiasis, *Echinococcus*)
  – Cancer: lung cancer, metastases (breast, lymphoma, ovaries), mesothelioma
  – PE: 25% of PEs are transudate.
• Collagen vascular disease: rheumatoid arthritis, systemic lupus erythematosus (LE), Wegener granulomatosis, sarcoidosis, Churg-Strauss
• GI: pancreatitis, esophageal rupture, abdominal abscess, after liver transplant; chylothorax: thoracic duct tear, malignancy
• Hemothorax: trauma, PE, malignancy, coagulopathy, aortic aneurysm
• Others: after coronary artery bypass graft; uremia, asbestos exposure, radiation; drug-induced:
  o Drugs: nitrofurantoin, bromocriptine, amiodarone, procarbazine, hydralazine, procainamide, quinidine, methotrexate, methysergide, interleukin-2, mitomycin, practolol, minoxidil, bleomycin, cyclophosphamide, dantrolene, valproic acid, sulfasalazine, minocycline, acebutolol
– Meigs syndrome; yellow nail syndrome; ovarian stimulation syndrome; lymphangiomatosis; acute respiratory distress syndrome (ARDS)
– Chylothorax: thoracic duct tear, malignancy, associated with lymphoma

**RISK FACTORS**
• Occupational exposures/drugs
• PE, TB, bacterial pneumonias
• Opportunistic infections (in HIV patients when CD4 count is <150 cells/μL)

**COMMONLY ASSOCIATED CONDITIONS**
Hypoproteinemia, heart failure, cirrhosis

**DIAGNOSIS**
Presumptive diagnosis in 50% of cases. Small pleural effusions; radiographic area <2 intercostal spaces (<300 mL) are asymptomatic.

**HISTORY**
Dyspnea, fever, malaise, and weight loss; chest pain, cough, hemoptysis, and dull pain

**PHYSICAL EXAM**
- Pleural effusion >300 mL: tachypnea, asymmetric expansion of the thoracic cage; decrease/absent tactile fremitus; dullness to percussion; decreased/inaudible breath sounds, egophony, pleural friction rub
- Ascites suggest the following: hepatic hydrothorax, ovarian cancer, and Meigs syndrome.
- If associated with unilateral swelling in lower extremity, consider DVT with PE.

**DIFFERENTIAL DIAGNOSIS**
Empyema, malignancy, inflammatory, fungal, tuberculosis

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Pleural fluid: appearance, pH, WBC differential, total protein, lactate dehydrogenase (LDH), glucose, Gram stain and culture, and acid-fast bacilli staining. Consider polymerase chain reaction (PCR) for *Mycobacterium tuberculosis* and *Streptococcus pneumoniae* (1,2)[A].
- If comorbidities implying risk, consider amylase, triglycerides, cholesterol, LE cells, cytology, antinuclear antibodies (ANAs), adenosine deaminase, tumor markers, rheumatoid factor, cytology, creatinine (2)[A].
- Light criteria, transudate versus exudate (98% sensitivity; 80% specificity); fluid is considered an exudate if any of the following (2)[A]:
  - Ratio of pleural fluid-to-serum protein levels >0.5; ratio of pleural fluid-to-serum LDH levels >0.6; pleural fluid LDH level >2/3 the upper limit for serum LDH level (1,3) [A]
- Other exudate criteria (4)[A]:
  - Serum-effusion albumin gradient ≤1.2 (sensitivity 87%; specificity 92%); cholesterol effusion >45 mg/dL and LDH effusion >200 mg/dL (sensitivity 90%; specificity 98%)
- Empyema: pus, putrid odor; culture. A putrid odor suggests an anaerobic empyema: LDH levels >1,000 IU/L (normal serum = 200 IU/L); glucose, <60 mg/dL; low pH
- Malignancy: cytology, red, bloody; glucose, normal to low, depending on the tumor burden; RBCs, >100,000/mm³
- Lupus pleuritis: LE cells present; pleural fluid-to-serum ANAs ratio >1; glucose <60 mg/dL; pleural fluid-to-serum glucose ratio <0.5
- Fungal: positive KOH, culture; peritoneal dialysis: protein, <1 g/dL; glucose, 300 to 400 mg/dL
- Urinothorax: creatinine: pleural/blood >0.5; high LDH pleural fluid, with low protein levels
- Hemothorax: hematocrit: pleural/blood >0.5; benign asbestos effusion: unilateral, exudative; have elevated eosinophil count
- TB pleuritis: lymphocytes >80% predominance effusion; elevated levels of adenosine deaminase >50 U/L and interferon-γ >140 pg/mL; positive acid-fast bacillus (AFB) stain, culture; total protein >4 g/dL, nuclear acid amplification (NAA), LDH levels elevated in about 75% of patients (often >500 units/L)
- Chylothorax: milky; triglycerides >110 mg/dL; lipoprotein electrophoresis (chylomicrons)
- Amebic liver abscess: anchovy paste effusion; Waldenström macroglobulinemia and multiple myeloma: protein >7 g/dL
- Esophageal rupture: high salivary amylase; pleural fluid acidosis, pH <6; amylase-rich: acute pancreatitis, chronic pancreatic pleural effusion, malignancy, esophageal rupture; rheumatoid pleurisy: glucose <60 mg/dL; pleural fluid/serum glucose <0.5
- Lymphocytosis: tuberculous pleurisy, lymphoma, sarcoidosis, chronic rheumatoid pleurisy, yellow nail syndrome, or chylothorax (80–95% of the nucleated cells); carcinomatosis in half of cases (50–70% are lymphocytes)
- Pleural fluid eosinophilia (>10% of total nucleated cells): pneumothorax, hemothorax, malignancy, drugs, pulmonary infarction, fungal (coccidioidomycosis, cryptococcosis, histoplasmosis), benign asbestos pleural effusion
- Low glucose (<60 mg/dL): TB, malignancy, rheumatoid pleurisy, parapneumonic, empyema, hemothorax, paragonimiasis, Churg-Strauss syndrome
- RBC count >100,000/mm³: trauma, malignancy, PE, injury after cardiac surgery, asbestos pleurisy, pancreatitis, TB
- Pleural fluid LDH >1,000 IU/L: suggests empyema, malignant effusion, rheumatoid effusion, or pleural paragonimiasis
- pH >7.3: rheumatoid pleurisy, empyema, malignant effusion, TB, esophageal rupture, or lupus nephritis
- Mesothelial cells in exudates: TB is unlikely if there are >5% of mesothelial cells.
- S. pneumoniae accounts for 50% of cases of parapneumonic effusions in
AIDS patients, followed by *Staphylococcus aureus, Haemophilus influenzae, Mycoplasma pneumoniae, Legionella, Nocardia, and Bordetella bronchiseptica*. exudate with low count of nucleated cells

- *Pneumocystis jirovecii* is an uncommon cause in HIV. Usually it is a small effusion, unilateral or bilateral, and serous to bloody in appearance. Demonstration of the trophozoite or cyst is mandatory.
- Cancer-related HIV pleural effusion: Kaposi sarcoma, Castleman disease, and primary effusion lymphoma. Kaposi sarcoma: mononuclear predominance, exudate, pH >7.4; LDH, 111 to 330 IU/L; glucose >60 mg/dL
- Chest x-ray (CXR): posteroanterior–anteroposterior views
  - Upright x-rays show a concave meniscus in the costophrenic angle that suggests >250 mL of pleural fluid; homogeneous opacity, with visibility of pulmonary vessels through diffuse haziness and absence of air bronchogram; 75 mL of fluid will obliterate the posterior costophrenic sulcus.
  - Lateral x-rays show blunting of the posterior costophrenic angle and the posterior gutter; decubitus x-rays to exclude a loculated effusion and underlying pulmonary lesion or pulmonary thickening
  - Supine x-rays show costophrenic blunting, haziness, obliteration of the diaphragmatic silhouette, decreased visibility of the lower lobe vasculature, and widened minor fissure.
- Ultrasonography (US): detects as 5 to 50 mL of pleural fluid; identifies loculated effusions; site for thoracocentesis, pleural biopsy, or pleural drainage
- Chest CT scan with contrast for patients with undiagnosed pleural effusion; CT pulmonary angiography if PE is suspected

**Follow-Up Tests & Special Considerations**

75% of patients with exudative effusions have a non-CHF cause.

- NT-proBNP: biomarker of CHF-associated effusion; >1,500 pg/mL; sensitivity and specificity 94% (2)[A]
- In patients with a lymphocytic effusion, further investigation should be considered for tuberculosis, sarcoidosis, lymphoma, chylothorax, and pseudochoylothorax.

**Diagnostic Procedures/Other**

Diagnostic thoracentesis indicated for the following:

- Clinically significant pleural effusion (>10 mm thick on US or lateral
decubitus x-ray with no known cause)
- CHF: asymmetric effusion, fever, chest pain, or failure to resolve after diuretics
- Parapneumonic effusions

**TREATMENT**

Oxygen support

**GENERAL MEASURES**

- Therapeutic thoracentesis, if symptomatic
- Chest tube thoracostomy drainage: >1/2 hemithorax; complicated parapneumonic effusion (positive Gram stain or culture, pH <7.2, or glucose <60 mg/dL); empyema; hemothorax. Recommended limit is 1,000 to 1,500 mL in a single thoracentesis procedure (5)[B].

**MEDICATION**

*First Line*
- CHF: diuretics (75% clearing in 48 hours); parapneumonic effusion: antibiotics; rheumatologic conditions/inflammation: steroids and NSAIDs

*Second Line*
- Symptomatic nonmalignant effusions that are refractory to treatment may be managed with repeated therapeutic thoracentesis or pleurodesis.

**ISSUES FOR REFERRAL**

- Uncertain etiology; malignant effusion; high-risk diagnostic thoracentesis; decortication
- Video-assisted thoracoscopy for sclerosis; peritoneal shunts for symptomatic recurrence

**ADDITIONAL THERAPIES**

- Pleurodesis for symptomatic patients whose pleural effusion reaccumulates too quickly for repeat therapeutic thoracentesis
- Talc poudrage to be a highly effective method 95% credible interval (Cr-1) 1 to 5 (5)[A]
- Tunneled pleural catheter is the preferred treatment for patients with
malignant pleural effusion and limited survival.

- Sclerosing agents for malignant effusions: doxycycline, bleomycin, talc, and minocycline; talc is more efficacious. The relative risk of nonrecurrent effusion was 1.34 (95% CI 1.16–1.55) in favor of talc compared with bleomycin, tetracycline, or mustine.

**SURGERY/OTHER PROCEDURES**

- Percutaneous pleural biopsy if a cause is not clear after thoracentesis
  - Close pleural biopsy: Pleura is diffusely involved (TB pleuritis, noncaseating granuloma in rheumatoid pleuritis).
  - CT-guided needle biopsy: pleural mass; video-assisted thoracoscopic pleural biopsy: Negative percutaneous biopsy, patchy disease, or CT scan does not show obvious mass.

- Parapneumonic effusion should be sampled if free-flowing, but layer is >10 mm on a lateral decubitus film; loculated, thickened pleura on a contrast-enhanced CT scan, clearly delineated by US open pleural biopsy by thoracotomy.

- Contraindications for thoracocentesis: anticoagulation, bleeding diathesis, thrombocytopenia <20,000/mm³, mechanical ventilation.

- Bronchoscopy: when malignancy is suspected (pulmonary infiltrate or mass on CXR or CT scan, hemoptysis, massive pleural effusion, or shift of the mediastinum toward the side of effusion).

- Thoracoscopy

**CONTRAINDICATIONS FOR THORACOCENTESIS**

- No statistically significant difference in mortality between primary surgical and nonsurgical management of pleural empyema for all age groups (6)[A]

- Video-assisted thoracoscopic surgery may reduce length of hospital stay compared to thoracostomy (6)[A].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Treat any underlying medical disorder.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

*Patient Monitoring*
Check for the amount and quality of fluid drained, air leak (bubbling), and oscillation.
Repeat a CXR when drainage decreases to <100 mL/day to evaluate complete clearing.
For a large effusion, reevaluate catheter position; if positioned appropriately, consider fibrinolytics.

**Diet**
Cardiac diet in patients with heart failure; correct hypoproteinemia.

**Prognosis**
- Malignant effusion: poor
- Low-pH malignant effusions have shorter survival and poorer response to chemical pleurodesis than those with pH >7.3.
- Low pleural fluid pH (≤7.15): high likelihood of pleural space drainage
- 68% 30-day and 84% 1-year mortality among patients with bilateral malignant pleural effusion
- Pleural fluid pH ≤7.28 associated with reduced survival (odds ratio 4.42, 95% CI 2.39–8.46 for <1-month survival)
- Uncomplicated parapneumonic effusions and effusions from PE, tuberculous pleurisy, and postcardiac injury syndrome may persist for several weeks.
- Benign asbestos pleural effusion, rheumatoid pleurisy, and radiation pleuritis often persist for months to years.
- Malignant pleural effusions, on the other hand, seldom resolve spontaneously.

**Complications**
- Pleural effusion: constrictive fibrosis, pleurocutaneous fistula
- Thoracentesis: pneumothorax (5–10%); hemothorax (~1%); empyema; spleen/liver laceration; reexpansion pulmonary edema (if >1.5 L is removed)

**References**
4. Wilcox ME, Chong CA, Stanbrook MB, et al. Does this patient have an exudative pleural effusion? The rational clinical examination systematic

**ADDITIONAL READING**

**CODES**

**ICD10**

- J90 Pleural effusion, not elsewhere classified
- J91.0 Malignant pleural effusion
- J94.0 Chylous effusion

**CLINICAL PEARLS**

- Bilateral pleural effusion suggests heart failure, malignancy in absence of cardiomegaly, and tuberculosis or parasitic infection in children.
- Ascites and pleural effusion suggest hepatic hydrothorax, ovarian cancer, or Meigs syndrome.
- Consider diagnostic thoracocentesis in patient with heart failure: fever, pleuritic chest pain, unilateral effusion or effusion of markedly disparate size, effusion not associated with cardiomegaly, effusion fails to respond to management of heart failure
- If NT-proBNP is unavailable, the fluid can be considered a transudate if the total protein gradient (serum minus pleural fluid) is >3.1 g/dL in a patient with convincing clinical picture of heart failure who is taking diuretics.
PNEUMONIA, BACTERIAL

Naureen Rafiq, MBBS • Khalid Bashir, MD

BASICS

Bacterial pneumonia is an infection of the pulmonary parenchyma by a bacterial organism.

DESCRIPTION

Bacterial pneumonia can be classified as the following:

- Community-acquired pneumonia (CAP): lower respiratory tract infection not acquired in a hospital, long-term care facility, or during other recent contact with the health care system
- Medical care–associated pneumonia
  - Hospital-acquired pneumonia (HAP): pneumonia within ≥48 hours after admission and did not appear to be incubating at time of admission
  - Ventilator-associated pneumonia (VAP): Pneumonia that develops >48 hours after endotracheal intubation.
  - Health care–associated pneumonia (HCAP): Pneumonia that occurs in a nonhospitalized patient with extensive health care contact, such as the following:
    - IV therapy/wound care within past 30 days
    - Residing in a nursing home/long-term care
    - Hospitalization in an acute care hospital for ≥2 days within the past 90 days; hemodialysis clinic within the past 30 days

EPIDEMIOLOGY

- Influenza and pneumonia are the eight leading cause of death in the United States with about 53,282 deaths in 2013.
- HAP is the leading cause of death among nosocomial infections and is one of the leading causes of death in the ICU.
- Rates of infection are 3 times higher in African Americans than in whites and are 5 to 10 times higher in Native American adults and 10 times higher in Native American children.
- Mortality rate in children is approximately 1.6 million a year. Hospitalization rate for children with CAP is still highest among the very young ages (<18
months). Respiratory viruses are the most commonly detected causes of pneumonia (1).

**Incidence**
- CAP: 5 to 11 cases/1,000 persons with increased incidence occurring in the winter months
- HAP: 5 to 10 cases/1,000 admissions; incidence increase 6- to 20-fold in ventilated patients (2)[A]

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Adults, CAP
  - Typical (85%): *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Staphylococcus aureus*, group A *Streptococcus*, *Moraxella catarrhalis*
  - Atypical (15%): *Legionella* sp., *Mycoplasma pneumoniae*, *Chlamydophila pneumoniae*
- Adults, HCAP/HAP/VAP
  - Aerobic gram-negative bacilli: *Pseudomonas aeruginosa*, *Escherichia coli*, *Klebsiella pneumoniae*, and *Acinetobacter* sp.
  - Gram-positive cocci: *Streptococcus* sp. and *S. aureus* (including MRSA)
- Children
  - Birth to 20 days: *E. coli*, group B *Streptococci*, *Listeria monocytogenes*
  - 3 weeks to 3 months: *Chlamydia trachomatis*, *S. pneumoniae*
  - 4 months to 18 years
    - Typical: *S. pneumoniae*
    - Atypical: *C. pneumoniae*, *M. pneumoniae*

**RISK FACTORS**
CAP
- Age >65 years
- HIV/immunocompromised
- Recent antibiotic therapy/resistance to antibiotics
- Asthma, CAD, COPD, chronic renal failure, CHF, diabetes, liver disease, VAP, HAP, HCAP
- Hospitalization for ≥2 days during past 90 days
- Severe illness
- Antibiotic therapy in the past 6 months
- Poor functional status as defined by activities of daily living score
- Immunosuppression (including steroid users) (3)
GENERAL PREVENTION

- All children 2 to 59 months of age should be routinely vaccinated with pneumococcal conjugate (PCV13); given at 2, 4, and 6 months of age; a 4th dose at 12 to 15 months of age.
- Adults ≥65 years who have not received vaccine naïve, ACIP currently recommends PCV13 followed by pneumococcal polysaccharide (PPSV23) ≥1 year interval. If they received PPSV23 vaccine before age 65 years, they should receive a dose of PCV13 followed by a subsequent PPSV23 ≥1 year after PCV13 and at least 5 years have passed since their previous PPSV23 dose.
- For adults ≥65 years old who have already received PPSV23, a dose of PCV13 is indicated after ≥1 year.
- Adults 19 to 64 years who have chronic diseases, including alcoholism and tobacco use, should receive PPSV23.
- Adults ≥19 years old with immunocompromising conditions, asplenia, CSF leaks, cochlear implants who have not received PPSV23 or PCV13 should receive one dose of PCV13 followed by PPSV23 after ≥8 weeks. If a second dose of PPSV23 is recommended, it should be given 5 years after 1st dose.
- Adults >19 years, previously given PPSV23 should receive a PPCV13 dose ≥1 year after last PPSV23. If additional PPSV23 is required, it should be given ≥8 weeks after PCV13 and 5 years after most recent dose of PPSV23.
- Annual influenza vaccine

DIAGNOSIS

HISTORY

- Fever, chills, rigors, malaise, fatigue
- Dyspnea
- Cough, with/without sputum
- Pleuritic chest pain
- Myalgias
- GI symptoms

ALERT

High fever (>104°F [40°C]), male sex, multilobar involvement, and GI and neurologic abnormalities have been associated with CAP caused by *Legionella*. 
Geriatric Considerations
Older adults with pneumonia often present with weakness, mental status change, or history of falls.

PHYSICAL EXAM
- Fever >100.4°F (38°C), tachypnea, tachycardia
- Rales, rhonchi, egophony, increased fremitus, bronchial breath sounds, dullness to percussion, asymmetric breath sounds, abdominal tenderness

DIFFERENTIAL DIAGNOSIS
Bronchitis, asthma exacerbation, pulmonary edema, lung cancer, pulmonary tuberculosis, pneumonitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Routine laboratory testing to establish an etiology in outpatients with CAP is usually unnecessary.
- For hospitalized patients with CAP, a CBC, sputum Gram stain, procalcitonin, and two sets of blood cultures
- More extensive diagnostic testing in patients with CAP is recommended if:
  - Blood cultures: ICU admission, cavitary infiltrates, leukopenia, alcohol abuse, severe liver disease, asplenia, positive pneumococcal urine antigen test (UAT), pleural effusion
  - Sputum Gram stain and cultures: ICU admission, failure of outpatient treatment, cavitary infiltrates, alcohol abuse, severe COPD/structural lung disease, positive Legionella UAT, positive pneumococcal UAT, pleural effusion
  - Legionella UAT: ICU admission, failure of outpatient treatment, alcohol abuse, travel in past 2 weeks, pleural effusion
  - Pneumococcal UAT: ICU admission, failure of outpatient treatment, leukopenia, alcohol abuse, severe liver disease, asplenia, pleural effusion
- A chest x-ray (CXR) is indicated when pneumonia is suspected or with an acute respiratory infection and
  - Vital signs: temperature >100°F (37.8°C); heart rate (HR) >100 beats/min; respiratory rate (RR) >20 breaths/min
  - At least two of the following clinical findings: decreased breath sounds, rales, no asthma
Early in disease course, CXR may be negative.
Evidence of necrotizing/cavitary pneumonia should raise suspicion for MRSA pneumonia, especially with history of prior MRSA skin lesions.

**Diagnostic Procedures/Other**
For VAP/HAP: By bronchoscopic or nonbronchoscopic means, obtain a lower respiratory tract sample for culture prior to initiation/change of therapy. Serial evaluations may be needed (2)[A].
Safe cessation of antibiotics can be done from a good quality negative sputum culture.

**TREATMENT**

**MEDICATION**

**First Line**
- Adults
  - CAP, outpatient
    - No significant differences in efficacy between antibiotic option in adults
    - Previously healthy, no antibiotics in past 3 months
      - Azithromycin 500 mg PO 1 time, then 250 mg PO daily for 4 days; clarithromycin 500 mg PO BID for 10 days; erythromycin 500 mg PO BID for 10 days, or
      - Doxycycline 100 mg PO BID for 10 days
    - Comorbid conditions, immunosuppressed, antibiotic use in past 3 months
      - Levofloxacin 750 mg PO daily for 5 days; moxifloxacin 400 mg PO daily for 5 days; or
      - Amoxicillin 1 g PO TID; amoxicillin-clavulanate 2 g PO BID + macrolide/doxycycline for 5 days
    - Treatment may be stopped if
      - Afebrile for >48 hours
      - Supplemental oxygen no longer needed
      - No more than one of the following:
        - HR >100 beats/min
        - RR >24 breaths/min
        - Systolic blood pressure (BP) ≤90 mm Hg
  - CAP, inpatient (non-ICU)
    - IV antibiotics initially, then switch to oral after clinical improvement
- Treatment duration depends on clinical improvement.
  - Cefotaxime; ceftriaxone; ampicillin-sulbactam + macrolide (clarithromycin; erythromycin) for 5 to 14 days or
  - Moxifloxacin; levofloxacin for 5 to 14 days
- If *Pseudomonas* is a consideration
  - Piperacillin-tazobactam; cefepime; imipenem; meropenem + levofloxacin or
  - Piperacillin-tazobactam; cefepime; imipenem; meropenem + aminoglycoside and azithromycin or
  - Piperacillin-tazobactam; cefepime; imipenem; meropenem + aminoglycoside + levofloxacin
- If MRSA is a consideration
  - Add vancomycin or linezolid HCAP/HAP/VAP.
- Use IV antibiotics.
  - Early onset (<5 days) and no risk factors for multidrug-resistant pathogens
    - Ceftriaxone; ampicillin-sulbactam; ertapenem or
    - Levofoxacin; moxifloxacin
  - Late onset (≥5 days) or risk factors for multidrug-resistant pathogens (antibiotic therapy in preceding 90 days; high frequency of antibiotic resistance in community/hospital; immunosuppressive disease/therapy; risk factors for HCAP)
    - MRSA coverage: linezolid or vancomycin + β-lactam cefepime; ceftazidime; imipenem; meropenem; piperacillin-tazobactam + either fluoroquinolone (levofloxacin) or aminoglycoside (amikacin; gentamicin; tobramycin) (level II)
    - Short-course versus prolonged-course antibiotic therapy for HAP in critically ill adults. For patients with VAP due to NF-GNB, a shorter antibiotic course may increase the risk of recurrence (4)[A].
    - Drug-resistant *S. pneumoniae* should be treated with high-dose amoxicillin, amoxicillin/clavulanate, cefpodoxime with a macrolide, or a respiratory fluoroquinolone.
- Adult IV antibiotic doses
  - β-Lactams (ampicillin-sulbactam 3 g q6h; aztreonam 2 g q6h; cefepime 1 to 2 g q8–12h; cefotaxime 1 g q6–8h; ceftazidime 2 g q8h; ceftriaxone 2 g daily; imipenem 500 mg q6h; meropenem 1 g IV q8h)
  - Aminoglycosides (amikacin 20 mg/kg daily; gentamicin 7 mg/kg daily; tobramycin 7 mg/kg daily)
  - Fluoroquinolones (levofloxacin 750 mg daily; moxifloxacin 400 mg
Macrolides (azithromycin 500 mg daily; clarithromycin 500 mg daily; erythromycin 500 to 1,000 mg q6h)
- Vancomycin 15 mg/kg q12h
- Linezolid 600 mg q12h
- Telavancin is an antibiotic which covers MRSA infection. Telavancin is approved for the treatment of HAP and VAP caused by *S. aureus*. This medication is indicated only when alternative agents cannot be used.

**Pediatric, outpatient (≥3 months)**
- Antibiotic treatment in preschool-aged children is not routinely required because viral pathogens are more common (5)[A].
- Oral antibiotics are as efficacious as IV in CAP (length of stay and oxygen requirement were reduced in those given oral antibiotics).
- Typical bacterial pneumonia
  - Amoxicillin 90 mg/kg/day PO BID (max 4 g/day) (5)[A]
  - Amoxicillin-clavulanate 90 mg/kg/day PO BID (max 4 g/day) (5)[A]
  - Alternative: levofloxacin 16 to 20 mg/kg/day PO BID for children 6 months to 5 years, 10 mg/kg/day daily for children ≥5 years (max 750 mg/day) (5)[C]
- Atypical bacterial pneumonia
  - Azithromycin 10 mg/kg PO on day 1 (max 500 mg), then 5 mg/kg/day (max 250 mg) on days 2 to 5 (4)[C]
  - Clarithromycin 15 mg/kg/day PO BID (max 1 g/day) (4)[C]
  - Erythromycin 40 mg/kg/day PO daily (4)[C]

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Clinical judgment and use of a validated severity of illness score are recommended to determine if inpatient management is indicated.
- The Pneumonia Severity Index (PSI) is a clinical prediction rule used to calculate the probability of morbidity and mortality among patients with CAP. PSI is risk stratified from I to V. PSI risk class from I to III can be treated as outpatients and IV to V should be hospitalized. PSI can be calculated at [http://pda.ahrq.gov/clinic/psi/psicalc.asp](http://pda.ahrq.gov/clinic/psi/psicalc.asp).
The SMART-COP (systolic BP, multilobar chest radiography, albumin, RR, tachycardia, confusion, oxygen level, and arterial pH) is a new method to predict which patients will require intensive respiratory/vasopressor support. A score of $\geq 3$ has sensitivity of 92% to identify those patients who will receive intensive treatment.

Patients with COPD or CHF are more likely to require ICU admission when suffering from CAP.

Clinical prediction tools do not replace a physician’s clinical judgment.

**Pediatric Considerations**

Inpatient treatment of children is recommended in the following settings: infants $\leq 3$ to 6 months; presence of respiratory distress (tachypnea, dyspnea, retractions, grunting, nasal flaring, apnea, altered mental status, $O_2$ sat $<90%$); or if known to have CAP as result of a virulent pathogen such as community-associated MRSA should be hospitalized (6).

- Discharge criteria: clinical stability: temperature $\leq 100^\circ F$ (37.8°C); HR $\leq 100$ beats/min; RR $\leq 24$ beats/min; systolic BP $\leq 90$ mm Hg; $O_2$ sat $\geq 90\%$ or $PaO_2 \geq 60$ mm Hg on room air; ability to maintain oral intake; normal mental status

---

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

Consider chest CT if patient is failing to improve on current management.

**PATIENT EDUCATION**

Smoking cessation, vaccinations

**COMPLICATIONS**

Necrotizing pneumonia, respiratory failure, empyema, abscesses, cavitation, bronchopleural fistula, sepsis

**REFERENCES**

**CODES**

**ICD10**
- J15.9 Unspecified bacterial pneumonia
- J15.4 Pneumonia due to other streptococci
- J14 Pneumonia due to Hemophilus influenzae

**CLINICAL PEARLS**
- Bacterial pneumonia can usually be treated empirically based on its classification as CAP or HCAP/HAP/VAP.
- A severity of illness score is helpful in determining the need for hospitalization of adult patients but does not replace a physician’s clinical judgment.
PNEUMONIA, MYCOPLASMA

Kenneth A. Ballou, MD • Andrew G. Alexander, MD • Maegen Dupper, MD

BASICS

DESCRIPTION

- Bronchopulmonary infection caused by the *Mycoplasma* species, *Mycoplasma pneumoniae*
- Smallest free-living organism; fastidious and slow-growing; first isolated in cattle in 1898
- Most frequently affects children/young adults but can also occur in the elderly; often causes epidemics in close communities
- Infection may be asymptomatic, most often confined to the upper respiratory tract; however, may progress to pneumonia (5–10%).
- Course is usually acute with an incubation period of 1 to 4 weeks.
- Synonym(s): primary atypical pneumonia (PAP); Eaton agent pneumonia; cold agglutinin–positive pneumonia; walking pneumonia

Geriatric Considerations

The highest rate of ICU admissions for community-acquired pneumonia (CAP) due to *M. pneumoniae* occurs in seniors.

Pediatric Considerations

- Plays a significant role in pneumonias in children of all ages (pneumonia <5 years is more commonly viral)
- Increased incidence of asthma exacerbation in older children
- All infants 3 to 6 months with suspected bacterial pneumonia should be hospitalized.

EPIDEMIOLOGY

Incidence

- Estimated 1 million cases per year in the United States
- Responsible for 20% of CAP requiring hospitalizations annually
- Infection occurs most frequently in fall/winter seasons but may develop year
round.

**Prevalence**
- Predominant sex: male = female
- Predominant age group affected: 5 to 20 years
  - May occur at any age
  - Rare in children <5 years of age
- Responsible for up to 15–20% of all cases of CAP yearly
  - Most common cause of pneumonia in school children and young adults who do not have a chronic underlying condition

**ETIOLOGY AND PATHOPHYSIOLOGY**
- *M. pneumoniae* is a short-rod mucosal pathogen, which lacks a cell wall and thus not visible on Gram stain.
- Can grow under both aerobic and anaerobic conditions
- Highly contagious, *M. pneumoniae* is transmitted primarily by aerosol droplets.
- Pathogenicity linked to its filamentous tips, which adhere selectively to respiratory epithelial cell membrane proteins with production of \( H_2O_2 \) and superoxide radicals, damaging cilia
- Many pathogenic features of infection are believed to be immune-mediated, not directly induced.
- Decreased ciliary movement produces prolonged paroxysmal, hacking cough.
- Incubation period is 2 to 3 weeks.

**ALERT**
- Infection by *M. pneumoniae* has come to be recognized as a worldwide cause of CAP.
- *M. pneumoniae* infection may worsen asthma symptoms as well as cause wheezing in children without asthma.

**RISK FACTORS**
- Immunocompromised state (e.g., HIV, transplant recipients, chemotherapy)
- Smoking
- Close community living (e.g., military barracks, prisons, hospitals, dormitories, schools, household contacts)

**GENERAL PREVENTION**
Consider droplet isolation of active cases.

**COMMONLY ASSOCIATED CONDITIONS**
- Asthma exacerbations as a result of proinflammatory cytokine release
- Chronic obstructive pulmonary disease

**DIAGNOSIS**

**HISTORY**
- Infection may be asymptomatic.
- Gradual onset of headache, malaise, low-grade fevers, chills
- Symptoms of upper respiratory infection then occur, including incessant, nonproductive, worsening cough (which may become mildly productive late in the disease); rhinorrhea, pharyngitis, and sinusitis
- Pneumonia may occur with associated pleural effusion.
- The presence of pleuritic chest pain warrants a higher suspicion of *M. pneumoniae*.
- Extrapulmonary findings may develop in 5–10% of patients, including arthralgias, skin rashes, cervical adenopathy, hemolysis, congestive heart failure (CHF), and cardiac conduction abnormalities.
- Neurologic symptoms develop more commonly in children and may include encephalitis, aseptic meningitis, cranial nerve palsies, cerebellar ataxia, ascending paralysis, and coma.
- Persistent cough is common during convalescence; other sequelae are rare.

**PHYSICAL EXAM**
- Toxicity increases with advancing age or comorbidity.
- Hacking/pertussis-like cough may be present along with fever and lassitude.
- Normal lung findings with early infection, but rhonchi, rales, and/or wheezes may develop several days later.
- Mild pharyngeal injection without exudates
- Minimal/no cervical adenopathy
- Erythematous tympanic membranes or bullous myringitis in patients >2 years of age is an uncommon but unique sign.
- Some patients may develop a pleural friction rub.
- Various exanthems, including erythema multiforme and Stevens-Johnson syndrome
DIFFERENTIAL DIAGNOSIS
- Viral/bacterial/fungal pneumonia
- Tuberculosis
- Other atypical pneumonias, including *Chlamydia pneumoniae*, *Chlamydophila psittaci*, *Coxiella burnetii* (Q fever), *Francisella tularensis* (tularemia), *Pneumocystis jiroveci*, *Legionella pneumophila*

DIAGNOSTIC TESTS & INTERPRETATION
- *M. pneumoniae* is typically a clinical diagnosis and treated empirically; however, when specific pathogen testing is indicated, polymerase chain reaction (PCR) is the test of choice (3)[C].
- No clinical or radiographic findings can differentiate between *M. pneumoniae* and other atypical pneumonia pathogens (*Chlamydia/Legionella*).

**Initial Tests (lab, imaging)**
- WBC count may be normal or elevated.
- Hemolytic anemia has been described but is rare.
- Elevated erythrocyte sedimentation rate (ESR) may be present but is nonspecific.
- When available, PCR for *M. pneumoniae* DNA in nasopharyngeal and throat swabs as well as bronchoalveolar lavage respiratory secretions, CSF, and tissue samples may be the most sensitive and specific.
- CXR shows reticulonodular pattern with patchy areas of lower lobe consolidation, although this is not specific. Small pleural effusion may be present in 10–15% cases.

**Follow-Up Tests & Special Considerations**
- Sputum Gram stains are not helpful because *M. pneumoniae* lacks a cell wall and cannot be stained.
- *M. pneumoniae* is difficult to culture and requires 7 to 21 days to grow; culturing is successful in 40–90% of cases but does not provide information to guide treatment, thus infrequently performed.
- Complement fixation serologic assay shows 4-fold rise in IgM antibody titer at 2 to 4 weeks after symptom onset; this is an older technique.
- Positive cold agglutinins (titer of ≥1:128 or rising 4-fold) in 50% of infections but can take 1 to 2 weeks to develop; not sensitive/specific; not routinely recommended.
- CT of chest may show a combination of patchy tree-in-bud opacities with
segmental ground glass opacities.

## TREATMENT

### GENERAL MEASURES

- Avoid sick contacts.
- Treatment is usually empiric and must be comprehensive to cover all likely pathogens in the context of the clinical setting.
- Specific examples of common antibiotic treatment regimens include azithromycin, doxycycline, and levofloxacin. A sample azithromycin course would be 500 mg PO on day 1 with 250 mg daily for days 2 to 5. Levofloxacin is frequently prescribed 500 mg daily for 7 to 10 days.

### ALERT

There is insufficient evidence regarding the efficacy of antibiotics in pediatric patients <24 months of age infected with *M. pneumoniae*. However, some studies show benefit to treating with a macrolide and amoxicillin to cover *M. pneumoniae* in addition to other likely agents causing CAP (4)[A].

### Pregnancy Considerations

- Azithromycin: pregnancy Category B (preferred treatment)
- Clarithromycin, levofloxacin, and moxifloxacin: pregnancy Category C

### MEDICATION

#### First Line

- **Azithromycin**
  - <3 months of age: not established (5)[B]
  - >3 months of age: day 1, 10 mg/kg PO × 1 (not to exceed 500 mg); days 2 to 5: 5 mg/kg PO daily (not to exceed 250 mg/day)
  - Adults: 500 mg PO × 1 followed by 250 mg PO daily × 4 days
- **Doxycycline**
  - Children <8 years of age: not recommended
  - Children >8 years of age (≤45 kg): 2 to 4 mg/kg/day up to 200 mg/day PO divided BID for 10 to 14 days
– Children >8 years of age (≥45 kg): Refer to adult dosing.
– Adults: 100 mg PO BID × 7 to 14 days
– Useful in macrolide-resistant strains of *M. pneumoniae*

**Clarithromycin**
– Children <6 months of age: not established
– Patients >6 months of age: 15 mg/kg/day PO divided q12h for 10 to 14 days
– Adults: 250 to 500 mg PO BID for 10 to 14 days

**Minocycline**
– 200 mg PO/IV × 1 dose and then 100 mg BID for 7 to 10 days

**Erythromycin**
– Children: 20 to 50 mg/kg/day (base) PO divided q6–8h for 10 to 14 days
– Adults: 500 mg (base) PO q6h × 10 to 14 days

**Second Line**

**Levofloxacin**
– Children <18 years of age: not recommended
– Adults: 750 mg PO daily × 5 days

**Moxifloxacin**
– Children <18 years of age: not recommended
– Adults: 400 mg/day PO for 7 to 10 days

– Levofloxacin and moxifloxacin show good activity against *M. pneumoniae*. Consider use with comorbid conditions and other pneumonia pathogens; also useful if macrolide resistance is suspected.

**ADDITIONAL THERAPIES**

– Albuterol inhaler: 2 puffs q4–6h as needed for wheezing
– **Dexamethasone may downregulate cytokine release (6)[B].**
– Acetaminophen/ibuprofen as needed for fever
– Up to 10.9% of hospitalized patients may require mechanical ventilation.
– Plasmapheresis in cases of severe hemolytic anemia

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

– CAP score risk class IV/V
– Advanced age with comorbidities
– Complicating neoplastic disease
– Significant cerebrovascular, cardiac, renal, liver, or GI symptoms
– Altered mental status
• Inability to maintain oxygen saturation
• Tachycardia/tachypnea
• Hypotension
• Neurologic symptoms
• Signs of Stevens-Johnson syndrome
• Significant hemolysis (autoimmune hemolytic anemia, cold agglutinin disease)
• Change from IV to PO antibiotic may be made when:
  – Respiratory distress and hypoxia have resolved.
  – Patients are tolerating oral hydration.
  – No significant complications are present.
• Generally, no need for 24-hour observation on PO antibiotics prior to discharge

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

• Clearing of condition on CXR should be documented in patients >50 years of age.
• In smokers, document a clear CXR in 6 to 8 weeks.
• Worsening symptoms/development of rash or meningeal/neurologic signs should prompt immediate presentation to medical attention.
• Antibiotic prophylaxis for exposed contacts is not routinely recommended.
• For household contacts who may be predisposed to severe mycoplasmal infection, macrolide or doxycycline prophylaxis should be used.

**DIET**

• No special diet considerations
• Ensure adequate hydration.

**PATIENT EDUCATION**

• Smoking cessation
• Contact and droplet precautions
• Adequate handwashing techniques

**PROGNOSIS**

• Symptoms usually resolve in 2 weeks.
Some constitutional symptoms may persist for several weeks.
With correct therapy, even most severe cases can expect complete recovery.

COMPLICATIONS

- All complications are rare, except reactive airway disease, hemolytic anemia, and erythema multiforme.
- Reactive airway disease may persist indefinitely and can cause acute chest syndrome in patients with sickle cell anemia.
- Meningoencephalitis
- Aseptic meningitis
- Peripheral neuropathy
- Transverse myelitis/acute transverse myelitis
- Cerebellar ataxia
- Acute disseminated encephalomyelitis
- Guillain-Barré syndrome
- Encephalitis (especially in children)
- Polyneuritis/polyarthritis
- Stevens-Johnson syndrome
- Pericarditis/myocarditis
- Respiratory distress syndrome
- Cerebral ataxia
- Thromboembolic phenomena
- Pleural effusion
- Nephritis
- Occasional deaths occur primarily among the elderly and persons with sickle cell disease.

REFERENCES

**ADDITIONAL READING**

**CODES**

ICD10

J15.7 Pneumonia due to Mycoplasma pneumoniae

**CLINICAL PEARLS**

- Most common atypical respiratory pathogens include *M. pneumoniae*, *C. pneumoniae*, and *L. pneumophila*.
- Atypical pneumonia is usually a clinical diagnosis.
- Watch closely for complicating symptoms that could indicate worsening
disease.
- Atypical pneumonia with *M. pneumoniae* usually responds to empiric treatment.
- Outbreaks of *M. pneumoniae* can be seen in close communities (i.e., dormitories).
- Presentation of infection is typically a gradual onset of symptoms.
PNEUMONIA, PNEUMOCYSTIS JIROVECI
Thomas J. Hansen, MD

BASICS

DESCRIPTION
- *Pneumocystis jiroveci* causes pneumonia primarily in immunocompromised patients.
- The fungus that causes this pneumonia in humans was previously called *Pneumocystis carinii*.
- The name was formally changed to *Pneumocystis jiroveci* in 2001, following the discovery that the fungus that infects humans is unique and distinctive from the fungus that infects animals.
- *P. jiroveci* is extremely resistant to traditional antifungal agents, including both amphotericin and azole agents.
- To prevent confusion, the term PCP, which used to represent *P. carinii* pneumonia, now represents *Pneumocystis* pneumonia (1).

ALERT
No combination of symptoms, signs, blood chemistries, or radiographic findings is diagnostic of *P. jiroveci* pneumonia (2).

EPIDEMIOLOGY
- *P. jiroveci* has a worldwide distribution, and most children have been exposed to the fungus by 2 to 4 years (3).
- The reservoir and mode of transmission for *P. jiroveci* is still unclear.
  - Human studies favor an airborne transmission model, with person-to-person spread being the most likely mode of infection acquisition (2).

Incidence
- Infants with HIV infection have a peak incidence of PCP between 2 and 6 months (3).
- HIV-infected infants have a high mortality rate, with a median survival of only 1 month.
**Prevalence**
- The prevalence of *P. jiroveci* colonization among healthy adults is 0–20%.
- Recent studies have demonstrated the transient nature of *P. jiroveci* colonization in asymptomatic, immunocompetent patients (2).
- 50% of patients with PCP are coinfected with ≥2 strains of *P. jiroveci* (3).
- There is evidence that distinct strains are responsible for each episode in patients who develop multiple episodes of PCP (3).

**ETIOLOGY AND PATHOPHYSIOLOGY**
Mode of transmission is unknown; likely respiratory from infected host

**RISK FACTORS**
Individuals at risk (2)
- Patients with HIV/AIDS infection, especially if not receiving prophylactic treatment for PCP
- Patients who are receiving high doses of glucocorticoids
- Patients who have an altered immune system not due to HIV
- Patients who are receiving chronic immunosuppressive medications
- Patients who have hematologic or solid malignancies resulting in malignancy-related immune depression

**GENERAL PREVENTION**
- Indications for prophylaxis
  - HIV-infected adults (3)
    - Should start when CD4 count is <200 cells/μL or if the patient develops oropharyngeal candidiasis
  - HIV-infected children (3)
    - Prophylaxis should be provided for children ≥6 years based on adult guidelines.
    - For children aged 1 to 5 years, start when CD4 count is <500 cells/μL.
    - For infants <12 months, start when the CD4 percentage is <15%.
  - Non–HIV-infected adults receiving immunosuppressive medications or with underlying immune system deficits should receive PCP prophylaxis, but currently, there are no specific guidelines on when to start this.
- Medication
  - Trimethoprim-sulfamethoxazole (TMP-SMX)
    - Adults: 1 double-strength tablet daily or 1 double-strength tablet 3 times per week
Children >2 months: 150 mg TMP/m²/day in divided doses q12h for 3 days/week
  – Atovaquone suspension
    o Adults: 1,500 mg PO once daily with food
    o Children: not to exceed 1,500 mg/day
      ■ 1 to 3 months: 30 mg/kg/day PO once daily
      ■ 4 to 24 months: 45 mg/kg/day PO once daily
      ■ >24 months: 30 mg/kg/day PO once daily
      ■ Adolescents ≥13 years: Refer to adult dosing.
  – Dapsone
    o Adults only: 50 mg BID or 100 mg once daily
  – Pentamidine
    o Adults only: 300 mg aerosolized every 4 weeks

Discontinuation of prophylaxis
  – When CD4+ cell counts are >200 cells/µL for a period of 3 months in the adult population
  – There are no clear guidelines for discontinuation of prophylaxis in children.

COMMONLY ASSOCIATED CONDITIONS
  ● HIV/AIDS
  ● Chronic obstructive pulmonary disease (COPD)
  ● Interstitial lung disease
  ● Connective tissue diseases treated with corticosteroids
  ● Cancer and organ transplant patients on immunosuppressive medication

DIAGNOSIS

HISTORY
  ● HIV-infected patients
    – Subacute onset over several weeks
      o Progressively worsening dyspnea
      o Tachypnea
      o Cough: nonproductive or productive of clear sputum
      o Low-grade fever, chills
      o Weakness, fatigue, malaise
  ● Non–HIV-infected immunocompromised patients
    – More acute onset with fulminant respiratory failure
- Abrupt tachypnea, dyspnea
- Fever
- Dry cough

**PHYSICAL EXAM**
- Fever
- Tachypnea
- Tachycardia
- Lung exam is normal or near normal.

**DIFFERENTIAL DIAGNOSIS**
- Tuberculosis
- Bacterial pneumonia
- Fungal pneumonia
- Viral pneumonia

**DIAGNOSTIC TESTS & INTERPRETATION**
*P. jiroveci* cannot be cultured. Therefore, a diagnosis relies on detection of the organism by colorimetric or immunofluorescent stains or by polymerase chain reaction (PCR) (3)[C].
- ABG: reveals hypoxemia and increased alveolar–arterial gradient that varies with severity of disease
- LDH: Serum lactate dehydrogenase is frequently increased (nonspecific; likely due to underlying lung inflammation and injury).
- CD4 cell count is generally <200 cells/μL in HIV-infected patients with PCP.
- S-adenosylmethionine levels are significantly lower in a patient with PCP. The levels increase with successful treatment (4)[B].
- Comprehensive metabolic profile
- Chest x-ray (CXR) (2)[C]
  - Bilateral, symmetric, fine, reticular interstitial infiltrates involving perihilar areas; becomes more homogeneous and diffuse as severity of infection progresses
  - Less common patterns include upper lobe involvement in patients receiving aerosolized pentamidine, solitary or multiple nodular opacities, lobar infiltrates, pneumatoceles, and pneumothoraces.
  - May be normal in up to 30% of patients with PCP (1)[C]
- High-resolution CT is more sensitive than CXR.
Diagnostic Procedures/Other
- Fiberoptic bronchoscopy with bronchoalveolar lavage (BAL) is the preferred diagnostic procedure to obtain samples for direct fluorescent antibody staining.
  - Sensitivities range from 89% to >98%.
- Pneumocystis trophic forms or cysts obtained from induced sputum, BAL fluid, or lung tissue, which can be visualized using conventional stains.
- PCR can detect Pneumocystis from respiratory sources, but the potential remains for false positives (2)[C].

TREATMENT
The recommended duration of therapy differs in patients who are with/without AIDS:
- In patients with PCP who do not have AIDS, the typical duration of therapy is 14 days.
- Treatment of PCP in patients who have AIDS was increased to 21 days due to the risk for relapse after only 14 days of treatment (2)[C].

MEDICATION
- TMP-SMX (2)[C]
  - Adult dosing
    - TMP: 15 to 20 mg/kg/day, PO or IV, divided into 4 doses
  - Pediatric dosing (>2 months) (2)[C]
    - TMP: 15 to 20 mg/kg/day in divided doses q6–8h
  - Reduce doses of TMP-SMX in patients with renal failure.
  - Patients should receive 21 days of therapy.
- Treatment response to Pneumocystis therapy often requires at least 7 to 10 days before clinical improvement is documented.
- Pregnancy risk factor: Category C (2)[C]
- Precautions
  - History of sulfa allergy
  - There is an emergence of drug-resistant PCP, especially against TMP-SMX.

Second Line
- Pentamidine (for moderate to severe cases)
  - Adults and children: 4 mg/kg IV or IM once daily
Dapsone + trimethoprim (adults only)
  – Dapsone 100 mg PO once daily, plus
  – Trimethoprim 5 mg/kg PO TID
    o Check the glucose-6-phosphate dehydrogenase level before beginning dapsone, as hemolysis may result.

Clindamycin + primaquine (adults only)
  – Clindamycin 600 to 900 mg IV q8h or 300 to 450 mg PO QID, plus
  – Primaquine 30 mg PO once daily

Atovaquone
  – Adults: 750 mg PO BID (>13 years of age)
  – Children: 40 mg/kg/day PO divided BID (max 1,500 mg)

Note: Pentamidine has greater toxicity than TMP-SMX: hypotension, hypoglycemia, pancreatitis (2)[C].

ADDITIONAL THERAPIES
Adjunctive corticosteroid (prednisone or methylprednisolone) (2)[C],(5)[A]
  – Adjunctive corticosteroids are shown to provide benefits in patients who have HIV and symptoms of moderate to severe PCP.
  – Corticosteroids provide the greatest benefit to HIV patients who have hypoxemia manifested as a partial pressure of arterial oxygen <70 mm Hg or an alveolar–arterial oxygen gradient ≥35 mm Hg on room air.
  – Adults and children >13 years of age: prednisone, 40 mg PO BID on days 1 to 5; 40 mg daily on days 6 to 11; 20 mg daily on days 12 to 21

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
  – No set criteria for hospital admission
  – Five predictors of mortality in HIV-associated Pneumocystis pneumonia (6)
    – Increased age of the patient
    – Recent IV drug use
    – Total bilirubin >0.6 mg/dL
    – Serum albumin <3 g/dL
    – Alveolar–arterial oxygen gradient ≥50 mm Hg (6)[C]

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
In patients with HIV/AIDS: Patients with previous episodes of PCP should receive lifelong secondary prophylaxis unless they respond well to highly active antiretroviral therapy (HAART) and have a CD4 count >200 cells/μL for at least 3 months.

Patient Monitoring
Serum lactate dehydrogenase levels, pulmonary function test results, and ABG measurements generally normalize with treatment.

DIET
No special diet needed

SEE ALSO
HIV/AIDS

CODES
ICD10
B59 Pneumocystosis
CLINICAL PEARLS

- Colonization with *P. jiroveci* is common in the pediatric population.
- PCP only occurs in immunocompromised patients.
- Patients with HIV are at risk once their CD4 count is <200 cells/μL. At that time, TMP-SMX should be initiated as prophylaxis. Prophylaxis may end after HAART has been initiated and the CD4 count is >200 cells/μL for 3 months.
- Patients who are immunocompromised are also at risk. Currently, no clear clinical guidelines are available as to when to initiate or end prophylaxis.
- The first-line treatment is TMP-SMX. The typical duration of therapy is 14 days in non–AIDS-infected patients and 21 days in AIDS-infected patients.
POLYARTERITIS NODOSA

Katherine S. Upchurch, MD • De-Ann R. Williams, MBBS

BASICS

DESCRIPTION

- Polyarteritis nodosa (PAN) is an antineutrophil cytoplasmic antibody (ANCA)-negative necrotizing arteritis of medium or small arteries without glomerulonephritis or vasculitis of arterioles, capillaries, or venules (1).
- Involved systems include GI tract, peripheral nervous system (sensory and motor), central nervous system (CNS), renal (without glomerulonephritis), skin, testes/epididymis, heart (1,2)
- Features depend on location of vasculitis: mesenteric ischemia–related symptoms, new onset or worsening hypertension (HTN), mononeuritis multiplex, purpuric or nodular skin lesions, or livedo reticularis (2).
- Renal disease in PAN usually manifests as HTN and mild proteinuria with/without azotemia. Renal infarction may occur (2).
- PAN formerly encompassed several distinct entities (classic PAN, microscopic PAN, cutaneous PAN). With ANCA testing, microscopic PAN appears pathophysiologically unrelated to the other two.
  - Classic PAN is ANCA-negative (1,3).
  - Microscopic PAN has ANCAs directed against myeloperoxidase (MPO) and involvement of small arterioles (microscopic polyangiitis [MPA]). This is now classified as ANCA-associated vasculitis (1).
  - Cutaneous (or limited) PAN is a chronic disease with cutaneous lesions with characteristic histopathologic features of PAN. There are few systemic manifestations, although myalgias and peripheral motor neuropathy (mononeuritis multiplex) or sensory neuropathy may be present. ANCA positivity is variable (2,4).
- Synonym(s): periarteritis; panarteritis; necrotizing arteritis

EPIDEMIOLOGY

Incidence

- Predominant age: Peaks in 5th to 6th decade; incidence rises with age.
- 1.5:1 male predominance
Prevalence
Rare: 2 to 33 cases/1 million adults (4)

ETIOLOGY AND PATHOPHYSIOLOGY
- Segmental, transmural, necrotizing inflammation of medium and small muscular arteries, with intimal proliferation, thrombosis, and ischemia of the organ/tissue supplied by the affected arteries; aneurysm formation at vessel bifurcations (2)
- Hepatitis B–related PAN results in direct injury to the vessel due to viral replication or deposition of immune complexes, with complement activation and subsequent inflammatory response (2).
- Most cases are idiopathic; 20% are related to hepatitis B or C infection.
- In patients with PAN and hepatitis B, HBsAg has been recovered from involved vessel walls.

Genetics
Mutations of adenosine deaminase 2 (ADA 2) have been identified in families with PAN (5).

RISK FACTORS
Hepatitis B infection > hepatitis C infection (cutaneous PAN)

COMMONLY ASSOCIATED CONDITIONS
- Hepatitis B (strong association with classic PAN)
- Hepatitis C (less strongly linked to cutaneous PAN)
- Hairy cell leukemia
- 27 cases of systemic PAN following Hepatitis B vaccination
- Minocycline (symptoms resolve on stopping drug, reoccur if rechallenged)
- Case-based associations with CMV infection, amphetamines, and interferon

DIAGNOSIS
There are no formal diagnostic criteria for PAN (1,2). Suspect PAN with:
- Acute, sometimes fulminant multisystem disease with a relatively short prodrome (i.e., weeks to months)
- Vasculitic skin rash with sensorimotor symptoms/findings
- Recent-onset HTN with systemic symptoms
Unexplained sensory and/or motor neuropathy with systemic symptoms
Hepatitis B infection with multisystem disease

HISTORY
General: Symptoms reflect specific organ involvement (2).
- Constitutional symptoms (fever, weight loss, malaise)
- Organ-specific symptoms
  - Focal muscular weakness/extremity numbness
  - Myalgia and arthralgia
  - Rash
  - Recurrent postprandial pain, intestinal angina, nausea, vomiting, and bleeding
  - Altered mental status, headaches, mononeuritis multiplex
  - Testicular/epididymal pain, neurogenic bladder (rare)

PHYSICAL EXAM
Findings/course reflect specific organ involvement (2).
- Peripheral nervous system: peripheral neuropathy
- Renal: HTN
- Skin: purpura, urticaria, polymorphic rashes, subcutaneous (SC) nodules (uncommon, but characteristic), livedo reticularis; deep skin ulcers, especially in lower extremities; Raynaud phenomenon (rare); single digit gangrene (rare)
- GI: acute abdomen; rebound, guarding, tenderness
- CNS: seizures, altered mental status, papillitis
- Lung: signs of pleural effusion—dullness to percussion; decreased breath sounds
- Cardiac: signs of congestive heart failure and/or myocardial infarction—S3 gallop; pericarditis (friction rub is rare)
- Genitourinary: testicular/epididymal tenderness (can mimic testicular torsion)
- Musculoskeletal: arthritis (usually large joint in lower extremities)

DIFFERENTIAL DIAGNOSIS
- Other forms of vasculitis (ANCA-associated, such as GPA, Churg-Strauss syndrome, and MPA; Henoch-Schönlein purpura, drug-induced vasculitis, cryoglobulinemia, Goodpasture syndrome)
- Buerger disease
- Systemic lupus erythematosus (SLE)
- Embolic disease (atrial myxoma, cholesterol emboli)
Thrombotic disease (antiphospholipid antibody syndrome)
Dissecting aneurysm
Ehlers-Danlos syndrome
Multiple sclerosis, systemic amyloidosis
Infection (subacute endocarditis, HIV infection, trichinosis, rickettsial diseases)

**DIAGNOSTIC TESTS & INTERPRETATION**

- No specific laboratory abnormalities. Confirm diagnosis with biopsy if possible (3)[A].
- Angiography (conventional, CT angiography, or MR angiography) may reveal microaneurysms and/or beading of bifurcating blood vessels.
- Avoid contrast in renal disease.
- Nonspecific laboratory abnormalities:
  - Elevated ESR and CRP
  - Mild proteinuria, elevated creatinine
  - Hepatitis B surface antigen positive in 10–50%
  - Hepatitis C antibody/hepatitis C virus RNA
  - ANCA, anti-proteinase 3 (PR3), and anti-MPO are negative. Positive ANCA argues against PAN.
  - Rheumatoid factor may be positive.
  - Anemia of chronic disease (2,3)

**Initial Tests (lab, imaging)**

Lab tests to look for evidence of systemic disease and rule out other causes (2,3):

- CBC, ESR, CRP (elevated) (3)[C]
- Chemistries: elevated creatinine/BUN (3)[C]
- Hepatitis B serology: often positive; hepatitis C less commonly positive
- LFTs: abnormal if associated hepatitis B, C, or involvement of hepatobiliary tract
- Urinalysis: proteinuria/hematuria, generally no cellular casts or active urinary sediment (3)[C]
- ANA, cryoglobulins (3)[C]
- **ANCA, anti-MPO, and anti-PR3 (3)[A]**
- Complement levels (C3, C4)
- Angiographic demonstration of aneurysmal changes/beading of small and medium-sized arteries
Diagnostic Procedures/Other
- Electromyography and nerve conduction studies in patients with suspected mononeuritis multiplex. If abnormal, consider sural nerve biopsy.
- Arterial/tissue biopsy
- Skin biopsy from edges of ulcers; include deep dermis and SC fat to assess small muscular artery involvement (excisional not punch biopsy) (2,3).

Test Interpretation
- Necrotizing inflammation with fibrinoid necrosis of small and medium-sized muscular arteries; segmental, often at bifurcations and branchings. Venules are not involved in classic PAN.
- Capillaritis/other lung parenchymal involvement by vasculitis strongly suggests another process (microscopic PAN, granulomatosis with polyangiitis [GPA; formerly known as Wegener granulomatosis], Churg-Strauss syndrome, or antigranular basement membrane disease).
- Acute lesions with infiltration of polymorphonuclear cells through vessel walls into perivascular area; necrosis, thrombosis, infarction of involved tissue
- Aneurysmal dilatations, including aortic dissection
- Peripheral nerves: 50–70% (vasa nervorum with necrotizing vasculitis)
- GI vessels: 50% (at autopsy) with bowel necrosis; gallbladder and appendix vasculature: 10%
- Muscle vessels: 50%
- Testicular vessels involved in symptomatic males
- The key differences from other necrotizing vasculitides are lack of granuloma formation and sparing of veins and pulmonary arteries (2).

TREATMENT

GENERAL MEASURES
Aggressively treat HTN to prevent associated complications (stroke, myocardial infarction, heart failure).

MEDICATION
First Line
- Severe (life-threatening) disease: corticosteroids (CS) (high-dose prednisone,
methylprednisolone, or parenteral Solu-Medrol) (3,6)[A]
- Only 50% of patients achieve and maintain remission with CS. Other patients require additional immunosuppressive therapy.
- Cyclophosphamide (CTX) in combination with CS: improves survival and spares use of chronic steroids in moderate/severe PAN (3,6)[A]
  ○ CTX has risk of infertility and malignancy.
- Plasma exchange for refractory and renal disease (3)[A]
- Less severe disease: CS alone ± other immunosuppressive agents (azathioprine, methotrexate, mycophenolate mofetil) (3)[A],(4)[C],(6)[A]
- HBV-associated PAN: antiviral agents, short-term CS, plasma exchange (4)[C]

**Second Line**
- There is no well-defined second-line therapy in PAN
- Infliximab and rituximab anecdotally reported to be of benefit in refractory PAN (3,4)[C].

**ADDITIONAL THERAPIES**
- For patients receiving IV CTX, mercaptoethanesulfonate reduces bladder exposure to carcinogenic metabolites (3).
- Prophylactically treat patients on CTX for *Pneumocystis jiroveci (carinii)* pneumonia with trimethoprim-sulfamethoxazole (use dapsone or atovaquone in intolerant/allergic patients) (3).

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Depends on extent and involvement of specific organs

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- CBC, urinalysis, renal and hepatic function tests
- Acute-phase reactants (e.g., ESR, CRP) may help monitor disease activity.
- Be alert for:
  - Side effects of immunosuppressant medications
– Delayed appearance of neoplasms, especially bladder malignancy in patients treated with CTX (Check annual U/A, urinary cytology with urologic evaluation if microscopic hematuria.) (4)[C]
– Steroid-induced osteoporosis

**DIET**
Low salt (HTN)

**PATIENT EDUCATION**
ACR website: [www.rheumatology.org](http://www.rheumatology.org)

**PROGNOSIS**
- Expected outcome of untreated PAN is poor.
- Steroid and cytotoxic treatment increase 5-year survival rate to 75–80% (2).
- Survival is greater for hepatitis B–related PAN as a result of the introduction of antiviral treatments.
- Patients presenting with proteinuria, renal insufficiency, GI tract involvement, cardiomyopathy, or CNS involvement have a worse prognosis.

**COMPLICATIONS**
- End-organ damage from ischemia
- Complications from immunosuppressive agents

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Hepatitis B; Hepatitis C

**CODES**

**ICD10**

- M30.0 Polyarteritis nodosa
- M30.1 Polyarteritis with lung involvement [Churg-Strauss]
- M30.8 Other conditions related to polyarteritis nodosa

**CLINICAL PEARLS**

- PAN is a necrotizing vasculitis of small- to medium-sized muscular arteries with lack of granuloma formation that spares veins and pulmonary arteries.
- Clinical features of PAN depend on target organ involvement.
- Skin biopsies at ulcer edges (include deep dermis and SC fat) improve diagnostic yield.
- Check hepatitis B and C serologies.
- ANCA is negative in classic PAN.
- Treatment involves use of immunosuppressive drugs; choice depends on extent and severity of disease.
POLYCYSTIC KIDNEY DISEASE
Maricarmen Malagon-Rogers, MD

BASICS

DESCRIPTION
- A group of monogenic disorders that results in renal cyst development
- The most frequent are two genetically distinct conditions: autosomal dominant polycystic kidney disease (ADPKD) and autosomal recessive polycystic kidney disease (ARPKD).
- ADPKD is one of the most common human genetic disorders.

EPIDEMIOLOGY
- ADPKD is generally late onset.
  - Mean age of end-stage kidney disease (ESKD) 57 to 69 years
  - More progressive disease in men than in women
  - Up to 90% of adults have cysts in the liver.
- ARPKD usually present in infants
  - A minority in older children and young adults may manifest as liver disease.
  - Nonobstructive intrahepatic bile dilatation is sometimes seen.
  - Found on all continents and in all races

Incidence
- Mean age of ESKD: PKD1 mutation, 54.3 years versus PKD2 mutation, 74 years
- ARPKD affects 1/20,000 live births; carrier level is 1/70.
- ADPKD affects 1/400 to 1,000 live births.

Prevalence
As ESKD, ADPKD: 8.7/1 million in the United States; 7/1 million in Europe

ETIOLOGY AND PATHOPHYSIOLOGY
- ADPKD
  - PKD1 and PKD2 mutations disrupt the function of polycystins on the primary cilium, forming fluid-filled cysts that progressively increase in
size, leading to gross enlargement of the kidney, and distortion of the renal architecture.
– Glomerular hyperfiltration compensates for the progressive loss of healthy glomeruli, and therefore, by the time GFR decline becomes detectable, as much as $\frac{1}{2}$ of the original functional glomeruli are irreversibly lost.
– The majority of patients with ADPKD ultimately progress to ESKD (1).

**ARPKD**
– PKHD1 product fibrocystin is also located in cilia.
**ADPKD:** Cysts arise from only 5% of nephrons:
– Autosomal dominant pattern of inheritance but a molecularly recessive disease with the 2-hit hypothesis
– Requires genetic and environmental factors
**ARPKD:** Mutations are scattered throughout the gene with genotype–phenotype correlation.

**Genetics**
**ADPKD**
– Autosomal dominant inheritance
– 50% of children of an affected adult are affected.
– 100% penetrance; genetic imprinting and genetic anticipation are seen as well.
– Two genes isolated
  o PKD1 on chromosome 16p13.3 (85% of patients) encodes polycystin 1.
  o PKD2 on chromosome 4q21 (15% of patients) encodes polycystin 2.
**ARPKD**
– Autosomal recessive inheritance
– Siblings have a 1:4 chance of being affected; gene PKHD1 on chromosome 6p21.1–p12 encodes fibrocystin.

**RISK FACTORS**
– Large inter- and intrafamilial variability
– A more rapidly progressive clinical course is predicted by onset of ESKD at <55 years, development of stage III CKD at <40 years old, onset of HTN at <18 years, total kidney volume greater than the expected for a given age, or presence of multiple complications (gross hematuria, microalbuminuria) (1).

**GENERAL PREVENTION**
Genetic counseling
COMMONLY ASSOCIATED CONDITIONS

- **ADPKD**
  - Cysts in other organs
    - Polycystic liver disease in 58% of young age group to 94% of 45-year-olds
    - Pancreatic cysts: 5%
    - Seminal cysts: 40%
    - Arachnoid cysts: 8%
  - Vascular manifestations
    - Intracerebral aneurysms in 6% of patients without family history and in 16% with family history
    - Aortic dissections
  - Cardiac manifestations: mitral valve prolapse: 25%
  - Diverticular disease

- **ARPKD**: liver involvement: affected in inverse proportion to renal disease; congenital hepatic fibrosis with portal HTN

DIAGNOSIS

HISTORY

- **ADPKD**
  - Positive family history (15% are de novo mutations.)
  - Flank pain: 60%
  - Hematuria
  - UTI
  - HTN: 50% aged 20 to 34 years; 100% with ESKD
  - Renal failure
  - Presymptomatic screening of ADPKD is not currently recommended for at-risk children (2).
    - Blood pressure should be routinely measured in these patients.

- **ARPKD**
  - 30% of affected neonates die:
    - Enlarged echogenic kidneys and oligohydramnios are diagnosed in utero.
    - Later in childhood: HTN
  - Adolescents and adults present with complications of portal HTN:
    - Esophageal varices
    - Hypersplenism
PHYSICAL EXAM
- HTN
- Flank masses

DIFFERENTIAL DIAGNOSIS
- ADPKD and ARPKD
- Tuberous sclerosis: prevalence 1/6,000
- Von Hippel-Lindau syndrome: prevalence 1/36,000
- Nephronophthisis: accounts for 10–20% of cases of renal failure in children; medullary cystic kidney disease
- Renal cystic dysplasias: multicystic dysplastic kidneys: grossly deformed kidneys; most common type of bilateral cystic diseases in newborns (prevalence: 1/4,000)
- Simple cysts: most common cystic abnormality
  - Localized or unilateral renal cystic disease
  - Medullary sponge kidney
  - Acquired renal cystic disease
- Renal cystic neoplasms: benign multilocular cyst (cystic nephroma)

DIAGNOSTIC TESTS & INTERPRETATION
Electrolytes, BUN/creatinine, urine analysis plus urinary citrate

Initial Tests (lab, imaging)
- ADPKD
  - Renal dysfunction
    - Impaired renal concentration (3), hypocitraturia aciduria
    - Hyperfiltration
    - Elevated creatinine
    - Urinalysis: hematuria and mild proteinuria
- ARPKD
  - Electrolyte abnormalities and renal insufficiency
  - Anemia, thrombocytopenia, leukopenia
- ADPKD
  - US: It is the easiest diagnostic method; however, it is suboptimal for disease exclusion at age <40 years (2)[C].
    - Renal enlargement is universal.
    - In at-risk patients: By age 30 years, two renal cysts (bilateral or unilateral) are 100% diagnostic. In children, it sometimes appears similar
to ARPKD; may be diagnosed in utero
- Presence of hepatic cysts in young adults is pathognomonic for ADPKD.
- In the absence of family history, bilateral renal enlargement and cysts make the diagnosis.
  - CT scan/MRI ideally should be part of the initial evaluation (2)[C].
  - Kidney volume assessed by CT or MRI is a main predictor of progression.
  - Helpful in identifying cysts in other organs
- In subjects <40 years, fewer than five cysts by MRI excludes the diagnosis (2)[B].

- ARPKD
  - US: Kidneys are enlarged, homogeneously hyperechogenic (cortex and medulla).
  - CT scan is more sensitive if diagnosis is in doubt.
  - Presence of hepatic fibrosis helps the diagnosis.

**Follow-Up Tests & Special Considerations**
- Diagnosis and prevention of secondary problems because of renal and liver abnormalities.
- Follow-up of combined renal volume to assess disease severity.
- Beyond age 2 years, renal size decreases in ARPKD but continues to grow in ADPKD at an average rate of 5.27% per year. Total kidney volume identifies patients with progressive disease (2).

**Diagnostic Procedures/Other**
- Genetic testing is available for *PKD1* and *PKD2* in ADPKD when imaging results are equivocal and for potential living related donors (4)[C].
- For *PKHD1* in ARPKD, a prenatal diagnosis is feasible in about 72% of patients.

**Test Interpretation**
- ADPKD
  - Kidneys are diffusely cystic and, although enlarged, retain their general shape.
  - Cysts range from a few millimeters to several centimeters and are distributed evenly throughout the cortex and medulla.
  - They arise in all segments of the nephron, although they arise initially from the collecting ducts.
- One kidney may be larger than the other.

**ARPKD**
- Disease is a spectrum, ranging from severe renal disease with mild liver damage to mild renal disease with severe liver damage.
- Renal enlargement is due to fusiform dilatation of the collecting ducts in the cortex and medulla in the newborn period.
- Liver lesion is diffuse but limited to fibrotic portal areas.

### TREATMENT

#### GENERAL MEASURES
- **HTN:** moderate sodium restriction, weight control, and regular exercise
- **Medications:** ACE inhibitors; angiotensin receptor blockers (ARBs)
- **Pain:** narcotics and other analgesics; bed rest; limit NSAIDs (they worsen renal function).
- **Urolithiasis:** treated with alkalinization of urine and hydration therapy; surgery as needed
- **UTIs/infections of cysts:** lipid-soluble antibiotics more effective (e.g., trimethoprim-sulfamethoxazole and chloramphenicol); fluoroquinolones also useful
- **Dialysis for ESKD patients**
- **Hematuria:** Reduce physical activity.

#### MEDICATION
- No specific drug therapy is yet available for PKD, although several studies are being conducted for specific treatments (2,5)[C].
- **HTN:** should be very well controlled to prevent complications. ACE inhibitors are preferred if no contraindications are present.
  - The use of antihypertensive medications has been found to decrease mortality (6)[B].
- **Hyperlipidemia:** statins preferred

#### ISSUES FOR REFERRAL
- Nephrologist primary management
- Urologic consultation for management of symptomatic/infected cysts
- Genetic counseling is critical.
SURGERY/OTHER PROCEDURES

- Indications for surgical intervention
  - Uncontrollable HTN
  - Severe back and loin pain, abdominal fullness
  - Renal deterioration due to enlarging cysts
  - Hematuria/hemorrhage or recurrent UTI
- Open and laparoscopic cyst unroofing: may decrease pain and narcotics requirements; has not been proven to prevent renal failure or to prolong current renal function
- Percutaneous cyst aspiration ± injection of sclerosing agent; not usually performed secondary to recurrent fluid accumulation
- Renal transplant for ESKD

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

Severe pain, gross hematuria with clots

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

None in early stages of the disease; avoid vigorous activity if disease advances. Recurrent gross hematuria is secondary to trauma, associated with faster decline of renal function.

Patient Monitoring

- Monitor BP and renal function. Encourage hydration. Treat UTI and stone disease aggressively.
- Avoid nephrotoxic drugs.
- Creatinine and BP monitoring at least twice a year; more often as needed
- Screening for intracranial aneurysms (7)

DIET

- Low-protein diet may retard renal insufficiency.
- Limit caffeine because this might increase cyst growth.
- High water intake to decrease ADH >3 L/day (5) [C]
PROGNOSIS
- Renal failure in 2% by age 40 years; 23% by age 50 years; 48% by age 73 years
- ADPKD accounts for 10–15% of dialysis patients.
- No increased incidence of renal cell cancer

COMPLICATIONS
- Cyst rupture, infection, or hemorrhage
- Progression to renal failure
- Renal calculi

SEE ALSO

Chronic Kidney Disease

CODES

ICD10

- Q61.3 Polycystic kidney, unspecified
- Q61.19 Other polycystic kidney, infantile type
- Q61.2 Polycystic kidney, adult type

CLINICAL PEARLS

- Most PKD patients eventually develop ESKD. No specific treatment has been proven to prevent EKRD, but hydration and control of BP are reasonable goals and should be started soon.

- Patients may benefit from a nephrology consultation after the initial diagnosis to counsel regarding disease progression prevention. Then, they can be followed by primary care if the disease was an incidental finding or no significant kidney dysfunction is present.
POLYCYSTIC OVARIAN SYNDROME (PCOS)
Melissa Dennis, MD • Rachel Soffer Parritz, MD

BASICS

DESCRIPTION

- Polycystic ovarian syndrome (PCOS) is a common endocrine disorder with heterogeneous manifestations that affects 6–10% of the U.S. population.
- Hyperandrogenism, insulin resistance, and anovulation, typically presenting as amenorrhea or oligomenorrhea.
- Diagnostic clinical characteristics include menstrual dysfunction, infertility, hirsutism, acne, obesity, and metabolic syndrome. The ovaries are often polycystic on imaging.
- The etiology of PCOS is unknown but can be modified by lifestyle factors.
- System(s) affected: reproductive, endocrine/metabolic, skin/exocrine.
- Synonym(s): Stein-Leventhal syndrome; polycystic ovary disease.

ALERT

- Condition may begin at puberty.
- Predisposes to and is associated with obesity, hypertension, diabetes, metabolic syndrome, hyperlipidemia, infertility, insulin-resistance syndrome, endometrial hyperplasia, and uterine cancer.
- In the United States, 40% of women with PCOS are not obese.

EPIDEMIOLOGY

Prevalence

- Incidence and prevalence are still highly debated due to a wide spectrum of diagnostic features: The National Institutes of Health (NIH) criteria require chronic anovulation in addition to clinical or biochemical signs of hyperandrogenism. The prevalence based on NIH criteria is 6.5–8%.
- Predominant age: reproductive age
- Predominant sex: females only

ETIOLOGY AND PATHOPHYSIOLOGY
PCOS is a multifactorial functional disorder of unclear etiology.
Recent evidence points to a primary role for insulin resistance with hyperinsulinemia.
Increased GnRH pulsations in the hypothalamus lead to increased production of luteinizing hormone (LH) with limited production of FSH.
Hyperandrogenism: Ovaries are the main source of excess androgens. Polycystic ovaries have thickened thecal layers, which secrete excess androgens in response to LH. LH receptors are overexpressed in thecal and granulosa cells of polycystic ovaries.
Ovarian follicles: Abnormal androgen signaling may account for abnormal folliculogenesis causing polycystic ovaries.
Insulin resistance: Women with PCOS have insulin resistance similar to that in type 2 diabetes. Elevated levels of insulin decrease sex hormone–binding globulin (SHBG), increasing bioavailability of testosterone. Insulin may also act directly on adrenal glands, ovaries, and hypothalamus to enhance androgen production. Insulin resistance also causes elevated insulin levels.
Insulin resistance may cause the frequently associated metabolic syndrome and frank diabetes mellitus.

**Genetics**
- Likely a combination of polygenic and environmental factors
- Implicated genes include *DENND1A* and *THADA*.

**RISK FACTORS**
See “Commonly Associated Conditions”; cause and effect are difficult to extricate in this disorder.

**GENERAL PREVENTION**
None known; focus on early diagnosis and treatment to prevent long-term complications.

**COMMONLY ASSOCIATED CONDITIONS**
- Infertility
- Obesity
- Obstructive sleep apnea
- Hypertension
- Diabetes mellitus
- Endometrial hyperplasia/carcinoma
• Fatty liver disease
• Mood disturbances and depression
• Hirsutism

**DIAGNOSIS**

**HISTORY**

• A comprehensive history, including a family history of diabetes and premature onset of cardiovascular disease, is important in the differential diagnosis.
• Focus on the onset and duration of the various signs of androgen excess, menstrual history, and concomitant medications, including the use of exogenous androgens (1).
• Unpredictable, heavy, or absent menstrual cycles

**PHYSICAL EXAM**

• Vital signs: elevated body mass index (BMI)
• General appearance: central obesity, hirsutism, acne
• Skin: male hair pattern, acne, seborrhea, acanthosis nigricans
• Pelvic: ovarian enlargement

**ALERT**

Look specifically for signs of virilization, such as hair pattern, deepened voice, and clitoromegaly as they indicate significant testosterone levels beyond that of PCOS.

**DIFFERENTIAL DIAGNOSIS**

• Cushing syndrome
• HAIR-AN syndrome
• Androgen-secreting ovarian or adrenal tumor
• Prolactin-producing pituitary adenoma
• Hyperthecosis
• Adult-onset adrenal hyperplasia
• Partial congenital adrenal hyperplasia (21-hydroxylase deficiency)
• 11β-Hydroxylase deficiency
• 17β-Hydroxysteroid dehydrogenase deficiency
• Acromegaly
• Drug-induced hirsutism, oligo-ovulation (e.g., danazol, steroids, valproic acid)
• Thyroid disease
• Idiopathic hirsutism
• Polycystic ovaries

**DIAGNOSTIC TESTS & INTERPRETATION**

• The value of measurement of circulating androgens to document PCOS is uncertain but should include calculating free testosterone concentration using mass spectrometry of total testosterone and measurement of SHBG (2)[C].
• Most common diagnostic criteria used is Rotterdam criteria (need 2 of 3):
  – Oligo- or anovulation
  – Clinical and/or biochemical signs of hyperandrogenism
  – Transvaginal ultrasonographic polycystic ovaries and exclusion of other etiologies; therefore, consider exclusion of Cushing disease, congenital adrenal hyperplasia, and androgen-secreting tumors.
• Ultrasonographic polycystic ovaries are not necessary for the diagnosis of PCOS.
• More recent criteria also focus on similar criteria while acknowledging that there may be forms of PCOS without overt evidence of hyperandrogenism (3)[C].

**Initial Tests (lab, imaging)**

• Screening workup should rule out pregnancy, thyroid disease, hyperprolactinemia, and premature ovarian failure with human chorionic gonadotropin (hCG), TSH, prolactin, FSH, respectively.
• Hirsute women should have a free testosterone determination (based on total testosterone minus SHBG) and a DHEA-S.
• Consider 17-OH progesterone if congenital adrenal hyperplasia is suspected.
• Typical findings in PCOS include testosterone increased but <200 ng/dL (6.94 nmol/L), mild elevation in DHEA-S but <800 μg/dL (20.8 μmol/L), mild increase in 17-OH progesterone level, increased estrogen level, and decreased SHBG.
• More elevated levels of testosterone or DHEA-S may be associated with an androgen-secreting tumor of the ovaries or adrenal glands.
• Anovulation can be determined by a midluteal phase progesterone level (>3 ng/mL if the woman has ovulated).
• LH/FSH level ≥2.5 to 3.0 L in ~50% of women with PCOS, but LH testing is not generally necessary
• Drugs that may alter lab results:
  – Oral contraceptive pills (OCPs)
- Steroids
- Antidepressants
- Transvaginal ultrasound findings: one or both ovaries with ≥12 follicles measuring 2 to 9 mm or increased ovarian volume to 10 cm³

**Follow-Up Tests & Special Considerations**
- Consider fasting serum glucose, insulin level, and plasminogen activator inhibitor-1 determinations to establish presence of insulin resistance and glucose intolerance, especially if diagnosis is in doubt.
- Overnight dexamethasone suppression test to rule out Cushing syndrome in the appropriate setting
- Endometrial biopsy to rule out hyperplasia and/or carcinoma, if indicated
- If the syndrome is diagnosed, determination of fasting glucose and fasting lipid levels should be performed and formal glucose tolerance test is considered.

**ALERT**
Prolonged or heavy bleeding should prompt an endometrial biopsy for evaluation of endometrial hyperplasia and possible cancer.

**Test Interpretation**
- Ovary is usually enlarged with a smooth white glistening capsule.
- Ovarian cortex is lined with follicles in all stages of development, but most atretic.
- Thecal cell proliferation with an increase in the stromal compartment

**TREATMENT**

**GENERAL MEASURES**
Lifestyle changes including appropriate nutrition and exercise to decrease body weight by as little as 5% can restore ovulation and increase insulin sensitivity (4) [A]. Treatment plan should be individualized based on patient needs and desires.

**MEDICATION**
- The goal of treatment in PCOS depends on symptoms and patient’s goals for fertility.
- Treatment can be divided into four main categories: (i) restore menses, (ii)
decrease insulin resistance, (iii) ameliorate androgen excess, (iv) assist in fertility.

**First Line**

- **Restore menses when pregnancy not desired:**
  - OCPs and progestins provide improvement in menstrual irregularity and provide endometrial protection.
  - Low-dose OCPs (30 to 35 μg); newer formulations containing progestins with lower androgenicity (e.g., norethindrone, desogestrel, norgestimate, drospirenone) may be particularly beneficial, but all OCPs increase SHBG and decrease excess androgen.
  - Levonorgestrel IUD offers endometrial protection and pregnancy prevention but will not counteract hyperandrogenism (2).

- **If unable to tolerate OCPs, then intermittent medroxyprogesterone (Provera) 10 mg PO or micronized progesterone (Crinone and Prometrium): 200 mg PO for 10 to 14 days can be given every 1 to 3 months (2)[C]. These offer endometrial protection. However, these will not counteract hyperandrogenism nor protect against pregnancy. Decrease insulin resistance:**
  - Metformin may help to correct metabolic abnormalities in women who are insulin resistant. Initial dose is 500 mg daily for 1 week, increasing by 500 mg/week to a total of 1,500 to 2,000 mg/day divided BID; take with food.
    - Overall, data support the usefulness of metformin on both cardiometabolic risk and reproduction assistance in PCOS women.
    - Thiazolidinediones may increase likelihood of ovulation and treat insulin resistance.

- **If pregnancy is desired:**
  - Ovulation induction with clomiphene (Clomid, Serophene) and/or exogenous gonadotropins. Live birth rate with Clomid is 22.5%. Dosing starts on day 5 with 50 mg daily for 5 days.
  - Letrozole: an aromatase inhibitor for management of infertility. Live birth rate with letrozole is 27.5%, which is significantly higher than with Clomid. However, this effect may only be present in obese women.
  - Metformin: 500 to 2,000 mg PO divided BID has been shown to improve hyperandrogenism and restore ovulation. Some providers will choose to continue metformin throughout the 1st trimester or the entire pregnancy if there is a history of spontaneous abortion or glucose intolerance. It does improve ovulation rates and insulin resistance but does not improve live birth rates alone or in combination with clomiphene when used for ovulation induction (5)[B].
– Metformin reduces the incidence of gestational diabetes.

**Second Line**

- **Acne:**
  - OCPs with low doses of cyproterone or drospirenone
  - Spironolactone: 50 to 200 mg daily in 1 to 2 divided doses for acne and hirsutism not addressed by OCP therapy. This medication is unsafe in pregnancy, and potassium levels must be followed closely when used.
- **Hirsutism:**
  - Eflornithine hydrochloride 13.9% cream twice daily
  - Finasteride 2.5 to 5.0 mg daily

**ISSUES FOR REFERRAL**

- To reproductive endocrinologist for all women who cannot achieve pregnancy with Clomid
- To endocrinologist if Cushing syndrome, congenital adrenal hyperplasia, or adrenal or ovarian tumors are found during the workup

**ADDITIONAL THERAPIES**

Mechanical means of hair removal, including laser, electrolysis, waxing, and depilatory, may improve cosmesis.

**SURGERY/OTHER PROCEDURES**

Ovarian wedge resection and laparoscopic laser drilling are controversial and rarely used today.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

Acupuncture may assist with cycle normalization and weight loss.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

6-month intervals to evaluate response to therapy and to monitor weight and medication side effects.
**Patient Monitoring**

- Counsel patient about the risk of endometrial and breast carcinoma, insulin resistance, and diabetes as well as obesity and its role in infertility.
- See patient frequently throughout the menstrual cycle, depending on which drug combination is used to induce ovulation.
- All patients with PCOS who have not received medication or IUD for endometrial protection and have been amenorrheic for 1 year should undergo endometrial biopsy.

**DIET**

In overweight patients, weight loss is the most successful therapy because it improves cardiovascular risk, insulin sensitivity, menstrual patterns, and infertility: Counsel on lifestyle dietary changes; consider referral to nutritionist and weight center. No specific diet plan is proven to be better than another.

**PATIENT EDUCATION**

- Provide patient with information about PCOS, such as from [http://www.acog.org/](http://www.acog.org/).
- Discuss the chronic nature of this condition and the risks and benefits and side effects of potential treatments.
- Review the importance of weight loss, if applicable. Modest weight loss of 5–10% of initial body weight has been demonstrated to improve many of the features of PCOS.

**PROGNOSIS**

- Fertility prognosis is good but may need assisted reproductive technologies.
- Proper follow-up and screening can prevent endometrial carcinoma.
- Early detection of diabetes may decrease morbidity and mortality associated with cardiovascular risk factor.

**COMPLICATIONS**

- Reproductive: infertility
- Metabolic: insulin resistance, diabetes mellitus, cardiovascular disease
- Psychosocial: increased anxiety, mood disorder, eating disorder, depression
- Predisposes to endometrial hyperplasia and as high as 9% lifetime risk of endometrial cancer

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: [Amenorrhea, Secondary](#)

**CODES**

**ICD10**
- E28.2 Polycystic ovarian syndrome
- L68.0 Hirsutism

**CLINICAL PEARLS**
- Based on Rotterdam criteria, PCOS is diagnosed based on 2 of 3 of: (i) oligo-ovulation, (ii) clinical or biochemical signs of hyperandrogenism, (iii) polycystic ovaries.
- Polycystic ovaries are not required for the diagnosis of PCOS.
- All patients with anovulation should be evaluated for pregnancy.
Chronic anovulation should be treated because chronic estrogen stimulation in absence of progesterone may lead to endometrial hyperplasia.

Specific therapies must be individualized according to the needs and desires of each patient.
POLYCYTHEMIA VERA

Imola K. Osapay, MD • Scott D. Everett, MD

BASICS

DESCRIPTION

- Polycythemia vera (PV) is a chronic myeloproliferative clonal stem cell disorder marked by increased production of red blood cells (erythrocytosis) with excessive erythroid, myeloid, and megakaryocytic elements in the bone marrow.
- Morbidity and mortality are primarily related to complications from blood hyperviscosity leading to thrombosis development as well as malignant transformation. Untreated patients may survive 6 to 18 months. Adequate treatment may extend life to >10 years.
- Myelofibrosis can develop in the bone marrow, leading to progressive hepatosplenomegaly.
- Synonyms: primary polycythemia; maladie de Vaquez disease; Waldenström disease; primary PV; PV rubra; polycythemia, splenomegalic; Vaquez-Osler disease

EPIDEMIOLOGY

Incidence

- Predominant age: 50 to 75 years; however, can occur in early adulthood and childhood
- Predominant sex: male > female (slightly)
- Incidence in the United States in 2012: 2.8/100,000 population of men and 1.3/100,000 population of women; highest for men 70 to 79 years at 24/100,000 persons per year

Prevalence

In the United States in 2010, estimates ranged from 45 to 57 cases/100,000 patients.

ETIOLOGY AND PATHOPHYSIOLOGY

JAK2 V617F mutation associated with clonal proliferative disorder
Genetics

*JAK2 V617F* (tyrosine kinase) mutation: >97% of patients with PV have an activating mutation; this is helpful in differentiating from secondary erythrocytosis. Homozygote carriers will have higher incidence of symptoms such as pruritus but will not have higher incidence of disease than heterozygotes.

**RISK FACTORS**
- PV may be slightly more prevalent among Jews of Eastern European descent than other Europeans or Asians.
- Familial history is rare.

**COMMONLY ASSOCIATED CONDITIONS**
- Budd-Chiari syndrome
- Ischemic digits
- Mesenteric artery thrombosis
- Myocardial infarction
- Cerebrovascular accident or transient ischemic attack
- Venous thromboembolism and pulmonary embolism

**DIAGNOSIS**

**HISTORY**
- Patients may be asymptomatic or present with nonspecific complaints, including fatigue, malaise, weight loss, sweating, and subjective weakness.
- Erythromelalgia (burning pain of feet/hands, occasionally with erythema, pallor, cyanosis, or paresthesias)
- Pruritus, especially after bathing (aquagenic pruritus)
- Arterial and venous occlusive events
- Headaches
- Blurred vision or blind spots
- Tinnitus, vertigo, dizziness
- Spontaneous bruising/bleeding
- Peptic ulcer disease (due to alterations in gastric mucosal blood flow)
- Early satiety due to enlarged spleen
- Bone pain (ribs and sternum)
- Gout
- Insomnia
• Depressed mood

PHYSICAL EXAM
• Hypertension (46%)
• Splenomegaly (75%), palpable spleen (36%)
• Hepatomegaly (30%)
• Facial plethora (ruddy cyanosis)
• Bone tenderness (especially ribs and sternum)
• Skin excoriations from significant pruritus
• Gouty tophi or arthritis
• Injection of the conjunctival small vessels and/or engorgement of the veins of the optic fundus

DIFFERENTIAL DIAGNOSIS
• Secondary erythrocytosis:
  – Sleep apnea
  – Emphysema
  – Cigarette smoking
  – Renal artery stenosis
  – Carbon monoxide poisoning
  – Drugs: diuretics, testosterone, erythropoietin (EPO)
• Hemoglobinopathy
• Ectopic EPO production
• Spurious polycythemia

DIAGNOSTIC TESTS & INTERPRETATION
• CBC; if suspicion is high, then obtain EPO level and gene testing for JAK2 V617F.
• If the only indication of PV is elevated Hgb/Hct, a CBC should be repeated. Further testing is unnecessary if the Hgb/Hct return to normal.

Initial Tests (lab, imaging)
• 2016 World Health Organization diagnostic criteria requires all three major criteria or the first 2 major criteria and the minor criterion*(1).
  – Major criteria:
    o Hemoglobin (Hgb) >16.5 g/dL (men); Hgb >16.0 g/dL (women) or Hct >49% (men); Hct >48% (women) or increased cell mass (>25% above mean normal predictive value).
Bone marrow biopsy showing hypercellularity for age with trilineage growth (panmyelosis) including prominent erythroid, granulocytic, and megakaryocytic proliferation with pleomorphic, mature megakaryocytes (difference in sizes)

- Presence of JAK2 V617F or similar mutation such as JAK2 exon 12 mutation
  - Minor criteria:
    - Serum EPO level below normal *criterion number 2 (BM biopsy) may not be required in cases with substantive absolute erythrocytosis: Hgb >18.5 g/dL in men (Hct, 55.5%) or >16.5 g/dL in women (Hct, 49.5%) if major criterion 3 and minor criterion are present. However, initial myelofibrosis (present in up to 20% of points) can only be detected by performing a bone marrow biopsy; this finding may predict a more rapid progression to overt myelofibrosis (post-PV MF).

- Diagnosis can be made reliably based on clinical symptoms, presence of JAK2 V617F mutation, and low EPO (2).
- Other lab findings that are common but not specific
  - Hyperuricemia
  - Hypercholesterolemia
  - Elevated serum vitamin B\textsubscript{12} levels
  - Prolonged PT, aPTT due to low plasma volume
  - Thrombocytosis (>400,000 platelets/mm\textsuperscript{3})
  - Leukocytosis (>12,000/mm\textsuperscript{3})
  - Leukocyte alkaline phosphatase (100,000 units in the absence of fever or infection)
- CT or US to assess for splenomegaly, although not necessary for diagnosis
- Arterial oxygen saturation (<92% SaO\textsubscript{2}) and carboxyhemoglobin (COHb)
- Bone marrow biopsy is not necessary. There is no staging system for this disease.

**Diagnostic Procedures/Other**
- Bone marrow aspiration if performed shows hypercellularity of erythroid, granulocytic and megakaryocytic lines, or myelofibrosis.
- Cytogenetic testing (JAK2 V617F)

**Test Interpretation**
- If JAK2 V617F mutation testing is negative and the EPO level is normal or high, then PV is excluded; investigate causes of secondary erythrocytosis.
Other causes of erythrocytosis such as ectopic EPO production from a renal tumor, hypoxia from chronic lung, or cyanotic heart disease can be excluded with low or undetectable serum EPO level and normal oxygen saturation.

**TREATMENT**

**GENERAL MEASURES**

- Risk factors: Patients >60 years with history of thrombosis are high risk. Those who are <60 years with no history of thrombosis but with elevated platelets (>150,000) are intermediate risk. <60 years, with normal platelets and no history of thrombosis are low risk.
- Although not curative, modern therapy for PV can relieve symptoms and prolong survival.
- Phlebotomy and low-dose aspirin is first-line therapy for all patients.
- If secondary PV, address etiology: aggressive treatment of obstructive sleep apnea, COPD (esp. smoking cessation), renal disease; consider lowering dose in testosterone replacement.
- Phlebotomy reduces the blood hyperviscosity, improves platelet function, restores systemic pressures, and decreases risk of thrombosis.
- Phlebotomy:
  - Reduce hematocrit to <45%; will significantly lower rate of cardiovascular death and major thrombosis (3)[A]
  - Performed initially as often as every 2 to 3 days until normal hematocrit reached; phlebotomies of 250 to 500 mL. Reduce to 250 to 350 mL in elderly patients or patients with cerebrovascular disease.
  - Frail patients should have volume replaced with saline solution to avoid postural hypotension.
  - High risk for thrombosis or presence of elevated platelet count is indication for cytoreductive therapy.
  - Complications of phlebotomy: chronic iron deficiency (symptomatology: pica, angular stomatitis, and glossitis), possible muscle weakness, and dysphagia that is the result of esophageal webs (very rare).
- Other therapies:
  - Maintain hydration.
  - Pruritus therapy: H₁ and H₂ blockers, SSRIs, oatmeal baths, interferon α-2b
  - Uric acid reduction therapy
MEDICATION

First Line

- Primary therapies:
  - Low-dose aspirin 81 mg PO has been associated with a statistically nonsignificant reduction in the risk of fatal thrombotic events without increasing bleeding complications when used in conjunction with phlebotomy (4)[A].
  - Hydroxyurea is recommended for patients at high risk for thrombosis (age >60 years or history of thrombotic event) and with splenomegaly and hepatomegaly. Common starting dose 500 to 1,500 mg PO daily, titrating to control hematocrit and platelet count. Be aware that hydroxyurea can lead to higher risk of leukemic transformation (5)[A].
  - Radioactive phosphorus (32P) may control Hgb level and platelet count by destroying overactive marrow cells. May take up to 3 months before affecting cells. Consider for patients intolerant or nonadherent to hydroxyurea or short expected survival due to mutagenic potential.
  - Tyrosine kinase inhibitor imatinib 400 to 800 mg daily was shown to have moderate cytoreductive effects in PV (6)[B].
  - Pegylated interferon α-2a is effective in controlling erythrocytosis, although dosing is generally limited secondary to intolerable side effects.
  - Refer to hematologist/oncologist for further dosing and instructions.

- Symptomatic/adjunctive:
  - Allopurinol 300 mg/day PO for uric acid reduction
  - Cyproheptadine 4 to 16 mg PO daily as needed for pruritus
  - H2-receptor blockers or antacids for GI hyperacidity; cimetidine is also used for pruritus.
  - SSRIs (paroxetine or fluoxetine) have shown some efficacy in controlling pruritus.
  - Ultraviolet light may help with pruritus.

Second Line

Myelosuppression: chlorambucil or busulfan; busulfan at 2 to 4 mg daily may be effective option for elderly patients with advanced PV refractory or intolerant to hydroxyurea, but significant rate of transformation was observed.

ISSUES FOR REFERRAL

Referral to a hematologist to assist in diagnosis and management
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Monitor hematocrit often and phlebotomize as needed to maintain target goal.

DIET
- Avoid high-sodium diet; can cause fluid retention
- Avoid iron supplement, a permissive chronic state of iron deficiency can help decrease blood production.

PATIENT EDUCATION
- Perform leg and ankle exercises to prevent clots.
- Continuous education regarding possible complications and seeking treatment early for any change or increase in symptoms

PROGNOSIS
- PV cannot be cured but can be controlled with treatment.
- Survival is >15 years with treatment.
- Patients are at risk for developing postpolycythemic myelofibrosis (PPMF) and an increased risk of malignant transformation.

COMPLICATIONS
- Splenomegaly or hepatomegaly
- Budd-Chiari syndrome
- Vascular thrombosis (major cause of death) (20%)
- Transformation to acute leukemia (5%)
- Transformation to myelofibrosis (10%)
- Hemorrhage
- Peptic ulcer
- Uric acid stones
- Secondary gout
- Increased risk for complications and mortality from surgical procedures. Assess risk/benefits and ensure optimal control of disorder before any elective surgery.

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

Myeloproliferative Neoplasms

**CODES**

**ICD10**

- D45 Polycythemia vera
- D75.1 Secondary polycythemia
CLINICAL PEARLS

- Erythrocytosis: Hgb >16.5 g/dL in men, >16.0 g/dL in women
- JAK2 mutations are an important component of myeloproliferative disorders.
- Bone marrow biopsy can help in diagnosis showing hypercellularity and trilineage growth.
- Common complications include thrombosis, malignant transformation, and myelofibrosis.
- All patients should take low-dose aspirin unless there is major bleeding or GI intolerance.
- Phlebotomy is first-line treatment, and consultation with an experienced hematologist is recommended.
POLYMYALGIA RHEUMATICA
Ronald G. Chambers Jr., MD, FAAFP • Megan Babb, DO

BASICS

DESCRIPTION
- A clinical syndrome characterized by pain and stiffness of the shoulder, hip girdles, and neck. Patients may use the term stiffness and pain interchangeably (1).
- Primarily impacts the elderly, associated with morning stiffness and elevated markers of inflammation
- System(s) affected: musculoskeletal; hematologic/lymphatic/immunologic
- Synonym(s): senile rheumatic disease, polymyalgia rheumatica (PMR) syndrome, pseudo-polyarthritis rhizomélique

Geriatric Considerations
- Incidence increases with age.
- Average age of onset ~70 years

Pediatric Considerations
Rare in patients <50 years of age. The peak incidence of PMR is between ages 70 and 80 years (2).

EPIDEMIOLOGY

Incidence
- Incidence increases after age 50 years. Incidence of PMR and giant cell arteritis (GCA) in the United States is 50 and 18 per 100,000 people respectively.
- Predominant sex: female > male (2 to 3:1)
- Most common in Caucasians, especially those of northern European ancestry

Prevalence
- Prevalence in those >50 years old: 700/100,000

ETIOLOGY AND PATHOPHYSIOLOGY
- Unknown. Symptoms relate to enhanced immune system and periarticular
inflammatory activity.

- **Pathogenesis**
  - Polygenic; involves multiple environmental and genetic factors
  - Significant association between histologic evidence of GCA and parvovirus B19 DNA in temporal artery specimen

**Genetics**
Associated with human leukocyte antigen determinants (HLA-DRB1*04 and DRB1*01 alleles)

**RISK FACTORS**
- Age >50 years
- Presence of GCA

**COMMONLY ASSOCIATED CONDITIONS**
Concurrent GCA (temporal arteritis) in ~15–30% of patients; more commonly in females than males

**DIAGNOSIS**

**HISTORY**
- Suspect PMR in elderly patients with new onset of proximal limb pain and stiffness (neck, shoulder, hip).
- Difficulty rising from chair or combing hair (proximal muscle involvement)
- Nighttime pain
- Systemic symptoms in ~25% (fatigue, weight loss, low-grade fever)

**PHYSICAL EXAM**
- Decreased range of motion (ROM) of shoulders, neck, and hips
- Muscle strength is usually normal—may be limited by pain and/or stiffness.
- Muscle tenderness
- Disuse atrophy
- Synovitis of the small joints and tenosynovitis
- Coexisting carpal tunnel syndrome

**DIFFERENTIAL DIAGNOSIS**
- Rheumatoid arthritis (RA)
• Palindromic rheumatism
• Late-onset seronegative spondyloarthropathies (e.g., psoriatic arthritis, ankylosing spondylitis)
• Systemic lupus erythematosus; Sjögren syndrome; fibromyalgia
• Polymyositis-dermatomyositis (Check creatine phosphokinase, aldolase.)
• Thyroid disease
• Hyperparathyroidism, hypoparathyroidism
• Hypovitaminosis D
• Osteoarthritis
• Rotator cuff syndrome; adhesive capsulitis
• RS3PE syndrome (remitting seronegative symmetrical synovitis with pitting edema)
• Occult infection or malignancy (e.g., lymphoma, leukemia, myeloma, solid tumor)
• Myopathy (e.g., steroid, alcohol, electrolyte depletion)
• Depression

DIAGNOSTIC TESTS & INTERPRETATION
• Consider PMR in patients >50 years of age with proximal pain and stiffness. In these cases, obtain laboratory work and consider a diagnostic/therapeutic trial of low-dose steroids.
• Temporal artery biopsy if symptoms of GCA present
• ESR (Westergren) elevation >40 mm/hr
  – ESR generally elevated, sometimes >100 mm/hr
  – ESR normal (<40 mm/hr) in 7–22% of patients
• Elevated C-reactive protein
• Normochromic/normocytic anemia
• Anti-cyclic citrullinated peptide (anti-CCP) antibodies usually negative (in contrast to elderly-onset RA)
• Rheumatoid factor (RF): negative (5–10% of patients >60 years have positive RF without RA)
• Mild elevations in liver function tests, especially alkaline phosphatase
• Antibodies to ferritin peptide may be a useful diagnostic marker.
• Prednisone may alter lab results.
• Other disorders may cause elevation of ESR (e.g., infection, neoplasm, renal failure).
• Normal EMG
• Normal muscle histology
Initial Tests (lab, imaging)
- ESR (usually >40 mm/hr)
- C-reactive protein
- CBC
- MRI is not necessary for diagnosis but may show periarticular inflammation, tenosynovitis, and bursitis.
- US may show bursitis, tendinitis, and synovitis.
- MRI, PET, and temporal artery US may help in diagnosis of PMR.
- Recent ACR/EULAR Classification Criteria help confirm the clinical diagnosis (3).
- 18F-fluorodeoxyglucose PET scanning prior to glucocorticoid therapy improves diagnostic accuracy (4).
- A scoring algorithm (3) was devised consisting of the following: morning stiffness >45 minutes (2 points), hip pain/limited ROM (1 point), absence of RF and anti-citrullinated protein antibody (ACPA) (2 points), and absence of peripheral joint pain (1 point).
- A score of >4 has 68% sensitivity and 78% specificity.

Diagnostic Procedures/Other
Biopsy the temporal artery in patients with symptoms suggestive of GCA. Treat empirically pending biopsy results.

TREATMENT

GENERAL MEASURES
- Address risk of steroid-induced osteoporosis.
  - Obtain dual energy x-ray absorptiometry and check 25-OH vitamin D levels if necessary.
  - Consider antiresorptive therapies (bisphosphonates) based on recommendations for treatment of corticosteroid-induced osteoporosis.
- Encourage adequate calcium (1,500 mg/day) and vitamin D (800 to 1,000 U/day) supplementation.
- Physical therapy for ROM exercises, if needed

MEDICATION

First Line
● Prednisone: 10 to 20 mg/day PO initially; expect a dramatic (diagnostic) response within days. 15 mg/day is effective in almost all patients.
  – May increase to 20 mg/day if no immediate response
  – If no response to 10 to 20 mg/day within a week, reconsider diagnosis.
● Divided-dose steroids (BID or TID) may be useful initially (especially if symptoms recur in the afternoon).
● Consider using delayed-release prednisone taken at bedtime, which may help treat morning stiffness compared to immediate-release prednisone.
● Begin slow taper by 2.5 mg decrements every 2 to 4 weeks to a dose of 7.5 to 10.0 mg/day. Below this dose, taper by 1 mg/month to prevent relapse.
● Increase prednisone for symptom relapse (common).
● Corticosteroid treatment often lasts several years.
● May stop after 6 to 12 months if symptom-free and ESR is normal
● Contraindications
  – Use steroids with caution in patients with chronic heart failure, diabetes mellitus (or other immunocompromised state), and systemic fungal or bacterial infection.
  – Treat any concurrent infections.
● Precautions
  – Long-term steroid use (>2 years) is associated with sodium and water retention, exacerbation of chronic heart failure, hypokalemia, increased susceptibility to infection, osteoporosis, fractures, hypertension, cataracts, glaucoma, avascular necrosis, depression, and weight gain.
  – Patients may develop temporal arteritis while on low-dose corticosteroid treatment for polymyalgia. This requires an increase in dose to 40 to 60 mg.
  – Alternate-day steroids are not effective.

Second Line
● NSAIDs usually are not adequate for pain relief.
● Methotrexate modestly reduces relapse rate and lowers the cumulative dose of steroid therapy.
● There is conflicting steroid-sparing evidence for anti-tumor necrosis factor (anti-TNF) agents (infliximab, etanercept).
● Anti–interleukin-6 (anti–IL-6) therapy under study (5,6)
● Corticosteroid injections (shoulder) may help reduce pain and duration of morning stiffness, allowing for increased levels of activity.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Monthly evaluations initially and during medication taper; every 3 months otherwise
- Follow ESR as steroids are tapered; ESR and CRP should decline as symptoms improve.
- Follow up immediately for symptoms of GCA (e.g., headache, visual loss, and diplopia).
- Monitor side effects of corticosteroid therapy (osteoarthritis, hypertension, and hyperglycemia).
- If patient is asymptomatic, do not treat elevated ESR (do not increase steroid dose to normalize ESR).

DIET
- Regular diet
- Adequate calcium and vitamin D

PATIENT EDUCATION
- Review adverse effects of corticosteroids.
- Discuss the symptoms of GCA and instruct to present immediately if any occur.
- Follow up if symptoms recur during steroid taper.
- Never abruptly stop steroids.
- Ensure adequate calcium and vitamin D intake.
- Patient resources:
  - Arthritis Foundation: www.arthritis.org/
  - American College of Rheumatology: http://www.rheumatology.org/Practice/Clinical/Patients/Diseases_And_Conditions/Polymyalgia_Rheumatica/

PROGNOSIS
- Most patients require at least 2 years of corticosteroid treatment.
- Exacerbation or relapse is common if steroids tapered too quickly.
- Prognosis is very good with proper treatment.
- Relapse is common (in 25–50% of patients).
- Higher age at diagnosis, female sex, high baseline ESR, increased plasma
viscosity, increased levels of soluble IL-6 receptor, or high initial steroid dose have been associated with a prolonged disease course and greater number of disease flares.

COMPLICATIONS

- Complications related to chronic steroid use
- Exacerbation of disease with taper of steroids; development of GCA (may occur when PMR is being treated adequately)

REFERENCES

ADDITIONAL READING

**SEE ALSO**

Arteritis, Temporal; Arthritis, Rheumatoid (RA); Depression; Fibromyalgia; Osteoarthritis; Polymyositis/Dermatomyositis

**CODES**

**ICD10**

- M35.3 Polymyalgia rheumatica
- M31.5 Giant cell arteritis with polymyalgia rheumatica

**CLINICAL PEARLS**

- Consider PMR in patients >50 years who present with hip, neck, and/or shoulder pain and stiffness.
- A normal ESR does not exclude PMR.
- If there is not a dramatic and rapid response to steroids, reconsider the diagnosis.
- Adjust steroids according to symptoms, not ESR.
POLYMYOSITIS/DERMATOMYOSITIS

Nehal R. Shah, MD • Christopher M. Wise, MD

BASICS
DESCRIPTION
- Systemic connective tissue disease characterized by inflammatory and degenerative changes in proximal muscles, sometimes accompanied by characteristic skin rash
  - If skin manifestations (Gottron sign [symmetric, scaly, violaceous, erythematous eruption over the extensor surfaces of the metacarpophalangeal and interphalangeal joints of the fingers]; heliotrope [reddish violaceous eruption on the upper eyelids]) are present, it is designated as dermatomyositis.
  - Different types of myositis include the following (1):
    o Idiopathic polymyositis
    o Idiopathic dermatomyositis
    o Polymyositis/dermatomyositis as an overlap (usually with lupus or systemic sclerosis or as part of mixed connective-tissue disease)
    o Myositis associated with malignancy
    o Necrotizing autoimmune myositis (often statin-associated) (2)
    o Inclusion-body myositis (IBM), a variant with atypical patterns of weakness and biopsy findings
- System(s) affected: cardiovascular, musculoskeletal, pulmonary, skin/exocrine
- Synonym(s): myositis; inflammatory myopathy; antisynthetase syndrome (subset with certain antibodies)

EPIDEMIOLOGY

Incidence
- Estimated at 1.2 to 19/million population/year
- Predominant age: 5 to 15 years, 40 to 60 years, peak incidence in mid-40s
- Predominant sex: female > male (2:1)

Prevalence
2.4 to 33.8 patients/100,000 population
Geriatric Considerations
Elderly patients with myositis or dermatomyositis are at increased risk of neoplasm.

Pediatric Considerations
Childhood dermatomyositis is likely a separate entity associated with cutaneous vasculitis and muscle calcifications.

ETIOLOGY AND PATHOPHYSIOLOGY
- Inflammatory process, mediated by T-cells and cytokine release, leading to damage to muscle cells (predominantly skeletal muscles)
- In patients with IBM, degenerative mechanisms may be important.
- Unknown; potential viral, genetic factors

Genetics
Mild association with human leukocyte antigen (HLA)-DR3, HLA-DRw52

RISK FACTORS
Family history of autoimmune disease (e.g., systemic lupus, myositis) or vasculitis

COMMONLY ASSOCIATED CONDITIONS
- Malignancy more common in dermatomyositis
- Progressive systemic sclerosis
- Vasculitis
- Systemic lupus erythematosus (SLE)
- Mixed connective tissue disease

DIAGNOSIS
HISTORY
- Symmetric proximal muscle weakness causing difficulty when
  - Arising from sitting or lying positions
  - Climbing stairs
  - Raising arms
- Joint pain/swelling
- Dysphagia
• Dyspnea
• Rash on face, eyelids, hands, arms

**PHYSICAL EXAM**
Proximal muscle weakness

• Shoulder muscles
• Hip girdle muscles (trouble standing from seated or squatting position, weak hip flexors in supine position)
• Muscle swelling, stiffness, induration
• Distal muscle weakness is seen only in patients with IBM.
• Rash over face (eyelids, nasolabial folds), upper chest, dorsal hands (especially knuckle pads), fingers (“mechanic’s hands”)
• Periorbital edema
• Calcinosis cutis (childhood cases)
• Mesenteric arterial insufficiency/infarction (childhood cases)
• Cardiac impairment; arrhythmia, failure

**DIFFERENTIAL DIAGNOSIS**

• Vasculitis
• Progressive systemic sclerosis
• SLE
• Rheumatoid arthritis
• Muscular dystrophy
• Eaton-Lambert syndrome
• Sarcoidosis
• Amyotrophic lateral sclerosis
• Endocrine disorders
  – Thyroid disease
  – Cushing syndrome
• Infectious myositis (viral, bacterial, parasitic)
• Drug-induced myopathies:
  – Cholesterol-lowering agents (statins)
  – Colchicine
  – Corticosteroids
  – Ethanol
  – Chloroquine
  – Zidovudine
• Electrolyte disorders (magnesium, calcium, potassium)
Heritable metabolic myopathies
Sleep-apnea syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Diagnosis of muscle component (myositis) usually relies on four findings:
- Weakness
- Creatine kinase (CK) and/or aldolase elevation
- Abnormal electromyogram (EMG)
- Findings on muscle biopsy

Presence of compatible skin rash of dermatomyositis

Initial Tests (lab, imaging)

- Increased CK, aldolase
- Increased serum AST (aspartate aminotransferase)
- Increased LDH (lactate dehydrogenase)
- Myoglobinuria
- Increased ESR
- Positive rheumatoid factor (<50% of patients)
- Positive antinuclear antibody (ANA) (>50% of patients)
- Leukocytosis (<50% of patients)
- Anemia (<50% of patients)
- Hyperglobulinemia (<50% of patients)
- Anti-HMGCR (3-hydroxy-3-methylglutaryl-coenzyme A reductase) and anti-SRP antibodies seen in patient with necrotizing autoimmune myositis
- Antisynthetase antibodies (anti–Jo-1 and non–Jo-1 synthetases) present in antisynthetase syndrome
  - Associated with an increased incidence of interstitial lung disease (ILD)
- Anti–MDA-5 antibody seen in overlap myositis with atypical rashes and severe ILD
- Anti-U1 RNP, anti–PM-Scl, and anti-Ku antibodies seen in overlap myositis
- Chest radiograph as part of initial evaluation to assess for associated pulmonary involvement or malignancy

Follow-Up Tests & Special Considerations

- Changes in muscle enzymes (CK or aldolase) correlate with improvement and worsening.
- MRI to assess muscle edema and inflammation may be used in some patients to determine best biopsy site or response to therapy.
**Diagnostic Procedures/Other**
- EMG: muscle irritability, low-amplitude potentials, polyphasic action potentials, fibrillations
- Muscle biopsy (deltoid or quadriceps femoris)

**Test Interpretation**
- Microscopic findings:
  - Muscle fiber degeneration
  - Phagocytosis of muscle debris
  - Perifascicular muscle fiber atrophy
  - Inflammatory cell infiltrates in adult form
  - Via electron microscopy: inclusion bodies (IBM only)
  - Sarcoplasmic basophilia
- Muscle fiber increased in size
- Vasculopathy (childhood polymyositis/dermatomyositis)

**TREATMENT**

**GENERAL MEASURES**
General evaluation for malignancy in all adults, particularly with dermatomyositis, at initial evaluation and during follow-up

**MEDICATION**

**First Line**
- Prednisone
  - 40 to 80 mg/day PO in divided doses (3)[B]
  - Consolidate doses and reduce prednisone slowly when enzyme levels are normal.
  - Probably need to continue 5 to 10 mg/day for maintenance in most patients.
- For steroid-refractory or steroid-dependent patients: azathioprine 1 mg/kg PO (arthritis dose) once daily or BID
  - Methotrexate 10 to 25 mg PO weekly, useful in most steroid-resistant patients
- Rash of dermatomyositis may require topical steroids or oral hydroxychloroquine.
- Patients with IBM have very poor response to steroids and other first- and
second-line drugs in general.

**Second Line**

- Other immunosuppressant drugs (e.g., cyclophosphamide, chlorambucil, cyclosporine, mycophenolate, tacrolimus) can be added to steroids.
- Combination methotrexate and azathioprine also may be useful in refractory cases.
- IVIG (4)[B] and rituximab (5)[B] have been reported to be helpful in a small series of patients with refractory disease. Rituxan may be more effective in patients with autoantibodies positive myositis (especially anti–Jo-1 and anti–Mi-2).
- Contraindications: Methotrexate is contraindicated with previous liver disease, alcohol use, pregnancy, and underlying renal disease (use with extreme caution in patients with serum creatinine >1.5 mg/dL in general).
- Precautions
  - Prednisone: Adverse effects associated with long-term steroid use include adrenal suppression, sodium and water retention, hypokalemia, osteoporosis, cataracts, and increased susceptibility to infection.
  - Azathioprine: Adverse effects include bone marrow suppression, increased liver function tests, and increased risk of infection.
  - Methotrexate: Adverse effects include stomatitis, bone marrow suppression, pneumonitis, and risk of liver fibrosis and cirrhosis with prolonged use.

**ISSUES FOR REFERRAL**

- Diagnostic uncertainty, usually related to elevated muscle enzymes without typical symptoms of findings of muscle weakness
- Poor response to initial steroid therapy
- Excessive steroid requirement (unable to taper prednisone to <20 mg/day after 4 to 6 months)

**SURGERY/OTHER PROCEDURES**

None indicated, other than initial biopsy

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Inability to stand, ambulate
- Respiratory difficulty
- Fever or other signs of infection
• Inpatient evaluation seldom needed

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
• Follow muscle enzymes along with muscle strength and functional capacity.
• Monitor for steroid-induced complications (e.g., hypokalemia, hypertension, and hyperglycemia).
• Bone densitometry and consideration of calcium, vitamin D, and bisphosphonate therapy
• If azathioprine, methotrexate, or other immunosuppressant is used, appropriate laboratory monitoring should be done periodically (e.g., hematology, liver enzymes, and creatinine).
• Attempt to decrease and/or discontinue steroid dose as patient responds to therapy.
• Maintain immunosuppression until patient’s muscle strength stabilizes for prolonged period depending on individual patient parameters, risks of medication, risk of relapse; time period undefined (months, years)

**DIET**
Moderation of caloric and sodium intake to avoid weight gain from corticosteroid therapy

**PATIENT EDUCATION**
• Curtail excess physical activity in early phases when muscles enzymes are markedly elevated.
• Emphasize range-of-motion exercises.
• Gradually introduce muscle strengthening when muscle enzymes are normal or improved and stable.

**PROGNOSIS**
• Residual weakness: 30%
• Persistent active disease: 20%
• 5-year survival 65–75%, but mortality is 3-fold higher than general population.
Survival is worse for women and African Americans and those with dermatomyositis, IBM, or cancer. Most patients improve with therapy. Patient with ILD have poor prognosis. Patients with IBM respond poorly to most therapies (6). 20–50% have full recovery.

**COMPLICATIONS**

- Pneumonia
- Infection
- Myocardial infarction
- Carcinoma (especially breast, lung)
- Severe dysphagia
- Respiratory impairment due to muscle weakness, ILD
- Aspiration pneumonitis
- Steroid myopathy
- Steroid-induced diabetes, hypertension, hypokalemia, osteoporosis

**REFERENCES**

**CODES**

**ICD10**
- M33.20 Polymyositis, organ involvement unspecified
- M33.90 Dermatopolymyositis, unspecified, organ involvement unspecified
- M33.92 Dermatopolymyositis, unspecified with myopathy

**CLINICAL PEARLS**

- Corticosteroids alone may be sufficient in patients who have rapid improvement in weakness and muscle enzymes. However, most patients require azathioprine, methotrexate, or other immunosuppressive medications.
- The risk of associated malignancy is higher in patients >50 years and in those with cutaneous manifestations.
- Elevated muscle enzymes (e.g., CK and aldolase) are seen frequently as transient phenomena in patients with febrile illness and injuries; may return to normal on repeat.
- In patients with persistently elevated muscle enzymes and symptoms and findings of muscle weakness, EMG followed by muscle biopsy should be the initial studies considered.
- Suspect IBM in older patients with very slow onset and progression of symptoms, poor response to steroids and immunosuppressive therapy, and atypical patterns (asymmetric, sometimes distal) of muscle weakness.
- Suspect autoimmune necrotizing myositis in patients who develop myopathy while taking lipid-lowering drugs (statins) but fail to improve or worsen after withdrawal of statin therapy.
POPLITEAL (BAKER) CYST
Shane L. Larson, MD • Adriel G. Dizon, MD

BASICS

DESCRIPTION
- A fluid-filled synovial sac arising in the popliteal fossa as a distention of (typically) the gastrocnemial-semimembranous bursa; not a true cyst
- Can be unilateral or bilateral
- Most frequent cystic mass around the knee
- Primary cysts are a distention of the bursa (arise independently without an intra-articular disorder).
- Secondary cysts occur if there is a communication between the bursa and knee joint, allowing articular fluid to fill the cyst.
- Associated with synovial inflammation

EPIDEMIOLOGY

Incidence
- Bimodal distribution
  - Children ages 4 to 7 years
  - Adults increasing with age
- Primary cysts usually seen in children <15 years
- Secondary cysts seen in adults

Prevalence
- Variable adult prevalence of 19–47% in symptomatic knees and 2–5% in asymptomatic knees
- In children: 6.3% in symptomatic knees; 2.4% in asymptomatic knees

ETIOLOGY AND PATHOPHYSIOLOGY

Associated intra-articular pathology includes
- Meniscal tears, mostly of the posterior horn
- Anterior cruciate ligament (ACL) insufficiency
- Degenerative articular cartilage lesions
- Rheumatoid arthritis (20%)
Osteoarthritis (50%)
Osteochondritis
Gout (14%)
Other potential factors
  – Infectious arthritis
  – Polyarthritis
  – Villonodular synovitis
  – Lymphoma
  – Sarcoidosis
  – Connective tissue diseases
Extension or herniation of synovial membrane of the knee joint capsule or connection of normal bursa with the joint capsule
May result from increased intra-articular pressure
Commonly seen with knee effusions
Direct trauma to the bursa is likely the primary cause in children because of no communication between the bursa and the joint.
A valve-like mechanism allowing one-way passage of fluid from the joint to the bursal connection has been described.

RISK FACTORS
Osteoarthritis of knee (most common)
Rheumatoid arthritis
Meniscal degeneration or tear
Advancing age
Ligamentous insufficiency

COMMONLY ASSOCIATED CONDITIONS
Any condition causing knee joint effusion

DIAGNOSIS

HISTORY
Painless mass arising in the popliteal fossa
Most cysts are asymptomatic.
Dull ache if cyst is large enough to impede joint motion—typically a restriction of flexion
Painful if cyst ruptures
Large cysts may cause entrapment neuropathy of the tibial nerve.
Vascular compression, most commonly of the popliteal vein, may produce claudication or thrombophlebitis.
Activity alters the cyst size.

**PHYSICAL EXAM**
- Examine in full extension and 90 degrees of flexion.
- Foucher sign: Mass increases with extension and disappears with flexion.
- Most commonly found in medial aspect of popliteal fossa lateral to the head of the gastrocnemius and medial to the neurovascular bundle
- Cyst is easiest to palpate when knee is slightly flexed and may occasionally be fluctuant or tender.
- Transillumination helps distinguish cyst from solid mass.
- Ruptured cysts are typically painful with associated swelling and bruising over the ipsilateral calf and ankle at the medial malleolus (crescent sign).
- Ruptured cysts also are associated with pseudothrombophlebitis, and rarely, compartment syndrome (1).

**DIFFERENTIAL DIAGNOSIS**
- Infection/abscess
- Lipoma, liposarcoma
- Fibroma, fibrosarcoma
- Hematoma
- Deep venous thrombosis
- Vascular tumor
- Popliteal vein varices
- Xanthoma
- Aneurysm (rare)
- Ganglion cyst
- Thrombophlebitis
- Muscular herniation (rare, related to trauma)

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- CBC, ESR (if septic arthritis suspected)
- Ensure not a popliteal aneurysm prior to aspiration. Send aspirate for cell count and culture to determine if fluid is infectious, inflammatory, or mechanical.
Ultrasound confirms presence and size; Doppler can differentiate Baker cysts from popliteal vessel aneurysms, DVT, or soft tissue tumors (2).

MRI helps assess derangements of internal joint structures and to identify cyst leakage.

**Follow-Up Tests & Special Considerations**
- Consider observation over invasive testing in children.
- Radiographs may show soft tissue density posteriorly.
- Arthrography may demonstrate communication with joint capsule or rupture.
- CT arthrography is superior for visualizing cystic details and can help distinguish lipomas, aneurysms, and malignancies from cysts.

---

**TREATMENT**

**GENERAL MEASURES**
- No treatment if asymptomatic
- Treat any associated underlying conditions.
- Compressive wrap or sleeve for comfort

**MEDICATION**
If etiology is identified from cellular fluid examination, treat the underlying condition.

**First Line**
Analgesics and NSAIDs for symptomatic relief

**ADDITIONAL THERAPIES**
- Physical therapy improves knee ROM and strength, particularly with coexisting pathology.
- Temporary relief with needle aspiration; recurrence common
- Improvement in joint ROM, knee pain, swelling, accompanied reduction in bursa size after aspiration, and intra-articular/intracystic corticosteroid injection (3)[B]
- A combination of physical therapy and corticosteroid injection with or without aspiration leads to best improvements in pain, function, and reduction in cyst size (4)[A].
- Sclerotherapy injections of ethanol or dextrose/sodium morrhuate shown to
have good results in small studies (5)[B].

SURGERY/OTHER PROCEDURES
- Consider excision when symptoms persist despite treatment or no etiology is found.
- Surgery usually not required in children
- Recurrence after standard surgery is common and is highest if chondral lesions are present.
- Arthroscopic surgery is highly successful if a valvular mechanism is identified, and intra-articular pathology is treated (6)[B].
- Excision via arthroscopy or open procedure often requires concomitant treatment of underlying pathology.

ONGOING CARE

PROGNOSIS
- Variable; many cysts remain asymptomatic.
- Some cysts resolve with treatment of underlying etiology (e.g., gout, rheumatoid arthritis).
- In children, most cysts resolve without treatment.

COMPLICATIONS
- Compartment syndrome in ruptured cyst
- Thrombophlebitis from compression of the popliteal vein
- Infection of popliteal cyst
- Hemorrhage into cyst if on anticoagulants

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Knee Pain

**CODES**

**ICD10**

- M71.20 Synovial cyst of popliteal space [Baker], unspecified knee
- M71.21 Synovial cyst of popliteal space [Baker], right knee
- M71.22 Synovial cyst of popliteal space [Baker], left knee

**CLINICAL PEARLS**
• Conservative treatment of Baker cysts is preferred in children, as most will spontaneously resolve.
• In adults, treatment of underlying cause may resolve Baker cysts.
• Pain, bruising, and swelling over the medial malleolus (crescent sign) suggest cyst rupture.
PORTAL HYPERTENSION

Walter M. Kim, MD, PhD • Jyoti Ramakrishna, MD

BASICS

DESCRIPTION

● Increased portal venous pressure >5 mm Hg that occurs in association with splanchnic vasodilatation, portosystemic collateral formation, and hyperdynamic circulation
● Most commonly secondary to elevated hepatic venous pressure gradient (HVPG; the gradient between portal and central venous pressures)
● Course is generally progressive, with risk of complications including acute variceal bleeding, ascites, hepatic encephalopathy, and hepatorenal syndrome.

EPIDEMIOLOGY

Incidence

● Prevalence: <200,000 persons in the United States
● Predominant age: adult
● Predominant sex: male > female

ETIOLOGY AND PATHOPHYSIOLOGY

● Causes generally classified as follows:
  – Prehepatic (portal vein thrombosis or obstruction)
  – Intrahepatic (most commonly cirrhosis)
  – Posthepatic (hepatic vein thrombosis, Budd-Chiari syndrome, right-sided heart failure)
● 90% of intrahepatic cases are due to cirrhosis secondary to the following:
  – Virus (hepatitis B, hepatitis C, hepatitis D)
  – Alcoholism
  – Schistosomiasis
  – Wilson disease
  – Hemochromatosis
  – Primary biliary cirrhosis (PBC)
  – Sarcoidosis
● Increased HVPG results in venous collateral formation in the distal esophagus, proximal stomach, rectum, and umbilicus.
- Gastroesophageal variceal formation is found in 40% of patients with portal hypertension.
- Progression of portal hypertension results in splanchnic vasodilation and angiogenesis.

**Genetics**
No known genetic patterns except those associated with specific hepatic diseases that cause portal hypertension

**RISK FACTORS**
See “Etiology and Pathophysiology.”

**Pediatric Considerations**
In children, portal vein thrombosis is the most common extrahepatic cause; intrahepatic causes are more likely to be biliary atresia, viral hepatitis, and metabolic liver disease.

**DIAGNOSIS**

**HISTORY**
- Ascites symptoms of heart failure including chest pain, shortness of breath, and/or edema
- Hematemesis
- Melena
- Oliguria
- Jaundice
- Weakness/fatigue
- History of chronic liver disease
- Alcoholic hepatitis
- Alcohol abuse

**PHYSICAL EXAM**
- Exam findings may be general or related to specific complications.
- General
  - Pallor
  - Icterus
  - Digital clubbing
– Palmar erythema
– Splenomegaly
– Caput medusa
– Spider angiomata
– Umbilical bruit
– Hemorrhoids
– Gynecomastia
– Testicular atrophy

Gastroesophageal varices
– Hypotension
– Tachycardia

Ascites
– Distended abdomen
– Fluid wave
– Shifting dullness with percussion

Hepatic encephalopathy
– Confusion/coma
– Asterixis
– Hyperreflexia

DIFFERENTIAL DIAGNOSIS
Usually related to specific presentations

Gastroesophageal varices with hemorrhage
– Portal hypertensive gastropathy
– Hemorrhagic gastritis
– Peptic ulcer disease
– Mallory-Weiss tear

Ascites
– Spontaneous bacterial peritonitis (SBP)
– Pancreatic ascites
– Peritoneal carcinomatosis
– Tuberculous peritonitis
– Hepatic malignancy
– Fluid overload from heart failure
– Nephrotic syndrome

Hepatic encephalopathy
– Delirium tremens
– Intracranial hemorrhage
– Sedative abuse
– Uremia
● Hepatorenal syndrome
  – Drug nephrotoxicity
  – Renal tubular necrosis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

Direct calculation of HVPG (approximation of the gradient in pressure between portal vein and IVC) is the gold standard in diagnosing portal hypertension:

- HVPG = wedged hepatic venous pressure (WHVP) – free hepatic venous pressure (FHV)
- WHVP is estimated by occlusion of the hepatic vein by a balloon catheter and measurement of the proximal static column of blood.
- FHV is estimated by direct measurement of the patent hepatic vein, intra-abdominal inferior vena cava, or right atrium.
- Esophageal varices generally develop when HVPG >10 mm Hg in compensated cirrhosis and HVPG >16 mm Hg in decompensated cirrhosis.
- Nonspecific changes associated with underlying disease:
  – Hypersplenism: anemia (also may be due to malnutrition or bleeding), leukopenia, thrombocytopenia
  – Hepatic dysfunction
    o Hypoalbuminemia
    o Hyperbilirubinemia
    o Elevated alkaline phosphatase
    o Elevated liver enzymes (AST, ALT)
    o Abnormal clotting (prothrombin time, international normalized ratio, partial thromboplastin time)
  – GI bleeding
    o Iron deficiency anemia
    o Elevated serum ammonia
    o Fecal occult blood
    o Thrombocytopenia
  – Hepatorenal syndrome
    o Elevated serum creatinine (Cr), blood urea nitrogen (BUN)
    o Urine Na <5 mEq/L (<20 mmol/L)
  – US and CT scan/MRI may detect cirrhosis, splenomegaly, ascites, and varices.
– US/duplex Doppler
  o Can determine presence and direction of flow in portal and hepatic veins
  o Useful in diagnosing portal vein thrombosis, shunt thrombosis, or the presence of ascites
– CT scan/MRI: angiographic measurement of hepatic venous wedge pressure via jugular or femoral vein
  o Correlates with portal pressure
  o Risk of variceal bleeding is increased if HVPG >12 mm Hg.
– Upper GI series may outline varices in esophagus and stomach.
– Transient elastography is an emerging method to determine hepatic fibrosis and to predict portal hypertension (1).

**Diagnostic Procedures/Other**
- Diagnostic paracentesis and calculation of the serum ascites-albumin gradient (SAAG) can differentiate between portal hypertensive (SAAG >1.1 g/dL) from nonportal hypertensive (SAAG <1.1 g/dL) causes of ascites.
- Endoscopy can diagnose esophageal and gastric varices and portal hypertensive gastropathy.

**Test Interpretation**
Specific for underlying disease

**TREATMENT**

**GENERAL MEASURES**
- Avoid sedatives that may precipitate encephalopathy.
- Limit sodium intake because cirrhotic patients avidly retain sodium (<2 g sodium per day).

**MEDICATION**
Therapy for encephalopathy: See “Hepatic Encephalopathy.”

**First Line**
- Prophylaxis against variceal bleeding (2,3)[A]:
  – Nonselective β-blockade
    o Nadolol: 20 to 40 mg PO once-daily dosing
    o Propranolol: Start with 20 to 40 mg PO BID to TID.
– Carvedilol: 6.25 mg PO once-daily dosing
– Doses may be titrated up as tolerated to maximum recommended doses; goal resting HR of 55 to 60 bpm

**Therapy for acute variceal hemorrhage:**
– Vasopressin: Start with 0.2 to 0.4 U/min IV; increase to maximum dose 0.8 U/min as needed; pediatric dose: 0.002 to 0.005 U/kg/min; do not exceed 0.01 U/kg/min. After bleeding stops, continue at same dose for 12 hours and then taper off over 24 to 48 hours.
– Octreotide: 50 μg IV bolus, followed by 50 μg/hr continuous infusion; pediatric dose: 1 μg/kg bolus followed by 1 μg/kg/hr is used traditionally; treat for up to 5 days.

**For prevention of recurrence and for overall reduction in mortality:**
– Propranolol: 10 to 60 mg/day PO BID to QID; pediatric dose: 0.5 to 1.0 mg/kg/day PO divided q6–8h
– Nadolol: 40 to 80 mg/day PO reduces portal venous blood inflow by blocking the adrenergic dilatation of the mesenteric arterioles.
– Tetrandrine, a calcium channel blocker, also has been found to reduce the rate of rebleeding with fewer side effects.

**Initial treatment for ascites (along with salt and fluid restriction):**
– Furosemide: 20 to 40 mg/day PO; pediatric dose: 1 to 2 mg/kg/dose PO ± IV albumin infusion
– Spironolactone: 50 to 100 mg/day PO; pediatric dose: 1 to 3 mg/kg/day PO

**Second Line**
– Terlipressin (2 mg IV q4h; titrate down to 1 mg IV q4h once hemorrhage is controlled; may be used for up to 48 hours) is a more selective splanchnic vasoconstrictor and may be associated with fewer complications. It is currently used when standard therapy with somatostatin or octreotide fails.
– Addition of nitrates, such as nitroglycerin or isosorbide mononitrate, reduces portal pressures and bleeding rates and has been shown to reduce mortality. Because the risk–benefit ratio is not clear, nitrates are not considered first-line treatment.
– Studies are ongoing for possible benefits of other agents including simvastatin, clonidine, verapamil, and losartan.

**ISSUES FOR REFERRAL**
Patients with portal hypertension should be managed longitudinally by both a primary care physician and a gastroenterologist.
Surgery/Others Procedures

- Treatments available for specific complications of portal hypertension (in addition to or if refractory to medications):
  - Gastroesophageal varices without hemorrhage
    - Endoscopic variceal ligation (EVL) is the preferred therapy for prevention of bleeding of large varices and requires serial interventions every 2 to 8 weeks until the varices are eradicated.
  - Gastroesophageal varices with hemorrhage
    - EVL or sclerosis (the first-line treatment in many cases for acute hemorrhage) within 12 hours of presentation (4)[A]

- Balloon tamponade (not used commonly when endoscopic treatment is available)
- Transjugular intrahepatic portosystemic shunt (TIPS)
- Portocaval shunting
- Ascites refractory to medical management
  - Large-volume paracentesis
  - Peritoneovenous shunt
  - TIPS
- Liver transplantation should be considered for patients with advanced disease.

Admission, Inpatient, and Nursing Considerations

- Acute GI bleeding should be managed in the inpatient setting, either on the regular medical floor if the patient is hemodynamically stable or in the ICU if the patient is unstable.
- Patients with mental status changes from encephalopathy need to be evaluated in the inpatient setting.
- Admission criteria/initial stabilization
  - Acute bleeding from the intestinal tract, either vomiting or per rectum
  - Acute confusional state/mental status changes
  - If acute variceal bleeding:
    - Type and cross patient’s blood.
    - Initial resuscitation with isotonic fluid until packed RBCs are available
    - Correct coagulopathy with vitamin K and fresh frozen plasma (FFP).
    - Endoscopy as soon as the patient is stabilized (for diagnosis and treatment)
  - Avoid sedatives that may precipitate encephalopathy.
  - Limit sodium administration because cirrhotic patients avidly retain
sodium.
- Restrict protein only if encephalopathic.

**ALERT**
If the patient is an active alcohol drinker, assess for alcoholic hepatitis and watch for signs and symptoms of withdrawal. Follow inpatient protocols for alcohol withdrawal management.

- Use isotonic fluid for hydration.
- Discharge criteria
  - For GI bleeding:
    - No active bleeding in 24 hours
    - Stable hemoglobin and hematocrit
    - Hemodynamically stable (especially heart rate)
  - For encephalopathy: improvement in or resolution of mental status changes to baseline

**ONGOING CARE**

**DIET**
In patients with cirrhosis, sodium restriction is important because cirrhotic patients avidly retain sodium.

**PATIENT EDUCATION**
Refrain from drinking alcohol. Resources for patients who have difficulty with not drinking alcohol can be obtained from Alcoholics Anonymous at [http://www.aa.org/](http://www.aa.org/).

**PROGNOSIS**
- Hepatic reserve defined by Child-Pugh classification: rating based on encephalopathy, ascites, bilirubin, albumin, prothrombin
- Variceal bleeding
  - 1/3 of patients with known varices will bleed eventually.
  - 50% rebleed, usually within 2 years, unless portal pressure is reduced by surgical or TIPS procedure.
  - 15–20% mortality rate
- Ascites and encephalopathy often recur.
- Prognosis of patients with ascites is poor: 50% 1-year survival without liver
transplant (compared with 90% for patients with cirrhosis and no ascites)

REFERENCES

ADDITIONAL READING

CODES

ICD10

K76.6 Portal hypertension

CLINICAL PEARLS

• Portal hypertension can be diagnosed based on physical examination in the setting of known risk factors, specifically cirrhosis.
- Endoscopic treatment is successful for acute variceal hemorrhage 85% of the time.
- Prognosis of patients with ascites is poor: 50% 1-year survival without liver transplant (compared with 90% for patients with cirrhosis and no ascites).
- Advantages and disadvantages of balloon tamponade for acute variceal bleed:
  - Advantages include rapid and often effective control of bleeding (30–90%) and common availability of device.
  - Disadvantages include recurrence of bleeding when balloon is deflated, patient discomfort, and risk of esophageal perforation.
POSTCONCUSSION SYNDROME (MILD TRAUMATIC BRAIN INJURY)

Eric M. Bankert, DO • Vicki R. Nelson, MD, PhD

Basics

Description

Postconcussion syndrome (PCS) is a constellation of symptoms involving physical, cognitive, and/or behavioral symptoms persisting after a concussion (mild traumatic brain injury [MTBI]) and may continue for weeks to years (1). It is unclear when concussive symptoms become postconcussive syndrome. A recent consensus defines persistent symptoms as lasting >10 to 14 days in adults and 4 weeks in children (2). Symptoms of PCS include (1)

- Cognitive
  - Poor focus
  - Poor organization
  - Diminished academic/intellectual performance
  - Slowed response time
- Physical
  - Headache
  - Nausea
  - Visual changes
  - Light and noise sensitivity
  - Tinnitus
  - Dizziness and balance problems
  - Fatigue and sleep disturbance
- Behavioral
  - Depression
  - Irritability/emotional lability
  - Apathy
  - Increased sensitivity to alcohol

Diagnosis is based on history and clinical symptoms.

Epidemiology
Incidence
The reported range of MTBI patients who develop PCS varies between 5% and 80%.
- This is due to difficulty differentiating postconcussion symptoms from PCS.
- 80–90% of concussion victims recover from postconcussion symptoms within 7 to 10 days, slightly longer in children/adolescents (2). A diagnosis of PCS is generally made in those patients whose concussive symptoms persist beyond the usual course.

Prevalence
Predominant sex: female > male. Female gender is not universally considered a risk factor.

ETIOLOGY AND PATHOPHYSIOLOGY
- Controversial; exact mechanism(s) unknown
- Microscopic axonal injury from shearing forces leads to inflammation causing secondary brain injury.
- Conflicting data on structural brain damage and correlation of imaging with physical symptoms (1,3,4)
- Because the pathophysiology of PCS is not well understood and because of symptom overlap with other psychiatric conditions, PCS remains a difficult condition to diagnose and to manage.
  - Only some with MTBI develop PCS; it is unclear what causes PCS symptoms to persist (4).
  - Psychiatric factors are commonly associated with, and may play a role in, the development of PCS. It can be challenging to differentiate pure psychiatric dysfunction from PCS (1,4).
  - Neuropsychiatry evaluation help differentiate PCS from other behavioral disorders.
  - Patient reported high symptom burden following MTBI is associated with increased risk of PCS (5)[B].

RISK FACTORS
- Strongest predictor is severity of initial symptoms (2).
- Retrograde amnesia, migraine, self-reported cognitive decline, insomnia, noise and light sensitivity developing or worsening after MTBI (1,3)
- Preexisting psychiatric disease including depression, anxiety, personality disorder, and posttraumatic stress disorder (PTSD)
• Preexisting expectation of poor outcomes following MTBI (1,3)
• Nonsport concussion/MTBI
• Unclear if previous history of concussion(s) is a risk factor for PCS
• Low socioeconomic status
• Loss of consciousness not predictive of PCS

GENERAL PREVENTION
• Education of players, coaches, parents, and athletic trainers about concussion, PCS, and appropriate safety rules
• Head injury precautions are advised. Evidence is lacking that these decrease incidence of MTBI/PCS.
• Screening and intervention for anxiety and depression

COMMONLY ASSOCIATED CONDITIONS
• PTSD
• Anxiety
• Depression
• Fibromyalgia
• Personality disorders (namely, compulsive, histrionic, and narcissistic)
• ADHD

DIAGNOSIS

HISTORY
• Detailed history of recent impact and closed head injury, including:
  – Mechanism
  – Timing of injury related to symptoms
  – Previous head injuries, including concussion, and timing of those injuries
  – Previous medical, psychiatric, or social history
  – Thorough characterization of associated symptoms, intensity, and duration
• Report of neurologic, cognitive, or behavioral symptoms by patient/family

PHYSICAL EXAM
Complete neurologic exam, including the following:
• Glasgow Coma Scale (GCS)
• Anxiety/depression screening
  – Patient Health Questionnaire-9 (PHQ-9)
– GAD-7

- Sport Concussion Assessment Tool (SCAT), NFL Sideline Concussion Assessment Tool, or computerized neuropsychological (CNP) (2)[C]

Differential Diagnosis

- Postconcussive symptoms
- PTSD
- Anxiety/depression
- Personality disorders
- Migraine headaches
- Chronic fatigue syndrome, fibromyalgia
- Evolving intracranial hemorrhage
- Exposure to toxins, including prescription and recreational drugs
- Endocrine/metabolic abnormality

Diagnostic Tests & Interpretation

Initial Tests (lab, imaging)

- Consider evaluation for infection, intoxication, and endocrine/metabolic abnormality if clinically appropriate.
- Brain imaging both on initial evaluation of MTBI and PCS is not routinely indicated.
- Imaging to evaluate for bleeding is appropriate with comorbidities or anticoagulation therapy.
- Imaging indicated if cervical spine injury is suspected

Follow-Up Tests & Special Considerations

- Several CNP tests help guide return to play decisions; if baseline testing is available, allows for comparison scores after MTBI
- Formal neuropsychiatric evaluations are likely superior to CNP testing when available. None of these tests should be used alone for decision making, especially if a patient is still symptomatic (1,2)[C].
- Common neuropsychological testing programs
  - Immediate Post-Concussion Assessment and Cognitive Testing (ImPACT)
  - Postconcussion Symptom Scale (PCSS)
  - Balance Error Scoring System (BESS)
  - Axon Sports Computerized Cognitive Assessment Tool (CCAT)
  - Automated Neuropsychological Assessment Metrics (ANAM)
TREATMENT

GENERAL MEASURES

- Return to full activity should progress according to stepwise concussion recommendations, which include immediate cognitive rest in the acute period (24 to 48 hours) followed by gradual return to daily activities as tolerated \((1,2)[C]\).
- Controlling cognitive stress and allowing for extra school accommodations may be beneficial \((2)\).
- Restrict individuals with concussion or PCS from sport activity until clinical symptoms have resolved and they have been weaned from any medications that might mask PCS symptoms \((1,2)[C]\).
- Physical therapy for coexisting cervical and vestibular injuries is beneficial. Cognitive-behavioral therapy helps address persistent mood issues \((5)\).
- Limited evidence that pharmacotherapy is beneficial.
- Subthreshold exercise helps in symptom resolution \((6)[B]\).

MEDICATION

**First Line**

Headache/neck pain

- Nonopioid pain control (e.g., NSAIDs) preferred
  - With use of opioid medications, sedation obscures cognitive evaluation.
  - Possible association between the use of opiates and increased risk of anxiety/depression in PCS patients \((4)[B]\)
  - Consider occipital nerve block.

**ALERT**

Avoid opiates and benzodiazepines \((4)[B]\).

- Depression/sleep disorders
  - Anxiety/depression screening starting in the 1st week post-MTBI
    o Melatonin for sleep
    o Tricyclic antidepressants or trazodone may help with concomitant sleep disturbance.
    o SSRIs
  - Consider referral to mental health specialist(s).
- Cognitive disorders
– Evaluation by neuropsychologist
– Consider SSRIs, especially if concomitant anxiety/depression.

ISSUES FOR REFERRAL
- Neuropsychiatric therapy including comprehensive cognitive evaluation for potential TBI rehabilitation
- Cognitive-behavioral therapy for anxiety and depression symptoms
- Occupational therapy for vocational rehabilitation
- Physical therapy for vestibular rehabilitation
- Neurology referral if primary care interventions for seizures, headache, vertigo, or cognition are unsuccessful
- Substance abuse counseling, if needed

COMPLEMENTARY & ALTERNATIVE MEDICINE
Massage therapy/osteopathic manipulative treatment for headache and neck pain

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Schedule regular follow-up to evaluate for persistent symptoms, efficacy of/need for neuropsychiatric evaluation, and the efficacy of/need for pharmacologic therapy.

Patient Monitoring
- Consider serial neuropsychological testing.
- Follow return to play guidelines (2)[C].

PATIENT EDUCATION
- Centers for Disease Control and Prevention: http://www.cdc.gov/headsup/
- Brain Injury Association of America: http://www.biausa.org/; (800) 444–6443

PROGNOSIS
- Prognosis generally is good.
- Adolescents may recover more slowly than adults.
COMPLICATIONS

- Repeat head injury or return to play before resolution of PCS can worsen/prolong symptoms.
- Case studies of second-impact syndrome, a rare but potentially fatal condition owing to a second head injury soon after the first, have been reported.

REFERENCES

ADDITIONAL READING

SEE ALSO
Concussion (Mild Traumatic Brain Injury)

CODES

ICD10
- F07.81 Postconcussional syndrome
- S06.9X0A Unsp intracranial injury w/o loss of consciousness, init
- S06.9X9A Unsp intracranial injury w LOC of unsp duration, init

CLINICAL PEARLS
- Imaging rarely useful for PCS. If necessary, head CT scan is the test of choice for acute injury to exclude intracranial bleeding.
- Coordinate multidisciplinary treatment plans for patients with persistent symptoms.
- Return to play/activity should not occur until the athlete is asymptomatic (or symptoms return to preevent baseline).
POSTTRAUMATIC STRESS DISORDER (PTSD)

Crystal Haydee Chavez, MD • Fozia Akhtar Ali, MD

BASICS

DESCRIPTION

- Posttraumatic stress disorder (PTSD) is an anxiety disorder defined as a reaction that can occur after exposure to an extreme traumatic event involving death, threat of death, serious physical injury, or a threat to physical integrity.
- This reaction has three cardinal characteristics:
  - Reexperiencing the trauma
  - Avoidance of anything related to the traumatic event and/or numbing of general responsiveness
  - Increased arousal
- Traumatic events that may trigger PTSD include natural/human disasters, serious accidents, war, sexual abuse, rape, torture, terrorism, hostage-taking, or being diagnosed with life-threatening disease.
- PTSD can be:
  - Acute: symptoms lasting <3 months
  - Chronic: symptoms lasting ≥3 months
  - Delayed: onset 6 months after trauma exposure, <5% of cases
  - Subclinical: waxing and waning course

EPIDEMIOLOGY

- ~30% of men and women who have spent time in a war zone experience PTSD.
- Four of the six trauma types associated with highest population proportions of lifetime PTSD episodes are related to intimate partner sexual violence.
- 16% children and adolescents exposed to trauma develop PTSD.

Incidence

~7.7 million American adults aged ≥18 years (3.5% of this age group) are diagnosed with PTSD each year.
Prevalence
Lifetime prevalence for PTSD ranges from 6.8% to 12.3% in the general population.

ETIOLOGY AND PATHOPHYSIOLOGY
- Biologic dimensions: Hyperactivity/hypersensitivity of catecholamine pathways and overactivity/oversensitivity of the central opioid pathways is seen; the amygdala and hippocampus dysfunction, with possible atrophy from overexposure to catecholamines, serotonergic dysregulation, glutamatergic dysregulation, and increased thyroid activity.
- Learning theory: Life-threatening fear is classically conditioned by event exposure; any internal or external cue reminiscent of the event produces an intense “fight or flight” fear response. The person avoids cues that trigger fear. This avoidance maintains fear.
- Cognitive theories: These models suggest that severe trauma becomes represented in complex memory structures. The activation of these memories triggers intense thoughts and emotions that are pathologic (causing personal discomfort and dysfunction).
- Psychodynamic theory: Traumatic memories overwhelm defense mechanisms. Repeated recall of the traumatic event with associated fear is an effort to understand the event in a less threatening way.

Genetics
- Monozygotic twins exposed to combat in Vietnam were at increased risk of the co-twin having PTSD compared with twins who were dizygotic.
- Data suggest an association between dopamine system variants and PTSD.

RISK FACTORS
- Pretrauma environment:
  - Female sex
  - Younger age
  - Psychiatric history
  - Sexual abuse
- Peritrauma environment:
  - Severity of the trauma
  - Peritrauma emotionality
  - Perception of threat to life
  - Perpetration of the trauma
• Posttrauma environment:
  – Perceived injury severity
  – Medical complications
  – Perceived social support
  – Persistent dissociation from traumatic event
• Subsequent exposure to trauma-related stimuli

GENERAL PREVENTION
• There is moderate evidence for hydrocortisone and some evidence for propranolol reducing development of full posttraumatic syndrome.
• Trauma-focused cognitive-behavioral therapy (CBT) and modified prolonged exposure delivered within weeks of a potentially traumatic event for people showing signs of distress have the most evidence in the treatment of acute stress and early PTSD symptoms, and the prevention of PTSD.

COMMONLY ASSOCIATED CONDITIONS
• Major depressive disorder
• Alcohol/substance abuse
• Panic disorder
• Obsessive-compulsive disorder
• Agoraphobia and/or social phobia
• Traumatic brain injury
• Smoking (especially with assaultive trauma)
• Major neurocognitive disorders, dementia, or amnesia

Pediatric Considerations
Oppositional defiant disorder and separation anxiety are common comorbid conditions.

DIAGNOSIS
HISTORY
Diagnosis is based on DSM-5 criteria:
• Criterion A: exposure to trauma (≥1 of the following):
  – Direct experience of a traumatic event
  – In-person witnessing of a traumatic event
  – Learning of a traumatic event involving a close friend or family member
– Repeated exposure to details of a traumatic event

**Criterion B:** intrusive symptoms associated with the traumatic event (≥1 of the following):
– Recurrent, involuntary, and intrusive distressing memories of the event
– Recurrent distressing dreams related to the event
– Dissociative reactions that simulate a recurrence of the event
– Intense or prolonged distress to stimuli that resemble an aspect of the event

**Criterion C:** avoidance of stimuli associated with the trauma (≥1 of the following):
– Avoidance of memories, thoughts, or feelings about the event
– Avoidance of external reminders that trigger memories, thoughts, or feelings about the event

**Criterion D:** negative cognitive and mood changes associated with the trauma (≥2 of the following):
– Inability to remember aspects of event
– Persistent and exaggerated negative opinion of self, others, or the world
– Distorted beliefs about the cause or consequences of the event
– Negative emotional state
– Diminished interest in significant activities
– Feeling detached from others
– Inability to experience positive emotions

**Criterion E:** hyperarousal (≥2 of the following):
– Difficulty sleeping/falling asleep
– Decreased concentration
– Hypervigilance
– Outbursts of anger/irritable mood
– Exaggerated startle response
– Self-destructive behavior

**Criterion F:** duration of the relevant criteria symptoms should be >1 month

**Criterion G:** clinically significant distress/impairment in functioning

**Criterion H:** relevant criteria not attributed to substance effects or other medical conditions

**Pediatric Considerations**

– Memories of the traumatic event may not appear distressing and may be seen as play reenactment.
– Reactions can include a fear of being separated from a parent, crying, whimpering, screaming, immobility and/or aimless motion, trembling, frightened facial expressions, excessive clinging, or regressive behavior.
Older children may show extreme withdrawal, disruptive behavior, and/or an inability to pay attention. Regressive behaviors, nightmares, sleep problems, irrational fears, irritability, refusal to attend school, outbursts of anger, fighting, somatic complaints with no medical basis, and decline in schoolwork performance. Furthermore, depression, anxiety, feelings of guilt, and emotional numbing are often present.

Parental posttraumatic stress has been shown to be a robust predictor of pediatric PTSD [1].

**PHYSICAL EXAM**

- Patients may present with physical injuries from the traumatic event.
- Mental status examination:
  - Thoughts and perceptions (e.g., hallucinations, delusions, suicidal ideation, phobias)
  - General appearance: disheveled, poor hygiene
  - Behavior: agitation; startle reaction extreme
  - Psychological numbness
  - Orientation may be affected.
  - Memory: forgetfulness, especially concerning the details of the traumatic event
  - Poor concentration
  - Poor impulse control
  - Altered speech rate and flow
  - Mood and affect may be changed: depression, anxiety, guilt, and/or fear

** Pediatric Considerations**

Elevated heart rate immediately following trauma is associated with development of PTSD [1].

**DIFFERENTIAL DIAGNOSIS**

- Acute stress disorder (symptoms <4 weeks)
- Generalized anxiety disorder
- Adjustment disorder
- Obsessive-compulsive disorder
- Schizophrenia
- Major depressive disorder
- Mood disorder with psychotic features
- Substance abuse
Personality disorders  
Dissociative disorders  
Conversion disorder

**TREATMENT**

Combination psychotherapy and pharmacotherapy, initiated soon after the trauma, result in better prognosis.

**MEDICATION**

**First Line**

- Depression, panic attacks, startle response, sleep disruption: may improve with SSRIs (2) [A]. All commonly used SSRIs have been shown to be effective.
  - Sertraline: 50 to 200 mg every day (FDA-approved)
  - Paroxetine: starting dose: 10 mg every day; may be increased in 10 mg increments at intervals ≥1 week (FDA-approved)
  - Fluoxetine: 20 mg every day/BID not to exceed 80 mg/day (demonstrates some efficacy for all three symptom clusters)

- Sleep disruption: Sleep disruption due to hyperarousal is ubiquitous in PTSD; standard sedatives, such as trazodone 50 to 300 mg at bedtime, mirtazapine 7.5 to 30.0 mg qhs, or amitriptyline 25 to 100 mg qhs

- Nightmares/nighttime hyperarousal: prazosin 2 to 15 mg qhs (3) [A], clonidine 0.1 to 0.2 mg qhs, amitriptyline 25 to 100 mg qhs

**Second Line**

Refractory/residual symptoms: Consider augmentation with:

- Depression: mirtazapine 15 to 45 mg/day; consider switch to a serotonin norepinephrine reuptake inhibitor (SNRI), such as venlafaxine XR 37.5 to 300.0 mg/day, duloxetine 60 to 120 mg/day or desvenlafaxine 50 to 100 mg/day. Nefazodone 300 to 600 mg/day in divided doses can be very effective but requires quarterly LFTs.

- Reexperiencing/intrusive thoughts: 1st-/2nd-generation antipsychotic medications: aripiprazole 5 to 15 mg/day, risperidone 0.5 to 2.0 mg/day, olanzapine 2.5 to 10.0 mg/day, quetiapine 50 to 400 mg/day (4) [A]. 2nd-generation Rx less prone to extrapyramidal symptoms (EPS): cognitive dulling.
• Hyperarousal: clonidine, start 0.05 mg BID/TID; slowly titrate to as much as 0.45 mg/day divided doses; guanfacine 1 to 3 mg/day in divided doses (long-acting forms of both clonidine and guanfacine now available). Also consider 2nd-generation antipsychotics quetiapine, risperidone, and olanzapine as above. Divided doses often more helpful.
• Impulsivity/explosiveness: anticonvulsants: valproic acid 500 to 2,000 mg/day, carbamazepine 200 to 600 mg/day, topiramate 50 to 200 mg/day
• Anxiety: Benzodiazepines (especially short-acting) should be avoided given the risk of substance abuse and questionable benefit in PTSD (5)[A]. Consider hydroxyzine 25 to 50 mg TID/QID PRN or risperidone 0.25 to 0.50 mg TID PRN.

ADDITIONAL THERAPIES
• Psychotherapeutic interventions:
  – Exposure therapies have shown the highest effectiveness for treatment of PTSD (6)[A]:
    o Behavioral and CBT: Early CBT, including virtual exposure, has been shown to speed recovery. CBT is considered the standard of care for PTSD by the U.S. Department of Defense.
    o 1-week intensive CBT was as effective as 3 months weekly CBT in one study.
    o Prolonged exposure therapy: Reexperience distressing trauma-related memories and reminders to facilitate habituation and successful emotional processing of memory.
    o Eye movement desensitization and reprocessing (EMDR) has been shown to benefit patients with PTSD.
  – Stress-reduction techniques:
    o Immediate symptom reduction (e.g., rebreathing in a bag for hyperventilation)
    o Early recognition and removal from a stress
    o Relaxation, meditation, and exercise techniques are also helpful in reducing the reaction to stressful events.
  – Telemedicine-based collaborative care (nurse, case manager, pharmacy, psychology, psychiatry) is more effective than usual care.
• Interpersonal psychotherapy:
  – Supportive psychotherapy with an emphasis on the here and now
• Social:
  – Consider social and/or spiritual support for trauma survivors.
Pediatric Considerations
There is very little evidence to support use of pharmacologic interventions for pediatric PTSD.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Inpatient care is necessary only if the patient becomes suicidal/homicidal or for treatment of comorbid conditions (e.g., uncontrolled psychosis, substance abuse).

ONGOING CARE

PATIENT EDUCATION
National Center for PTSD: www.ptsd.va.gov

PROGNOSIS
- Varies significantly from patient to patient
- In 50% of cases, the symptoms spontaneously remit after 3 months; however, in other cases, symptoms may persist, often for many years, and cause long-term impairment in life functioning.
- Factors associated with a good prognosis include:
  - Rapid engagement of treatment
  - Early and ongoing social support
  - Avoidance of retraumatization
  - Absence of other psychiatric disorders/substance abuse

COMPLICATIONS
Increased risk for panic disorder, agoraphobia, obsessive-compulsive disorder, social phobia, specific phobia, major depressive disorder, somatization disorder; impulsive behavior, suicide, and homicide. Victims of sexual assault are at especially high risk for developing mental health problems and committing suicide.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- F43.10 Post-traumatic stress disorder, unspecified
- F43.11 Post-traumatic stress disorder, acute
- F43.12 Post-traumatic stress disorder, chronic

**CLINICAL PEARLS**

- Treatment is often best accomplished with a combination of psychotherapy and pharmacotherapy.
- Symptoms usually wax and wane over the years.
PREECLAMPSIA AND ECLAMPSIA
(TOXEMIA OF PREGNANCY)

Jessica Marabella, MD

BASICS

DESCRIPTION

- **Preeclampsia:**
  - A disorder of pregnancy occurring after 20 weeks’ gestation characterized by new-onset hypertension (HTN), new-onset proteinuria, ± impaired organ function:
    - May progress from mild to life-threatening in hours to days
    - Reversible by delivery
- **Eclampsia:**
  - New-onset grand mal seizure activity with no history of underlying neurologic disease
- **Most postpartum cases of preeclampsia and eclampsia occur within 48 hours of delivery but can occur up to 4 weeks postpartum.**
- **System(s) affected:** cardiovascular, renal, reproductive, fetoplacental, CNS, hepatic, pulmonary
- **Synonym(s):** toxemia of pregnancy

EPIDEMIOLOGY

Prevalence

- **Predominant age**
  - Most in younger women, primiparous women
  - Older (>40 years) patients with preeclampsia have 4 times the incidence of seizures compared with patients in their 20s.
- **Preeclampsia occurs in 5–8% of all pregnancies.**
- **Eclampsia occurs:**
  - 1.6 to 10 out of 10,000 deliveries in developed countries
  - 6 to 157 out of 10,000 deliveries in developing countries
- **40% of eclamptic seizures occur before delivery; 16% occur >48 hours after delivery.**
- **Eclampsia is a main cause of perinatal mortality and morbidity (2–8% of all...**
ETIOLOGY AND PATHOPHYSIOLOGY

- Cause of preeclampsia is becoming clearer.
  - Abnormal placental implantation
  - Angiogenic factors
  - Genetic predisposition
  - Immunologic phenomena
  - Vascular endothelial damage and oxidative stress

- Systemic derangements in eclampsia include the following:
  - Cardiovascular: generalized vasospasm
  - Hematologic: decreased plasma volume, increased blood viscosity, hemoconcentration, coagulopathy
  - Renal: decreased glomerular filtration rate
  - Hepatic: periportal necrosis, hepatocellular damage, subcapsular hematoma
  - CNS: cerebral vasospasm and ischemia, cerebral edema, cerebral hemorrhage

Genetics

2 to 4 times increased risk in pregnant women with family history of preeclampsia

RISK FACTORS

- Nulliparity
- Age >40 years
- Family history of preeclampsia
- High body mass index
- Diabetes
- Chronic HTN
- Chronic renal disease
- Multifetal pregnancy
- Previous pregnancy with preeclampsia
- Systemic lupus erythematosus
- In vitro fertilization

GENERAL PREVENTION

- Adequate prenatal care
- Inadequate prenatal care results in 7 times increase in mortality.
Good control of preexisting HTN

Low-dose acetylsalicylic acid (ASA) (60 to 80 mg):

- ASA started early (12 to 20 weeks’ gestational age [GA]) may lower the risk of developing preeclampsia and the rate of preterm delivery and neonatal death in moderate- to high-risk patients (see “Risk Factors” as mentioned earlier) (1)[A].

Low-dose calcium supplementation has been shown to reduce the risk and severity of preeclampsia in calcium-deficient populations (1)[A].

Some evidence suggests vitamin C (1,000 mg/day) and vitamin E (400 IU/day) may reduce the risk for preeclampsia, but recent guidelines recommend against their use.

**COMMONLY ASSOCIATED CONDITIONS**

Abruptio placentae, placental insufficiency, fetal growth restriction, preterm delivery, fetal demise maternal seizures (eclampsia), maternal pulmonary edema, maternal liver/kidney failure, or maternal death

**DIAGNOSIS**

Preeclampsia diagnosis:

- New-onset elevated BP: SBP ≥140 mm Hg or DBP ≥90 mm Hg (on two occasions at least 4 hours apart) or ≥160/110 mm Hg after 20 weeks of gestation (within a shorter interval), and either
  - Proteinuria (>300 mg/24 hr or spot protein: creatinine ≥0.3) or
  - New-onset thrombocytopenia, renal insufficiency, impaired liver function, pulmonary edema, or cerebral/visual symptoms (1)[C]
- Define preeclampsia as either without or with severe features. The presence of new onset of one or more of below defines severe features (1):
  - BP ≥160/110 mm Hg
  - Platelets <100,000/μL
  - >2 times normal liver transaminase levels, severe persistent right upper quadrant (RUQ)/epigastric pain, or both
  - Creatinine >1.1 mg/dL or doubling of serum creatinine levels
  - Pulmonary edema
  - Cerebral or visual symptoms

Eclampsia diagnosis:

- New-onset grand mal seizure
- No history of neurologic disease
HISTORY

- May be asymptomatic. In some cases, rapid excessive weight gain (>5 lb/week; >2.3 kg/week); more severe cases are associated with epigastric/RUQ pain, headache, altered mental status, and visual disturbance. Note: Headache, visual disturbance, and epigastric or RUQ pain often precede seizure.
- Seizures may occur once/repeatedly.

PHYSICAL EXAM

BP criteria:
- Preeclampsia without severe features: elevated BP ≥140/90 mm Hg
- Preeclampsia with severe features: Elevated BP ≥160 systolic mm Hg or 110 mm Hg diastolic
- Eclampsia: tonic-clonic seizure activity (focal/generalized)
- Normal BP, even in response to treatment; does not rule out potential for seizures

DIFFERENTIAL DIAGNOSIS

- Chronic HTN: HTN before pregnancy; high BP before the 20th week
- Chronic HTN with superimposed preeclampsia
- Gestational HTN: Increased BP first discovered after 20 weeks, often close to term, with no proteinuria and without evidence of organ dysfunction. BP becomes normal by 12 weeks postpartum, or it is reclassified as chronic HTN.
- Seizures in pregnancy: epilepsy, cerebral tumors, meningitis/encephalitis, and ruptured cerebral aneurysm. Until other causes are proven; however, all pregnant women with convulsions should be considered to have eclampsia.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Routine spot urine testing or urinalysis for protein should be done at each prenatal visit in all hypertensive patients.
- Complete blood count (CBC), including platelets, creatinine, serum transaminase levels, and uric acid as baseline in hypertensive patients and if preeclampsia suspected or possible
- Coagulation profiles: Abnormalities suggest severe disease.
- 24-hour urine or protein/creatinine ratio if urine protein dips 1+ on more than one occasion, or if preeclampsia is being considered
- Daily fetal movement monitoring by mother ("kick counts")
- US imaging is used to monitor growth and cord blood flow; perform, as indicated, based on clinical stability and laboratory findings.
- Nonstress test (NST) at diagnosis and then twice weekly until delivery
- Biophysical profile (BPP) if NST is nonreactive (1)[C]
- US imaging for growth progress every 3 weeks, and amniotic fluid volume at least once weekly (1)[C]
- With seizures, CT scan and MRI should be considered if focal findings persist or uncharacteristic signs/symptoms are present.

**Follow-Up Tests & Special Considerations**
Disseminated intravascular coagulation, thrombocytopenia, liver dysfunction, and renal failure can complicate preeclampsia associated with HELLP syndrome.

**Test Interpretation**
CNS: cerebral edema, hyperemia, focal anemia, thrombosis, and hemorrhage. Cerebral lesions account for 40% of eclamptic deaths.

---

**TREATMENT**

**GENERAL MEASURES**
- Preeclampsia without severe features:
  - Outpatient care
  - Maternal: daily home BP monitoring; daily weights; weekly labs (CBC, creatinine, liver function test [LFT])
  - Fetal:
    o Patient-measured: daily "kick counts"
    o NST/BPP/US (see imaging section above)
    o Delivery at 37 weeks (induction of labor) (1,2)[C]
    o Steroids for gestation <37 weeks
- Preeclampsia with severe features:
  - Inpatient care
  - Maternal:
    o Daily labs
    o IV magnesium sulfate (MgSO₄) as seizure prophylaxis
    o Antihypertensive therapy titrated to keep systolic BP <160 mm Hg and diastolic BP <110 mm Hg (some recommend <150/100 mm Hg)
postpartum)

– Fetal:
  o Continuous heart monitoring
  o Daily US with BPP
  o Check amniotic fluid levels and fetal growth.
– Definitive management (delivery) depends on GA (1,2)[C].
– <23 weeks:
  o Offer to terminate pregnancy.
– At 23 to 34 weeks:
  o Antihypertensives
  o Evaluate maternal–fetal condition.
  o Steroids to enhance fetal lung maturity
  o Plan delivery at 34 weeks with magnesium sulfate prophylaxis.
  o If HELLP syndrome (full or partial), severe oligohydramnios, significant renal dysfunction, persistent symptoms, fetal growth restriction, onset of labor, OR PROM, proceed to delivery.
– At ≥34 weeks: magnesium sulfate, steroids, and proceed to delivery (1)[C]; steroids indicated up to 37 weeks

**ALERT**

- Regardless of GA, emergent delivery is recommended if there are signs of maternal hypertensive crisis, abruptio placentae, uterine rupture, or fetal distress.
- Seizures: control of convulsions, correction of hypoxia and acidosis, lowering of BP, steps to effect delivery as soon as convulsions are controlled
- Administer betamethasone 12 mg IM daily × 2 doses or dexamethasone 6 mg every 12 hours × 4 doses if delivery <37 weeks possible.

**MEDICATION**

**First Line**

- Seizure prophylaxis for women with severe preeclampsia:
  – Magnesium sulfate: loading dose 4 g IV in 200 mL normal saline over 20 to 30 minutes; maintenance dose 1 to 2 g/hr IV continuous infusion (Although recent guidelines suggest it not be universally administered for seizure prophylaxis to prevent eclampsia, the quality of the evidence is low, and the strength of the recommendation is qualified.) (1)[C]

- Blood pressure control:
  – Antihypertensives are inadvisable for mildly elevated BP (without severe
– Labetalol (IV): 20 mg over 2 minutes followed at 20 to 30 minutes intervals with doses of 20 to 80 mg titrated to keep BP <160/110 mm Hg; max of 300 mg/24 hr (contraindicated in asthma, heart disease, congestive heart failure)
– Hydralazine (IV): 5 to 10 mg over 2 minutes, followed at 20 minutes intervals with 5 to 10 mg IV boluses; titrated to keep BP <160/110 mm Hg; max of 25 mg/24 hr

– Nifedipine sustained-release (PO) (used in the postpartum): 30 to 120 mg/day (caution with combination of nifedipine and magnesium sulfate resulting in hypotension and neuromuscular blockade) (3)[A]

**Eclampsia/seizures:**
– Magnesium sulfate for seizures
  o 4 to 6 g IV over 15 to 20 minutes followed by 1 to 2 g/hr infusion
  o Further boluses of magnesium may be given for recurrent convulsions with the amount given based on the neurologic examination and patellar reflexes.
  o Contraindications: myasthenia gravis, renal failure, pulmonary edema
– Levels of 6 to 8 mEq/mL are considered therapeutic, but monitor clinical status of:
  o Patellar reflexes are present.
  o Respiration are not depressed.
  o Urine output is ≥25 mL/hr.
– May be given safely, even in the presence of renal insufficiency

**Fluid therapy**
– Ringer lactated solution with 5% dextrose at 60 to 120 mL/hr, with careful attention to fluid–volume status
– Calcium carbonate (1 g, administered slowly IV) may reverse magnesium-induced respiratory depression (1,2)[C].

**Second Line**
– In randomized trials, magnesium sulfate was found to be superior to phenytoin in treatment and prevention of eclampsia and probably more effective and safer than diazepam.
– Diazepam 2 mg/min until resolution or 20 mg given or
– Lorazepam 1 to 2 mg/min up to total of 10 mg or
– Phenytoin 15 to 20 mg/kg at a maximum rate of 50 mg/min or
– Levetiracetam 500 mg IV or oral may be repeated in 12 hours (dose needs to be adjusted in renal impairment) or
– Phenobarbital 20 mg/kg infused at 50 mg/min; may repeat with additional 5 to
10 mg/kg after 15 minutes

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Without severe features: restricted activity and close monitoring; with severe features: restricted activity, in hospital
- Women with a history of preeclampsia should report this to physicians caring for them in later life. It is a potent cardiovascular disease risk factor.

**DIET**

- Salt restriction is inadvisable because the patient often is experiencing intravascular hypovolemia.
- Calcium supplementation may be recommended for women who have low calcium intake (<600 mg/day).

**PATIENT EDUCATION**

American Congress of Obstetricians and Gynecologists, 409 12th St. SW, Washington, DC 20024-2188; (800) 762-ACOG; [http://www.acog.org/](http://www.acog.org/)

**PROGNOSIS**

- For nulliparous women with preeclampsia before 30 weeks of gestation, the recurrence rate for the disorder may be as high as 40% in future pregnancies.
- 25% of eclamptic women will have HTN during subsequent pregnancies, but only 5% of these will be severe and only 2% will be eclamptic again.
- Preeclamptic, multiparous women may be at higher risk for subsequent essential HTN; they also have higher mortality during subsequent pregnancies than do primiparous women.

**COMPLICATIONS**

- Most women do not have long-term sequelae from eclampsia, although many may have transient neurologic deficits.
- A history of preeclampsia is equivalent to traditional risk factors for cardiovascular disease. Women with a history of preeclampsia should be strongly advised to avoid obesity and smoking. Other signs of metabolic syndrome should be closely monitored as well.
- Intrauterine growth restriction (IUGR)
• Maternal and/or fetal death

REFERENCES

ADDITIONAL READING

CODES

ICD10

• O14.90 Unspecified pre-eclampsia, unspecified trimester
• O15.00 Eclampsia in pregnancy, unspecified trimester
• O14.00 Mild to moderate pre-eclampsia, unspecified trimester

CLINICAL PEARLS

• Management of preeclampsia depends on both the severity of the condition and the GA of the fetus.
• Diagnosis no longer requires presence of proteinuria.
• Low-dose ASA starting in early pregnancy in high-risk patients may lower rate of preeclampsia.
Continue to monitor maternal blood pressures postpartum—still at risk for developing preeclampsia.
PREMENSTRUAL SYNDROME (PMS) AND PREMENSTRUAL DYSPHORIC DISORDER (PMDD)

Jeremy Golding, MD, FAAFP

BASICS

DESCRIPTION

- Premenstrual syndrome (PMS), a complex of physical and emotional symptoms sufficiently severe to interfere with everyday life, occurs cyclically during the luteal phase of menses.
- Premenstrual dysphoric disorder (PMDD) is a severe form of PMS characterized by severe recurrent depressive and anxiety symptoms, with premenstrual (luteal phase) onset, that remits a few days after the start of menses.
- PMDD is now included as a full diagnostic category in the 5th edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5).
- System(s) affected: endocrine/metabolic, nervous, reproductive

EPIDEMIOLOGY

Prevalence

- Many women have some physical and psychological symptoms before menses (this is not PMS).
- Premenstrual disorders affect up to 12% of the U.S. population (1). 3–8% of menstruating women have PMDD.

ETIOLOGY AND PATHOPHYSIOLOGY

Not well understood. Leading theories postulate metabolites of progesterone interact with central neurotransmitter receptors (serotonin and γ-aminobutyric acid [GABA]), provoking downstream effects of decreased GABA-mediated inhibition and decreased serotonin levels. Women with PMS/PMDD have similar levels of progesterone but seem to have an increased sensitivity to its metabolites, compared with women without PMS/PMDD.
Genetics
- Role of genetic predisposition is controversial; however, twin studies do suggest a genetic component.
- Involvement of gene coding for the serotonergic 5HT1A receptor and allelic variants of the estrogen receptor-α gene (ESR1) is suggested.

RISK FACTORS
- Age: usually present in late 20s to mid-30s
- History of mood disorder (major depression, bipolar disorder), anxiety disorder, personality disorder, or substance abuse
- Family history
- Low parity
- Tobacco use
- Psychosocial stressors/history of trauma
- High BMI

DIAGNOSIS

HISTORY
- DSM-5 criteria (1):
  - Symptoms occur 1 week before menses, improve in the first few days after menses begin, and are minimal/absent in the week following menses (over most menstrual cycles during the past year).
  - ≥5 of the following (1 must be among the first 4):
    - Marked depressed mood, feelings of hopelessness, or self-deprecating thoughts
    - Marked anxiety, tension, and/or feelings of being keyed up or on edge
    - Marked affective lability (mood swings)
    - Marked irritability or anger or increased interpersonal conflicts
    - Decreased interest in usual activities and social withdrawal
    - Lethargy, easy fatigability, or lack of energy
    - Appetite change, overeating, food cravings
    - Hypersomnia or insomnia
    - Feeling out of control or overwhelmed
    - Subjective difficulty concentrating
    - Physical symptoms, such as abdominal bloating, breast tenderness, headaches, weight gain, and joint/muscle pain
• For PMDD, emotional symptoms must be sufficiently severe to interfere with work, school, usual social activities, or relationships with others.
• Symptoms may be superimposed on an underlying psychiatric disorder but may not be an exacerbation of another condition, such as panic disorder/major depression.
• Criteria should be confirmed by prospective patient record of symptoms for a minimum of two consecutive menstrual cycles (without confirmation, “provisional” should be noted with diagnosis).
• Use the Daily Record of Severity of Problems (available online at http://www.aafp.org/afp/2011/1015/p918-fig1.pdf) or similar inventory (1)[C].
• Symptoms should not be attributable to drug abuse, medications, or other medical conditions.

PHYSICAL EXAM
No specific physical exam required; may consider thyroid and pelvic exams if indicated by additional patient symptoms

DIFFERENTIAL DIAGNOSIS
• Premenstrual exacerbation of underlying psychiatric disorder
• Psychiatric disorders (especially bipolar disorder, major depression, anxiety)
• Thyroid disorders
• Perimenopause
• Premenstrual migraine
• Chronic fatigue syndrome
• Irritable bowel syndrome (painful symptoms)
• Seizures
• Anemia
• Endometriosis (painful symptoms)
• Drug/alcohol abuse

DIAGNOSTIC TESTS & INTERPRETATION
• The repetitive nature of symptoms precludes need for labs if a classic history is present.
• Consider
  – Hemoglobin to rule out anemia
  – Serum thyroid-stimulating hormone (TSH) to rule out hypothyroidism
• Imaging with pelvic ultrasound to diagnose causes of pelvic pain and dysmenorrhea may be needed.
TREATMENT

GENERAL MEASURES
Although evidence is lacking for aerobic exercise in treating PMS/PMDD, it is often recommended as part of an integrated care plan.

MEDICATION

First Line
- SSRIs show a small to moderate effect in the treatment of physical, functional, and behavioral symptoms of PMS and PMDD compared to placebo (2)[A]:
  - Both intermittent luteal phase dosing and continuous full-cycle dosing are effective with no clear evidence of difference between modes of administration (2)[A].
  - All SSRIs tested appeared effective (2)[A].
  - SSRIs are effective at low doses. Higher doses have increased effect but are accompanied by increased side effects (2)[A].
- Fluoxetine (Prozac, Sarafem) 20 mg/day every day or 20 mg/day only during luteal phase, or 90 mg once a week for 2 weeks in luteal phase
- Sertraline (Zoloft) 50 to 150 mg/day every day or 50 to 150 mg/day only during luteal phase
- Citalopram (Celexa) 10 to 30 mg/day every day or 10 to 30 mg/day only during luteal phase

Adverse effects (number needed to harm [NNH] with moderate-dose SSRI):
- nausea (NNH = 7), asthenia (NNH = 9), somnolence (NNH = 13), fatigue (NNH = 14), decreased libido (NNH = 14), and sweating (NNH = 14) (2)[A]
- Contraindications: patients taking monoamine oxidase inhibitors (MAOIs)
- Precautions
  - Increased risk of suicidal thinking and behavior in children and adolescents with depressive disorders; uncertain if this risk applies to those taking SSRIs for PMDD
  - Bipolar disorder
  - Seizure disorder
  - QTc prolongation (with citalopram)
  - Hepatic dysfunction
  - Renal dysfunction
- Possible interactions
  - MAOIs
– Selegiline
– Pimozide
– Thioridazine
– Cimetidine, omeprazole, and QTc-prolonging agents (with citalopram)

**Second Line**
Alternative therapies should be considered if no response to SSRIs:

- Spironolactone (Aldactone) 50 to 100 mg/day for 7 to 10 days during luteal phase; helpful for fluid retention; adverse reactions: lethargy, headache, irregular menses, hyperkalemia
- Oral contraceptive pills (OCPs)
  - OCPs can cause adverse effects similar to PMDD symptoms (3)[B].
  - Extended-cycle use of OCPs (e.g., 12 weeks on and 1 week off) or a shorter placebo interval (e.g., 24 active pills with 4 placebo days [24/4] compared with 21/7 preparations) may be beneficial (3)[B].
  - OCPs containing the progestin drospirenone (structurally similar to spironolactone) may improve physical symptoms and mood changes associated with PMDD (4)[A]. Caution: Risk of venous thromboembolism may be modestly higher than with other OCPs (3)[B].
  - Continuous administration of levonorgestrel/ethinyl estradiol may improve patient symptoms in PMDD (3)[B].
    - Suggested OCP formulations:
      - Ethinyl estradiol 0.02 to 0.03 mg/drospirenone 3 mg
        (Gianvi/Loryna/Nikki/Ocella/Syeda/Vestura/Yasmin/Yaz Zarah): 1 tablet/day
      - Ethinyl estradiol 0.02 to 0.03 mg/drospirenone 3 mg/levomefolate 0.451 mg (Beyaz/Safyral): 1 tablet/day
      - Levonorgestrel 90 μg/ethinyl estradiol 20 μg (Amethyst/Lybrel): 1 tablet/day
- Anxiolytics
  - Alprazolam (Xanax) 0.25 mg TID–QID only during luteal phase; taper at onset of menses (other benzodiazepines not studied for PMDD); caution: addictive potential
  - Buspirone (Buspar) 10 to 30 mg/day divided BID–TID in the luteal phase
- Ovulation inhibitors
  - Gonadotropin-releasing hormone (GnRH) agonists: leuprolide (Lupron) depot 3.75 mg/month IM
    - Precautions: Menopause-like side effects (e.g., osteoporosis, hot flashes,
headaches, muscle aches, vaginal dryness, irritability) limit treatment to 6 months; may be first step if considering bilateral oophorectomy for severe, refractory PMDD

- Danazol (Danocrine) 300 to 400 mg BID; adverse reactions: androgenic and antiestrogenic effects (e.g., amenorrhea, weight gain, acne, fluid retention, hirsutism, hot flashes, vaginal dryness, emotional lability)
- Estrogen, transdermal preferred, 100 to 200 μg:
  o Precautions: increased risk of blood clot, stroke, heart attack, and breast cancer
  o Requires concomitant progesterone add-back therapy to protect against uterine hyperplasia and endometrial cancer

**ISSUES FOR REFERRAL**
Referral to psychiatrist may be indicated for mood/anxiety disorders if patient has no symptom-free period.

**ADDITIONAL THERAPIES**
Cognitive-behavioral therapy (CBT) is theoretically helpful for PMS/PMDD given its application for symptom reduction in other mood disorders, but direct evidence is lacking.

**SURGERY/OTHER PROCEDURES**
Bilateral oophorectomy, usually with concomitant hysterectomy, is an option for rare, refractory cases with severe, disabling symptoms.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Acupuncture demonstrated superiority to progestins, anxiolytics, and sham acupuncture with no evidence of harm (6)[A].

- Some data support the use of the following (7)[A]:
  - Calcium: 600 mg BID
  - Vitamin B₆: 50 to 100 mg/day
  - Chasteberry (*Vitex agnus-castus*): 4 mg/day of extract containing 6% of agnuside (or 20 to 40 mg/day of fruit extract)
  - Omega-3 fatty acids 2 g/day

- Data insufficient regarding the following (7)[A]:
  - Magnesium: 200 to 400 mg/day
- Vitamin D: 2,000 IU/day
- Vitamin E: 400 IU/day
- Manganese: 1.8 mg/day
- St. John’s wort: 900 mg/day
- Soy: 68 mg/day isoflavones
- Ginkgo: 160 to 320 mg/day
- Saffron: 30 mg/day

Evidence supporting efficacy and/or safety of herbal products is lacking; the following products/interventions have not been found useful for PMS/PMDD, although not all studies are of high quality and able to eliminate possibility of benefit completely (7)[A]:
- Evening primrose oil
- Black currant oil
- Black cohosh
- Wild yam root
- Dong quai
- Kava kava
- Light-based therapy

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Increased risk of suicidal thinking and behavior in children and adolescents with depressive disorders on initiation of SSRIs; uncertain if this risk applies to those taking SSRIs for PMDD

DIET
- Reduce consumption of salt, sugar, caffeine, dairy products, and alcohol (anecdotal reports).
- Eat small, frequent portions of food high in complex carbohydrates (limited data).

PATIENT EDUCATION
- Counsel patients to eat a balanced diet rich in calcium, vitamin D, and omega-3 fatty acids and low in saturated fat and caffeine.
Counsel women that they are not “crazy.” PMDD is a real disorder with a physiologic basis. Although incompletely understood, successful treatment is often possible.

PROGNOSIS
- Many patients can have their symptoms adequately controlled. PMS disappears at menopause.
- PMS can continue after hysterectomy, if ovaries are left in place.

ADDITIONAL READING

**CODES**

**ICD10**

N94.3 Premenstrual tension syndrome

**CLINICAL PEARLS**

• Have the patient keep a daily log of her symptoms and menses. Symptoms beginning in the week before menses and abating before the end of menses, occurring over at least 2 months, and sufficiently severe to interfere with daily functioning are diagnostic of PMS.

• The difference between PMS and PMDD is that PMDD is a severe form of PMS characterized by recurrent depressive and anxiety symptoms with luteal phase onset, sufficiently severe to disrupt social and occupational functioning. These symptoms remit a few days after the onset of menses.

• PMDD is not the same as more generalized depressive/anxiety disorders. PMDD-associated symptoms of depression and anxiety begin to resolve within the first few days of menses.

• Treatment only during the luteal phase is likely as effective as continuous-cycle treatment with SSRIs but has fewer adverse effects.
BASICS

The goal of prenatal care is to ensure the birth of a healthy baby with minimal risk for the mother by the following:

- Identifying the patient who is at risk for complications
- Estimating the gestational age (GA) as accurately as possible
- Evaluating the health status of mother and fetus
- Encouraging and empowering the patient to do her part to care for herself and her baby-to-be
- Intervening when fetal abnormalities are present to prevent morbidity

GENERAL PREVENTION

- A recommended prenatal care schedule consists of the following:
  - Monthly visits to a health care professional for weeks 4 to 28 of pregnancy
  - Visits twice monthly from 28 to 36 weeks
  - Weekly after week 36 (delivery at weeks 38 to 40)
- Recommendations for use of dietary supplements in pregnancy
  - Folic acid supplementation (0.4 to 0.8 mg) prior to conception; 4 mg for secondary prevention
  - Calcium: 1,000 to 1,300 mg/day; supplement may be beneficial for women with high risk for gestational hypertension or communities with low dietary calcium intake.
  - Iron: Screen for anemia (Hgb/Hct) and treat if necessary.
  - Vitamin A: Pregnant women in industrialized countries should limit to <5,000 IU/day.
  - Vitamin D: Consider supplementation in women with limited exposure to sunlight.
- Routine screening for thyroid and vitamin D deficiency during pregnancy is not recommended.

DIAGNOSIS
HISTORY
At the initial visit, a complete medical, obstetrical, family, and psychosocial history should be obtained and updated throughout the pregnancy.

- Assess and counsel as appropriate regarding the following:
  - Lifestyle, nutrition, safety of medications (teratogenicity, category); tobacco, alcohol, and drug use; toxins; relationship issues/domestic violence; stressors/supports; work environment; risk factors
- Domestic violence
  - ACOG guidelines recommend that physicians screen all pregnant patients for intimate partner domestic violence.
    - At the first prenatal visit
    - At least once per trimester
    - At the postpartum checkup

PHYSICAL EXAM
- A full physical exam should be performed at the first prenatal appointment.
- At each subsequent prenatal visit, the following should be recorded:
  - Weight: Suggested pregnancy weight gain is 25 to 35 lb for normal-weight women with lower weight gains (11 to 20 lb) recommended for obese women.
  - BP
    - ACOG defines hypertension as BP >140 mm Hg systolic or >90 mm Hg diastolic (1).
    - Monitor BP especially closely in patients with chronic hypertension (predating pregnancy), preeclampsia/eclampsia, or gestational hypertension.
  - UA for glucose and protein; 24-hour protein excretion is the gold standard but not practical.
  - Fundal height
  - Fetal heart rate: usually audible by 12 weeks’ GA with a Doppler instrument
  - Routine fetal movement counts not recommended
  - Fetal position by abdominal palpation at 36 weeks
  - Pelvic/cervical exam if indicated

DIAGNOSTIC TESTS & INTERPRETATION
Cervical cancer screening
- A Pap smear should be obtained when indicated by standard Pap screening
guidelines, regardless of gestation (ACOG, USPSTF, ASCCP, ACS, and ASCP guidelines state that women <21 years should not be screened regardless of age of sexual initiation or other risk factors).

- Squamous intraepithelial lesions can progress during pregnancy but often regress postpartum.
- LSIL in pregnancy: colposcopy preferred, but it is acceptable to defer colposcopy to postpartum (2)
- Colposcopy only to exclude the presence of invasive cancer in high-risk women
- Cervical biopsy should be avoided unless a malignancy is suspected. Endocervical sampling is contraindicated.
- First prenatal visit
  - Lab tests
    - Hematocrit or hemoglobin
    - Blood type: A, B, AB, or O
    - Rhesus type and antibody screen: Rh(+) or Rh(−)
    - Hemoglobin electrophoresis for patients at risk for sickle cell disease or thalassemia
    - Urine testing for glucose and protein
    - Urine culture
    - Rubella titer
    - Syphilis test
    - Gonorrhea/chlamydia screening
    - Hepatitis B surface antigen
    - HIV testing
    - Routine screening for bacterial vaginosis, toxoplasmosis, CMV, and parvovirus not recommended
    - Cystic fibrosis screening (information should be made available to all couples)
      - Cystic fibrosis carrier screening should be offered before conception or early in pregnancy when one partner is of Caucasian, European, or Ashkenazi Jewish descent.
  - Screening tests (for birth defects), noninvasive
    - US nuchal translucency (NT): measures thickness at the back of the neck of the fetus
    - Blood screens: human chorionic gonadotropin (hCG), pregnancy-associated plasma protein A (PAPP-A), quad screen: α-fetoprotein (AFP), unconjugated estriol (UE3), hCG, inhibin-A (INH-A)
    - Cell-free DNA testing should be offered as an alternative noninvasive
method of screening for fetal aneuploidies to high-risk pregnant women between 10 and 22 weeks’ gestation. Women who elect cell-free DNA testing will also need an AFP test for neural tube defects (NTDs). The assay also allows screening for aneuploidy, rhesus typing in Rh(D)-negative women, and single-gene disorders (limited to detection of paternally inherited mutation). Because of a small but real risk for false-positive results, most experts advise using these assays as screening tests and confirming positive result with invasive prenatal diagnostics.

- **1st-trimester screening** between 11 and 14 weeks’ GA using both NT and hCG/PAPP-A blood testing is an effective protocol in the general population and is more effective than NT alone, with an 83% detection rate for Down syndrome, with false-positive rate of 5%. Detects trisomy 21 (Down syndrome) and trisomy 18 (Edward syndrome); may be performed either as a single combined stand-alone test (US NT 1 blood [HCG and PAPP-A]) or as part of a sequential “step-by-step” 1st- and 2nd-trimester screening process (see the following discussion)

- **2nd-trimester screening protocols**
  - Obtain “multiple marker”/quad screen between 15 and 21 weeks’ GA, optimally between 16 and 18 weeks; ~84% detection rate for trisomy 21, trisomy 18, and NTDs, with false-positive rate of 5%, or  
  - 2-step integrated screening protocol: combines information collected during the 1st and 2nd trimesters of the pregnancy to determine the risk of Down syndrome, trisomy 18, or open NTD:
    - Two options: stepwise sequential integrated screen (~91% detection rate with false-positive rate 3.3%):
      - 1st trimester: NT measurement, plus blood (hCG, PAPP-A):
        - If calculated risk for Down syndrome is ≥1:30, then additional steps are recommended (genetic counseling, US, and chorionic villi sampling [CVS]).
        - If calculated risk for Down syndrome is <1:30 then
          - 2nd-trimester quad screen (AFP, UE3, hCG, INH-A) is required, or
          - Serum integrated screen: 88% detection rate with false-positive rate of 4.5%; requires a 1st-trimester PAPP-A blood test without NT measurement, and a 2nd-trimester (16- to 18-week quad screen)

- Diagnostic tests (for birth defects), invasive
  - ACOG guidelines: All pregnant women, not just women ≥35 years, should be offered invasive prenatal diagnostic testing, such as CVS and
amniocentesis to detect possible genetic abnormalities in their fetuses (3) [C].

- Women found to be at increased risk of having a baby with Down syndrome with 1st-trimester screening should be offered genetic counseling and the option of CVS or midtrimester amniocentesis. If screening tests show increased risk of birth defect, there are two possible diagnostic tests:
  - CVS: 1st trimester: usually done after 10 weeks (10 to 12 weeks). Small sample of the placenta; chorionic tissue sample obtained either transcervical (TC) or transabdominal (TA); complication: pregnancy loss rate of 1.0–1.5%
  - Amniocentesis
    - 1st trimester: usually at 11 to 13 weeks but higher rate of pregnancy loss and complication than either CVS or early 2nd-trimester procedures; therefore, not recommended
    - 2nd trimester: usually done after 15 weeks (15 to 18 weeks). The prenatal diagnostic technique associated with the lowest risk of pregnancy loss. Small sample of amniotic fluid from the amniotic sac surrounding the developing fetus is obtained by an US-guided TA approach; complication: pregnancy loss rate of ≤0.5%

- 24 to 28 weeks

  - Obtain diabetes screen (4)[B].
  - See the following discussion: Repeat hematocrit or hemoglobin, and repeat antibody screen in Rh-negative mother prior to receiving prophylactic Rh immunoglobulin.
    - Gestational diabetes mellitus (GDM) screening
    - The ADA and ACOG define women at increased risk of overt diabetes who need earlier screening based on body mass index (BMI). ≥25 kg/m² (≥23 kg/m² in Asian Americans) plus one or more of the following:
      - Physical inactivity
      - Previous pregnancy history of:
        - GDM
        - Macrosomia (≥4,000 g)
        - Stillbirth
      - Hypertension (140/90 mm Hg or being treated for hypertension)
      - HDL cholesterol ≤35 mg/dL (0.90 mmol/L)
      - Fasting triglyceride ≥250 mg/dL (2.82 mmol/L)
      - Hgb A1C ≥5.7%, impaired glucose tolerance or impaired fasting glucose
- PCOS, acanthosis nigricans, nonalcoholic steatohepatitis, morbid obesity, and other conditions associated with insulin resistance
- Cardiovascular disease
- Family history of diabetes—1st degree-relative (parent or sibling)
- Ethnicity of African American, American Indian, Asian American, Hispanic, Latina, or Pacific Islander

Gestational diabetes: fasting plasma glucose > 92 mg/dL but is < 126 mg/dL at any GA. At 24 to 28 weeks of gestation, a 75-g 2-hour oral glucose tolerance test (OGTT) with at least one abnormal result: FBG ≥ 92 mg/dL, but < 126 mg/dL or 1-hour ≥ 180 mg/dL, or 2-hour ≥ 153 mg/dL.

- The following guidelines for GDM are established by ACOG:
  - Specified cutoffs define GDM.
    - A value of > 130 mg/dL will identify 90% of women with GDM, but 20–25% of all women screened will need to continue to the 3-hour OGTT (4).
    - Raising the value to > 140 mg/dL will identify only 80% of women with GDM but decrease to 14–18% the number of women who will need to continue to the 3-hour OGTT (4).
  - Screening test: 1-hour OGTT (nonfasting)
    - 50 g PO glucose load with blood glucose testing 1 hour later
    - Carpenter and Coustan positive screen: > 130 mg/dL
    - National Diabetes Data Group (NDDG) positive screen: > 140 mg/dL
  - Diagnostic test: 3-hour OGTT (fasting)
    - If abnormal 1-hour OGTT screening test, may be followed by a 3-hour OGTT
    - 100 g PO glucose load with blood drawn: fasting, 1, 2, and 3 hours after ingestion of glucose
    - Either the plasma or serum glucose level designated by Carpenter and Coustan or by the NDDG is appropriate to use:
      - A positive diagnosis of GDM requires that ≥ 2 thresholds be exceeded.
      - Carpenter and Coustan standard:
        - * > 95 (fasting), > 180 (1-hour), > 155 (2-hour), > 140 (3-hour)
      - NDDG standard:
        - * > 105 (fasting), > 190 (1-hour), > 165 (2-hour), > 145 (3-hour)
  - ACOG (based on NIH consensus panel findings) still supports the “2 step” approach (24- to 28-week 1-hour venous glucose
measurement following 50 g oral glucose solution), followed by a 3-hour OGTT if positive

- Although the diagnosis of GDM is based on two abnormal values on the 3-hour OGTT, ACOG states, due to known adverse events, one abnormal value may be sufficient to make the diagnosis.
- 1-step approach (75 g OGTT) on all women will increase the diagnosis of GDM but sufficient prospective studies demonstrating improved outcomes still lacking.
- ACOG does acknowledge that some centers may opt for “1 step” if warranted based on their population.

- 35 to 37 weeks
  - Group B Streptococcus (GBS) culture: Screen all women at 35 to 37 weeks’ gestation using a 2-swab rectal and vaginal culture to identify women colonized with GBS (5)[B].
  - High-risk patients: High-risk patients should be screened again for gonorrhea, chlamydia, HIV, and syphilis.

- Postterm pregnancy
  - Rate of stillbirth increases with GA by 1/3,000 per week at 37 weeks; 3/3,000 per week at 42 weeks; and 6/3,000 at 43 weeks. In one meta-analysis, routine induction of labor at 41 weeks’ gestation reduced rates of perinatal death without increased rates of cesarean delivery.
  - For gestational periods beyond 42 weeks, fetal well-being should be assessed with nonstress testing and US assessment of amniotic fluid volume.

---

**TREATMENT**

**ISSUES FOR REFERRAL**

Abnormal screening labs or imaging may prompt referral to maternal–fetal medicine specialist or other medical specialist, as indicated.

---

**ONGOING CARE**

**PATIENT EDUCATION**

- Immunizations during pregnancy. The following vaccines are considered safe per CDC (5):
– Women should get Tdap during each pregnancy (ideally, the vaccine should be given between 27 and 36 weeks of pregnancy). Hep B and influenza are safe; likely safe include meningococcal, rabies. Contraindicated during pregnancy or safety not established: live vaccines including BCG, MMR, and varicella
– Patients should be made aware of the tests that are performed routinely, as well as other tests that might be elected (e.g., CVS or amniocentesis), as well as the choices that would be available if testing were abnormal (pregnancy termination, preparation for the birth of an infant with congenital anomalies, further testing).

- Prevention
  – Preconception counseling offers the opportunity to discuss individualized risks.
  – To decrease the risks of NTDs, preconception folate supplementation is indicated.

- Recommendations
  – Airline travel: generally safe until up to 4 weeks from EDD; lengthy trips associated with increased risk of thrombosis
  – Caffeine: Limit to <200 mg/day. Correlation between IUGR and miscarriage with caffeine is undetermined at this time.
  – Exercise: Healthy women with uncomplicated pregnancies should continue to exercise.
  – Seat belts/air bags: ACOG recommends that pregnant women wear lap and shoulder seatbelts and should not turn off air bags.
  – Sexual activity: Intercourse is not associated with adverse outcomes.

- Alcohol, cigarettes, and illicit drugs are injurious to fetal and maternal health.

- Pregnancy-safe medications (teratogenicity)

REFERENCES

**CODES**

**ICD10**
- Z34.90 Encntr for suprvsn of normal pregnancy, unsp, unsp trimester
- Z36 Encounter for antenatal screening of mother
- Z34.00 Encntr for suprvsn of normal first pregnancy, unsp trimester

**CLINICAL PEARLS**

Prenatal care and screening are best accomplished using standardized flow sheets and checklists to ensure that the complex sequence of evaluations and education is performed consistently and properly.
PREOPERATIVE EVALUATION OF THE NONCARDIAC SURGICAL PATIENT

Andrew Grimes, MD • Stacy L. Jones, MD

BASICS

DESCRIPTION

- Preoperative medical evaluation should determine the presence of established or unrecognized disease or other factors that may increase the risk of perioperative morbidity and mortality in patients undergoing surgery.
- Specific assessment goals include the following:
  - Conducting a thorough medical history and physical exam to assess the need for further testing and/or consultation
  - Recommending strategies to reduce risk and optimize patient condition prior to surgery
  - Encouraging patients to optimize their health for possible improvement of both perioperative and long-term outcomes
- Synonym(s): preoperative diagnostic workup; preoperative preparation; preoperative general health assessment

EPIDEMIOLOGY

Overall patient morbidity and mortality related to surgery is low. One large study of inpatients looking at 30-day mortality in the United States showed a rate of 1.32%. This rate varies by type of procedure and varies by country. Preoperative patient evaluation and subsequent optimization of perioperative care can reduce both postoperative morbidity and mortality.

RISK FACTORS

- Functional capacity (1): Exercise tolerance is one of the most important determinants of cardiac risk:
  - Self-reported exercise tolerance may be an extremely useful predictive tool when assessing risk. Patients unable to meet a 4-metabolic equivalents (METs) demand (defined in the “Diagnosis” section) during daily activities have increased perioperative cardiac and long-term risks.
  - Patients who report good exercise tolerance require minimal, if any, additional testing.
Levels of surgical risk
- An increased risk for major adverse cardiac events (MACE) is associated with procedures that are intrathoracic, intra-abdominal, or vascular procedures that are suprainguinal in nature (1).

Clinical risk factors (1): history of ischemic heart disease, the presence of compensated heart failure or a history of prior congestive heart failure (CHF), cerebrovascular disease, diabetes mellitus (DM), and renal insufficiency; these risk factors plus surgical risk can dictate the need for further cardiac testing.

Age: Patients > 70 years of age are at higher risk for perioperative complications and mortality and have a longer length of stay in the hospital postoperatively (likely attributed to increasing medical comorbidities with increasing age). Age alone should not be a deciding factor in the decision to proceed or not proceed with surgery.

DIAGNOSIS

HISTORY
- Evaluate pertinent medical records and interview the patient. Many institutions provide standard patient questionnaires that screen for preoperative risk factors:
  - History of present illness and treatments
  - Past medical and surgical history
  - Patient and family anesthetic history and associated complications
  - Current medications (including over-the-counter [OTC] medications, vitamins, supplements, and herbals) as well as reasons for use
  - Allergies (including specific reactions)
  - Social history: tobacco, alcohol, drug use, and cessation
  - Family history: prior illnesses and surgeries
- Systems (both history and current status)
  - Cardiovascular: Inquire about exercise capacity.
    o 1 MET: can take care of self, eat, dress, and use toilet; walk around house indoors; walk a block or 2 on level ground at 2 to 3 mph
    o 4 METs: can climb flight of stairs or walk uphill, walk on level ground at 4 mph, run a short distance, do heavy work around house, participate in moderate recreational activities
    o 10 METs: can participate in strenuous sports such as swimming, singles
tennis, football, basketball, or skiing

- Note presence of CHF, cardiomyopathy, ischemic heart disease (stable vs. unstable), valvular disease, hypertension (HTN), arrhythmias, murmurs, pericarditis, history of pacemaker or implantable cardioverter defibrillator (ICD):
  - Rhythm management devices (pacemakers and automatic ICDs [AICD]) affect the perioperative course. Most importantly, the following information needs to be available for proper management: name of cardiologist who manages the device, type of device, manufacturer, last interrogation, and any problems that have occurred recently. Based on this information and the location and type of surgery, a perioperative plan of management will be made (2).
  - Stents: Patients with coronary stents are maintained on dual antiplatelet therapy (DAPT) for a prescribed period of time. This is typically done with a thienopyridine, such as clopidogrel, in combination with aspirin. The perioperative period is associated with a prothrombotic state. Premature discontinuation of DAPT markedly increases the risk of acute stent thrombosis, myocardial infarction (MI), and death. Elective surgery should be delayed and DAPT continued for a minimum of 30 days after bare metal stent placement and 6 months after placement of a drug-eluting stent. Several caveats to these recommendations exist. Extending the time period for DAPT after stent placement is indicated in certain scenarios such as stent placement in the setting of an acute cardiac syndrome. Any perioperative disruption in the patient’s DAPT regimen needs to be discussed with the patient’s cardiologist and surgeon. The risk of perioperative bleeding must be weighed against the risks of discontinuation of DAPT prior to surgery (3).

- Pulmonary: Chronic and active disease processes should be addressed: chronic infections, bronchitis, emphysema, asthma, wheezing, shortness of breath, cough (productive or otherwise):
  - Sleep apnea: Patients with obstructive sleep apnea (OSA) are at increased risk for perioperative adverse events. Screening tools (such as the STOP/BANG) can help risk stratify patients. Additional evaluation should be considered if a patient has associated significant systemic disease, hypoventilation syndrome, severe pulmonary HTN, or resting hypoxemia (4).
  - Often, patients with an existing diagnosis of OSA who use positive airway pressure (PAP) at night are asked to bring their PAP machine to the hospital or surgery center when they are admitted for surgery. For
patients with suspected but previously undiagnosed OSA, PAP therapy should be considered on a case by case basis.

- Some studies suggest that even short periods (3 weeks) of treatment with PAP can improve some indices of ventilation and therefore may reduce postoperative morbidity.
  - GI: hepatic disease, gastric ulcer, inflammatory bowel disease, hernias (especially hiatal), significant weight loss, nausea, vomiting, history of postoperative nausea and vomiting: Any symptoms consistent with gastroesophageal reflux disease (GERD) should be optimally treated.
  - Hematologic: anemia, serious bleeding, clotting problems, blood transfusions, hereditary disorders
  - Renal: kidney failure, dialysis, infections, stones, changes in bladder function
  - Endocrine: nocturia, parathyroid, pituitary, adrenal disease, thyroid disease
    - Diabetes: Evidence that hyperglycemia in the perioperative period is associated with increased perioperative complications. Although recommendations vary, most experts recommend keeping perioperative blood glucose levels <180.
  - Neurologic/psychiatric: seizures, stroke, paralysis, tremor, migraine headaches, nerve injury, multiple sclerosis, extremity numbness, psychiatric disorders (e.g., anxiety, depression)
  - Musculoskeletal: arthritis, lower back pain
  - Reproductive: possibility of pregnancy in women of childbearing potential
- Mouth/upper airway: dentures, crowns, partials, bridges, teeth (loose, chipped, cracked, capped)

**PHYSICAL EXAM**

- Assess vital signs, including arterial BP bilaterally.
- Check carotid pulses; auscultate for bruits.
- Examine lungs by auscultating all lung fields and listening for rales, rhonchi, wheezes, or other sounds indicating disease.
- Examine cardiovascular system by auscultating heart and noting any irregular rhythms or murmurs; precordial palpation
- Palpate abdomen.
- Examine airway and mouth for ease of intubation, neck mobility, and size of tongue; note any lesions or dental deformities.
- If a regional anesthesia technique is being contemplated, perform a relevant, focused neurologic exam.
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Laboratory testing should not be obtained routinely prior to surgery unless indicated (5)[C]. Specific tests should be requested if the evaluator suspects findings from the clinical evaluation that may influence perioperative patient management.
- Labs performed within the past 4 months prior to evaluation are reliable unless the patient has had an interim change in clinical presentation or is taking medications that require monitoring of plasma level or effect.
- CBC (5)[C]
  - Hemoglobin: if a patient has symptoms of anemia or is undergoing a procedure with major blood loss; extremes of age; liver or kidney disease
  - WBC count: if symptoms suggest infection or myeloproliferative disorder or the patient is at risk for chemotherapy-induced leukopenia
  - Platelet count: if history of bleeding, myeloproliferative disorder, liver or renal disease, or the patient is at risk for chemotherapy-induced thrombocytopenia
- Serum chemistries (electrolytes, glucose, renal and liver function tests): should be obtained for extremes of age; in known renal insufficiency, CHF, liver dysfunction, or endocrine abnormalities; or the patient is on medications that alter electrolyte levels, such as diuretics
- PT/PTT: if history of a bleeding disorder, chronic liver disease, or malnutrition, or those with recent or chronic antibiotic or anticoagulant use
- Urinalysis: Routine urinalysis is not recommended preoperatively.
- Pregnancy test: controversial; should be considered for all female patients of childbearing age
- CXR is not generally indicated. It can be considered in patients with recent upper respiratory tract infection and in those with suspected cardiac or pulmonary disease (because there is a likelihood for unanticipated findings), but these indications are not considered unequivocal.

Diagnostic Procedures/Other

- ECG (1)[C]
  - Preoperative resting 12-lead ECG is reasonable for patients with known coronary disease, known peripheral vascular disease, significant arrhythmia, or known significant structural heart disease.
  - ECGs are not indicated for asymptomatic patients undergoing low-risk procedures.
The American Heart Association (AHA) guidelines recommend using the Revised Cardiac Risk Index or the ACS NSQUIP online risk calculator to make an estimate of risk of MACE in the perioperative period. If the risk of MACE is low (<1%), then proceed with surgery. If the risk is >1%, the functional capacity needs to be considered. For patients with a functional capacity of >4 METs, then proceed with surgery. If the functional capacity is <4 METs or unknown, consider pharmacologic stress testing if it will change management (1).

PFTs: Definitive data regarding the efficacy of preoperative testing are lacking. The most important factor is preoperative optimization of patients with chronic obstructive pulmonary disease (COPD) or reactive airways disease with indicated use of antibiotics, bronchodilators, and inhaled corticosteroids. Spirometry can help guide therapy. Upper abdominal and thoracic surgery has a higher risk of postoperative pulmonary complications.

TREATMENT

MEDICATION

- Reducing cardiac risk
  - Elective surgery should be delayed or cancelled if the patient has any of the following: unstable coronary syndromes (unstable or severe angina), recent MI (<30 days), decompensated heart failure, significant arrhythmias, or severe valvular disease.
  - Active HF should be treated with diuretics, afterload reduction, and β-adrenergic blockers.
  - Perioperative β-blockade has been shown to reduce mortality and the incidence of perioperative MIs in high-risk patients. Studies conflict, however, in which patients need to be treated, the dosage and timing of treatment, and for what surgeries. Patients chronically on β-blockers should have the medication continued in the perioperative period. When β-blockers are discontinued in the perioperative period, 30-day mortality increases. β-Blockers are reasonable for vascular surgery patients with at least one clinical risk factor. It is not recommended to start β-blockers on the day of surgery in β-blocker naive patients (1).
  - Perioperative statin use may have a protective effect on reducing cardiac complications. Currently, the AHA has a class I indication for perioperative statin therapy for patients already on statins prior to their surgery. There is
also evidence that vascular surgery patients benefit from perioperative statins.

- A recent review examined prophylactic use of aspirin in the perioperative period and did not find a significant effect on perioperative mortality or risk for MI in patients undergoing noncardiac surgery and may be associated with an increased risk of perioperative bleeding. There were important exclusion criteria including patients with recent stent placement.

Reducing pulmonary risk
- Recommend cigarette cessation for at least 8 weeks prior to elective surgery.
- Patients with asthma should not be wheezing and should have a peak flow of at least 80% of their predicted or personal-best value.
- Treatment of COPD and asthma should focus on maximally reducing airflow obstruction and is identical to treatment of nonsurgical patients.
- Lower respiratory tract infections (bacterial) should be treated with appropriate antibiotic therapy.

The Heart Rhythm Society (HRS)/American Society of Anesthesiologists (ASA) Expert Consensus Statement on the perioperative management of patients with implantable defibrillators, pacemakers and arrhythmia monitors: facilities and patient management this document was developed as a joint project with the American Society of Anesthesiologists (ASA), and in collaboration with the American Heart Association (AHA), and the Society of Thoracic Surgeons (STS). *Heart Rhythm*. 2011;8(7):1114–1154.

**ADDITIONAL READING**

**SEE ALSO**

Algorithm: Preoperative Evaluation of Noncardiac Surgical Patient

**CODES**

**ICD10**
- Z01.818 Encounter for other preprocedural examination
- Z01.811 Encounter for preprocedural respiratory examination
- Z01.812 Encounter for preprocedural laboratory examination

**CLINICAL PEARLS**

- The preoperative evaluation should include medical record evaluation, patient interview, and physical exam.
- The minimum for the physical exam includes airway, pulmonary, and cardiovascular exams.
- Functional capacity, the level of surgical risk, and clinical risk factors determine if further cardiac testing is needed.
- No preoperative tests are routine.
- Active cardiac conditions should lead to delay or cancellation of nonemergent surgery.
BASICS

DESCRIPTION

- Presbycusis is an age-related hearing loss (HL), showing increased incidence with age. It often presents as difficulty communicating in noisy conditions.
- May be divided into central and peripheral causes:
  - Central presbycusis: age-related change in the auditory portions of the central nervous system negatively impacting auditory perception, speech-communication performance, or both
  - Peripheral presbycusis: age-related, bilateral sensorineural HL (SNHL) typically symmetric
- Represents a lifetime of insults to the auditory system from toxic noise exposure and natural decline
- Initially presents as high-frequency SNHL with tinnitus (ringing)
- Impacts the “clarity” of sounds (i.e., ability to detect, identify, and localize sounds)
- Due to mild and progressive nature, presbycusis is often treated with amplification alone.
- Can lead to adverse effects on physical, cognitive, emotional, behavioral, and social function in the elderly (e.g., depression, social isolation)

EPIDEMIOLOGY

Incidence

According to an ongoing community-based epidemiologic study, the 10-year cumulative incidence rates of HL are as follows, approximately:

- Age 48 to 59 years: M (31.7%), F (15.6%); all (21.8%)
- Age 60 to 69 years: M (56.8%), F (40.7%); all (45.5%)
- Age 70 to 79 years: M (87.1%), F (70.6%); all (73.7%)
- Age 80 to 92 years: M (100%), F (100%); all (100%)

Prevalence

- 10% of the population develops SNHL severe enough to impair
communication.
- Increases to 40% in the population >65 years of age
- 80% of HL cases occur in elderly patients.
- Only 10–20% of older adults with HL have ever used hearing aids (HAs).
- Predominant sex: male > female
- Hearing levels are poorer in industrialized societies than in isolated or agrarian societies.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- The external ear transmits sound energy to the tympanic membrane. The middle ear ossicles amplify and conduct the sound waves into the inner ear (cochlea) via the oval window. The organ of Corti, located in the cochlea, contains hair cells that detect these vibrations and depolarize, producing electrical signals that travel through the auditory nerve to the brain. Toxic noise exposure traumatizes the hair cells and leads to cell death and HL. New research also suggests that overexcitation of the neurosynapses causes increased glutamate, which is also neurotoxic (1).
  - Sensory presbycusis: primary loss of the hair cells in the basal end of the cochlea (high frequency HL)
  - Neural presbycusis: loss of spiral ganglion cells (nerve cells induced by hair cells to produce action potentials to travel to the brainstem)
  - Strial (metabolic) presbycusis: atrophy of the stria vascularis (the cochlear tissue that generates the endocochlear electrical potential)
  - Cochlear conductive (mechanical) presbycusis: no morphologic findings (presumed stiffening of the basilar membrane)
  - Mixed presbycusis: combinations of hair cell, ganglion cell, and stria vascularis loss
  - Indeterminate presbycusis: no morphologic findings (presumed impaired cellular function)
- Presbycusis is caused by the accumulated effects of noise exposure, systemic disease, oxidative damage, ototoxic drugs, and genetic susceptibility.

**Genetics**
Presbycusis has a clear familial aggregation:
- Heritability estimates show 35–55% of the variance of sensory presbycusis is from genetic factors; even greater percentage in strial presbycusis
- Heritability is stronger among women than men.
RISK FACTORS

- Noise exposure (military, industrial, etc.)
- Ototoxic substances
  - Organic solvents
  - Heavy metals
  - Carbon monoxide
- Drugs
  - Aminoglycosides
  - Cisplatin
  - Salicylates
  - Diuretics
- Tobacco smoking
- Alcohol
- Lower socioeconomic status
- Family history of presbycusis
- Head trauma (temporal bone fractures)
- Cardiovascular disease (hypertension, atherosclerosis, hyperlipidemia); labyrinthine artery is terminal artery to the cochlea.
- Diabetes mellitus
- Autoimmune disease (autocochleitis/labyrinthitis)
- Metabolic bone disease
- Endocrine medical conditions: levels of aldosterone
- Alzheimer disease
- Otologic conditions (e.g., Ménière disease or otosclerosis)

GENERAL PREVENTION

- Avoid hazardous noise exposure.
- Use hearing protection.
- Maintain healthy diet and exercise.
- Screening
  - In the only published RCT on screening for HL, HA use was significantly higher in three screened groups (4.1% in those using a questionnaire, 6.3% using handheld audiometry, and 7.4% using both modalities) versus unscreened control participants (3.3%) at 1-year follow-up (2)[B].
  - Based on a 2011 review, according to the USPSTF, there is insufficient evidence to assess the relative benefits and harms of HL screening in adults ≥50 years (3)[A].
DIAGNOSIS

HISTORY
- Reduced hearing sensitivity and speech understanding in noisy/public environments
- Impaired localization of sound sources
- Increased difficulty understanding conversations, especially with women, due to higher frequency of spoken voice
- Presents bilaterally and symmetrically
- If unilateral HL, alternative diagnosis should be pursued.

Additional history if HL is suspected or detected (4)[B]:
- Time course of HL
- Symptoms of tinnitus, otalgia, otorrhea, or vertigo
- History of noise exposure, ear trauma, or head trauma
- Presence of any neurologic deficit

Reports from patient/family/caregiver (4)[B]
- Confusion in social situations
- Excessive volume of television/radio/computer
- Social withdrawal
- Anxiety in group settings

PHYSICAL EXAM
- Rinne and Weber tests are helpful for determining conductive versus SNHL but not recommended for general screening.
- Pneumatic otoscopy to evaluate for simple middle ear effusion as cause of conductive HL

DIFFERENTIAL DIAGNOSIS
- Complete canal occlusion (cerumen, foreign body)
- Large external ear tumors (e.g., polyp, exostosis, squamous cell)
- Otitis externa
- Chronic otitis media or effusion
- Cholesteatoma
- Otosclerosis
- Osteogenesis imperfecta
- Large middle ear tumors (e.g., facial nerve schwannomas, paragangliomas)
- Perilymph fistula (trauma/iatrogenic)
- Ménière disease
- Acoustic neuroma (usually unilateral)
- Vascular anomaly
- Acute noise-induced traumatic loss (explosion)
- Autoimmune HL

**DIAGNOSTIC TESTS & INTERPRETATION**

- Central: synthetic sentence identification test with ipsilateral competing message and the dichotic sentence identification test
- Peripheral: handheld audiometry; insert probe in ear (sealing canal) and have patient indicate if tones can be heard.
- Screening audiometry
  - Symmetric high-frequency HL in descending slope pattern
  - SNHL frequencies >2 KHz initially
  - Essential to determine global clinical hearing status and if etiology is conductive HL versus SNHL or pseudohypacusis (conversion)

**TREATMENT**

- HAs
  - Types
    - Analog HA: picks up sound waves through a microphone; converts them into electrical signals; amplifies and sends them through the ear canal to the tympanic membrane
    - Digital HA: programmable; may reduce acoustic feedback, reduce background noise, detect and automatically accommodate different listening environments, control multiple microphones
  - HAs have an average decibel gain of 16.3 dB.
  - Associated with hypersensitivity to loud sounds (“loudness recruitment”)
- Hearing-assistive technologies (HATs)
  - Can be used alone or in combination with HAs (for difficult listening conditions)
  - Addresses face-to-face communication, broadcast or other electronic media (radio, TV), telephone conversation, sensitivity to alerting signals and environment stimuli (doorbell, baby’s cry, alarm clock, etc.)
  - Includes personal FM systems, infrared systems, induction loop systems, hardwired systems, telephone amplifier, telecoil, TDD (telecommunication...
device for the deaf), situation-specific devices (e.g., television), alerting devices

- Aural rehabilitation (also known as audiologic orientation or auditory training) (4)[A]
  - Adjunct to HA or HATs
  - Involves education regarding proper use of amplification devices, coaching on how to manage the auditory environment, training in speech perception and communication, and counseling for coping strategies to deal with the difficulties of HAs or HATs

### ISSUES FOR REFERRAL
Refer to audiologist for formal evaluation and optimal fitting of HAs and/or HATs.

- Individuals receiving postfitting orientation/education have significantly fewer HA returns.
- Individuals receiving >2 hours of education and counseling report higher levels of satisfaction.

### SURGERY/OTHER PROCEDURES
- Cochlear implants (CIs)
  - Works by bypassing the ear canal, middle ear, and hair cells in the cochlea to provide electric stimulation directly to the auditory nerve
  - Indications include hearing no better than identifying ≤50% of key words in test sentences in the best aided condition in the worst ear and 60% in the better ear.
  - Incoming sounds are received through the microphone in the audio processor component (resembles a small HA), which converts them into electrical impulses and sends them to the magnetic coil (located on the skin). The impulses transmit these across intact skin via radio waves to the implanted component (directly subjacent to the coil). The pulses travel to the electrodes in the cochlea and stimulate the cochlea at high rates.
  - Receiving a unilateral CI is most common; some may receive bilateral CIs (either sequentially or in the same surgery). Others may wear a CI in 1 ear and an HA in the contralateral ear (bimodal fit).
  - Younger age at CI placement derives greatest benefit.
- Active middle ear implants (AMEIs) (6)[B]
  - Suitable for elderly adults who cannot wear conventional HAs for medical or personal (cosmetic) reasons and whose HL is not severe enough for a CI
– Comes in different models and may include components that are implantable under the skin

- Electric acoustic stimulation: use of CI and HA together in one ear
- Addresses the specific needs of patients presenting with good low-frequency hearing (a mild to moderate sensorineural HL in frequencies up to 1,000 Hz) but poorer hearing in the high frequencies (sloping to 60 dB or worse HL above 1,000 Hz)
  - Contraindications: progressive HL, autoimmune disease; HL related to meningitis, otosclerosis, or ossification; malformation of the cochlea; a gap in air conduction and bone conduction thresholds of >15 dB; external ear contraindications, active infection, or unwillingness to use amplification devices

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- During follow-up visits, check for compliance of HA use.
  - 25–40% of adults will either stop wearing them or use them only occasionally.
- Assess perceived benefit of HA and, if ineffective, for indications for possible surgical treatments.
- Annual audiograms
- Can follow up with audiologists for HA fittings if HA becomes uncomfortable
- Asymmetric HL should have evaluation via MRI for acoustic neuroma.
- Sudden SNHL is atypical and warrants urgent otolaryngologic evaluation/audiometry. The most recent recommendations by the American Academy of Otolaryngology recommend steroids empirically.

**PATIENT EDUCATION**
- Should be face-to-face; spoken clearly and unhurriedly, without competing background noise (e.g., radio, TV); and include a confirmation that the message is received
- Formal speech reading classes may be beneficial; however, availability may be limited.
REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- H91.10 Presbycusis, unspecified ear
- H91.13 Presbycusis, bilateral
- H91.11 Presbycusis, right ear
CLINICAL PEARLS

- Presbycusis is an age-related HL, showing increased incidence with age. It is often bilateral and initially begins as high-frequency HL. It presents as difficulty communicating in noisy conditions.
- There are more affected males than females.
- Compliance is only 25–40% for those who own HA. A referral to an audiologist is key for optimal evaluation, fitting for HAs, and other assistive technologies or surgical treatment.
- Indication for CIs include hearing no better than identifying ≤50% key words in test sentences in the best aided condition in the worst ear and 60% in the better ear.
- Early audiology referral for individuals with suspected HL may improve treatment efficacy.
PRESSURE ULCER

Marzena Gieniusz, MD

BASICS

DESCRIPTION

- A localized area of skin or underlying tissue injury resulting from pressure and/or shear
- Classified in stages according to the National Pressure Ulcer Advisory Panel (NPUAP):
  - Stage I: nonblanchable erythema—intact skin with nonblanchable redness; darkly pigmented skin may not have visible blanching.
  - Stage II: partial thickness skin loss—shallow open ulcer with a red-pink wound bed, without slough; or intact or open/ruptured serum-filled blister
  - Stage III: full thickness skin loss—subcutaneous fat may be visible but bone, tendon, or muscle is not exposed; slough, if present, does not obscure depth of tissue loss.
  - Stage IV: full thickness tissue loss—exposed bone, tendon, or muscle; slough or eschar may be present but does not completely obscure wound base.
  - Unstageable: depth unknown—base of the ulcer is covered by slough and/or eschar in the wound bed.
  - Suspected deep tissue injury: depth unknown—purple or maroon area of intact skin or blood-filled blister
- Synonyms: decubitus ulcer; bedsore; pressure injury

EPIDEMIOLOGY

Incidence
Dependant on setting and population: 0–53.4% (1,2)

Prevalence
Dependant on setting and population: 0–72.5% (1,2)

ETIOLOGY AND PATHOPHYSIOLOGY
Complex process of risk factors interacting with external forces (pressure and/or shear) (3)
RISK FACTORS
- Impaired mobility
- Malnutrition
- Reduced perfusion
- Sensory loss
- Medical devices

GENERAL PREVENTION
- Structured risk assessment (1)
- Skin and tissue assessment (1)
- Preventive skin care (1)
- Nutrition screening (1)
- Repositioning (1)
- Early mobilization (1)
- Support surfaces (1)
- Microclimate control (1)
- Prophylactic dressings (1)
- Electrical stimulation of the muscles (1)

COMMONLY ASSOCIATED CONDITIONS
- Advanced age
- Trauma
- Hip fractures
- Diabetes
- Cerebrovascular and cardiovascular disease
- Incontinence

DIAGNOSIS

HISTORY
- Risk factors
- Nutritional assessment (1)
- Pain assessment (1)
- Date of ulcer diagnosis
- Treatment course

PHYSICAL EXAM
• Full skin examination on initial contact and repeatedly throughout visits
• Assess location, stage, size (length, width, depth), identify presence of sinus tracts, undermining, tunneling, exudate, necrosis, odor, and signs of healing (e.g., granulation tissue) (1).
• Identify factors that may affect healing (impaired perfusion, sensation, presence of infection).

DIFFERENTIAL DIAGNOSIS
• Venous ulcers
• Arterial ulcers
• Incontinence associated dermatitis
• Skin tears
• Intertrigo
• Neuropathic ulcers
• Pyoderma gangrenosum, cancers, vasculitides, and other dermatologic conditions

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Wound culture: Do not culture surface drainage. If culture necessary, do deep tissue culture/bone biopsy.
• If systemic infection or that of bone, muscle is suspected add infectious workup, including inflammatory markers, CBC, blood cultures, x-ray. MRI may be necessary to confirm osteomyelitis.
• Ankle-brachial index and Doppler ultrasound (for lower extremity wounds)

Follow-Up Tests & Special Considerations
Additional tests may be indicated when additional medical illness complicates assessment. This may include testing for diabetes (i.e., A1c), thyroid disease (i.e., TSH), vascular disease, and other dermatologic diagnoses.

TREATMENT

GENERAL MEASURES
• Comprehensive initial assessment of the patient
• Pressure reduction/redistribution (4)[A]
• Nutritional support (e.g., protein containing supplements) (5)[B]
• Wound assessment and treatment
  – Wound bed preparation (tissue management, infection and inflammation control, moisture balance, epithelial edge advancement) (1)
  – Wound cleansing (1)[C]
  – Débridement (1)[C]
• Address immobility.
• Manage incontinence.
• Address pain.
• Assess goals of care and advance directives.

MEDICATION

First Line
• Wound dressings as appropriate for category of ulcer (hydrocolloid, hydrogel, alginate, foam, silver impregnated, honey impregnated, cadexomer iodine, gauze, silicone, collagen matrix, composite) (1)[C]
• Enzymatic débriding agents

Second Line
• Activated charcoal
• Topical antiseptics (hydrogen peroxide, Dakin’s solution, povidone-iodine)

ISSUES FOR REFERRAL
• Consider referral to wound care specialist (if available) for complex or nonhealing wounds.
• Consider vascular surgery for improvement of blood flow to wound via vascular bypass if appropriate.
• Consider surgical consultation for possible urgent drainage and/or débridement if advancing cellulitis; suspected source of sepsis; undermining, tunneling, sinus tracts, and/or extensive necrotic tissue that cannot otherwise be removed by nonsurgical débridement methods; or for stage III or IV that are not closing with conservative management (1)[C].
• Consider plastic surgery for skin graft/flap if appropriate.
• Consider dermatology referral if suspected pyoderma gangrenosum, cancer, vasculitis or other dermatologic conditions.

ADDITIONAL THERAPIES
• Direct contact electrical stimulation for recalcitrant stage II and any category/stage III and IV (1)[A]
Electromagnetic field for recalcitrant category/stage II and any stage III and IV (1)[C]
Pulsed radio frequency energy for recalcitrant stage II and any stage III and IV (1)[C]

COMPLEMENTARY & ALTERNATIVE MEDICINE
- Low-frequency ultrasound for débridement of necrotic soft tissue (not eschar) (1)[C]
- High-frequency ultrasound as adjunct for infected pressure ulcers (1)[C]
- Negative pressure wound therapy as early adjuvant treatment for deep, stage III and IV (1)[B]
- Consider course of hydrotherapy with pulsed lavage with suction for wound cleansing and débridement (1)[C].
- Phototherapy: short term UVC light if traditional therapies fail (1)[C]; laser not recommended (1)[C]; infrared is not recommended (1)[C].
- Hyperbaric and topical oxygen therapy not recommended for routine use (1)[C]
- Hydrotherapy with whirlpool should not be considered for routine use (1)[C].
- Vibration therapy not recommended (1)[C]
- Consider maggot débridement therapy.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization: refractory cellulitis, osteomyelitis, systemic infection, advanced nutritional decline, suspected patient mistreatment, inability to care for self
- Dressing changes 1 to 3 times daily based on wound assessment and plan of care.
- Assess risk factors according to scales.
- Assess for changing or new wounds.
- Discharge criteria: clinical improvement in wound and systemic illness; when applicable, safe, and appropriate location for discharge
FOLLOW-UP RECOMMENDATIONS
Weekly assessment by nurse with wound experience; biweekly assessment by physician

Patient Monitoring
- Home health nursing
- Change plan of care if no improvement in 2 to 3 weeks.

DIET
- Approximately 1.0 to 1.5 kg/day of protein
- Strict glycemic control
- Include micronutrients in diet or as supplements.

PATIENT EDUCATION
- Check skin regularly.
- Signs and symptoms of infection
- Report new or increased pain.
- Prevention of new wound where old wound healed
- Skin care, moisture prevention

PROGNOSIS
Variable, depending on the following:
- Removal of pressure
- Nutrition
- Wound care

COMPLICATIONS
- Infection
- Amputation

REFERENCES
3. Sibbald RG, Krasner DL, Woo KY. Pressure ulcer staging revisited:

**ADDITIONAL READING**

**CODES**

**ICD10**

- L89.95 Pressure ulcer of unspecified site, unstageable
- L89.91 Pressure ulcer of unspecified site, stage 1
- L89.92 Pressure ulcer of unspecified site, stage 2

**CLINICAL PEARLS**

- Create assessment and prevention protocols for all patients.
- Identify risk factors, reduce pressure, maximize nutrition, regular skin checks, and assess and treat wound appropriately.
- All care needs to be done in time-sensitive, patient-centered fashion.
PRETERM LABOR
Kara M. Coassolo, MD • John C. Smulian, MD, MPH

BASICS
DESCRIPTION
Contractions occurring between 20 and 36 weeks’ gestation at a rate of 4 in 20 minutes or 8 in 1 hour with at least one of the following: cervical change over time or dilation ≥2 cm (1)

EPIDEMIOLOGY
Preterm birth is the leading cause of perinatal morbidity and mortality in the United States.

Incidence
10–15% of pregnancies experienced at least one episode of preterm labor.

Prevalence
~12% of all births in the United States are preterm (9% spontaneous preterm births and 3% indicated preterm births).

ETIOLOGY AND PATHOPHYSIOLOGY
- Premature formation and activation of myometrial gap junctions
- Inflammatory mediator–stimulated contractions
- Weakened cervix (structural defect or extracellular matrix defect)
- Abnormal placental implantation
- Systemic inflammation/infections (e.g., UTI, pyelonephritis, pneumonia, sepsis)
- Local inflammation/infections (intra-amniotic infections from aerobes, anaerobes, Mycoplasma, Ureaplasma)
- Uterine abnormalities (e.g., cervical insufficiency, leiomyomata, müllerian anomalies, diethylstilbestrol exposure)
- Overdistension (by multiple gestation or polyhydramnios)
- Preterm premature rupture of membranes
- Trauma
- Placental abruption
Immunopathology (e.g., antiphospholipid antibodies)
Placental ischemic disease (preeclampsia and fetal growth restriction)

**Genetics**
Familial predisposition

**RISK FACTORS**
- Demographic factors, including single parent, poverty, and black race
- Short interpregnancy interval
- No prenatal care
- Prepregnancy weight <45 kg (100 lb), body mass index <20
- Substance abuse (e.g., cocaine, tobacco)
- Prior preterm delivery (common)
- Previous 2nd-trimester dilation and evacuation (D&E)
- Cervical insufficiency or prior cervical surgery (cone biopsy or loop electrosurgical excision procedure [LEEP])
- Abdominal surgery/trauma during pregnancy
- Uterine structural abnormalities such as large fibroids or müllerian abnormalities
- Serious maternal infections/diseases
- Bacterial vaginosis
- Bacteriuria
- Vaginal bleeding during pregnancy
- Multiple gestation
- Select fetal abnormalities
- Intrauterine growth restriction
- Placenta previa
- Premature placental separation (abruption)
- Polyhydramnios
- Ehlers-Danlos syndrome

**GENERAL PREVENTION**
- Patient education at each visit in 2nd and 3rd trimesters for those at risk and periodically in the last two trimesters for the general population
- If previous preterm birth, evaluate if etiology is likely to recur and target intervention to specific condition.
  - Weekly injections of 17α-hydroxyprogesterone (250 mg IM every week) from 16 to 36 weeks if previous spontaneous preterm birth
– Consider cerclage placement before 24 weeks’ gestation for those at high risk because of cervical insufficiency or significant or progressive cervical shortening (2)[A].

• For women with a short cervix in the 2nd trimester (<20 mm on transvaginal US), progesterone 200 mg/day per vagina for 24 to 34 weeks may decrease the risk of preterm delivery (3)[A].

**DIAGNOSIS**

Diagnosis is generally based on a combination of significant cervical changes (such as dilation, effacement) with regular contractions. However, there is no single test that will reliably diagnose or predict true preterm labor. The diagnosis is based on a combination of physical findings and diagnostic tests that are interpreted in the context of the degree of risk to the patient.

**HISTORY**

• Address risk factors, especially etiologies of previous preterm birth.
• Regular uterine contractions or cramping
• Dull, low backache or pain
• Intermittent lower abdominal pain
• Increased low pelvic pressure
• Change in vaginal discharge
• Vaginal bleeding
• Fluid leakage

**PHYSICAL EXAM**

• Sterile speculum exam for membrane rupture evaluation, cultures, and cervical inspection
• Bimanual cervical exam if intact membranes: dilation of the cervix >1 cm and/or effacement of the cervix >50%

**ALERT**

Avoid bimanual examination when possible if rupture of the membranes is suspected.

**DIFFERENTIAL DIAGNOSIS**

• Braxton-Hicks contractions/false labor
• Round ligament pain
- Lumbosacral muscular back pain
- Urinary tract or vaginal infections
- Adnexal torsion
- Degenerating fibroid
- Appendicitis
- Dehydration
- Viral gastroenteritis
- Nephrolithiasis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- In symptomatic women from 22 to 34 weeks’ gestation with intact membranes and no intercourse or bleeding in past 24 hours, obtain a fetal fibronectin (FFN) swab from the posterior vaginal fornix. FFN must be obtained prior to digital cervical exam.
  - If results are positive (≥50 ng/mL), patient is at a modest increased risk of preterm birth (positive predictive value [PPV] 13–30% for delivery within 2 weeks).
  - If results are negative, >97% of patients will not deliver in 14 days, so can consider avoiding complicated or high-risk interventions.
- Urinalysis and urine culture
- Cultures for gonorrhea and chlamydia
- Wet prep for bacterial vaginosis evaluation (although evidence for improved outcomes with treatment is weak)
- Vaginal introitus and rectal culture for group B Streptococcus
- pH and ferning test of vaginal fluid to evaluate for rupture of membranes
- CBC with differential
- Drug screen when appropriate
- US to identify number of fetuses and fetal position, confirm gestational age, estimate fetal weight, quantify amniotic fluid, and look for conditions making tocolysis contraindicated
- Transvaginal US to evaluate cervical length, funneling, and dynamic changes after obtaining FFN (if clinical assessment of the cervix is uncertain or if the cervix is closed on digital exam)

**Follow-Up Tests & Special Considerations**
- Repeat FFN as indicated by symptoms.
- After successful treatment, progressive changes of the cervix on repeat
examination or US (in 1 to 2 weeks) may indicate need for hospitalization.

**Diagnostic Procedures/Other**
- Monitor contractions with external tocodynamometer.
- Consider amniocentesis at any preterm gestational age to evaluate for intra-amniotic infection (cell count with differential, glucose, Gram stain, aerobic, anaerobic, *Mycoplasma, Ureaplasma* cultures).

**Test Interpretation**
- Placental inflammation
  - Acute inflammation usually caused by infection
  - Chronic inflammation caused by immunopathology
- Abruption

**TREATMENT**

**GENERAL MEASURES**
- Treat underlying risk factors (e.g., antibiotics for infections, hydration for dehydration).
- Liquids only or NPO if delivery is imminent
- Hospitalization is necessary if the patient is on IV tocolysis.

**MEDICATION**
Tocolysis may allow time for interventions such as transfer to tertiary care facility and administration of corticosteroids but may not prolong pregnancy significantly (4)[A].

**First Line**
- Tocolysis
  - Nifedipine: 30 mg PO loading dose, then 10 to 20 mg q6h for 24 hours, and then 10 to 20 mg PO q8h (do not use sublingual route); check BP often and avoid hypotension. Concurrent use with magnesium sulfate should be avoided to avoid theoretic risk of neuromuscular blockade.
  - Indomethacin: 50 to 100 mg PO initial dose, then 25 to 50 mg q6–8h for 24 hours (or, if available, 100-mg suppository per rectum q12h for 2 doses), and then 25 mg q6–8h; use for no longer than 72 hours due to risk of premature closure of ductus arteriosus, oligohydramnios, and possibly...
neonatal necrotizing enterocolitis. Use with caution in patients with platelet dysfunction, liver dysfunction, or allergy to aspirin.

- Contraindications to tocolysis: severe preeclampsia, hemorrhage, chorioamnionitis, advanced labor, intrauterine growth restriction, fetal distress, or lethal fetal abnormalities

- **Antibiotics:** antibiotics for group B *Streptococcus* prophylaxis if culture is positive or unknown

- **Steroids:** If mother is at 23 to 34 weeks’ gestation with no evidence of systemic infection, give glucocorticoids to decrease neonatal respiratory distress, intraventricular hemorrhage, necrotizing enterocolitis, and overall perinatal mortality; betamethasone 12 mg IM × 2 doses 24 hours apart (preferred choice) or dexamethasone 6 mg IM q12h for 4 doses ([5][A])

- Steroids may reduce the risk of respiratory morbidities in infants born in the late preterm period (34 + 0 to 36 + 6 weeks’ gestation). If delivery is likely during this time period, administration of steroids may be considered as above. Tocolysis is not recommended ([6][A]).

**Second Line**

- **Magnesium sulfate** by IV infusion has not been shown to be superior to placebo in prolonging pregnancy beyond 48 hours. The side effects are generally greater compared with calcium channel blockers or NSAIDs. Therefore, this agent should be used cautiously (standard dosages for tocolysis start with a 4- to 6-g IV bolus over 20 minutes followed by 2- to 3-g/hr infusion until contractions stop).

- Magnesium may decrease the risk of cerebral palsy when 12-hour course is given prior to an anticipated preterm birth.

- Relative contraindications to magnesium sulfate include myasthenia gravis, hypocalcemia, renal failure, or concurrent use of calcium channel blockers.

- **Terbutaline** 0.25 mg SC q30min for up to 3 doses until contractions stop and then 0.25 mg SC q6h for 4 doses (optional); if contractions persist or pulse >120 bpm, change to another tocolytic agent (may be poorly tolerated by mothers).

- Terbutaline PO or by infusion pump has been used in the past for treatment or prevention of preterm labor. Due to reports of serious cardiovascular events and maternal deaths, PO or long-term SC administration of terbutaline should not be given.

- Significant possible interactions include pulmonary edema from crystalloid fluids and tocolytic agents, especially magnesium sulfate.

- PO maintenance therapy with any agent is ineffective and is not
ISSUES FOR REFERRAL
- If delivery is inevitable but not immediate, consider transport to a tertiary care center or hospital equipped with a neonatal ICU.
- Consider consultation with maternal–fetal medicine specialist.

ADDITIONAL THERAPIES
- Pelvic rest (e.g., no douching or intercourse) and activity restriction are often recommended; however, data to prove the efficacy are lacking. Some reduction in physical activity may be reasonable; this should be individualized.
- Strict bed rest has not been demonstrated to be effective in most situations.

SURGERY/OTHER PROCEDURES
- For malpresentation or fetal compromise, consider cesarean delivery if labor is progressing.
- Cerclage for cervical insufficiency (until 24 weeks’ gestation)

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Suspected/threatened preterm labor
- IV access
- Continuous fetal and contraction monitoring
- Assess cervix for dilatation and effacement.
- Hydrate with 500 mL 5% dextrose normal saline solution or 5% dextrose lactated Ringer solution for first half hour and then at 125 mL/hr.
- Monitor for fluid overload (input/output monitoring, symptoms, lung auscultation, pulse oximetry), especially with tocolysis and multiple gestations.

Discharge Criteria
- Regular contractions and cervical change resolve.
- If cervix is dilated ≥3 cm or FFN is positive, individualize decision to discharge by gestational age and patient circumstances.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Weekly office visits with contraction monitoring, cervical checks, or cervical US if at high risk for recurrence
- Routine use of maintenance tocolysis is ineffective in preventing preterm birth.

DIET
Regular

PATIENT EDUCATION
Call physician or proceed to hospital whenever regular contractions last >1 hour, bleeding, increased vaginal discharge or fluid, decreased fetal movement.

PROGNOSIS
- If membranes are ruptured and no infection is confirmed, delivery often occurs within 3 to 7 days.
- If membranes are intact, 20–50% deliver preterm.

COMPLICATIONS
Labor resistant to tocolysis, pulmonary edema, infection with preterm rupture of membranes

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- O60.00 Preterm labor without delivery, unspecified trimester
- O60.02 Preterm labor without delivery, second trimester
- O60.03 Preterm labor without delivery, third trimester

**CLINICAL PEARLS**

- Treatment of preterm labor may delay delivery to facilitate short-term interventions.
- Steroids improve neonatal outcomes.
- Progesterone therapy can prevent recurrence of preterm birth in next pregnancy.
PRIAPISM
Sundonia J. Williams Wonnum, PhD, BCD, LCSW • Christine M. Broszko, MD

BASICS
DESCRIPTION
- Penile (or less common clitoral) erection lasting for >4 hours and unrelated to sexual stimulation or arousal
- Classified into three types: ischemic, nonischemic, and stuttering:
  - Ischemic (low-flow, veno-occlusive) priapism, associated with ischaemia of the corpora cavernosa, is prolonged and painful and requires urgent clinical intervention.
  - Nonischemic (high-flow, arterial) priapism is less common and often painless, could be related to prior trauma, and does not require urgent treatment.
  - Stuttering priapism (recurrent, ischemic) is episodic, short-lived, and self-limited.
- Malignant priapism is a rare condition resulting most commonly from penile metastases from primary bladder, prostatic, rectosigmoid, and renal tumors.
- System(s) affected: reproductive, vascular
- Functional impairment: neurophysiological, sexual, psychosocial (quality of life) (1)

Pediatric Considerations
- In children, nearly all priapism is caused by either sickle cell disease (SCD) (65% of cases) or leukemia, idiopathic, penile trauma (e.g., post circumcision), or illicit drugs (up to 35% of cases) and typically begins to occur during adolescent years.
- Neonatal priapism is also rare and last >4 hours in newborn infants occurring in the first few days of life and lasts 2 to 12 days (2).

EPIDEMIOLOGY
Incidence
- Prevalence: In the United States, one study estimates 1,868 to 2,960 cases of
priapism each year, with increasing incidence related to nonhematologic causes from 1998 to 2006.

- Age: There has been an age shift since 2008 toward men in their 40s. The incidence doubles in men aged >40 years (2.9 vs. 1.5/100,000 person-years).
- Race: 61.1% black (correlated with incidence of SCD), 30% white, 6.3% Hispanic
- Anatomy and physiology:
  - The penis consists of three longitudinally oriented corpora: two dorsolaterally paired corpora cavernosa that are responsible for penile erection and a single ventral corpus spongiosum that surrounds the glans penis and extends distally to form the glans penis
  - In general, the penile artery (which is a branch of the internal pudendal artery that, in turn, is a branch from the internal iliac artery) supplies the penis. It divides into three branches: dorsal artery, bulbar artery (supplies the corpus spongiosum), and cavernosal artery (the main blood supply to the erectile tissue).
  - During an erection, smooth muscle relaxation of the cavernosal arterioles results in high-volume inflow to the sinusoids, resulting in compression of the exiting venules. This leads to significant volume expansion of the corpora cavernosa.
  - During the flaccid resting state, the sympathetic nervous system is predominantly in control. Penile tumescence and erection are driven by the parasympathetic nervous system through the generation of nitric oxide (NO).
  - Smooth muscle relaxation occurs via usage of the phosphodiesterase type 5 (PDE5A) pathway, which generates cyclic guanosine monophosphate (cGMP).

**ETIOLOGY AND PATHOPHYSIOLOGY**

- In ischemic priapism, decreased venous outflow results in increased intracavernosal pressure. This leads to erection, decreased arterial inflow, blood stasis, local hypoxia, and acidosis (a compartment syndrome). Penile tissue necrosis and fibrosis may occur if priapism persists beyond 24 hours. The exact mechanism is unknown and may involve trapping of erythrocytes in the veins, draining the erectile bodies.
- In nonischemic priapism, increased arterial flow without decreased venous outflow results in a sustained, nonpainful, partially rigid erection.
- Aberrations in the PDE5A pathway have been proven in mice to be one mechanism of priapism.
Causes: ischemic priapism
- Idiopathic, estimated to about 50% (1)
- Intracavernosal injections of vasoactive drugs for erectile dysfunction
- Oral agents for erectile dysfunction
- Pelvic vascular thrombosis
- Prolonged sexual activity
- Leukemia and other malignancies that can infiltrate the corpora
- SCD and trait
- Other blood dyscrasias (G6PD deficiency, thalassemia, thrombophilia)
- Pelvic hematoma or neoplasia (penis, urethra, bladder, prostate, kidney, rectal)
- Cerebrospinal tumors
- Asplenism
- Fabry disease
- Tertiary syphilis
- Total parenteral nutrition, especially 20% lipid infusion (results in hyperviscosity)
- Bladder calculus
- UTIs, especially prostatitis, urethritis, cystitis
- Several drugs suspected as causing priapism (i.e., chlorpromazine, prazosin, cocaine [can be directly injected into penis], trazodone, and some corticosteroids), anticoagulants (heparin and warfarin), phosphodiesterase inhibitors (sildenafil, others), immunosuppressants (tacrolimus), antidepressants, methylphenidate, and antihypertensives (hydralazine, propranolol, guanethidine). Some case reports on antipsychotics (quetiapine, risperidone, aripiprazole).
- Intracavernous fat emulsion
- Hyperosmolar IV contrast
- Spinal cord injury
- General or spinal anesthesia
- Heavy alcohol intake

Causes: nonischemic priapism
- The most common cause is penile or perineal trauma resulting in a fistula between the cavernous artery and the corpus cavernosum.
- Acute spinal cord injury
- Rarely, iatrogenic causes for the management of ischemic priapism can result in nonischemic priapism.
- Certain urologic surgeries have also resulted in nonischemic priapism.
RISK FACTORS
- SCD has a lifetime risk of ischemic priapism 29–42%.
- Dehydration correlated with SCD or trait
- Prior history of priapismic episodes (stuttering priapism) (1,2)

GENERAL PREVENTION
- Avoid dehydration (SCD cases).
- Avoid excessive sexual stimulation.
- Avoid causative drugs (see “Etiology and Pathophysiology”) when possible.
- Avoid physical activity with a high risk of blunt trauma to the genital area.

COMMONLY ASSOCIATED CONDITIONS
- SCD (42.9%) or sickle cell trait (2.5%)
- Drug abuse (7.9%)
- G6PD deficiency
- Leukemia
- Neoplasm

DIAGNOSIS

HISTORY
- Prior priapism episodes or prolonged erections after waking and degree of pain
- Duration of erection
- Perineal or penile trauma (blunt force or needle injury)
- Urination difficult during erection
- History of any hematologic abnormalities (e.g., SCD or trait)
- Cardiovascular disease
- Medications
- Recreational drugs

PHYSICAL EXAM
- Ischemic priapism: Penis is fully erect, painful, or tender; corpora cavernosa are rigid; and corpora spongiosum and glans are flaccid.
- Nonischemic priapism: Penis is partially erect (not tender or painful), and the corpora cavernosa are semi-rigid and nontender, with the glans and corpora spongiosum flaccid.
- Perineum, abdomen, and lymph node exam also valuable to rule out underlying condition
- A complete penile, scrotal, and perineal exam is necessary to identify course and/or trauma.
- Determine if a penile prosthesis is present.
- Penile gangrene (rare)

**DIAGNOSTIC TESTS & INTERPRETATION**

- CBC with reticulocyte count to detect leukemia or platelet abnormalities
- Sickling hemoglobin (Hgb) solubility test and Hgb electrophoresis
- Coagulation profile
- Platelet count
- Urinalysis/urine toxicology
- Corporal blood gas (CBG) should be obtained to distinguish ischemic from nonischemic priapism.
- A color duplex or Doppler ultrasound of the penis and perineum may be necessary to differentiate ischemic (no blood flow in the cavernosal arteries) from nonischemic (high blood flow) priapism (1); pelvic vascular thrombosis, partial thrombosis of corpora cavernosa, and corpus spongiosum may be detected.
- Penile arteriography can be used to identify the presence and arterial cavernous fistula or pseudoaneurysms (nonischemic).

**TREATMENT**

- Treatments for priapism are determined based on the three main types: ischemic, nonischemic, and stuttering.
  - Ischemic priapism requires immediate treatment to preserve future erectile function (a longer delay in treatment means a higher chance of future impotence and possibly necrosis). Urgent urologic consultation is recommended.
    - Cavernosal aspiration with a large bore needle with irrigation (success rate ~30%) (1,3)
    - Cavernosal injection of phenylephrine (α-adrenergic sympathomimetic) with monitoring of patient’s BP and pulse (success rate ~65%) (3). Inject q5min until detumescence (15 to 60 minutes).
    - Continue aspiration, irrigation, and phenylephrine for several hours. If this fails, shunt procedures are considered (first a distal shunt).
– Nonischemic priapism
  o Initial observation
  o If nonischemic priapism does not resolve without or with clinical intervention, arteriography and embolization with absorbable materials (5% rate of impotence vs. 39% with permanent materials) or surgical ligation as a last resort (3)

– Stuttering priapism
  o The initial goal is to prevent future priapismic episodes.
  o Manage acute episodes pharmacologically (similar to ischemic cases)—aspiration/irrigation in combination with intracavernous injections of α-adrenergic agonists (e.g., pseudoephedrine and etilefrine 50 to 100 mg daily is effective in approximately 72% of cases).
  o Hormonal manipulation to smother circulating testosterone to suppress the action of androgens associated with the erection (duration varies from weeks to years)
  o Digoxin for regulation of smooth muscle tone and to promote penile detumescence (3)

  • In all cases, particularly SCD cases, treat the underlying condition (e.g., SCD does not delay intracavernous treatment).
  • Although blood transfusion is an option, particularly in SCD cases, other interventions should be explored and exhausted first (4).
  • There are no widely accepted guidelines on treatment among children (2).

GENERAL MEASURES
• Reassure the patient about the outcome, if warranted.
• Provide continuous caudal or spinal anesthesia if the etiology is neurogenic.
• Treat any underlying cause or disease process.
• In SCD cases: IV hydration; supplemental oxygen; partial exchange or repeated transfusions to reduce percentage of sickle cells to <50%
• Relieve the patient's pain; do not delay this while waiting for urologic consultation.
• Initiating proper management depends on whether the priapism is ischemic or nonischemic.

MEDICATION
• Analgesics (e.g., opioids) for pain, if needed
• Intracavernous injection of phenylephrine is recommended by the American Urological Association for ischemic priapism.
• Phenylephrine minimizes risk of cardiovascular side effects that are more
common with other sympathomimetics; terbutaline has been studied and may be effective (uncontrolled trials showed a 65% resolution rate) for priapism caused by self-injection of agents to treat erectile dysfunction (3).

- Ketoconazole 200 mg TID and prednisone 5 mg daily for 2 weeks; then tapering to ketoconazole 200 mg nightly for 6 months has been shown (with limited evidence) to prevent recurrent ischemic priapism.
- For stuttering priapism, a trial of gonadotropin-releasing hormone (GnRH) agonists or antiandrogens is effective; self-injection of phenylephrine is also effective.
- PDE5 inhibitors also have a role in the prevention of priapism in patients suffering from stuttering priapism.

**ISSUES FOR REFERRAL**
A urologist should be consulted in all cases of suspected priapism to ensure the highest likelihood of preserved reproductive and vascular function.

**SURGERY/OTHER PROCEDURES**
- For ischemic priapism, after penile ring block, introduction into corpora cavernosa with aspiration of 20 to 30 mL of blood from corpus cavernosum; may follow with intracavernous injection of phenylephrine of 1% phenylephrine in normal saline (1)
- Other interventions:
  - Distal shunts
    - Percutaneous: Ebbehoj, Winter, or T-shunt
    - Open: Al-Ghorab or corporal snake
  - Proximal shunts
    - Open: Quackles or Sacher
    - Saphenous vein shunt
    - Deep dorsal vein shunt

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Further evaluation of underlying etiologies and reduction of vasoactive drug therapy as indicated

*Patient Monitoring*
Close follow-up with a urologist is recommended.

**PATIENT EDUCATION**
Information about long-term outlook, referral for counseling, and options if patient is suffering from erectile dysfunction as a result of priapism

**PROGNOSIS**
- Even with excellent treatment for a prolonged priapism, complete detumescence may require several weeks secondary to edema (1).
- Impotence due to irreversible corporal fibrosis is likely in ischemic priapism and is up to 90% if the priapism lasts >24 hours.
- Despite early intervention, ischemic priapism is likely to result in impotence in up to 50% of men.

**COMPLICATIONS**
Erectile dysfunction (i.e., impotence)

**REFERENCES**

**ADDITIONAL READING**
**SEE ALSO**

Anemia, Sickle Cell; Erectile Dysfunction

**CODES**

**ICD10**

- N48.30 Priapism, unspecified
- N48.39 Other priapism
- N48.31 Priapism due to trauma

**CLINICAL PEARLS**

- Priapism is a prolonged penile erection that lasts >4 hours and is unrelated to sexual stimulation. If priapism lasts >24 hours, it likely results in permanent sexual impairment.
- Priapism can occur in children, particularly in SCD. Treatment should address both the underlying disease as well as developmental needs.
- In evaluating priapism, the clinician must distinguish ischemic from nonischemic priapism by history and physical exam, as well as cavernosal blood gas and possibly ultrasound, if needed.
- Ischemic priapism is an emergent condition that requires immediate urologic evaluation and treatment.
- The most common causes of ischemic priapism are idiopathic, related to SCD or treatments for erectile dysfunction, or related to use of substances (medicinal or recreational).
PROSTATE CANCER

Sara L. Valente, MD • Jason K. Frankel, MD • Joseph R. Wagner, MD

BASICS

DESCRIPTION

- The prostate is a male reproductive organ that contributes seminal fluid to the ejaculate.
- The prostate gland is about the size of a walnut, averaging 20 to 25 g in volume in an adult male; tends to enlarge after age 50 years.
- Three distinct zones delineate the functional anatomy of the prostate: peripheral zone (largest, neighbors rectal wall, palpable on DRE, most common location for prostate cancer), central zone (contains the ejaculatory ducts), and transition zone (located centrally, adjacent to the urethra).
- Prostatic epithelial cells produce prostate-specific antigen (PSA), which is used as a tumor marker and in screening.

EPIDEMIOLOGY

Incidence

According to the National Cancer Institute SEER data, an estimated 161,360 men in the United States will be newly diagnosed with carcinoma of the prostate (CaP) in 2017 (1).

Prevalence

- About 3 million men are living with CaP in the United States (1).
- An estimated 26,730 men in the United States will die of CaP in 2017 (1).
- Mean age at diagnosis is 66 years.
- Prostate cancer is the most commonly diagnosed nonskin cancer in men in the United States (~11.6% lifetime risk) and second leading cause of cancer death in men (only ~3% of all CaP results in CaP-related death) (1).
- Autopsy studies find foci of latent CaP in 50% of men in their 8th decade of life.
- Probability of clinical CaP 10.9% (1 in 9) in men aged ≥70 years.
ETIOLOGY AND PATHOPHYSIOLOGY

- Adenocarcinoma: >95%; nonadenocarcinoma: <5% (most common transitional cell carcinoma)
- Cells generally stain positive for PSA and prostatic acid phosphatase (PAP).
- Location of CaP: 70% peripheral zone, 20% transitional zone, 5–10% central zone

**Genetics**
Elevated risk if first-degree relative diagnosed with CaP suggesting genetic component; specifics unclear

**RISK FACTORS**
- Age >50 years
- African American race
- Positive family history
- Poorly understood environmental factors

**GENERAL PREVENTION**
There are no FDA-approved drugs or diet modifications to prevent CaP.

- Finasteride has been studied for this purpose in a phase III trial called the Prostate Cancer Prevention Trial. A moderate risk reduction associated with an increased risk of high-grade disease was encountered. Therefore, it has not been FDA-approved for prevention (2)[A].

**ALERT**
Screening for prostate cancer is controversial:

- U.S. Preventive Services Task Force (USPSTF) currently recommends against screening (Grade D) but is considering changing the recommendation to “The USPSTF recommends that clinicians inform men ages 55 to 69 years about the potential benefits and harms of PSA–based screening for prostate cancer (Grade C)”(3)[A].
- For men ages 55 to 69 years, the AUA panel recommends shared decision making between physician and patient regarding PSA screening.
- PSA screening is not recommended in men age <40 years, age >70 years, or any man with <10 years of estimated life expectancy.
HISTORY
- Inquire about family history of CaP, symptoms of bladder outlet obstruction, and other voiding symptoms.
- Anorexia and weight loss, bone pain or neurologic deficits from spinal cord compression (with metastasis), hematuria, hematospermia (rare)

PHYSICAL EXAM
- DRE to assess for prostatic masses, firmness, or asymmetry
- Evaluate lumbar spine and lymph nodes for evidence of metastasis.

DIFFERENTIAL DIAGNOSIS
Benign prostatic hyperplasia, prostatitis, prostatic intraepithelial neoplasia (PIN), prostate stones, atypical small acinar proliferation (ASAP)
- The high predictive value of ASAP for subsequent adenocarcinoma warrants repeat biopsy within 3 months.

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
PSA, DRE, and clinical history primarily determine need for prostate biopsy:
- In general, total PSA ≥4 ng/mL is concerning for CaP (sensitivity 21%, specificity 91%).
  - Other benign conditions can elevate PSA (infection, inflammation, normal growth, natural PSA fluctuations, normally high variants).
  - Rectal manipulation will not significantly elevate PSA.
- Age-/race-adjusted “normal” PSA values (ng/mL) (4):

<table>

<td>0–5.5</td>
<td>0–6.5</td>
</tr>
</tbody>
</table>

- 5-α-Reductase inhibitors decrease PSA by ~50% (2).
- Other PSA metrics used to aid in CaP diagnosis: PSA velocity, PSA doubling time, PSA density, percentage free PSA
  - Total PSA velocity: ≥0.75 ng/mL/year or >20% baseline for higher values
increases CaP risk.
- Free PSA and age/race-adjusted PSA helpful in evaluating risk. For patients with PSA between 4 and 10 ng/mL, a low percent free PSA is associated with higher risk of CaP.
- PSAD (PSA density) ≥0.15 associated with higher prevalence of CaP
- Screening tests that utilize serum biomarkers in conjunction with clinical information to predict CaP risk are also available (e.g., 4Kscore, PHI).

- Prostate biopsy
  - Decision to biopsy involves PSA, DRE findings, and overall clinical suspicion of CaP with consideration of comorbidities and life expectancy.
  - Standard biopsy includes systematic random cores from the peripheral zone-base, mid, and apex, generally 8 to 12 cores.
  - The Gleason Grade is the standard pathologic grading system:
    o Ranks specimens from 1 (most differentiated) to 5 (least differentiated) based on architectural pattern identified
    o Primary and secondary patterns are identified and reported, and the sum is the Gleason score (e.g., 3 + 4 = 7).
    o Most prostate cancer are scored 6 to 10, with 10 having the worst prognosis.

- Staging (5)
  - TNM (tumor, node, and metastasis) staging is used to generate a clinical and pathologic stage, which primarily directs treatment. Clinical staging is as follows:
    o T1: cancer found incidentally on TURP or found on biopsy for elevated PSA
    o T2: cancer found on DRE but confined to the prostate
    o T3: cancer found to be extended locally outside of the prostate and/or the seminal vesicle
    o T4: invading adjacent organs
    o N1: denotes local lymph node spread
    o M1: distant metastasis

**Follow-Up Tests & Special Considerations**
- Bone scan and/or CT scan and/or MRI may be indicated for high-risk cancers.
- Biopsy if suspicious nodal findings
- Alkaline phosphatase associated with bony mets
- Genetic testing (e.g., Prolaris, Oncotype Dx, Decipher) is emerging as a prognostic modality.
**TREATMENT**

Treatment options include (5):

- **Watchful waiting:** monitoring with expectation to provide palliation with symptoms
- **Active surveillance:** close monitoring of PSA, DRE, and repeat biopsy at regular intervals
- **Radical prostatectomy:** ± pelvic lymph node dissection (PLND)
- **Radiation therapy:** external beam (EBRT)
- **ProtecT trial (2016)** found watchful waiting had equal cancer-specific and all-cause mortality compared to surgery or radiotherapy. In the treatment arms, there were less disease progression (including metastatic disease) but resulted in significantly more morbidity (urinary and bowel dysfunction, erectile dysfunction) (6)[B].
- **Brachytherapy:** radioactive implants placed in prostate; option for early clinical stage localized to the prostate
- **Androgen deprivation therapy (ADT)** may be surgical or nonsurgical:
  - Bilateral orchiectomy (surgical castration)
  - Gonadotropin-releasing hormone (GnRH) agonist, antagonist, or antiandrogen (medical castration)
- **Chemotherapy:** includes multiple chemotherapeutic agents used to treat castrate-resistant prostate cancer

**RISK FACTORS**

Treatment options based on risk: low-, intermediate-, and high-risk categories; this is based on risk of recurrence after definitive treatment. Must meet all three criteria to be low risk; any one criterion moves patient to a higher risk group (5)[A]:

<table>
<thead>
<tr>
<th>Risk Category</th>
<th>Clinical Stage</th>

<tr>
<td>High</td>
<td>T3a</td>
<td>&gt;20</td>
<td>8–10</td>
</tr>
</tbody>
</table>

- **Localized CaP**
  - Low risk:
    - Mainstay of therapy is active surveillance.
    - Radical prostatectomy and radiation therapy may be offered.
– Intermediate risk:
  o Mainstay of therapy is radical prostatectomy or radiation therapy.
  o Radical prostatectomy has shown a possible survival benefit in intermediate prostate cancer.
– High risk:
  o Mainstay of therapy is radical prostatectomy or radiation therapy.
  o Adjuvant radiation may be considered based on adverse pathologic findings after prostatectomy.

**ALERT**
Life expectancy determination as well as educating the patient of the risks and benefits of surveillance and treatment options is critical.

- Locally advanced CaP:
  – Mainstay of therapy is ADT and radiation. Surgery and adjuvant radiation may also play a role.
- Metastatic CaP:
  – Mainstay of therapy is RT and ADT.
  – Early chemotherapy (docetaxel) may be considered for high-volume disease.
  – ADT specifics:
    o GnRH agonists include leuprolide or goserelin.
    o GnRH antagonists include degarelix: an alternative to GnRH agonists; suppresses testosterone production and avoids flare phenomenon observed with GnRH agonists.
    o Side effects of ADT: osteoporosis, gynecomastia, erectile dysfunction (ED), decreased libido, obesity, lipid alterations, greater risk of diabetes, and cardiovascular disease.
    o Flare phenomenon (disease flare: hot flashes, fatigue) can occur owing to transient increase in testosterone levels on initiation of GnRH agonist therapy.
    o If spinal cord metastases are present, the concern for cord compression with a testosterone flare can be avoided by starting antiandrogen therapy prior to initiation of a GnRH agonist.
    o Combined androgen blockade with GnRH agonist and antiandrogen (e.g., bicalutamide, nilutamide, or flutamide) may be used to prevent flare.
- Castration-resistant prostate cancer (CRPC)
  – CRPC is defined as progression of disease following ADT. Treatment includes the following:
Nonmetastatic
- Continue ADT, no further treatment has been shown to increase overall survival.
- Antiandrogen or androgen synthesis inhibitor (e.g., ketoconazole) may be added.

Asymptomatic metastatic: no previous therapy with docetaxel:
- Abiraterone: inhibitor of CYP17A (adrenal androgen production), used with prednisone
- Enzalutamide: androgen receptor inhibitor
- Docetaxel: chemotherapeutic that inhibits microtubules
- Sipuleucel-T: immunotherapy

Symptomatic metastatic: no previous therapy with docetaxel
- Abiraterone, enzalutamide, docetaxel
- Radum-223 (radiopharmaceutical) for patients with symptomatic bony metastases and no visceral metastasis

Symptomatic metastatic: previous therapy with docetaxel:
- Good performance status: abiraterone, enzalutamide, cabazitaxel
- Poor performance status: Mainstay is palliative care; may attempt further therapy based on patient wishes

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- Prostatectomy: PSA and DRE are recommended at regular intervals. PSA threshold-defining biochemical recurrence is evolving; however, recent data suggest a cutoff of 0.2 ng/mL (5). A CT and bone scan are usually obtained. If the PSA recurrence is thought to be from local disease, salvage radiation is considered. For metastatic disease, androgen deprivation is considered (5).
- XRT: PSA and DRE are recommended at regular intervals. Biochemical recurrence is defined as PSA increase ≥2 ng/mL above nadir; a CT and bone scan is usually obtained. If the PSA recurrence is thought to be from local disease, salvage prostatectomy or cryosurgery is considered. For metastatic disease, androgen deprivation is considered (5).

PROGNOSIS
- Localized disease is frequently curable; advanced disease has a favorable prognosis if lesions are hormone sensitive.
- 5-year CaP survival by stage: local 100%, regional 100%, distant 29.3% (1)
- Recurrence risk increased if adverse pathologic features are present: extraprostatic extension, seminal vesicle invasion, positive surgical margins.

**COMPICATIONS**

- Prostatectomy: Urinary incontinence and ED are the most common long-term issues.
- Radiation therapy: urinary incontinence, ED, radiation cystitis, and radiation proctitis
- Treatment options for ED: PDE5 inhibitors, intracavernosal injections, intraurethral suppositories, vacuum pump, penile prosthesis
- Treatment options for incontinence: oral medications, urethral sling, artificial sphincter

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

C61 Malignant neoplasm of prostate

**CLINICAL PEARLS**

• Prostate cancer is clinically diverse, ranging from low-risk/indolent disease to high-risk/aggressive disease.
• Most men with CaP are asymptomatic.
• The use of PSA for CaP screening is controversial and necessitates an open conversation between medical provider and patient regarding benefits/risks.
• Active surveillance is an important treatment option to consider for low-risk patients.
• Care must be taken when interpreting PSA levels in patients taking 5-α-reductase inhibitors.
PROSTATIC HYPERPLASIA, BENIGN (BPH)

Angela M. Ling, MSN, FNP-C • James E. Hougas III, MD, FAAFP • Sara M. DeSpain, MD

BASICS
- Benign prostatic hyperplasia (BPH) is due to proliferation of both the smooth muscle and epithelial cell lines of the prostate which causes increased volume and may cause compression of the urethra and obstructive symptoms.
- Clinically presents with storage and/or voiding symptoms collectively referred to as lower urinary tract symptoms (LUTS). These include difficulty initiating stream, frequency, or dysuria.
- Symptoms do not directly correlate to prostate volume. It is estimated that half of all men with histologic evidence of BPH experience moderate to severe LUTS.
- Progression may result in upper and lower tract infections and may progress to direct bladder outlet obstruction and acute renal failure (ARF).

EPIDEMIOLOGY
Age related, nearly universal development in men

Incidence
Incidence increases with age; estimates of prevalence vary from 70% to 90% by the age of 80 years (estimated at 8–20% by age 40 years).

ETIOLOGY AND PATHOPHYSIOLOGY
- Develops in prostatic periurethral or transition zone
- Hyperplastic nodules of stromal and epithelial components increase glandular components.
- Etiology is unknown.

COMMONLY ASSOCIATED CONDITIONS
- LUTS
  - LUTS can be divided into two groups: filling/storage symptoms and
voiding symptoms.
- Filling/storage symptoms include frequency, nocturia, urgency, and urge incontinence.
- Voiding symptoms include difficulty initiating stream, incomplete voiding, or weak stream.
- Can lead to acute or chronic obstructive symptoms

- Sexual dysfunction, including erectile dysfunction and ejaculatory disorders
- LUTS can also be secondary to cardiovascular, respiratory, or renal disease

**RISK FACTORS**
- Most significant risk factor is age.
- Increased risk with higher free prostate-specific antigen (PSA) levels, heart disease, and use of β-blockers
- Low androgen levels from cirrhosis/chronic alcoholism can reduce the risk of BPH.
- Obesity and lack of exercise can cause LUTS to be more significant.
- No evidence of increased or decreased risk with smoking, alcohol, or any dietary factors

**GENERAL PREVENTION**
- The disease appears to be part of the aging process.
- Symptoms can be managed through weight loss, regulation of fluid intake, decreased intake of caffeine, and increased physical activity.

**DIAGNOSIS**

**HISTORY**
- Evaluate symptom severity with the American Urological Society Symptom Index or the International Prostate Symptom Score (IPSS).
- Screen for other causes of symptoms such as infection, procedural history, or neurologic causes. Evaluate for comorbid conditions which may produce similar symptoms such as diabetes, congestive heart failure (CHF), or Parkinson disease.
- Review medication list. Particularly diuretics and anticholinergic medications; also, decongestants (increased sphincter tone), opiates (impaired autonomic function), or tricyclic antidepressants (anticholinergic effects)
- Review family history for BPH and prostate cancer.
- Screen for gross hematuria.
- IPSS scoring of LUTS (patient survey tracking severity) (2):
  - Questionnaire: Over the past month, how often have you:
    o 1. Had the sensation of not emptying your bladder completely after you finished urinating?
    o 2. Had to urinate again <2 hours after you finished urinating?
    o 3. Found you stopped and started again several times when you urinated?
    o 4. Found it difficult to postpone urination?
    o 5. Had a weak urinary stream?
    o 6. Had to push or strain to begin urination?
    o 7. Been up to urinate from the time you went to bed at night until the time you got up in the morning?
    o 8. How would you feel if you were to spend the rest of your life with your current symptoms?
  - Scoring of the questionnaire:
    o Questions 1 to 6: no symptoms = 0 points, 1 in 5 times = 1 point, less than half = 2 points, about half = 3 points, more than half = 4 points, most of the time = 5 points
    o Question 7: no occurrence = 0 points, 1 time = 1 point, 2 times = 2 points, 3 times = 3 points, 4 times = 4 points, and 5 times or more = 5 points
    o Question 8: 0 = delighted, 1 = pleased, 2 = mostly satisfied, 3 = mixed, 4 = mostly dissatisfied, 5 = unhappy, 6 = terrible
    o Symptoms are classified as mild (total score 0 to 7), moderate (total score 8 to 19), and severe (total score 20 to 35).
- Nocturia >2 times per night warrants a frequency/volume chart for 2 to 3 days to detect urinary patterns.

**PHYSICAL EXAM**
- Digital rectal exam (DRE) finding of symmetrically enlarged prostate, but size does not always correlate with symptoms
- Signs of renal failure due to obstructive uropathy (edema, pallor, pruritus, ecchymosis, nutritional deficiencies)
- If DRE is suggestive of prostate cancer, or if there is hematuria, recurrent infections, concern for stricture, or evidence of neurologic disease, the patient should be referred to urology.

**DIFFERENTIAL DIAGNOSIS**
- Obstructive
– Prostate cancer
– Urethral stricture or valves
– Bladder neck contracture (usually secondary to prostate surgery)
– Inability of bladder neck or external sphincter to relax appropriately during voiding

• Neurologic
  – Spinal cord injury or stroke
  – Parkinsonism
  – Multiple sclerosis

• Medical
  – Poorly controlled diabetes mellitus
  – CHF

• Pharmacologic
  – Diuretics
  – Decongestants
  – Anticholinergics
  – Opioids
  – Tricyclic antidepressants

• Other:
  – Bladder carcinoma
  – Overactive bladder
  – Nocturnal polyuria (>33% of the 24-hour urine volume occurs at night)
  – Bladder calculi
  – UTI
  – Prostatitis
  – Urethritis/sexually transmitted infections
  – Obstructive sleep apnea (OSA) (nocturia)
  – Caffeine
  – Polyuria (either isolated nocturnal polyuria or 24-hour polyuria)

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

• Urinalysis (UA) in all patients presenting with LUTS can help rule out other etiologies such as bladder/kidney stones, cancer, UTI, or urethral strictures.
• PSA for men with a life expectancy of 10 years and who would be surgical candidates if prostate cancer was identified
• PSA levels also correlate with prostate volume which can help guide treatment choice.
With bladder cancer risk factors (smoking history or hematuria), obtain urine cytology.
If nocturia is the main concern, consider using a frequency volume chart for urine output.
Sleep study if OSA or primary nocturnal polyuria is suspected
Serum creatinine measurement is not recommended (AUA recommendation).

**Follow-Up Tests & Special Considerations**
- No further testing is recommended in uncomplicated LUTS; further testing if symptoms do not respond to medical management or if initial evaluation suggests underlying disease
- Uroflow: volume voided per unit time (peak flow <10 mL/s is abnormal)
- Postvoid residual (PVR): either with catheterization or bladder ultrasound (>100 mL = incomplete emptying)
- Transrectal ultrasound: assessment of gland size; not necessary in the routine evaluation
- Abdominal ultrasound: can demonstrate increased PVR or hydronephrosis; not necessary in the routine evaluation

**Diagnostic Procedures/Other**
- Pressure-flow studies (urine flow vs. voiding pressures) to determine etiology of symptoms
  - Obstructive pattern shows high voiding pressures with low-flow rate.
- Cystoscopy
  - Demonstrates presence, configuration, cause (stricture, stone), and site of obstructive tissue
  - May help determine therapeutic option
  - Not recommended in initial evaluation unless other factors, such as hematuria, are present

**TREATMENT**

**GENERAL MEASURES**
- Treatment ranges from watchful waiting to lifestyle modifications, medications, or surgical management.
- Mild symptoms (score of <7) or moderate symptoms (score 8 to 15) that are non-bothersome require no treatment. Reevaluate annually.
For moderate to severe symptoms, try lifestyle interventions regulation of fluid intake, avoidance of alcohol and caffeine, exercise, diet, and eliminating/reducing contributing medications.

Medical treatment requires interval follow-up of 2 to 4 weeks for α-blockers and 3 months for 5-α-reductase inhibitors until symptoms improved and then annually.

Patients with complications including obstruction and urinary retention require bladder drainage.

**MEDICATION**

- Should be used as additive therapy; lifestyle modifications are still encouraged.
- Two main classes of medications: α-adrenergic antagonists and 5-α-reductase inhibitors
- The combination of these two medication classes is effective for long-term management of BPH and demonstrated large prostates.
  - **α-Adrenergic antagonists**
    - First-line option for moderate/severe and bothersome LUTS. Affect contraction of smooth muscle in the prostatic urethra and bladder neck. Show benefit over placebo. Typically take 2 to 4 weeks to show improvement. May affect blood pressure; require dose titration and blood pressure monitoring. AUA recommends alfuzosin (Uroxatral), doxazosin (Cardura), and tamsulosin (Flomax) as they are thought to be more selective and have less effect on blood pressure. Prazosin (Minipress) and phenoxybenzamine (Dibenzyline) have insufficient evidence and are not recommended. Most common adverse effect is dizziness; may cause orthostatic hypotension
    - **Doxazosin** (Cardura): 1 to 8 mg/day PO; may delay the occurrence of acute urinary retention but does not decrease incidence
    - **Tamsulosin** (Flomax): 0.4 to 0.8 mg/day PO
    - **Alfuzosin** (Uroxatral): 10 mg/day PO
    - **Terazosin** (Hytrin): Start at 1 mg PO daily at bedtime, max 20 mg daily.
    - **Contraindications:**
      - Use caution in patients who are also using phosphodiesterase type 5 inhibitors for erectile dysfunction.
      - Do not use in men pursuing cataract surgery until they are postoperative due to the risk for perioperative floppy iris syndrome.
  - **5-α-Reductase inhibitors**
○ Block conversion of testosterone to dihydrotestosterone, gradually reduce prostatic volume therefore are of most benefit when prostate volume exceeds 40 mL. Require 6 months to show clinical benefit. Two equally effective options:
  ■ Finasteride (Proscar): 5 mg/day PO
  ■ Dutasteride (Avodart): 0.5 mg/day PO

○ Should not be used in patients without evidence of enlarged prostates
○ Show reduced risk of acute urinary retention, less need for surgical intervention and less overall incidence of prostate cancer
○ Used in patients with refractory hematuria after other causes have been ruled out
○ Side effects include decreased libido and erectile dysfunction.

- A PSA value in a patient taking a 5-α-reductase inhibitors will be artificially low by up to 50%.
- Combination therapy of α-blocker plus 5-α-reductase inhibitor is superior to monotherapy with an α-blocker only in men with evidence of enlarged prostates.
- Combination therapy is superior to monotherapy to prevent progression but increase risk of drug-related adverse events.
- Anticholinergic agents are appropriate for irritative LUTS without an elevated PVR. Options include solifenacin (Vesicare), tolterodine (Detrol LA), or oxybutynin (Ditropan XL); should be avoided in patients with PVR >250 mL
- If patient also experiences erectile dysfunction, phosphodiesterase-5 inhibitors have been shown to have mild improvement of LUTS; can use Tadalafil (Cialis): 5 mg/day PO but avoid use in combination with α-blockers or in those with CrCl <30 mL/min

**Geriatric Considerations**
Use caution with anticholinergics, antihistamines, sympathomimetics, tricyclic antidepressants, opioids.

**ISSUES FOR REFERRAL**
- Moderate or severe LUTS that does not respond to medical management
- BPH-related complications such as recurrent UTIs or hematuria, renal insufficiency, and urinary retention
- Abnormal PSA or prostate exam
- Any history of urethral trauma or stricture, or neurologic disease of the bladder/urinary system
SURGERY/OTHER PROCEDURES

- Indications for surgery:
  - Urinary retention due to prostatic obstruction, recurrent, no improvement with medications
  - Intractable symptoms due to prostatic obstruction AUA score >8 and symptoms
  - Obstructive uropathy (renal insufficiency)
  - Recurrent or persistent UTIs due to prostatic obstruction
  - Recurrent gross hematuria due to enlarged prostate
  - Bladder calculi

- Surgical procedures: TURP remains the gold standard of surgical procedures; however, for selected patient populations, there are other options available.

- Common complications of TURP:
  - Bleeding can be significant.
  - TURP syndrome: hyponatremia secondary to absorption of hypotonic irrigation fluid
  - Retrograde ejaculation
  - Urinary incontinence

- Other options include transurethral needle ablation (TUNA) and transurethral microwave thermotherapy (TUMT), or transurethral incision of the prostate (TUIP). Open prostatectomy is more common when prostate exceeds 100 g. Transurethral laser ablation is an alternative option for patients on anticoagulants.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Saw palmetto (*Serenoa repens*) has been thoroughly studied in a subject in Cochrane review and did not improve LUTS. Other agents including pygeum, Cernilton, and herbs with $\beta$-sitosterols have been studied less; however, no current evidence to support their use. Acupuncture failed to show improvement in LUTS in one clinical trial as well. There are no recommended complementary or alternative treatments for BPH.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
**Patient Monitoring**
- Symptom index (IPSS) monitored every 3 to 12 months
- DRE yearly in patients who choose watchful waiting
- PSA yearly in patients who choose watchful waiting: should not be checked while patient is in retention, recently catheterized, or within a week of any surgical procedure to the prostate
- Consider monitoring PVR, if elevated.

**DIET**
Avoid large boluses of oral or IV fluids or alcohol intake; caffeine may exacerbate symptoms as well.

**PATIENT EDUCATION**
National Kidney and Urologic Diseases Information Clearinghouse, Box NKUDIC, Bethesda, MD 20893; 301-468-6345

**PROGNOSIS**
- Symptoms improve or stabilize in 70–80% of patients.
- 25% of men with LUTS will have persistent storage symptoms after prostatectomy.
- Of men with BPH, 11–33% have occult prostate cancer.

**COMPLICATIONS**
- Urinary retention (acute or chronic)
- Bladder stones
- Prostatitis
- Hematuria

**REFERENCES**

**ADDITIONAL READING**
mebooksfree.com

**CODES**

**ICD10**

- N40.0 Enlarged prostate without lower urinary tract symptoms
- N40.1 Enlarged prostate with lower urinary tract symptoms

**CLINICAL PEARLS**

- Although medical therapy has changed the management of BPH, it has only delayed the need for TURP by 10 to 15 years, not eliminated it.
- Urinary retention, obstructive uropathy, recurrent UTIs, elevated PSA, bladder calculi, hematuria, and failure of medical therapy are indications for surgical management of BPH.
PROSTATITIS
Kyle B. Stephens, DO

BASICS

DESCRIPTION
- Painful or inflammatory condition affecting the prostate gland with or without bacterial etiology, often characterized by urogenital pain, voiding symptoms, and/or sexual dysfunction
- Significant impact on quality of life
- <10% bacteria-proven infection
- National Institutes of Health’s classification
  - Class I: acute bacterial prostatitis: symptomatic with fever, perineal pain, dysuria, and obstructive symptoms; polymorphonuclear leukocytes (PMNL) and bacteria in urine
  - Class II: chronic bacterial prostatitis: symptomatic chronic or recurrent bacterial infection with pain and voiding disturbances; PMNL and bacteria in expressed prostatic secretions (EPS), or urine after prostate massage, or in semen
  - Class III: chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS)
    - Inflammatory (subtype IIIA): chronic symptoms with PMNL in EPS/urine after prostate massage or in semen
    - Noninflammatory (subtype IIIB): chronic symptoms without presence of PMNL in EPS/urine after prostate massage or in semen
  - Class IV: asymptomatic inflammatory prostatitis: incidental finding during prostate biopsy for infertility, cancer workup; presence of PMNL and/or bacteria in EPS/urine after prostatic massage or in semen
- System(s) affected: genitourinary, renal, reproductive

EPIDEMIOLOGY

Incidence
- Two million cases annually in the United States
- Predominant age: 30 to 50 years old, sexually active; chronic is more common in those >50 years.
- Bacterial prostatitis occurs more frequently in patients with HIV.

mebooksfree.com
**Prevalence**
- Affects approximately 8.2% of males
- Lifetime probability of diagnosis >25%
- Accounts for 8% of visits to urologists and 1% of visits to primary care physicians
- Percentage of cases by class: class I: <1%, class II: 5–10%, class III: 80–90%, class IV: 10%

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Acute bacterial prostatitis (class I)
  - Likely, etiology from ascending urethral infection with intraprostatic reflux of infected urine into prostatic ducts, often associated with cystitis
  - Can occur after instrumentation of prostate
  - Usually gram-negative bacteria (*Escherichia coli* [most common]; *Proteus, Klebsiella, Serratia*, and *Enterobacter* species; *Pseudomonas aeruginosa*)
  - Rarely, gram-positive bacteria (*Staphylococcus aureus, Streptococcus*, and *Enterococcus* species)
  - Confirmed staphylococcal prostatitis should warrant evaluation for hematogenous spread, including endovascular source.
  - Atypical bacteria include *Chlamydia trachomatis, Trichomonas vaginalis*, and *Ureaplasma urealyticum*.
  - Consider *Neisseria gonorrhoeae* or *C. trachomatis* in sexually active men <35 years.
- Chronic bacterial prostatitis (class II)
  - Similar pathogens as discussed earlier
  - Often occurs as recurrent episodes of infection by same organism
  - Progression from acute to chronic prostatitis is poorly understood but could result from inadequate treatment of acute prostatitis.
- CP/CPPS (class III)
  - Unclear etiology, possibly due to difficult-to-culture infection but noninfectious etiology also proposed
  - Inciting agent may cause inflammation or neurologic damage in or around the prostate and lead to pelvic floor neuromuscular and/or neuropathic pain.
  - No correlation between histologic inflammation of prostate and presence or absence of symptoms
  - Patients with chronic inflammation on histology have shorter time to symptomatic progression.
**RISK FACTORS**
- Urinary tract infections
- HIV infection
- Prostatic calculi
- Urethral stricture
- Urinary catheterization: indwelling, intermittent
- Genitourinary instrumentation including prostate biopsy (especially in patients with prior quinolone intake), transurethral resection of prostate, cystoscopy
- Urinary retention
- Benign prostatic hypertrophy
- Unprotected sexual intercourse
- Trauma (e.g., bicycle, horseback riding)

**GENERAL PREVENTION**
Antibiotic prophylaxis for genitourinary instrumentation and prostatic biopsy

**COMMONLY ASSOCIATED CONDITIONS**
- Benign prostatic hypertrophy
- Cystitis
- Urethritis
- Sexual dysfunction, including erectile dysfunction and premature ejaculation

**DIAGNOSIS**

**HISTORY**
- Acute prostatitis (class I):
  - Acutely ill with fever, chills, malaise
  - Low back pain, myalgias
  - Frequency, urgency, dysuria, nocturia
  - Prostatodynia, pelvic pain, perineal pain
  - Cloudy urine
  - Obstructive voiding symptoms: poor stream, hesitancy
- Chronic prostatitis (classes II and III):
  - More insidious presentation than class I
  - Symptoms for 3 of 6 previous months
  - Low-grade fever (class II only)
  - Prostatodynia, perineal pain
– Dysuria, frequency, urgency
– Lower abdominal pain
– Low back, testicular, and/or penile pain
– Hematospermia
– Sexual dysfunction/painful ejaculation

**PHYSICAL EXAM**
- Vital signs (unstable vitals suggest sepsis)
- Back exam (CVA tenderness)
- Abdominal exam (bladder distension)
- Prostate exam
  - Class I: Prostate is very tender, warm, firm, and edematous.
  - Class II: often normal but enlarged, tender, edematous, nodular prostate also encountered
  - Class III: often normal prostate

**ALERT**
Avoid vigorous massage of the prostate in acute bacterial prostatitis; may induce iatrogenic bacteremia; safe if done gently

**DIFFERENTIAL DIAGNOSIS**
- Lower urinary tract infection
- Pyelonephritis
- Cystitis (bacterial, interstitial)
- Urethritis
- Prostatic abscess
- Acute/chronic urinary retention
- Benign prostatic hypertrophy malignancy (prostate, bladder)
- Obstructive calculi
- Foreign body

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Suspected acute prostatitis (class I)
  - Urinalysis; urine Gram stain/culture and sensitivity
  - CBC with differential; blood culture if fever, chills, or signs of sepsis are present
- Suspected chronic bacterial prostatitis (class II)
– Urinalysis; urine/EPS/semen: Gram stain/culture and sensitivity
– Review previous urine culture results.
– National Institutes of Health—Chronic Prostatitis Symptom Index (NIH-CPSI): 9-question symptom survey
  (http://www.prostatitis.org/symptomindex.html)
– Diagnostic gold standard: Meares-Stamey 4-glass test (not performed often)
– 2-glass test (pre- and postmassage urine testing) more common and easier with equivalent sensitivity and specificity
  o Cultures of midstream preprostate massage urine and EPS/postmassage urine
– Consider urinary flow rate and postvoid residual volume if urinary retention is present.

- Suspected CP/CPPS (class III)
  – Diagnosis of exclusion
  – Urinalysis; urine/EPS/semen: Gram stain/culture and sensitivity
  – Hematuria if present: urine cytology, cystoscopy, CT urography with or without contrast
  – PSA is not indicated unless malignancy is suspected.
  – Concomitant abdominal pain: CT abdomen
  – Testicular pain: scrotal US
  – Sensation of incomplete bladder emptying: postvoid residual volume with bladder US or catheterization
  – Lumbar radiculopathy: MRI spine

**Follow-Up Tests & Special Considerations**
- Failure to respond to initial antibiotic therapy: US, CT, or MRI to image prostate and urology referral
- US or CT or MRI if prostatic calculi, malignancy, or abscess is suspected
- Acute bacterial: urinalysis and culture 30 days after initiating treatment
- Chronic bacterial: urinalysis and culture every 30 days (may take several months of treatment to clear)

**Diagnostic Procedures/Other**
- Needle biopsy or aspiration for culture
- Urodynamic testing (prostatodynia) if indicated
- Cystoscopy (in persistent nonbacterial prostatitis to rule out bladder cancer, interstitial cystitis)
## TREATMENT

### GENERAL MEASURES
- Analgesics/antipyretics/stool softeners
- Hydration
- Sitz baths to relieve pain and spasm
- Suprapubic catheter for urinary retention
- Anxiolytics, antidepressants if anxiety and/or depression are present

### MEDICATION

#### First Line

<table>
<thead>
<tr>
<th>Scenario</th>
<th>Medication</th>
</tr>
</thead>
</table>
| Acute bacterial (outpatient)     | - Fluoroquinolone (e.g., ciprofloxacin 500 mg PO q12h or levofloxacin 500 mg PO once daily) for 2 to 4 weeks *or*
|                                 | - Trimethoprim-sulfamethoxazole 1 double-strength tab PO q12h for 2 to 4 weeks *or*  
|                                 | - If gram-positive cocci are seen in initial urine Gram stain, start with amoxicillin 500 mg PO q8h. Adjust antibiotics once culture and sensitivities report is available.  
|                                 | - Local sensitivity pattern should guide therapy.  
|                                 | - If at risk for sexually transmitted infection (STI) pathogens: ceftriaxone 250 mg IM for 1 dose plus doxycycline 100 mg PO q12h daily for 1 week or azithromycin 1 g PO single dose  
| Acute bacterial (inpatient)      | - Ampicillin 2g IV q6h or fluoroquinolone (e.g., ciprofloxacin 400 mg IV q12h or levofloxacin 500 mg q24h); begin oral therapy after afebrile for 24 to 48 hours.  
| Chronic bacterial (class II)     | - Fluoroquinolone (e.g., levofloxacin 500 mg PO) once daily for 4 weeks or ciprofloxacin 500 mg PO q12h for 4 to 12 weeks  
|                                 | - Combination therapy with azithromycin may help to eradicate atypical pathogens.  
|                                 | - Anti-inflammatory agents for pain symptoms and α-blockers for urinary symptoms  
| CP/CPPS (class III)              | - Heterogeneous condition with no universally effective treatment  
|                                 | - Treatment choice is patient-centered, focusing on symptoms relief of four
domains: pain, lower urinary tract symptoms (LUTS), psychological stress, and sexual dysfunction.
- α-Blockers, antibiotics, and combinations of these therapies achieve greatest improvement in clinical symptoms scores compared to placebo.
- Tamsulosin 0.4 mg PO once daily at bedtime for 4 to 6 weeks; continue if there is a positive response.

**Second Line**
- Piperacillin or ticarcillin with aminoglycoside, erythromycin, tetracycline, cephalexin, fluoroquinolones, dicloxacillin, nafcillin IV, vancomycin IV
- Finasteride (in patients >45 years, class IIIA, and enlarged prostate glands)
- Atypical: may benefit from erythromycin, doxycycline

**ISSUES FOR REFERRAL**
Urology referral if antibiotic treatment fails, symptoms persist (especially obstructive voiding symptoms), hematuria, elevated PSA; or for surgical drainage if an abscess persists after ≥1 week of therapy

**ADDITIONAL THERAPIES**
- Psychotherapy if sexual dysfunction is present
- 5-α-Reductase inhibitors, nonsteroidal anti-inflammatory medications, pelvic floor physical therapy, transurethral microwave thermotherapy, circumcision

**SURGERY/OTHER PROCEDURES**
Surgical resection can be considered for refractory cases of recurrent bacterial prostatitis or to drain an abscess, when necessary.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Class III: Acupuncture, electro-acupuncture, phytotherapies (pollen extract, quercetin), heat therapy, low-intensity pulsed US, and myofascial release have limited data to support.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Proven or suspected abscess
- Unstable vital signs (sepsis)
• Immunocompromised
• Failed outpatient treatment

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

• Negative urine culture at 7 days predictive of cure after completion of treatment course
• Consider prostatic abscess in patients who do not respond well to therapy.

**Patient Monitoring**

NIH-CPSI: 9 questions, which can be used to evaluate severity of patient symptoms and response to treatment within three domains:

• Pain
• Urinary symptoms
• Quality of life

**PROGNOSIS**

• Fever and dysuria usually resolve in 2 to 6 days.
• Acute infection usually improves in 3 to 4 weeks.
• Course of chronic prostatitis is often prolonged and difficult to cure; 55–97% cure rate depending on population and drug used
• 20% have reinfection or persistent infection.

**COMPLICATIONS**

• Prostatic abscess (common in HIV infected)
• Pyelonephritis
• Gram-negative sepsis, bacteremia
• Urinary retention
• Epididymitis
• Infertility
• Chronic bacterial prostatitis (following acute prostatitis)
• Metastatic infection (spinal, sacroiliac)

**REFERENCES**

**SEE ALSO**

- Prostate Cancer; Prostatic Hyperplasia, Benign (BPH); Urinary Tract Infection (UTI) in Males
Algorithm: Hematuria

CODES

ICD10

- N41.9 Inflammatory disease of prostate, unspecified
- N41.0 Acute prostatitis
- N41.1 Chronic prostatitis

CLINICAL PEARLS

- Vigorous prostatic massage is contraindicated in acute prostatitis.
- Fluoroquinolones are recommended first-line antibiotic for bacterial prostatitis, both acute and chronic (class I and class II).
- At least 14 to 30 days of antibiotic therapy is required for acute prostatitis; longer for chronic bacterial prostatitis.
- Antibiotic therapy is not proven to be effective in CP/CPPS (class III).
- Imaging is often not needed.
PROTEIN C DEFICIENCY

Donald J. Fahey-Ahrndt, MD • James E. Hougas III, MD, FAAFP

BASICS

DESCRIPTION

- Protein C is a vitamin K–dependent factor synthesized, in an inactive form, by the liver.
- Activated protein C inhibits generation of thrombin by inactivating factors Va and VIIIa, using protein S as a cofactor.
- Deficiency in protein C activity therefore leads to a prothrombotic state.
- System(s) affected: cardiovascular, pulmonary, integumentary, hematologic, and immunologic

EPIDEMIOLOGY

Prevalence

- 0.3% of the general population
- 3–5% of persons with venous thromboembolism (VTE)
- Mean age of first thrombosis is 45 years.
- There is no known gender predominance.

ETIOLOGY AND PATHOPHYSIOLOGY

- Protein C deficiency (PCD) can be inherited or acquired.
- Genetic mutations can lead to two types of PCD; however, the distinction between the two is clinically irrelevant.
  - Type I (most common) results in the reduction of protein C levels.
  - Type II results in a decreased functionality, despite having normal levels of protein C.
- Acquired PCD can occur in many disease states such as:
  - Liver disease
  - Disseminated intravascular coagulation (DIC)
  - Severe infections (especially meningococcemia)
  - Autoantibody inhibitors directed toward protein C
  - Cancer and chemotherapy (i.e., L-asparaginase, 5-FU, methotrexate, and
cyclophosphamide)
– Initial use of vitamin K antagonists (warfarin)
– Vitamin K deficiency (malnutrition or malabsorption of fat-soluble vitamins)

**Genetics**
- Autosomal dominant inheritance pattern with incomplete penetrance
- At least 160 genetic mutations have been described in the protein C gene that can lead to a functional deficiency.
- Heterozygous patients often have mild or asymptomatic disease.
- Homozygous patients, or those with another coexisting genetic thrombophilia, often have more severe disease.
- Additionally, mutations in other genes (GCKR, EDEM2, BAZ1B, etc.) are associated with variability in the levels of protein C expression in the general population, although their clinical significance is currently unknown.
- Patients with PCD who start warfarin without concomitant heparin are at increased risk of developing warfarin-induced skin necrosis (WISN). This is thought to be due to the shorter half-life of protein C (5 to 8 hours) compared to other vitamin K–dependent clotting factors. However, not all patients who develop WISN have PCD (1).

**ALERT**
The prevention of warfarin necrosis has been achieved by avoiding loading doses of warfarin and the use of heparin bridging. Screening all patients for inherited or acquired forms of PCD prior to initiating warfarin is not cost-effective nor prognostic, as many patients with documented deficiency do not progress to WISN (1)[C].

**GENERAL PREVENTION**
Because PCD is usually a congenital disease, there are no preventive measures.

**COMMONLY ASSOCIATED CONDITIONS**
- VTE at any site, often spontaneous
- Arterial thrombosis is rare, and a causative relationship has not been clearly demonstrated.
- Homozygosity can be associated with catastrophic thrombotic complications at birth (e.g., purpura fulminans).
- Recurrent pregnancy losses
DIAGNOSIS

HISTORY

- Recurrent VTE
- VTE at <40 years of age
- Thrombosis in unusual locations (e.g., mesentery, sagittal sinus, portal vein)
- Family history of thrombosis or spontaneous abortion
- Often has other usual risk factors for provoked VTE

PHYSICAL EXAM

Normal

DIFFERENTIAL DIAGNOSIS

- Factor V Leiden
- Protein S deficiency
- Antithrombin deficiency
- Dysfibrinogenemia
- Dysplasminogenemia
- Hyperhomocysteinemia
- Prothrombin 20210 mutation
- Elevated factor VIII, IX, or XI levels
- Antiphospholipid antibody syndrome
- DIC
- Heparin-induced thrombocytopenia (HIT)

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Initial evaluation of a new clot in patients should include a CBC with peripheral smear, INR, aPTT, hepatic and renal function tests as well as appropriate imaging.
- Testing for heritable causes of thrombophilia in unselected patients presenting with a first-time VTE (provoked or unprovoked) is not indicated (2,3)[C].
- Consider screening for antiphospholipid syndrome rather than other thrombophilia (PCD) for women with recurrent early pregnancy loss (three losses prior to 10 weeks’ gestation) (4)[B].

Follow-Up Tests & Special Considerations
Testing for heritable or acquired thrombophilia are suggested in the following circumstances (5)[C]:
- First episode of VTE and patient age <40 years
- Recurrent VTE regardless of the presence of risk factors
- Patients with VTE at unusual sites

Testing for PCD should be considered in patients with history of WISN (3)[C].

Testing for protein C and S deficiencies should be done urgently in neonates and children suspected to have purpura fulminans (2,3)[B].

Testing for hereditary thrombophilia should only be considered in asymptomatic first-degree relatives of those with proven hereditary thrombophilia if they are female, of childbearing age, and have no history of prior pregnancy complications (3,4)[C].

When ordering additional testing for hereditary or acquired thrombophilia, the following conditions should be considered (3)[C]:
- Antiphospholipid antibody syndrome
- Antithrombin III deficiency
- Factor V Leiden
- PCD
- Protein S deficiency
- Prothrombin G20210A

Testing for PCD is done using two separate lab tests:
- An immunoassay for a quantitative assessment of protein C levels
- A functional activity assay using a snake venom protease to activate protein C

Test Interpretation

Drugs that may alter lab results
- Oral contraceptives can raise protein C levels.
- Warfarin reduces protein C levels and should be discontinued 2 to 3 weeks before reliable testing.

Disorders that may alter lab results
- Liver disease reduces protein C levels.

ALERT
Acute thrombosis can lower protein C levels. Repeat confirmatory test of low protein C level at a separate time is advisable. If a normal level of protein C is obtained at presentation, then deficiency can be excluded.
TREATMENT
Treat active thrombosis; follow-up

GENERAL MEASURES
- Individuals with PCD should be educated regarding signs and symptoms of VTE.
- Women with any of the following history should avoid estradiol-containing contraceptives and hormone replacement therapy during menopause (3)[A]:
  - Diagnoses of PCD
  - First-degree relative with PCD
  - First-degree relative with VTE at age <50 years
- Women may use progestin-only hormonal contraception options.
- Routine anticoagulation for asymptomatic patients with PCD is not recommended (4)[C].
- Anticoagulation is recommended for at least 3 months in patients with inherited thrombophilia following their first VTE (2,5)[B].
  - There is some argument for indefinite anticoagulation; however, data is limited (3)[C].
  - Shared decision making should be used to discuss duration of therapy beyond 3 months (3)[C].
- Indefinite anticoagulation is indicated for patients with recurrent VTE (4)[A].
- Treat VTE as an outpatient when possible if clinically stable (4)[B].
- Severe congenital PCD may be treated with protein C concentrates.

Pregnancy Considerations
- Heparin-based products should be used during pregnancy when therapeutic or prophylactic treatment of VTE is needed.
- For pregnant women with known PCD but no personal history of VTE or additional thrombotic risk factors (i.e., family hx of VTE in first-degree relative <50 years of age, obesity, prolonged immobility), antepartum and postpartum clinical monitoring is recommended over prophylactic therapy (5)[C].
- For pregnant women with known PCD, no personal history of VTE but with an additional thrombotic risk factor, antepartum surveillance is recommended with postpartum prophylactic therapy for 6 weeks of either prophylactic- or intermediate-dose (5)[C].
- For pregnant women with known PCD and previous VTE, it is recommended
to give postpartum preventative therapy with either prophylactic or intermediate dose LMWH. This could also be given antepartum versus surveillance at the provider’s discretion (5)[C].

**First Line**

- **LMWH (4)[A]:** initially started with warfarin for a minimum of 5 days and two consecutive INRs between 2 and 3 to bridge. Additionally, LMWH may be started 5 to 10 days prior to starting dabigatran or edoxaban.
  - Enoxaparin (Lovenox) 1 mg/kg SC BID or 1.5 mg/kg/day SC
  - Tinzaparin (Innohep): 175 anti-Xa IU/kg/day SC
  - Dalteparin (Fragmin) 200 U/kg/day
- **Novel oral anticoagulants (NOACs):**
  - Rivaroxaban (Xarelto) 15 mg PO BID with food for 21 days and then 20 mg PO QD with food
  - Apixaban (Eliquis) 10 mg PO BID for 7 days and then 5 mg PO BID
  - Dabigatran (Pradaxa) 150 mg PO BID (after 5 to 10 days of parenteral anticoagulation)
  - Edoxaban (Savaysa) 60 mg PO QD (after 5 to 10 days of parenteral anticoagulation)
- **Oral vitamin K antagonist:**
  - Warfarin (Coumadin) titrated to an INR of 2 to 3 (4)[A]
- **Factor Xa inhibitors:**
  - Fondaparinux (Arixtra) <50 kg: 5 mg/day SC; 50 to 100 kg: 7.5 mg/day SC; >100 kg: 10 mg/day SC; contraindicated if CrCl <30 mL/min
- **Contraindications**
  - Active bleeding precludes anticoagulation; risk of bleeding is a relative contraindication to long-term anticoagulation.
- **Precautions**
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Monitor kidney function, drug–drug interactions, and CBC, including platelets (concern for heparin-induced thrombocytopenia).

**Second Line**

- **Heparin 80 U/kg IV bolus followed by 18 U/kg/hr; adjust dose depending on PPT.**
- In patients requiring large daily doses of heparin, measure an anti-Xa level for dose guidance.
- Alternatively, and for outpatients, unfractionated heparin can be given at 333
U/kg and then 250 U/kg SC, without monitoring (4)[C].

**ISSUES FOR REFERRAL**
Patients with suspected PCD should be referred to a hematologist.

**SURGERY/OTHER PROCEDURES**
- Anticoagulation may be held for surgical interventions.
- In patients with acute proximal DVT of the lower extremity and an absolute contraindication to anticoagulation, inferior vena cava (IVC) filters are recommended; otherwise, the use of an IVC filter in addition to anticoagulants is not recommended (4)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Life-threatening VTE
- Significant bleeding while on anticoagulant therapy

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Warfarin requires periodic monitoring of the INR to maintain a range of 2 to 3 (monthly, after initial stabilization).
- LMWH is the treatment of choice in pregnancy. Periodic monitoring with anti-Xa levels is recommended in these patients.

**DIET**
Unrestricted (except if on warfarin—avoid varying diet with foods that have significant amounts of vitamin K)

**PATIENT EDUCATION**
- Patients should be educated about signs and symptoms of VTE as well as the use of oral anticoagulant therapy if taking such.
- Avoid NSAIDs while on warfarin.
- Avoid OCPs, as they increase risk of thrombosis.
PROGNOSIS
When compared with normal individuals, persons with PCD have normal life spans.

COMPLICATIONS
Primary or recurrent VTE

REFERENCES

CODES
ICD10
D68.59 Other primary thrombophilia

CLINICAL PEARLS
- Testing for heritable causes of thrombophilia in unselected patients presenting with a first episode of VTE (provoked or unprovoked) is not indicated.
- Screening, and therefore prophylactic treatment, of asymptomatic family members is not justified with the possible exception of females of
childbearing age with no previous history of pregnancy complications.

- Asymptomatic patients with PCD do not need prophylactic anticoagulation because the risk of thrombosis is low.
- Patients with PCD presenting with first-time VTE should be anticoagulated for at least 3 months. Other risk factors and shared decision making should be used to determine if anticoagulation should be used for a longer duration.
- Recurrent VTE is an indication for indefinite anticoagulation.
PROTEIN S DEFICIENCY

Oscar Cabrera-Marante, MD • Tais González Pessolani, MD • Gonzalo Carreno-Tarragona, MD

BASICS

DESCRIPTION

- Protein S is a vitamin K–dependent glycoprotein, produced mainly in the liver that acts as a cofactor for protein C.
- Protein C becomes activated when thrombin binds to the endothelial receptor, thrombomodulin.
- Activated protein C, with protein S (a cofactor), inactivates clotting factors Va and VIIIa enhancing fibrinolysis.
- Protein S is also able to directly inhibit factors Va, VIIa, and Xa independently of activated protein C.
- Protein S deficiency is a congenital thrombophilia, which increases the risk of thromboembolism.
- It primarily affects the venous system.
- System(s) affected: cardiovascular; hematologic/ immunologic; pulmonary

EPIDEMIOLOGY

Incidence

- Mean age of first thrombosis: 2nd decade
- Predominant sex: male = female

Prevalence

- 0.3% of general population
- Found in 3% of persons with venous thrombosis (VT)

ETIOLOGY AND PATHOPHYSIOLOGY

- It is an autosomal dominant disease.
- Only the free form of protein S (40%) acts as a cofactor for activated protein C. Protein S reversibly binds to the C4b protein, which leads to conditions in which free protein S is low, but total protein S is normal. These individuals are prone to thrombosis. Conditions with reduced protein S: pregnancy, oral
contraceptives, warfarin; DIC, liver disease, nephrotic syndrome, HIV, L-asparaginase chemotherapy, and acute thrombosis

- Transient autoantibodies can develop against protein S in patients with acute varicella (1)[C].

**Genetics**

- Is due to heterozygous mutations in the PROS1 gene
- Heterozygotes have an odds ratio (OR) of VT of 1.6 to 11.5.
- Homozygosity or compound heterozygosity, if untreated, is usually incompatible with adult life.
- Homozygotes can have a fulminant thrombotic event in infancy, termed *neonatal purpura fulminans*.

**RISK FACTORS**

- Oral contraceptives, pregnancy, and the use of HRT increase the risk of VT in patients with protein S deficiency (2)[A].
- Patients with protein S deficiency and other prothrombotic states, have further increased rate of thrombosis (2)[A].
- Arterial thrombosis is more frequent in patients with protein S deficiency who smoke.
- Patients heterozygous for protein S deficiency who are initiated on warfarin without concomitant heparin can develop warfarin-induced skin necrosis because the half-life of other vitamin K–dependent clotting factors (e.g., prothrombin, factor IX, and factor X) is much longer than the anticoagulant protein S (4 to 8 hours), leading to a transient hypercoagulable state when protein S becomes depleted. These patients develop extremely low levels of protein S and develop necrosis of the skin over central areas of the body such as the breast, abdomen, buttocks, and genitalia (2)[A].

**Pregnancy Considerations**

Increased thrombotic risk and pregnancy losses

**GENERAL PREVENTION**

There are no preventive measures.

**COMMONLY ASSOCIATED CONDITIONS**

- Deep and superficial VT, often unprovoked
- Up to 50% of homozygotes will have thrombosis.
Homozygosity is associated with catastrophic thrombotic complications at birth: *neonatal purpura fulminans.*

- Sites of thrombosis can be unusual, including the mesentery, cerebral veins, and axillary veins.
- Arterial thrombosis is rare, but reported in several case reports.
- Skin necrosis in patients treated with warfarin.
- Recurrent pregnancy losses (3)
- High prevalence of mental disorders was described (4).

**DIAGNOSIS**

**HISTORY**

Any inherited thrombophilias should be suspected in:

- Unprovoked VTE at age <50 years
- VTE with a strong family history of VT or known familial protein S deficiency
- VTE in unusual sites as mesenteric or cerebral vein
- Recurrent VTE

**PHYSICAL EXAM**

Normal

**DIFFERENTIAL DIAGNOSIS**

Other inherited thrombophilias:

- Factor V Leiden (in Caucasians)
- Protein C deficiency (in Caucasians)
- Antithrombin deficiency
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocystinemia
- Prothrombin G20210A mutation
- Elevated factor VIII levels
- Acquired VT risk factors: surgery, immobility, cancer, myeloproliferative neoplasms, trauma, antiphospholipid syndrome, paroxysmal nocturnal hemoglobinuria, pregnancy, hormone replacement therapy, postpartum, disseminated intravascular coagulation
DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- For evaluation of new clot in patient at risk: CBC with peripheral smear, PT/INR, aPTT, thrombin time, lupus anticoagulant, antiphospholipid antibodies, anticardiolipin antibody, anti-β₂-glycoprotein I antibody, activated protein C resistance, protein S antigen and resistance, antithrombin III assay, fibrinogen, factor V Leiden, prothrombin G20210A
- Immunoassay for quantitative assessment of total and free protein S levels
- Protein S activity assay (mainly after obtaining activated protein C resistance)
- Disorders that may alter lab results: acute thrombosis, vitamin K antagonists (VKA), any acute illness response, liver disease and pregnancy-reduce protein S levels. Direct oral anticoagulants affect protein S activity assay.
- Heparin and low-weight heparin do not alter lab results.
- Total protein S levels are markedly decreased in newborns and young infants; use age-adjusted norms.

TREATMENT

GENERAL MEASURES

- Routine anticoagulation for asymptomatic patients with protein S deficiency is not recommended.
- Antithrombotic therapy recommendations for patients with protein S deficiency can be guided by antithrombotic therapy for VTE disease guidelines.

Patients with unprovoked VTE and who have a low or moderate bleeding risk, are suggested to receive extended anticoagulant therapy (no scheduled stop date) over 3 months of therapy (2)[B],(4), and those who have a high bleeding risk are recommended to receive 3 months of anticoagulant therapy over extended therapy (1)[B],(4).

Patients with a second unprovoked VTE and who have a low bleeding risk are recommended to receive extended anticoagulant therapy (no scheduled stop date) over 3 months (1)[B],(4); those with moderate bleeding risk are suggested to receive extended anticoagulant therapy over 3 months of therapy (2)[B],(4), and those who have high bleeding risk are suggested to receive 3 months of anticoagulant therapy over extended therapy (no scheduled stop date) (2)[B],(4).
Patients with VTE and no cancer are suggested to receive dabigatran, rivaroxaban, apixaban, or edoxaban over VKA therapy as long-term (first 3 months) anticoagulant therapy (2)[B],(4).

Treatment of thrombosis with low-molecular-weight heparin (LMWH) is recommended over unfractionated heparin, unless the patient has severe renal failure.

Treat as outpatient, if possible.

Prophylaxis should be considered in risk situations such as surgery, immobility or postpartum, especially in patients with family history.

The role of family screening for protein S deficiency is unclear because most patients with this mutation do not have thrombosis. Screening should be considered for women considering oral contraceptives or pregnancy and who have a family history of protein S deficiency (5)[B].

MEDICATION

- **LMWH**
  - Enoxaparin (Lovenox) 1 mg/kg SC BID:
    - Alternatively, 1.5 mg/kg/day SC
  - Tinzaparin (Innohep) 175 anti-Xa IU/kg/day SC
  - Dalteparin (Fragmin) 200 IU/kg/day

- **Factor Xa inhibitor**
  - Fondaparinux (Arixtra) <50 kg: 5 mg/day SC; 50 to 100 kg: 7.5 mg/day SC; >100 kg: 10 mg/day SC; contraindicated if CrCl <30 mL/min

- **Novel oral anticoagulants (NOACs):**
  - Dabigatran 150 mg PO BID (after 5 to 10 days of parenteral anticoagulation)
  - Rivaroxaban 15 mg PO BID for 21 days and then 20 mg PO QID
  - Apixaban 10 mg PO BID for 7 days and then 5 mg PO BID
  - Edoxaban 60 mg PO QID (after 5 to 10 days of parenteral anticoagulation)

- **Oral anticoagulant: warfarin (Coumadin):** 5 mg/day PO then adjusted to an INR of 2 to 3. LMWH initially for a minimum of 5 days and two consecutive INRs between 2 and 3, at which time it can be stopped; contraindications
  - Active bleeding precludes anticoagulation; risk of bleeding is a relative contraindication to long-term anticoagulation.
  - Warfarin is contraindicated in patients with a prior history of warfarin-induced skin necrosis.

- **Precautions**
  - Observe patient for signs of embolization, further thrombosis, or bleeding.
  - Avoid IM injections.
– Periodically, check stool and urine for occult blood; monitor CBC, including platelets.
– Heparin: thrombocytopenia and/or paradoxical thrombosis with thrombocytopenia
– Warfarin: necrotic skin lesions (typically breasts, thighs, and buttocks)
– LMWH: Adjust dose in renal insufficiency.

**Significant possible interactions**
– Agents that intensify the response to oral anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfinpyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
– Agents that diminish the response to oral anticoagulants: aminoglutethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

**ISSUES FOR REFERRAL**
– Patients with suspected protein S deficiency should be seen by a hematologist.
– Screening and prophylactic treatment of asymptomatic family members is not justified (6).

**SURGERY/OTHER PROCEDURES**
– Anticoagulation must be held for surgical interventions.
– For most patients with DVT, recommendations are against routine use of vena cava filter in addition to anticoagulation (1)[B]. IVC filter is only recommended in case of contraindication to anticoagulation (4)[A].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
– Life-threatening VT
– Significant bleeding while on anticoagulant therapy
– Look for signs of bleeding while on anticoagulation therapy.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Warfarin requires periodic (monthly after initial stabilization) monitoring of the INR.
- Periodic measurement of INR to maintain a range of 2 to 3
- LMWH is the treatment of choice in pregnancy. Periodic monitoring with anti-Xa levels is recommended in some cases, such as overweight and borderline renal failure.

**DIET**
Unrestricted

**PATIENT EDUCATION**
- Patients should be educated about use of oral anticoagulant therapy if taking such.
- Patients undergoing warfarin therapy should avoid drinking alcohol on a daily basis.
- Avoid NSAIDs while on warfarin.

**PROGNOSIS**
- Persons with protein S deficiency have normal lifespan.
- By age 45 years, 50% of the people heterozygous for protein S deficiency will have VT; half will be spontaneous.

**COMPLICATIONS**
Recurrent thrombosis (requires indefinite anticoagulation)

**REFERENCES**
5. Langlois NJ, Wells PS. Risk of venous thromboembolism in relatives of

**CODES**

**ICD10**
D68.59 Other primary thrombophilia

**CLINICAL PEARLS**

- Asymptomatic patients with protein S deficiency do not require prophylactic anticoagulation because the risk of thrombosis is low; asymptomatic patients do not require anticoagulation.
- Patients with protein S deficiency and DVT should be anticoagulated for at least 6 months, especially if first episode.
PROTEINURIA

Lovella Duru Kanu, MD

BASICS

DESCRIPTION

Urinary protein excretion of >150 mg/day

- Nephrotic-range proteinuria: urinary protein excretion of >3.5 g/day; also called heavy proteinuria
- Three pathologic types:
  - Glomerular proteinuria: increased permeability of proteins across glomerular capillary membrane
  - Tubular proteinuria: decreased proximal tubular reabsorption of proteins
  - Overflow proteinuria: increased production of low-molecular-weight proteins

Pediatric Considerations

- Proteinuria: Normal is daily excretion of up to 100 mg/m^2 (body surface area).
- Nephrotic-range proteinuria: daily excretion of >1,000 mg/m^2 (body surface area)

Pregnancy Considerations

- Proteinuria in pregnancy beyond 20 weeks’ gestation is a hallmark of preeclampsia/eclampsia and demands further workup.
- Proteinuria in pregnancy before 20 weeks’ gestation is suggestive of underlying renal disease.

ETIOLOGY AND PATHOPHYSIOLOGY

- Glomerular proteinuria: increased filtration/larger proteins (albumin) due to the following:
  - Increased size of glomerular basement membrane pores and
  - Loss of proteoglycan negative charge barrier
- Tubular proteinuria: Tubulointerstitial disease prevents proximal tubular reabsorption of smaller proteins (β_2_-microglobulin, immunoglobulin [Ig] light chains, retinol-binding protein, amino acids).
- Overflow proteinuria: proximal tubular reabsorption overwhelmed by

mebooksfree.com
increased production of smaller proteins

- **Glomerular proteinuria**
  - Primary glomerulonephropathy
    - Minimal-change disease
    - Idiopathic/primary membranous glomerulonephritis
    - Focal segmental glomerulonephritis
    - Membranoproliferative glomerulonephritis
    - IgA nephropathy
  - Secondary glomerulonephropathy
    - Diabetic nephropathy
    - Autoimmune/collagen vascular disorders (e.g., lupus nephritis, Goodpasture syndrome)
    - Amyloidosis
    - Preeclampsia
    - Infection (HIV, hepatitis B and C, poststreptococcal, endocarditis, syphilis, malaria)
    - Malignancy (GI, lung, lymphoma)
    - Renal transplant rejection
    - Structural (reflux nephropathy, polycystic kidney disease)
    - Drug-induced (NSAIDs, penicillamine, lithium, heavy metals, gold, heroin)

- **Tubular proteinuria**
  - Hypertensive nephrosclerosis
  - Tubulointerstitial disease (uric acid nephropathy, hypersensitivity, interstitial nephritis, Fanconi syndrome, heavy metals, sickle cell disease, NSAIDs, antibiotics)
  - Acute tubular injury

- **Overflow proteinuria**
  - Multiple myeloma (light chains; also tubulotoxic)
  - Hemoglobinuria
  - Myoglobinuria (in rhabdomyolysis)
  - Lysozyme (in acute monocytic leukemia)

- **Benign proteinuria**
  - Functional (fever, exercise, cold exposure, stress, CHF)
  - Idiopathic transient
  - Orthostasis (postural)

**RISK FACTORS**

- Hypertension
- Diabetes
- Obesity
- Strenuous exercise
- CHF
- UTI
- Fever

**Genetics**
No known genetic pattern

**GENERAL PREVENTION**
Control of weight, BP, and blood glucose reduces the risk of proteinuria.

**COMMONLY ASSOCIATED CONDITIONS**
- Hypertension (common)
- Diabetes mellitus (DM) (common)
- Preeclampsia (common)
- Multiple myeloma (rare)

**DIAGNOSIS**

**HISTORY**
- Frothy/foamy urine
- Change in urine output
- Blood- or cola-colored urine
- Recent weight change
- Swelling
- Rule out systemic illness: diabetes, heart failure, autoimmune, poststreptococcal infection.

**PHYSICAL EXAM**
- BP
- Weight
- Peripheral edema
- Periorbital/facial edema
- Ascites
- Palpation of kidneys
Check lungs, heart for signs of CHF.

**DIFFERENTIAL DIAGNOSIS**
Includes all causes listed under “Etiology and Pathophysiology”

**DIAGNOSTIC TESTS & INTERPRETATION**
Screening for proteinuria is not cost-effective unless directed at groups with hypertension/diabetes, older persons, and so forth.

**Initial Tests (lab, imaging)**
- Urinalysis (UA) quantitatively estimates proteinuria:
  - Only sensitive to albumin; will not detect smaller proteins of overflow/tubular etiologies
  - False-positive finding if urine pH >7, highly concentrated (specific gravity [SG] >1.015), gross hematuria, mucus, semen, leukocytes, iodinated contrast agents, penicillin analogues, sulfonamide metabolites
  - False-negative finding if urine is dilute (SG 1.005), albumin excretion <20 to 30 mg/dL, protein is nonalbumin
  - Sensitivity, 32–46%; specificity, 97–100%
  - Also can perform sulfosalicylic acid test to detect nonalbumin protein
- If UA positive, perform urine microscopy. Refer to nephrologist if positive for signs of glomerular disease.
- If UA shows trace to 2+ protein, rule out transient proteinuria with repeat UA at another visit:
  - More common than persistent proteinuria
  - Causes include exercise, fever, CHF, UTI, and cold exposure.
  - Reassure patient that transient proteinuria is benign and requires no further workup.
- If initial UA shows 3+ to 4+ protein or repeat UA is positive, measure creatinine clearance and quantify proteinuria with 24-hour urine collection (gold standard) or spot urine protein-to-creatinine (P/C) ratio (acceptable practice) ([1][A]):
  - Numerical P/C ratios correlate with total protein excreted in grams per day (i.e., ratio of 0.2 correlates with 0.2 g during a 24-hour collection).
  - Patients age <30 years with 24-hour urine excretion of <2 g/day and normal creatinine clearance should be tested for orthostatic proteinuria:
    o Benign condition is present in 2–5% of adolescents.
    o Diagnosed with a normal urine P/C ratio in first morning void and an
elevated urine P/C ratio in a second specimen taken after standing for several hours
- If protein excretion >2 g/day, consider nephrology referral and begin workup for systemic/renal disease.
- Patients with persistent proteinuria not explained by orthostatic changes should undergo renal ultrasound to rule out structural abnormalities (e.g., reflux nephropathy, polycystic kidney).

Follow-Up Tests & Special Considerations
Renal/systemic disease workup can include the following:
- CBC, ferritin, ESR, serum iron
- Electrolytes, LFTs
- Lipid profile (ideally, fasting)
- Prothrombin time/international normalized ratio
- Anti-phospholipase A2 receptor antibody: positive in ~70% of primary membranous nephropathy
- Antinuclear antibodies: elevated in lupus
- Antistreptolysin O titer: elevated after streptococcal glomerulonephritis
- Complement C3/C4: low in most glomerulonephritis
- HIV, syphilis, and hepatitis serologies: all associated with glomerular proteinuria
- Serum and urine protein electrophoresis: abnormal in multiple myeloma
- Blood glucose: elevated in diabetes
- All patients with diabetes should be screened for microalbuminuria.
- Patients with nephrotic-range proteinuria are at increased risk for hypercholesterolemia and thromboembolic events (~25% of adult patients) with highest risk in membranous nephropathy. Optimal duration of prophylactic anticoagulation is unknown but may extend for the duration of the nephrotic state (2).
- Proteinuric pregnant patients beyond 20 weeks’ gestation should be examined for other signs/symptoms of preeclampsia (e.g., hypertension, thrombocytopenia, elevated liver transaminases).

TREATMENT
- BP goal for both diabetic and nondiabetic adults is ≤140/90 mm Hg (3)[C].
- Proteinuria goal is <0.5 g/day (4)[A].
**GENERAL MEASURES**

- Limit protein intake to 0.8 g/kg/day in adults with DM or without DM and glomerular filtration rate (GFR) <30 mL/min/1.73 m². Soy protein may be renoprotective. Monitor protein intake with 24-hour urine urea excretion (4)[A].
- Limit sodium chloride intake to <2 g/day to optimize antiproteinuric medications (3)[B]. Effect on BP is further protective (4)[A].
- Limit fluid intake for urine output goal of <2 L/day. Larger urine volumes are associated with increased proteinuria and later GFR decline (4)[B].
- Smoking cessation: Smoking is associated with increased proteinuria and faster kidney disease progression (4)[B].
- Encourage supine posture (up to 50% reduction vs. upright) (4)[B].
- Discourage severe exertion (4)[B].
- Encourage weight loss (4)[B].

**MEDICATION**

***First Line***

- ACE inhibitors: first choice; use maximally tolerated doses; use even if normotensive (4)[A].
- Angiotensin receptor blockers (ARBs): proven antiproteinuric and renoprotective; ARBs are first choice if ACE inhibitors are not tolerated (4)[A].
- Combination ACE inhibitor and ARB should not be used. Although shown to reduce proteinuria, combination does not reduce poor CV outcomes and does increase risk of adverse drug reactions (5,6)[A].

***Second Line***

- β-Blockers: antiproteinuric and cardioprotective (4)[A]
- Dihydropyridine calcium channel blockers (DHCCBs): should be avoided unless needed for BP control; not antiproteinuric (4)[A]
- Non-DHCCB: antiproteinuric, may be renoprotective (4)[B]
- Aldosterone antagonists: antiproteinuric independent of BP control (4)[B]
- NSAIDs: antiproteinuric but also nephrotoxic; generally should be avoided (4)[C]

**ISSUES FOR REFERRAL**

Consider nephrology referral for possible renal biopsy if
• Impaired creatinine clearance
• Nephrotic-range proteinuria
• Unclear etiology of nonnephrotic-range proteinuria
• Diabetics with microalbuminuria

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

• Corticosteroids: No proven benefit in mortality or need for renal replacement in adults with nephrotic syndrome, although steroids are recommended in some patients who do not respond to conservative treatment. Classically, children with nephrotic syndrome respond better than adults, especially those with minimal-change disease (6)[A].
• Estrogen/progesterone replacement: may be renoprotective in premenopausal women but should be avoided in postmenopausal women (4)[B]
• Antioxidant therapy: may be antiproteinuric in diabetic nephropathy (4)[C]
• Sodium bicarbonate: not antiproteinuric but may block tubular injury caused by proteinuria; correcting metabolic acidosis may decrease protein catabolism (4)[C].
• Avoid excessive caffeine consumption: antiproteinuric in diabetic rat models (4)[C]
• Avoid iron overload (4)[C].
• Pentoxifylline: prevents progression of renal disease by unclear mechanisms (4)[C]
• Mycophenolate mofetil: antiproteinuric and renoprotective in animal models (4)[C]

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
All patients with persistent proteinuria should be followed with serial BP checks, UA, and renal function tests in the outpatient setting. Intervals depend on underlying etiology.

**PROGNOSIS**
• Transient and orthostatic proteinuria are benign conditions that do not convey
a poor prognosis.

- Clinical significance of persistent proteinuria varies greatly and depends on underlying etiology.
- Degree of proteinuria is associated with disease progression in chronic kidney disease.
- Independent of GFR, higher levels of proteinuria likely convey an increased risk of mortality, myocardial infarction, and progression to kidney failure.

**COMPLICATIONS**

- Progression to chronic renal failure and the need for dialysis/renal transplant
- Hypercholesterolemia
- Hypercoagulable state
- Increased risk for infection for patient with nephrotic syndrome
- In nephrotic syndrome, ACIP recommends first dose of PCV13, followed by first dose of PPSV23 ≥8 weeks and then second dose of PPSV23 5 years after the first PPSV.

**REFERENCES**

CODES

ICD10

- R80.9 Proteinuria, unspecified
- R80.2 Orthostatic proteinuria, unspecified
- R80.1 Persistent proteinuria, unspecified

CLINICAL PEARLS

- Transient and orthostatic proteinuria are benign conditions that do not convey a poor prognosis.
- Proteinuria >2 g/day likely represents glomerular malfunction and warrants a nephrology consultation.
- Clinical course varies greatly but, in general, the degree of proteinuria correlates with kidney disease progression.
- First-line therapy for persistent proteinuric patients is a high-dose ACE inhibitor.
PROTHROMBIN 20210 (MUTATION)

Katyayini Aribindi, MD • Adrian DaSilva-DeAbreu, MD • Raymundo A. Quintana, MD

BASICS

DESCRIPTION
- The G20210A is a gain of function mutation, where adenine is substituted for a guanine at the 20210 noncoding position of the prothrombin (a.k.a. factor II) gene.
- Prothrombin 20210 mutation is the second most common venous thrombophilia after the factor V Leiden (FVL) mutation.
- The mechanism of increasing the risk of thrombosis is incompletely understood but has been attributed to increased prothrombin or factor II levels in circulation by increased prothrombin protein translation without changing the levels of prothrombin mRNA transcription.
- Autosomal dominant condition, where heterozygotes have a 30% higher prothrombin level and a 3- to 4-fold increased risk of venous thromboembolism (VTE)
- System(s) affected: cardiovascular; hematologic/lymphatic/immunologic, nervous; pulmonary; reproductive, and hepatic
- Synonym(s): prothrombin G20210A mutation, prothrombin G20210A gene polymorphism, prothrombin gene mutation, and FII A^{20210} mutation

EPIDEMIOLOGY
- Found largely in Caucasian population with a prevalence ranging between 1% and 6% but overall it is about 2%
- In patients presenting with a VTE, prothrombin 20210 mutation has a prevalence that ranges from 4.6% to 18% with increased prevalence attributed to highly thrombophilic families.
- Mean age of first thrombosis is in the 2nd decade of life.
- Inheritance is similar between both genders (autosomal).

ETIOLOGY AND PATHOPHYSIOLOGY
- Noncoding substitution of adenine for guanine at the 20210 position at the terminal nucleotide of the 3’ resulting in a gain of function of prothrombin
gene, leading to increased levels of prothrombin (factor II), by increased translation of prothrombin mRNA but not transcription.

- The base change location is in the 3’ terminal nucleotide of the untranslated region associated with the mRNA sequence for polyadenylation. The gain of function is possible due to increased rate of processing, alteration of the site of cleavage, or increased mRNA stability.
- In the coagulation cascade, prothrombin (factor II) is the precursor of thrombin, which cleaves fibrinogen to fibrin. Elevated prothrombin activity leads to elevated thrombin levels and subsequent clot formation.
- The majority of thrombus formation occurs in the venous circulation: deep venous thrombosis (DVT)/PE, portal, hepatic, mesenteric, and cerebral.
- G20210A mutation is not known to be a risk factor for some arterial thrombotic events (myocardial infarction or acute ischemic stroke); however, studies have shown an increased prevalence of the mutation in patients with critical limb ischemia (1).

**Genetics**

- Caused by the G20210A mutation of the F2 gene (prothrombin gene) located in the short (p) arm of chromosome 11 that causes a gain of function.
- Heterozygotes have a 30% increased levels of prothrombin levels, with a 3- to 4-fold increase of VTE events. Homozygotes are at an even greater risk.
- There are three other prothrombin mutations not related to the G20210A area:
  - Yukuhashi: missense mutation G1787T, arginine for leucine at amino acid 596, leading to prolonged procoagulant activity.
  - C20209T: adjacent to G20210A mutation, primarily found in African individuals; newer studies have suggested a possible relationship between this mutation and recurrent pregnancy loss, although it is not fully understood.
  - A19911G: located in the intron of the prothrombin gene; may affect the G20210A mutation by increasing the odds ratio of the venous thromboembolic event. Mechanism is still unknown.

**RISK FACTORS**

- Being a hereditary condition, the presence of such mutation in the parents poses risk of transmission to offspring.
- Regarding the risk of developing VTE:
  - Patients have both the prothrombin 20210 mutation and FVL mutation, increasing the odds ratio of VTE by 20.
  - Virchow triad of thrombogenesis consists of stasis, endothelial injury, and
thrombophilia. Any condition that promotes stasis and endothelial injury will consequently increase the risk of VTE, for example, oral contraceptive, pregnancy, malignancy, orthopedic surgery, congestive heart failure, cerebrovascular accident in the past 3 months, air travel, obesity, and smoking

**Pregnancy Considerations**

- Increased thrombotic risk in patients with prothrombin 20210 mutation during pregnancy and in the postpartum state due to relative stasis
- Anticoagulation should begin in the 1st trimester, as the risk of VTE increases early in pregnancy and should be discontinued at onset of labor or before scheduled induction/cesarean delivery. Postpartum risk of VTE is usually greater, and anticoagulation can resume 4 to 6 hours after a vaginal delivery or 6 to 12 hours after surgery. Warfarin may begin immediately due to slow onset of action.
- C20209T mutation may have some relation with recurrent pregnancy loss; however, it is not well studied (2).  

**GENERAL PREVENTION**

Asymptomatic individuals with the mutation do not require any prophylactic anticoagulation. Exceptions are generally made for pregnant women with very high-risk thrombophilic mutations (usually FVL) with a strong family history. After the first VTE, lifelong prophylaxis may be warranted if some features are present: unprovoked or in a nontraditional area like hepatic, portal, mesenteric, or cerebral.

**COMMONLY ASSOCIATED CONDITIONS**

- VTE
- FVL

**DIAGNOSIS**

**HISTORY**

- Previous VTE
- Family history of VTE
- Family history of prothrombin 20210 mutation
PHYSICAL EXAM
- Unilateral swollen, erythematous, and tender calf is significant for a possible DVT.
- Positive Homans sign, sensitivity of 10–54%, specificity of 39–89% for DVT
- Tachycardia and probably chest pain and hypotension if PE is present
- Possible tender abdomen if thrombosis of hepatic, portal, or mesenteric veins is present

DIFFERENTIAL DIAGNOSIS
- FVL mutation
- Protein C deficiency
- Protein S deficiency
- Antithrombin deficiency
- Other causes of activated protein C resistance (e.g., antiphospholipid antibodies)
- Dysfibrinogenemia
- Dysplasminogenemia
- Homocystinemia
- Elevated factor VIII levels

DIAGNOSTIC TESTS & INTERPRETATION
Screening for prothrombin G20210A mutation in asymptomatic individuals is not recommended; except for those with very strong family history (3)[B]. Testing can take place in patients with thrombosis at a very early age, recurrent unprovoked VTE, or those with thrombosis in unusual locations.

Initial Tests (lab, imaging)
- This mutation can be diagnosed using PCR with electrophoresis or immunoassays.
- Imaging should be obtained as appropriate for the suspected site of thrombosis: US, CT scan, and V/Q scan.
- Testing for an inherited thrombophilic condition is reliable during an acute embolic event or with anticoagulation use (4)[A].

Follow-Up Tests & Special Considerations
Although prothrombin levels are elevated, this is not a sensitive test to make the diagnosis.
Diagnostic Procedures/Other
MR angiography (MRA), venography, or arteriography to detect thrombosis

Test Interpretation
Imaging is likely to show presence of arterial or venous thrombus.

TREATMENT
GENERAL MEASURES
Management of patients with a first time VTE with or without an acquired thrombophilic condition remains overall very similar.

MEDICATION
Is directed to treat those patients with VTE (prophylactic doses may vary). We recommend the reader to check the most updated doses, dose adjustments, and contraindications for the medications listed below. The doses listed apply to most adults.

First Line
In adult patients without cancer, the following oral anticoagulants are preferred over warfarin and low-molecular-weight heparin (LMWH): Dabigatran, rivaroxaban, apixaban, or edoxaban are preferred over warfarin (5)[A].

- Apixaban (Eliquis): Initial dose is 10 mg BID for 7 days, followed by 5 mg BID.
- Dabigatran (Prada): requires initial parenteral anticoagulation for 5 to 10 days, followed by 150 mg BID
- Edoxaban (Savaysa): requires initial parenteral anticoagulation for 5 to 10 days, followed by 60 mg daily
- Rivaroxaban (Xarelto): Initial dose is 15 mg BID with food for 21 days, followed by a daily dose of 20 mg with food.

Second Line
For patients without cancer that cannot be treated with NOAC, warfarin is preferred over LMWH (5)[A].

- Warfarin (Coumadin): Initial dose may range from 2 to 10 mg PO daily and then adjusted to an INR of 2 to 3.
• Enoxaparin (Lovenox): 1 mg/kg SC every 12 hours

**Medication Considerations**

• Contraindications
  – Active bleeding precludes anticoagulation.
  – Risk of bleeding is a relative contraindication to long-term anticoagulation.
  – Warfarin: history of warfarin skin necrosis
  – Doses of LMWH and new oral anticoagulants need to be adjusted in patients with renal dysfunction. They should be avoided in severe renal dysfunction.

• Precautions
  – Observe patient for signs of embolization, further thrombosis, or bleeding.
  – Periodically monitor CBCs.

• Complications of medications
  – Heparins: heparin-induced thrombocytopenia
  – Warfarin may cause necrotic skin lesions (typically breasts, thighs, or buttocks).

• Significant possible interactions
  – Agents that increase the effect of some anticoagulants: alcohol, allopurinol, amiodarone, anabolic steroids, androgens, many antimicrobials, cimetidine, chloral hydrate, disulfiram, all NSAIDs, sulfinpyrazone, tamoxifen, thyroid hormone, vitamin E, ranitidine, salicylates, acetaminophen
  – Agents that decrease the effect of some anticoagulants: aminogluthethimide, antacids, barbiturates, carbamazepine, cholestyramine, diuretics, griseofulvin, rifampin, oral contraceptives

**ISSUES FOR REFERRAL**

• Recurrent thrombosis on anticoagulation
• Difficulty anticoagulating
• Genetic counseling

**SURGERY/OTHER PROCEDURES**

• Anticoagulation must be held for surgical interventions.
• For most patients with DVT, recommendations are against routine use of vena cava filter in addition to anticoagulation, except in case with contraindication to anticoagulation (5)[A].
• Thrombectomy may be necessary in some cases.
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Admission criteria/initial stabilization: complicated thrombosis, such as pulmonary embolus; required heparin drip
- Patient can be safely discharged if patient is stable on anticoagulation.

ONGOING CARE

- Compression stockings for prevention
- DVT prophylaxis as appropriate if patient admitted to hospital

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Warfarin use requires periodic (weekly and then monthly after initial stabilization) INR measurements, with a goal of 2 to 3 (5).
- Heterozygosity for the prothrombin 20210 mutation increases the risk for recurrent VTE only slightly, thus its presence does not alter the length of anticoagulation treatment decision.

DIET

- No restrictions; unless taking warfarin
- Food rich in vitamin K may interfere with warfarin anticoagulation.
- Grapefruit and St. John’s Wort interfere with the cytochrome P450 and can alter the levels and clearance of anticoagulant therapy.

PATIENT EDUCATION

Patients should be educated about:
- Use of oral anticoagulant therapy
- Signs and symptoms of acute blood loss
- Avoidance of NSAIDs while on warfarin

PROGNOSIS

When compared with normal individuals, persons with prothrombin 20210 have normal lifespans.

COMPLICATIONS
Recurrence of deep vein thrombosis on anticoagulation
Bleeding on anticoagulation
Complications are usually location dependent and can lead to death, possibly from a massive pulmonary embolism, Budd-Chiari syndrome.
Venous stasis ulcers

ADDITIONAL READING

SEE ALSO

- Antithrombin Deficiency; Deep Vein Thrombophlebitis; Factor V Leiden;
- Protein C Deficiency; Protein S Deficiency
CODES

ICD10
D68.52 Prothrombin gene mutation

CLINICAL PEARLS

- Prothrombin 20210 mutation is the second most common inherited risk factor for VTE after FVL mutation.
- Asymptomatic patients with prothrombin 20210 mutation do not need anticoagulation or screening.
- Management of VTE is no different with or without the prothrombin G20210A mutation, with indefinite anticoagulation being strongly considered in people with an unprovoked VTE or in thrombus formation in a nontraditional area (hepatic, portal, mesenteric, or cerebral).
PRURITUS ANI

Anna L. Silverman, MD • Praphopphat Adhatamsoontra, MD, MPH • Marie L. Borum, MD, EdD, MPH

BASICS

DESCRIPTION

- Intense anal/perianal itching and/or burning
- Usually acute
- Classified as idiopathic (primary) or secondary (~75% of cases) to anorectal pathology

EPIDEMIOLOGY

Incidence

- Uncommon, 1–5% of the general population
- Predominant age: 30 to 60 years
- Predominant sex: male > female (4:1)

Prevalence

Difficult to estimate as often unreported; present in up to 2–3% of patients visiting primary care

ETIOLOGY AND PATHOPHYSIOLOGY

- Over 100 etiologies categorized by inflammatory, infectious, systemic, neoplastic, neuropathic, neurogenic, and psychogenic causes
- Pruritus may create an irresistible desire to scratch leading to a self-perpetuating itch–scratch–itch cycle.
- Consider primary pruritus ani when no other demonstrable causes can be found, including:
  - Poor anal hygiene
  - Loose or leaking stool that makes hygiene difficult. Patients with abdominal ostomy bags typically do not complain of pruritus.
  - Internal sphincter laxity
- Etiologies of secondary pruritus ani:
  - Inflammatory dermatologic diseases:
- Allergic contact dermatitis (soaps, perfumes, or dyes in toilet paper, topical anesthetics, oral antibiotics)
- Atopic dermatitis ± lichen simplex chronicus (patients also have asthma and/or eczema)
- Psoriasis (lesions tend to be poorly demarcated, pale, and nonscaling)
- Seborrheic dermatitis
- Lichen planus (may be seen in patients with ulcerative colitis and myasthenia gravis)
- Radiation dermatitis (3)
  - Colorectal/anorectal diseases: rectal prolapse, hemorrhoids, fissures or fistulas, chronic diarrhea/constipation, polyps
  - Infectious etiologies, may be sexually transmitted: bacteria (gonorrhea, chlamydia, syphilis), viruses (herpes simplex virus [HSV], condyloma acuminate from human papillomavirus [HPV], molluscum), parasites (pinworms, lice, scabies, or bed bugs), fungal (*Candida*, or dermatophytes like *tinea*); other bacteria (*Staphylococcus aureus*, *β*-hemolytic *Streptococcus*, *Corynebacterium minutissimum* [Erythrasma]) (3)
  - Malignancies: melanoma, basal cell/squamous cell carcinoma, colorectal cancer, leukemia, lymphoma, or (uncommon) the presenting symptom of Bowen or Paget disease
  - Mechanical factors: vigorous cleaning and scrubbing, tight-fitting clothes, synthetic undergarments
  - Systemic diseases (often presents as generalized pruritus): diabetes mellitus (most common), chronic liver disease, renal failure, hyperthyroidism, anemia
  - Chemical irritants: chemotherapy, diarrhea (often from antibiotic use)
  - Dietary elements (citrus, milk products, coffee, tea, cola, chocolate, beer, wine, tomatoes, nuts)
  - Psychogenic factors: anxiety–itch–anxiety cycle

**RISK FACTORS**
- Obesity
- Excess perianal hair growth, and/or perspiration
- Underlying anorectal pathology
- Underlying anxiety disorder
- Caffeine intake has been correlated with symptoms.

**GENERAL PREVENTION**
- Good perianal hygiene
Avoid mechanical irritation of skin (vigorous cleaning or rubbing with dry toilet paper or baby wipes, harsh soaps or perfumed products, excessive scratching with fingernails, or wearing tight/synthetic undergarments).

Minimize moisture in perianal area (absorbent cotton in anal cleft may help keep area dry).

Avoid laxative use (loose stool is an irritant).

DIAGNOSIS

HISTORY

Patient presents with complaint of anal and/or perianal itching, burning, or excoriation.

Inquire about:
- Timing (when it started, when it is worse)
- Frequency of cleansing and products used on affected area
- Change in bowel habits
- Melena or hematochezia
- Recent antibiotic use
- Skin disorders (psoriasis, eczema)
- Rectal or vaginal discharge, menstrual cycle
- Dietary history: Focus on the “C”s: caffeine, coffee, cola, chocolate, citrus, calcium (dairy) (3).
- Medical history (hepatitis, iron deficiency anemia, and diabetes in particular)
- Family history of colorectal cancer
- Anal receptive intercourse
- Change in toiletry products
- Household members (particularly children) with itching (possible pinworms)
- Clothing preference (tight, synthetic) (1)

PHYSICAL EXAM

Perianal visual inspection for erythema, hemorrhoids, anal fissures, maceration, lichenification, warts, polyps, excoriations, neoplasia, stool seepage

Classification based on gross appearance
- Stage 1: erythema, inflamed appearance
– Stage 2: lichenification
– Stage 3: lichenification, coarse skin, potential fissures or ulcerations (1)[C]
  • Digital rectal exam to evaluate for masses, internal sphincter tone, pain
  • Valsalva to evaluate for prolapse
  • Anoscopy to evaluate for hemorrhoids, fissures, other internal lesions

DIFFERENTIAL DIAGNOSIS
• “ITCHeS” acronym (4)
  – Infection: *Candida*, parasites (scabies, pinworms), HPV, HSV, bacterial (gram-positive bacteria, gonorrhea, chlamydia, syphilis)
  – Topical irritants: soaps/detergents, garments, deodorants, perfumes, stool leakage
  – Cutaneous/Cancer/Colorectal: eczema, psoriasis, lichen planus, lichen sclerosus, seborrhea, skin cancer, extramammary Paget disease, Bowen disease, fistula, fissure, prolapse, hemorrhoids, colorectal cancer
  – Hypersensitivity: foods (the “C’s” above), medications (colchicine, quinidine, mineral oil)
  – eSystemic: diabetes, iron deficiency anemia, uremia, cholestasis, hematologic malignancy

DIAGNOSTIC TESTS & INTERPRETATION

*Initial Tests (lab, imaging)*
Depending on history and exam findings, consider:
  • Pinworm tape test; stool for ova and parasites
  • CBC, comprehensive metabolic panel, A1c, thyroid studies to identify underlying systemic disease
  • Wood lamp examination will show coral-red fluorescence in erythrasma (3).
  • Skin scraping with potassium hydroxide (KOH) prep for dermatophytes or candidiasis (as etiology or as superinfection) and mineral oil prep for scabies
  • Perianal skin culture (bacterial superinfection)
  • Hemoccult testing of stool

*Pediatric Considerations*
Pinworms common in children. Also consider perianal Crohn disease (5).

*Follow-Up Tests & Special Considerations*
Anal DNA polymerase chain reaction (PCR) probe for gonorrhea and chlamydia.
Test for anal HPV if receptive anal intercourse.
**Diagnostic Procedures/Other**

- Biopsy suspicious lesions (e.g., lichenification, ulcerated epithelium, refractory cases) to exclude neoplasia; evaluate etiology.
- Consider colonoscopy if history, exam, or testing suggests colorectal pathology (family history of colorectal disease, especially if age >40 years, weight loss, rectal bleeding, change in bowel habits).

**Geriatric Considerations**

- Stool incontinence may be a predisposing factor.
- Consider systemic disease.
- Higher likelihood of colorectal pathology

---

**TREATMENT**

**GENERAL MEASURES**

- Proper anal hygiene. Avoid chemical and mechanical irritants and wear proper undergarments (1).
- High-fiber diet and/or bowel regimen to maintain regular bowel movements (1)
- Avoid tight-fitting clothing. Use cotton undergarments.
- Absorbent cotton, talcum powder, or cornstarch if excess moisture (1)
- Cotton gloves at night to control nocturnal scratching

**MEDICATION**

**First Line**

- Treat underlying infections: fungal or dermatophyte infection with topical imidazoles, bacterial infection with topical antibacterials.
- Treat underlying anorectal anatomic pathology: banding of prolapsing internal hemorrhoids, treat fistulas, or fissures.
- Break itch–scratch cycle with low-potency steroid cream such as hydrocortisone 1% ointment applied sparingly up to 4 times daily (1)[A]. Discontinue when itching subsides. Avoid use >2 weeks due to risk of skin atrophy.
- If no response with low-potency steroid, consider high-potency steroid cream.
- Antihistamines, particularly sedating antihistamines, may be useful in reducing nighttime itching until local measures take effect (4).
Tricyclic antidepressants may reduce nighttime scratching.
Zinc oxide can be used after steroid course for barrier protection (3)[C]; petroleum jelly is another barrier (mineral oil can worsen pruritus).

Low-dose topical capsaicin cream in combination with steroid cream if refractory symptoms (1)[A]

0.03% tacrolimus ointment as an option to avoid atrophy associated with prolonged steroid use (1)
Several small case series have shown symptomatic benefit with methylene blue injection—this may be an additional option for patients with refractory itch.

**Second Line**
Radiation may be used to destroy nerve endings (create permanent anesthesia) in intractable cases. This is almost never indicated but is very effective.

**ISSUES FOR REFERRAL**
- Intractable pruritus: Consider referral to gastroenterology (for colonoscopy) or dermatology (for additional treatment, possibly injections, or biopsies).
  Refractory or persistent symptoms should signal the possibility of underlying neoplasia, as pruritus ani of long duration is associated with a greater likelihood of colorectal pathology.
- Refer for colonoscopy if at risk for colon cancer.

**SURGERY/OTHER PROCEDURES**
As above, especially if concern for malignancy identified

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
See patient every 2 weeks if not improving. Ensure proper hygiene, and avoidance of irritants. Work up for systemic disease, and check for persistent lichenification. If refractory pruritus or lichenification does not resolve, consider underlying malignancy.

**DIET**
- Eliminate foods and beverages known or suspected to exacerbate symptoms: coffee, tea, chocolate, beer, cola, vitamin C tablets in excessive doses, citrus
fruits, tomatoes, or spices.

- Eliminate foods or drugs contributing to loose bowel movements or dermatitis.
- Add fiber supplementation to bulk stools and prevent fecal leakage in patients who have fecal incontinence or partially formed stools.

**PATIENT EDUCATION**

- Review proper anal hygiene:
  - Resist overuse of soap and rubbing.
  - Avoid products with irritating perfumes and dyes.
  - Avoid use of ointments and mineral oil.
  - Wear loose, light cotton clothing.
  - If moisture is a problem, use cotton, unmedicated talcum powder, or cornstarch to keep the area dry.
  - Cleanse perianal area after bowel movements with water-moistened cotton.
  - Dry area after bathing by patting with a soft towel or by using a hair dryer.
- Avoid medications that cause diarrhea or constipation.
- Avoid caffeine, cola, chocolate, citrus, tomatoes, tea, alcohol, nuts, milk products.[C]
- Use barrier protection if engaging in anal intercourse.
- If unable to completely empty rectum with defecation, use small plain-water enema (infant bulb syringe) after each bowel movement to prevent soiling and irritation.
- If symptoms persist, evaluate for underlying medical disease.

**PROGNOSIS**

- Conservative treatment successful in ~90% of cases
- Idiopathic pruritus ani often is chronic, waxing and waning.

**COMPLICATIONS**

- Bacterial superinfection at site of excoriations and potential abscess formation or penetrating infection via self-inoculation with colonic pathogens
- Lichenification
- Significant effect on quality of life

**REFERENCES**

### ADDITIONAL READING

### SEE ALSO

Pinworms; Pruritus Vulvae

### CODES

**ICD10**

L29.0 Pruritus ani

### CLINICAL PEARLS

- Pruritus ani is characterized by intense anal/perianal itching and/or burning.
- Skin irritation with itch–scratch–itch cycle
- Conservative treatment with perianal hygiene and reassurance is successful in 90% of patients.
- Consider trial of dietary elimination of “C”s—citrus, vitamin C supplements, calcium products, caffeine, coffee, cola, chocolate.
- Rule out infection (viral, bacterial, parasitic) in immunosuppressed patients.
- Consider underlying malignancy if refractory.
PRURITUS VULVAE

Maeve K. Hopkins, MA, MD • Michael P. Hopkins, MD, MEd

Basics

Description
- Pruritus vulvae is a symptom, or can be a primary diagnosis.
- If a primary diagnosis, other etiologies must be excluded.
- Pruritus vulvae as a primary diagnosis may also be more appropriately documented as vulvodynia (see “Vulvodynia” topic) or burning vulva syndrome.

Epidemiology
Symptoms may occur at any age during a woman’s lifetime.
- Young girls most commonly have infectious or hygiene etiology.
- The primary diagnosis is more common in postmenopausal women.

Incidence
The exact incidence is unknown, although most women complain of vulvar pruritus at some point in their lifetime.

Etiology and Pathophysiology
Vulvar tissue is more permeable than exposed skin due to differences in structure, occlusion, hydration, and susceptibility to friction. It is particularly vulnerable to irritants such as:
- Perfumes
- Soaps
- Laundry detergent
- Douches
- Toilet paper
- Sanitary napkins

Risk Factors
- High-risk sexual behavior
- Immunosuppression
- Obesity

**GENERAL PREVENTION**
- Attention should be paid to personal hygiene and avoidance of possible environmental factors.
- Tight-fitting clothing should be avoided.
- Only cotton underwear should be worn.

**COMMONLY ASSOCIATED CONDITIONS**
- Infectious etiology
  - Vaginal or vulvar candida
  - *Gardnerella vaginalis*
  - *Trichomonas*
  - Human papillomavirus
  - Herpes simplex virus
- Vulvar vestibulitis
- Lichen sclerosis
- Lichen planus
- Lichen simplex chronicus (squamous cell hyperplasia)
- Malignant or premalignant conditions
- Psoriasis
- Fecal or urinary incontinence
- Dermatophytosis
- Parasites: scabies, *Pthirus pubis*
- Extramammary Paget
- Dietary: methylxanthines (e.g., coffee, cola), tomatoes, peanuts
- Autoimmune progesterone dermatitis: perimenstrual eruptions
- Irritant or allergic contact dermatitis
- Atopic dermatitis

**DIAGNOSIS**
Pruritus vulvae is a diagnosis of exclusion.

**HISTORY**
- Persistent itching
- Persistent burning sensation over the vulva or perineum
- Change in vaginal discharge
- Postcoital bleeding
- Dyspareunia

**PHYSICAL EXAM**
- Visual inspection of the vulva, vagina, perineum, and anus
  - Superior surfaces of the labia majora—extending from mons to the anal orifice are most involved.
  - Vulvar skin is leathery or lichenified in appearance.
  - Papillomatosis may be a sign of chronic inflammation.
- Light touch identification of affected areas
- Cotton swab–applied pressure to vestibular glands

**DIAGNOSTIC TESTS & INTERPRETATION**
- Sodium chloride: *Gardnerella* or *Trichomonas*
- 10% potassium hydroxide: *Candida*
- Viral culture or polymerase chain reaction: herpes simplex virus
- Directed biopsy: human papillomavirus, lichen, malignancy
- Colposcopy with acetic acid or Lugol solution of vagina and vulva

**Follow-Up Tests & Special Considerations**
- A patch test may be performed by a dermatologist to assist in identifying a causative agent if contact dermatitis is suspected.
- Exam-directed tissue biopsies are essential in the postmenopausal population to rule out malignancy.

**Diagnostic Procedures/Other**
Biopsies should be collected from any ulceration, discoloration, raised areas, macerated areas, and the area of most intense pruritus.

**Test Interpretation**
- Only in the absence of pathologic findings can the primary diagnosis of pruritus vulvae be made.
- In one study, a specific clinicopathologic diagnosis was obtained in 89% of patients by using the most recent 2006 International Society for the Study of Vulvar Diseases (ISSVD) classifications (2).
TREATMENT
Identify the underlying cause or disease to target treatment.
- Stop all potential irritants.
- Eliminate bacterial and fungal infection.
- Cool the affected area: Use cool gel packs (not ice packs, which may cause further injury).
- Sitz baths and bland emollients to soothe fissured or eroded skin

MEDICATION
First Line
- 1st-generation antihistamines (3)
  - Hydroxyzine: Initiate with 10 mg before bedtime (slow increase up to 100 mg).
  - Doxepin: Initiate with 10 mg before bedtime (slow increase up to 100 mg).
  - 2nd-generation antihistamines are of little benefit.
- SSRIs (3)
  - Citalopram 20 to 40 mg in the morning may be helpful for daytime symptoms.
- Topical steroids (4)
  - Triamcinolone 0.1% applied daily for 2 to 4 weeks, then twice weekly
  - Hydrocortisone 1.0–2.5% cream applied 2 to 4 times daily (5)
  - Avoid long-term use due to risk of atrophy.
  - One randomized, controlled trial showed no difference between topical triamcinolone and placebo cream (6).

Second Line
Calcineurin inhibitors such as topical pimecrolimus 1% cream applied BID for 3 weeks (7). This may lead to an 80% reduction of pruritus.

ISSUES FOR REFERRAL
- Persistent symptoms should prompt additional investigation and referral to a gynecologist or gynecologic oncologist.
- Gynecologic oncology referral for proven or suspected malignancy
- Dermatology referral for patch testing to evaluate for contact dermatitis

ADDITIONAL THERAPIES
SC triamcinolone injections
- Alcohol nerve block
- Laser therapy
- GnRH analogues

**ONGOING CARE**

- Frequent evaluation, repeat cultures, and biopsies are necessary for cases resistant to treatment.
- Refractory cases may require referral to gynecologist or gynecologic oncology for further management.

**DIET**

Dietary alterations include avoidance of the following:

- Coffee and other caffeine-containing beverages
- Tomatoes
- Peanuts

**PATIENT EDUCATION**

- American Congress of Obstetricians and Gynecologists: [www.acog.org](http://www.acog.org)
- National Vulvodynia Foundation: [www.nva.org](http://www.nva.org)

**PROGNOSIS**

Conservative measures and short-term topical steroids control most patients’ symptoms.

**COMPLICATIONS**

Malignancy

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

mebooksfree.com
- L29.2 Pruritus vulvae
- N94.819 Vulvodynia, unspecified

**CLINICAL PEARLS**

- Pruritus vulvae is a common complaint.
- Pruritus vulvae is a diagnosis of exclusion once other causes of itching have been ruled out.
- Exam-directed biopsies from any ulceration, discoloration, raised areas, macerated areas, and the area of most intense pruritus are essential to rule out malignancy.
- Initial treatment is conservative.
PSEUDOFOLLICULITIS BARBAE

Maurice Duggins, MD

BASICS

DESCRIPTION

- Foreign-body inflammatory reaction from an ingrown hair resulting in the appearance of papules and pustules. This is found mainly in the bearded area (barbae) but may occur in other hairy locations such as the scalp, axilla, or pubic areas where shaving is done (1).
- A mechanical problem: extrafollicular and transfollicular hair penetration
- System(s) affected: skin/exocrine
- Synonym(s): chronic sycois barbae; pili incarnate; folliculitis barbae traumatica; razor bumps; shaving bumps; tinea barbae; pseudofolliculitis barbae (PFB)

EPIDEMIOLOGY

- Predominant age: postpubertal, middle age (14 to 25 years) (2)
- Predominant sex: male > female (can be seen in females of all races who wax/shave)

Incidence

- Adult male African Americans: unknown
- Adult male whites: unknown

Prevalence

- Widespread in Fitzpatrick skin types IV–VI (darker complexions) who shave
- 45–83% of African American soldiers who shave (1)

ETIOLOGY AND PATHOPHYSIOLOGY

- Transfollicular escape of the low-cut hair shaft as it tries to exit the skin is accompanied by inflammation and often an intraepidermal abscess.
- As the hair enters the dermis, more severe inflammation occurs, with downgrowth of the epidermis in an attempt to sheath the hair.
- A foreign-body reaction forms at the tip of the invading hair, followed by abscess formation.
- Shaving too close
- Plucking/tweezing or wax depilation of hair may cause abnormal hair growth in injured follicles.

**Genetics**
- People with curly hair have an asymmetric accumulation of acidic keratin hHa8 on hair shaft.
- Single-nucleotide polymorphism (disruption Ala12Thr substitution) affects keratin of hair follicle.

**RISK FACTORS**
- Curly hair
- Shaving too close or shaving with multiple razor strokes
- Plucking/tweezing hairs
- South Mediterranean/American, Middle Eastern, Asian, or African descent (skin types IV–VI)

**GENERAL PREVENTION**
- Prior to shaving, rinse face with warm water to hydrate and soften hairs.
- Use adjustable hair clippers that leave very low hair length above skin.
- Shave with either a manual adjustable razor at coarsest setting (avoids close shaves), a single-edge blade razor (e.g., Bump Fighter), a foil-guarded razor (e.g., PFB razor), or electric triple “O-head” razor.
- Empty razor of hair frequently.
- Shave in the direction of hair growth. Do not overstretch skin when shaving.
- Use a generous amount of the correct shaving cream/gel (e.g., Ef-Kay Shaving Gel, Edge Shaving Gel, Aveeno Therapeutic Shave Gel, Easy Shave Medicated Shaving Cream).
- Daily shaving reduces papules/pruritus.
- Regular use of depilatories

**COMMONLY ASSOCIATED CONDITIONS**
- Keloidal folliculitis
- Pseudofolliculitis nuchae

**DIAGNOSIS**
HISTORY
Pain on shaving; pruritus of shaved areas, irritated “razor bumps”

PHYSICAL EXAM
- Tender, exudative, erythematous follicular papules or pustules in beard area (less commonly in scalp, axilla, and pubic areas); range from 2 to 4 mm
- Hyperpigmented “razor or shave bumps”
- Alopecia
- Lusterless, brittle hair

DIFFERENTIAL DIAGNOSIS
- Bacterial folliculitis
- Impetigo
- Acne vulgaris
- Tinea barbae
- Sarcoidal papules

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Clinical diagnosis
- Culture of pustules: usually sterile; may show coagulase-negative Staphylococcus epidermidis (normal skin flora)
- Additional hormonal testing may be indicated in females with hirsutism and/or polycystic ovary syndrome: dehydroepiandrosterone sulfate, luteinizing hormone (LH)/follicle-stimulating hormone (FSH), and free and total testosterone (3)[C].

Test Interpretation
Follicular papules and pustules

TREATMENT
- Mild cases
  - Stop shaving or avoid close shaving for 30 days while keeping beard groomed and clean (1,2)[C].
  - Consider 5% benzoyl peroxide after shaving and application of 1% hydrocortisone cream at bedtime (or LactiCare HC lotion after shaving) (2)
– Tretinoin 0.025% cream; apply daily (1)[C].

**Moderate cases**

– Chemical depilatories (barium sulfide; Magic Shave powder); first test on forearm for 48 hours (for irritation) (1–3)[B]
– Consider eflornithine HCl cream (Vaniqa) to reduce hair growth and stiffness in combination with other therapies (1,4)[B].

**Severe cases**

– Laser therapy: Longer wavelength laser (e.g., neodymium [Nd]:YAG) is safer for dark skin (5)[B].
– Avoid shaving altogether; grow beard (1–3)[C].

**GENERAL MEASURES**

**Acute treatment**

– Dislodge embedded hair with sterile needle/tweezers.
– Discontinue shaving until red papules have resolved (minimum 3 to 4 weeks; longer if moderate or severe); can trim to length >0.5 cm during this time.
– Massage beard area with washcloth, coarse sponge, or a soft brush several times daily.
– Hydrocortisone 1.0–2.5% cream to relieve inflammation
– Selenium sulfide if seborrhea is present and to help reduce pruritus
– Systemic antibiotics if secondary infection is present

**Pregnancy Considerations**

Do not use tretinoin (Retin-A), tetracycline, or benzoyl peroxide.

**MEDICATION**

**First Line**

– Topical or systemic antibiotic for secondary infection
  – Application of clindamycin (Cleocin T) solution BID or topical erythromycin
  – Low-dose erythromycin or tetracycline 250 to 500 mg PO BID for more severe inflammation
  – Benzoyl peroxide 5%– clindamycin 1% gel BID: Administer until papule/pustule resolves.
– Mild cases: tretinoin 0.025% cream at bedtime; combination of the above therapies
– Moderate disease/chemical depilatories
– Disrupt cross-linking of disulfide bonds of hair to produce blunt (less sharp) hair tip.
– Apply no more frequently than every 3rd day: 2% barium sulfide (Magic Shave) or calcium thioglycollate (Surgex); calcium hydroxide (Nair)

**Contraindications**
– Clindamycin: hypersensitivity history; history of regional enteritis or ulcerative colitis; history of antibiotic-associated colitis
– Erythromycin, tetracycline, tretinoin: hypersensitivity history

**Precautions**
– Clindamycin: colitis, eye burning and irritation, skin dryness; pregnancy Category B
– Erythromycin: Use cautiously in patients with impaired hepatic function; GI side effects, especially abdominal cramping; pregnancy Category B (erythromycin base formulation)
– Chemical depilatories: Use cautiously; frequent use and prolonged application may lead to irritant contact dermatitis and chemical burns.
– Tetracycline: Avoid in pregnancy.
– Tretinoin: Severe skin irritation; avoid in pregnancy.
– Benzoyl peroxide: skin irritation and dryness, allergic contact dermatitis
– Hydrocortisone cream: local skin irritation, skin atrophy with prolonged use, lightening of skin color

**Significant possible interactions**
– Erythromycin: increases theophylline and carbamazepine levels; decreases clearance of warfarin
– Tetracycline: depresses plasma prothrombin activity

**Second Line**

**Chemical peels with either glycolic acid or salicylic acid**

**ISSUES FOR REFERRAL**

– Worsening or poor response to the above therapies after 4 to 6 weeks should prompt dermatology consultation.
– Occupational demands may also prompt earlier referral to dermatology for more aggressive therapy.

**SURGERY/OTHER PROCEDURES**

Laser treatment with long-pulsed Nd:YAG is helpful for severe cases.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- As needed
- Educate patient on curative and preventive treatment.

DIET
- No restrictions
- No dietary studies available

PATIENT EDUCATION
https://medlineplus.com

PROGNOSIS
- Good, with preventive methods
- Prognosis is poor in the presence of progressive scarring and foreign-body granuloma formation.

COMPLICATIONS
- Scarring (occasionally keloidal)
- Foreign-body granuloma formation
- Disfiguring postinflammatory hyperpigmentation (use sunscreens; can treat with hydroquinone 4% cream, Retin-A, clinical peels)
- Impetiginization of inflamed skin
- Epidermal (erythema, crusting, burns with scarring) and pigmentary changes with laser

REFERENCES

**ADDITIONAL READING**

**SEE ALSO**

- Folliculitis; Impetigo

**CODES**

**ICD10**

- L73.1 Pseudofolliculitis barbae
- B35.0 Tinea barbae and tinea capitis
- L73.8 Other specified follicular disorders

**CLINICAL PEARLS**
Electrolysis is not recommended as a treatment. It is expensive, painful, and often unsuccessful.
Combination of laser therapy with eflornithine is more effective than laser alone.
The aversive smell of sulfur could be a problem with some depilatory products.
Have patient test for skin sensitivity with a small (coin-sized) amount of the depilatory on the bearded area or forearm.
PSEUDOGOUT (CALCIUM PYROPHOSPHATE DIHYDRATE)
Pradeepa P. Vimalachandran, MD, MPH

BASICS

DESCRIPTION
- Autoinflammatory disease triggered by calcium pyrophosphate dihydrate (CPPD) crystal deposition within joints
- One of many diseases associated with pathologic deposition of crystal; mineralization and ossification
  - CPPD crystal deposition = chondrocalcinosis (calcification of hyaline or fibrocartilage), pseudogout, and pyrophosphate arthropathy
  - Monosodium urate crystal deposition = gout
  - Hydroxyapatite deposition associated with ankylosing spondylitis, osteoarthritis, and vascular calcification
- Suspect pseudogout in arthritis cases with a pattern of joint involvement inconsistent with degenerative joint disease (e.g., metacarpophalangeal joints, wrists).
- Clinical presentation is broad:
  - Asymptomatic CPPD (incidentally identified on radiograph by chondrocalcinosis with or without additional findings of osteoarthritis)
  - Acute CPPD arthritis (acute onset, self-limiting, synovitis)
  - Chronic CPPD crystal inflammatory arthritis
- Chronic CPPD crystal deposition may cause a progressive degenerative arthritis in numerous joints:
  - Primarily affects the elderly
  - Usually involves large joints
- Symptom onset is usually insidious.
- Definitive diagnosis requires the identification of CPPD crystals in synovial fluid.
- System(s) affected: endocrine/metabolic; musculoskeletal
- Synonyms: pseudogout; CPPD; pyrophosphate arthropathy; chondrocalcinosis
  —when calcification visibly seen within tissues on imaging

EPIDEMIOLOGY
**Prevalence**
- Predominant age: 80% of patients >60 years
- No gender predominance. Men more likely to present acutely; women more likely to present atypically
- Prevalence varies by method of identification (chondrocalcinosis on radiograph vs. CPPD crystals in synovial fluid).
- Chondrocalcinosis is present in 1:10 adults age 60 to 75 years and 1:3 by >80 years; however, only a small percentage develop arthropathy.
- 20–43% prevalence of CPPD crystals in synovial fluid of osteoarthritic joints at time of joint replacement

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Arthropathy results from an acute autoinflammatory reaction to CPPD crystals in the synovial cavity.
- CPPD crystal deposition occurs in three stages:
  - CPPD crystals first develop in the pericellular matrix of the articular cartilage via overproduction of anionic pyrophosphate (PPi).
  - PPi binds calcium to form CCPD crystals that are released from cartilage surface eliciting an inflammatory response. Neutrophils engulf CPPD crystals, inducing extracellular trap formation.
  - Increased CPPD crystal deposition in and around cartilage causes inflammation and damage. Cartilage degeneration is accelerated through mechanical wear and tear of the joint (2)[C].

**Genetics**
Uncommonly seen in familial pattern with autosomal dominant inheritance (<1% of patients); most cases are sporadic. Mutation in ANKH gene increases risk for calcium crystal formation.

**RISK FACTORS**
- Advanced age
- Joint trauma
- CPPD may occur as a complication in patients hospitalized for other medical and surgical illnesses.

**GENERAL PREVENTION**
Colchicine 0.6 mg BID may be used prophylactically to reduce frequency of episodes in recurrent CPPD.
COMMONLY ASSOCIATED CONDITIONS

- Gout
- Hyperparathyroidism
- Amyloidosis
- Hemochromatosis; ochronosis
- Hypothyroidism
- Wilson disease
- Hypomagnesemia
- Familial hypocalciuric hypercalcemia
- X-linked hypophosphatemic rickets
- Acromegaly

DIAGNOSIS

HISTORY

- Presentation often mimics gout (“pseudogout”).
- Acute CPPD: pain and swelling of ≥1 or more joints; knee involved in 50% of cases; ankle, wrist, toe, and shoulder involvement are also common.
- Can present in proximal joints (mimicking polymyalgia rheumatica), often accompanied by tibiofemoral and ankle arthritis and tendinous calcifications
- Multiple symmetric joint involvement (mimicking RA) in <5% of cases
- May develop after intra-articular injection of hyaluronic acid (Hyalgan, Synvisc)
- Chronic CPPD: progressive degenerative arthritis with superimposed acute inflammatory attacks

PHYSICAL EXAM

- Inflammation (erythema, warmth, tender to touch), joint effusion, decreased range of motion (ROM) of joint
- 50% associated with fever
- Any synovial joint may be involved.

DIFFERENTIAL DIAGNOSIS

- Illnesses that may cause acute inflammatory arthritis in a single or multiple joint(s):
  - Gout
  - Septic arthritis
– Trauma
● Other acute inflammatory arthritides:
   – Reiter syndrome
   – Lyme disease
   – Acute RA

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

Synovial fluid analysis shows an inflammatory effusion:

● Cell count 2,000 to 100,000 WBCs/mL
● Neutrophil predominance (80–90%)
● >50,000 WBC count increases likelihood of septic arthritis, 11% prevalence;
  >100,000 WBCs/mL, 22%
● Wet prep with polarized microscopy may demonstrate small numbers of
  positively birefringent crystals; high false-negative rate
● Consider the following to exclude underlying disease:
  – Serum calcium, phosphorus, and magnesium
  – Serum alkaline phosphatase
  – Serum parathormone (i-PTH)
  – Serum iron, total iron-binding capacity, and serum ferritin
  – Serum thyroid-stimulating hormone (TSH) level

● Plain radiograph
  – Radiographic findings in pseudogout are neither sensitive nor specific.
  – Punctate and linear calcifications may be visualized in articular hyaline or
    fibrocartilage, particularly of the knees, hips, symphysis pubis, and wrists.
  – Patients with chronic CPPD may demonstrate subchondral cysts and loose
    bodies (osseous fragmentation with formation of intra-articular radiodense
    bodies) in joints not typically affected by degenerative joint disease.

● Ultrasound (US)
  – US may be more useful than plain radiography for the diagnosis of
    pseudogout in peripheral joints, with a positive predictive value of 92% and
    negative predictive value of 93% (3)[C].
  – US imaging characteristics include joint effusion, synovial thickening, and
    hyperechoic deposits.

● MRI
  – Chondrocalcinosis evident as hypointense lesions, particularly of knee
    menisci
**Diagnostic Procedures/Other**

**ALERT**
Synovial fluid analysis with demonstration of CPPD crystals is required for diagnosis; aspiration may help relieve symptoms and speed resolution.

**Test Interpretation**
CPPD crystal deposition in articular cartilage, synovium, ligaments, and tendons

---

**TREATMENT**

**GENERAL MEASURES**
Target symptom relief (reduce inflammation):
- Rest and elevate affected joint(s).
- Apply ice/cool compresses to affected joints.
- Nonweight bearing on affected joint while painful; use crutches or a walker.

**MEDICATION**

**First Line**
- A combination of pharmacologic and nonpharmacologic measures is recommended.
- Acute attacks should be treated with cool packs, rest, and joint aspiration with or without steroid injection.
- Chronic inflammatory CPPD arthropathy should be managed prophylactically with oral NSAIDs and/or colchicine (3)[C].
- Oral NSAIDs
  - Ibuprofen 600 to 800 mg PO TID–QID with food; maximum 3.2 g/day
  - Naproxen 500 mg PO BID with food
  - Other NSAIDs at anti-inflammatory doses are effective, although indomethacin has higher complication rates (relative risk [RR] = 2.2) compared with ibuprofen (RR = 1.2).
- Contraindications:
  - History of hypersensitivity to NSAIDs or aspirin
  - Active peptic ulcer disease or history of recurrent upper GI lesions
  - Avoid in renal insufficiency.
  - Serious GI bleeding can occur without warning; patient should be instructed
on signs/symptoms. Administer proton pump inhibitor (PPI) or misoprostol 200 μg PO QID in patients at risk for NSAID-induced gastric ulcers.

- Oral colchicine
  - 0.6 mg QID or 0.6 mg/hr until symptoms relieved or vomiting/diarrhea develops; maximum dose per attack 4 to 6 mg; alternatively 0.5 to 1.0 mg/day may be used; avoid colchicine with significant renal insufficiency.

- Intra-articular steroid injection
  - Prednisolone–sodium phosphate 4 to 20 mg or triamcinolone diacetate 2 to 40 mg with local anesthetic

**ALERT**

Significant adverse effects of NSAIDs:

- May elevate BP in patients on antihypertensive therapy
- May blunt antihypertensive effects of ACE inhibitors
- May prolong prothrombin time (PT) in patients taking oral anticoagulants
- Avoid concomitant aspirin use.
- May blunt diuretic effect of furosemide and hydrochlorothiazide
- May increase plasma lithium level in patients taking lithium carbonate

**Second Line**

- Oral prednisone: 30 to 50 mg/day for 7 to 10 days
- IM triamcinolone acetonide 40 mg; if necessary, may repeat in 1 to 4 days
- Consider referring patients with large space-occupying tophaceous lesions for surgical removal.
- Alternative therapies for chronic CPPD
  - ACTH, anakinra (anti–IL-1), hydroxychloroquine, infliximab, probenecid, magnesium, ethylenediaminetetraacetic acid (EDTA) have all been suggested. Large scale studies are needed to evaluate effectiveness (4)[C].

**ALERT**

Recent randomized trial showed no significant effect of methotrexate in chronic-recurrent CPPD (5)[B].

** ISSUES FOR REFERRAL**

Consider consultation with orthopedist or rheumatologist if septic joint or patient is not responding.

**ADDITIONAL THERAPIES**
Physical therapy
- Isometric exercises to maintain muscle strength during the acute stage (e.g., quadriceps isometric contractions, leg lifts if knee affected)
- Begin joint ROM exercises as inflammation and pain subside.
- Resume weight bearing when pain subsides.

SURGERY/OTHER PROCEDURES
Perform arthrocentesis and joint fluid analysis.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Consider admission for septic arthritis if:
- Synovial fluid WBC count >50,000/mL
- Treat with appropriate antibiotics pending culture results.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Reevaluate response to therapy 48 to 72 hours after beginning treatment; reexamine in 1 week then as needed.

DIET
No known relationship to diet

PATIENT EDUCATION
- Rest affected joint.
- Symptoms usually resolve in 7 to 10 days.

PROGNOSIS
- Acute attack usually resolves in 10 days; prognosis for resolution of acute attack is excellent.
- Patients may experience progressive joint damage and functional limitation.

COMPLICATIONS
Recurrent acute attacks
Osteoarthritis

**Geriatric Considerations**
Elderly patients treated with NSAIDs require careful monitoring and are at higher risk for GI bleeding and acute renal insufficiency; no loading dose for colchicine due to high rates of renal insufficiency in elderly patients

**REFERENCES**

**ADDITIONAL READING**

- Sattui SE, Singh JA, Gaffo AL. Comorbidities in patients with crystal diseases

### CODES

#### ICD10

- M11.20 Other chondrocalcinosis, unspecified site
- M11.269 Other chondrocalcinosis, unspecified knee
- M11.29 Other chondrocalcinosis, multiple sites

### CLINICAL PEARLS

- Suspect CPPD in arthritis cases that do not follow a pattern typical of degenerative joint disease (e.g., metacarpophalangeal joints, wrists).
- Perform arthrocentesis to confirm diagnosis.
- If septic arthritis is considered, treat presumptively with antibiotics until culture results are available.
- NSAID therapy is the preferred pharmacologic treatment for acute flare.
- Oral steroids are useful if NSAIDs are contraindicated.
- Intra-articular steroids can be used *if* septic arthritis has been excluded.
PSORIASIS

Michael O. Needham, MD • Rebecca Matz, MD

BASICS

DESCRIPTION

- A chronic, inflammatory disorder most commonly characterized by cutaneous erythematous plaques with silvery scale. It is a complex immune-mediated disorder that results from a polygenic predisposition in the setting of environmental triggers. It is associated with flares related to systemic, psychological, infectious, and environmental factors; skin disease with multiple different phenotypic variations and degrees of severity
- Clinical phenotypes
  - Plaque (vulgaris): most common variant (~80% of cases); well-demarcated, red plaques with thick, silvery scale; symmetrically distributed most commonly on the scalp, extensor surfaces of extremities, and trunk
  - Guttate: <2% of psoriasis patients, usually in patients <30 years of age; presents abruptly with 1- to 10-mm droplet-shaped pink erythematous papules with fine scale over trunk and extremities; often preceded by group A β-hemolytic streptococcal infection 2 to 3 weeks prior
  - Inverse: affects intertriginous areas and flexural surfaces; pink-to-red plaques with minimal scale; absence of satellite pustules distinguishes it from candidiasis although may coexist.
  - Erythrodermic: generalized erythema and scaling, affecting 90% of body surface area (BSA) or more; associated with desquamation; hair loss; nail dystrophy; and systemic symptoms such as fever, chills, malaise, and/or high-output cardiac failure; usually requires hospital admission for management of dehydration, electrolyte abnormalities, and high risk of infection
  - Pustular: sterile pustules; several forms including generalized pustular psoriasis, localized pustular psoriasis, and impetigo herpetiformis (in pregnancy); generalized type can result in life-threatening bacterial superinfections, sepsis, and dehydration if left untreated.
  - Nail disease: pitting, oil spots, and onycholysis; nails involved in up to 50% of patients with psoriasis with lifetime incidence of 80–90%; increased association with psoriatic arthritis
– Psoriatic arthritis: 5–30% of patients; most commonly asymmetrical oligoarthritis involving the hands and feet

EPIDEMIOLOGY

Incidence
Predominant sex: male = female; predominant age: two peaks in incidence between the ages of 20 to 30 years and 50 to 60 years

Prevalence
- 2–4.7%—similar prevalence in all races
- ~80% of patients have mild to moderate disease (1).

ETIOLOGY AND PATHOPHYSIOLOGY
Psoriasis is a complex immune-mediated disorder with interactions between dendritic cells, T lymphocytes, neutrophils, and keratinocytes. It is considered a TH1- and TH17-driven disease with numerous cytokines including TNF-α, interferon-γ, IL-12, IL-17, and IL-23 playing pathogenic roles resulting in an inflammatory, hyperproliferative state.

Genetics
- Genetic predisposition (polygenic)
- 40% have psoriasis in a first-degree relative.
- Multiple susceptibility loci contain genes involved in immune system regulation (e.g., psoriasis susceptibility [PSORS1] locus on chromosome 6p21; polymorphisms in the IL-12/IL-13 receptor, the p40 subunit of IL-12 and IL-23, and the p19 subunit of IL-12) (2).
- HLA-Cw6 is most strongly correlated with early onset psoriasis.

RISK FACTORS
- Family history
- Obesity (may contribute to more severe disease)
- Local trauma; local irritation (Koebner phenomenon)
- HIV; streptococcal infection
- Mental stress (exacerbation)
- Medications (lithium, antimalarials, β-blockers, interferon, withdrawal of steroids)
- Smoking
- Alcohol
GENERAL PREVENTION
Avoid triggers, including trauma, sunburns, smoking, and exposure to certain medications (as mentioned earlier), alcohol, and stress; weight loss if obese

COMMONLY ASSOCIATED CONDITIONS
- Psoriatic arthritis
- Seborrheic dermatitis
- Obesity, metabolic syndrome, diabetes, CKD
- Cardiovascular disease; atherosclerotic disease
- Nonalcoholic fatty liver disease (NAFLD)
- Autoimmune: Crohn disease, ankylosing spondylitis
- Psychiatric/psychological: depression, suicide, emotional burden/anxiety, alcohol abuse
- Malignancy: nonmelanoma skin cancer with psoralen-UVA (PUVA) therapy

DIAGNOSIS

HISTORY
- May include sudden onset of clearly demarcated, erythematous plaques with overlying silvery scales; exacerbation of chronic plaques, especially on extensor surfaces and scalp; typically no or mild pruritus; triggers may include streptococcal/viral infection or trauma.
- Family history of similar condition

PHYSICAL EXAM
- Well-demarcated salmon pink-to-red erythematous papules and plaques; silvery scale
- Distribution favors scalp, auricular conchal bowls, and postauricular area; extensor surface of extremities, especially knees and elbows; umbilicus, lower back, intergluteal cleft, and nails
- Nail findings: pitting, oil spots, onycholysis
- Auspitz sign: pinpoint bleeding with removal of scale
- Koebner phenomenon: new psoriatic lesions arising at sites of skin injury/trauma
- Genitals affected in up to 40% of patients
- Sebopsoriasis: Psoriasis can overlap with seborrheic dermatitis as greasy scales on the eyebrows, nasolabial folds, postauricular and presternal areas.
DIFFERENTIAL DIAGNOSIS

- Plaque: seborrheic dermatitis (may coexist), nummular eczema, atopic dermatitis, contact dermatitis, lichen simplex chronicus (may coexist), tinea, pityriasis rubra pilaris, dermatomyositis, squamous cell carcinoma in situ, reactive arthritis
- Guttate: pityriasis rosea, pityriasis lichenoides chronica, secondary syphilis, small plaque parapsoriasis
- Inverse: cutaneous candidiasis, tinea, seborrheic dermatitis, contact dermatitis
- Pustular: subcorneal pustulosis, acute generalized exanthematous pustulosis, folliculitis
- Erythrodermic: cutaneous T-cell lymphoma, drug-induced erythroderma, pityriasis rubra pilaris

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
Clinical diagnosis based on history and physical exam. Labs generally not needed, although KOH to rule out tinea helpful. Consider x-rays if complaints of joint pain to evaluate for psoriatic arthritis.

Diagnostic Procedures/Other

- Psoriasis Area and Severity Index (PASI) evaluates overall severity and BSA involvement.
- Dermatology Life Quality Index (DLQI)

Test Interpretation

Biopsy: thickening of the stratum corneum (hyperkeratosis) with retention of nuclei (parakeratosis); elongation, thickening, and clubbing of rete ridges; dilated tortuous capillary loops in the dermal papillae; perivascular lymphocytic infiltrate, Munro microabscesses: neutrophils in stratum corneum

TREATMENT

GENERAL MEASURES
Adequate topical hydration (emollients); avoid triggers; weight loss

MEDICATION
**First Line**

- Mild-to-moderate disease
  - Emollients BID: petrolatum/ointments to maintain skin hydration and minimize pruritus and risk of koebnerization
  - Topical corticosteroids
    - Anti-inflammatory, antiproliferative, immunosuppressive, and vasoconstrictive effects
    - Local side effects: skin atrophy, hypopigmentation, striae, acne, folliculitis, and purpura. Systemic side effects: Risk is higher, with higher potency formulations used over a large surface for a prolonged period; pregnancy Category C
    - Applications are typically twice daily until lesions flatten/resolve, then taper to PRN use for maintenance.
    - Scalp: high potency in solution/foam vehicle; shampoos and sprays also available
    - Face, intertriginous areas, infants: low-potency corticosteroids: 1% hydrocortisone
    - Adult initial therapy: medium-potency corticosteroids daily 0.1% mometasone or triamcinolone; strong-potency corticosteroids: 0.05% betamethasone or fluocinonide daily; superpotency corticosteroids: clobetasol, halobetasol; caution with use over 2 to 4 weeks; avoid occlusive dressings; reserved for recalcitrant plaques
  - Vitamin D analogues: calcipotriene 0.005% cream daily to BID; good for plaque and also intertriginous; limits keratinocyte hyperproliferation; may be highly effective for short-term control in combination with a superpotent corticosteroid; should not be used with products that can alter pH, such as topical lactic acid; local side effects: burning, pruritus, edema, peeling, dryness, and erythema; pregnancy Category C
  - Topical retinoids: tazarotene 0.05% or 0.1% (Tazorac) daily; normalizes abnormal keratinocyte differentiation and diminishes hyperproliferation; may be combined with corticosteroids; side effects: local irritation, photosensitivity; pregnancy Category X
  - Topical calcineurin inhibitors: Tacrolimus 0.1% or pimecrolimus 1% may be used as steroid-sparing agents, especially in facial and intertriginous areas.
  - Comparison of topical therapies: Vitamin D analogues have slower onset of action than topical corticosteroids but longer disease-free periods for body plaques; for scalp, potent and superpotency steroids more effective (3)[A]
– Combination of superpotent steroids and vitamin D analogs has better efficacy than either as monotherapy or come in combination compounds (4) [A].

- Severe disease: may need combination therapy
  - Light therapy: locally immunosuppressive and antiproliferative. UVB (broad/narrow band [BB, NB]) or PUVA: Treatment protocols are skin type dependent: mixed studies as to whether PUVA or NBUVB more effective; PUVA with GI SE, photosensitivity, and increased risk of nonmelanoma skin cancers
  - Systemic therapies
    - Methotrexate: Immunosuppressive, blocks DNA synthesis; start with 5-mg test dose, then increase to 7.5 to 15.0 mg/week IV, PO, IM, or SC, and then increase 2.5 mg every 2 to 3 weeks, up to 25 mg; contraindicated in pregnancy; supplement with folic acid 1 mg/day to protect against side effects: hepatotoxicity, pulmonary toxicity, bone marrow suppression; baseline chest x-ray, monitor LFTs, renal function, CBC, testing for latent tuberculosis (TB); consider liver biopsy when cumulative dose reaches 1.0 to 1.5 g; avoid alcohol and medications that interfere with folic acid metabolism, including Bactrim, NSAIDS, sulfamethoxazole, or hepatotoxic agents (e.g., retinoids).
    - Cyclosporine: inhibits T-cell activation; start 2.5 mg/kg/day; if insufficient response after 4 weeks, increase by 0.5 mg/kg/day; additional dosage increases every 2 weeks (max dose: 5 mg/kg/day); pregnancy Category C; side effects: renal toxicity and hypertension, limit use to 6 months to 1 year: Monitor renal function, with Mg^{2+} and K^{+}, CBC, lipids, and BP.
    - Acitretin (Soriatane): systemic retinoid; start at 10 to 25 mg/day given with the main meal; effective for pustular psoriasis and as a maintenance therapy after stabilization with other agents; sometimes combined with UVB/PUVA; pregnancy Category X: pregnancy test before starting; two forms of contraception 1 month before, during, and for at least 3 years after treatment; avoid alcohol (may convert acitretin to etretinate); side effects: alopecia, xerosis, cheilitis, hepatotoxicity, hyperlipidemia, cataracts; monitor LFTs, renal function, lipid profile, CBC, regular eye exams.
  - Biologics: general guidelines: Screen for latent TB at baseline and yearly, hepatitis panel at baseline, avoid live vaccines; monitor CBC with differential, signs/symptoms of infections, heart failure, malignancy, drug-
induced lupus, demyelinating disorder. Some concern for “biologic fatigue” phenomenon, or loss of PASI 75 over time, likely due to antidrug antibodies. Each has been shown to be effective at 24 weeks with an NNT between 1 and 3. All should be considered effective first-line treatments (5) [A]. Pregnancy Category B

- TNF-α inhibitors: etanercept (Enbrel): Begin at 50 mg SC twice a week for 3 months then maintenance of 50 mg/week. Adalimumab (Humira): Dosing starts at 80 mg SC for 1 week, then 40 mg SC every other week. Infliximab (Remicade): 5 mg/kg IV at weeks 0, 2, and 6; maintenance doses of 5 mg/kg every 8 weeks thereafter; adjust interval, as needed; anaphylaxis-like infusion reaction occurs in <1% of patients.
- IL-12/IL-23 antagonist: ustekinumab (Stelara): patients <100 kg: 45 mg SC at weeks 0 and 4, then every 12 weeks; >100 kg: 90 mg can be given.
- IL-17a antagonists: secukinumab (Cosentyx). 300 mg SC on weeks 0, 1, 2, 3, and 4 then every 4 weeks. Ixekizumab (Taltz): 160 mg on week 0, then 80 mg on weeks 2, 4, 6, 8, 10, and 12, then 80 mg every 4 weeks.
- Phosphodiesterase-4 enzyme inhibitor: apremilast (Otezla): 10 mg PO, titrate up by 10 mg per day on days 2 to 5 to maintenance dose of 30 mg BID starting on day 6. Routine lab monitoring not required. Most common SE are GI symptoms, depression; pregnancy Category C

**Second Line**
Immunosuppressives: azathioprine, hydroxyurea, 6-thioguanine, fumaric acid esters, and topicals: salicylic acid; anthralin; coal tar

**ISSUES FOR REFERRAL**
Psoriasis >20% of BSA, psoriatic arthritis, severe extremity involvement, particularly hands and feet

**SURGERY/OTHER PROCEDURES**
Psoriasis and psoriatic medications can affect wound healing postoperatively; methotrexate: Monitor for postoperative infections; hold cyclosporine for 1 week before and after; some surgeons may prefer to hold therapy with biologics for up to 1 month before and after surgery.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Generalized pustular psoriasis/erythrodermic psoriasis: Rule out sepsis;
restoration of barrier function of skin with cleaning and bandaging; intensive topical corticosteroid therapy (like wet wraps), systemic therapy, particularly medications with a quick onset such as oral cyclosporine; management of electrolytes

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Measure BSA involvement to determine if therapy is working; change therapy or add agent if no improvement is seen.

DIET
Well-balanced diet and exercise to limit cardiovascular risk factors and decrease risk of associated conditions, including obesity, metabolic syndrome, diabetes, and atherosclerosis

PATIENT EDUCATION
National Psoriasis Foundation: www.psoriasis.org; 800-723-9166

PROGNOSIS
Guttate form may be self-limited and remit after months; chronic plaque type is lifelong, with intermittent spontaneous remissions and exacerbations; erythrodermic and generalized pustular forms may be severe and persistent.

COMPLICATIONS
Psoriatic arthritis, generalized pustular psoriasis, erythrodermic psoriasis, comorbidities (cardiovascular disease, metabolic syndrome, etc.)

Arthritis, Psoriatic

**CODES**

**ICD10**

- L40.9 Psoriasis, unspecified
- L40.50 Arthropathic psoriasis, unspecified
- L42 Pityriasis rosea

**CLINICAL PEARLS**

Chronic lifelong inflammatory skin condition with remissions and exacerbations; set realistic expectations with patient. Disease burden not limited to skin. If one medication does not work, use/combine with another agent.
PSYCHOSIS
Matthew J. Filippo, DO • Bernadette M. Stevenson, MD, PhD

BASICS
DESCRIPTION
A mental disorder in which thoughts and emotions are significantly impaired. Seen in schizophrenia, schizoaffective, bipolar, depression, substance use, medical problems, delirium, and dementia; symptoms include the following:
- Positive symptoms: hallucinations and delusions (fixed false beliefs not typical of patient’s cultural background)
- Negative symptoms: anhedonia, poverty of speech, lack of motivation, social withdrawal, affective blunting
- Cognition: decreased working memory, difficulty with attention, poor and slow information processing; disorganized speech and/or behavior

EPIDEMIOLOGY
Prevalence
- Schizophrenia: peak onset 18 to 25 years in males; peak onset 25 to 35 years in females
- 1% of the U.S. population; similar percentage worldwide; 1:1 male–female ratio
- Delusional disorder: 0.3% of population
- Bipolar: 1–3% of population
- Up to 20% prevalence in unipolar major depression

ETIOLOGY AND PATHOPHYSIOLOGY
- Neurodevelopmental predisposition plus 1st/3rd trimester in utero insult (e.g., infections, birth hypoxia) leads to exaggerated neuronal apoptosis in late adolescence with subsequent thalamic sensory overload. Increased dopaminergic mesolimbic transmission may contribute to delusions and hallucinations in schizophrenia. Dopamine deficiency in mesocortical pathways may contribute to frontal lobe hypoactivity often associated with negative symptoms including apathy and social withdrawal in schizophrenia.
Glutamate, neurosteroids, inflammation, and neurodevelopmental abnormalities are active areas of research.

- Postulated stress-diathesis model: Those biologically at risk develop psychosis when under stress.

**Genetics**
Schizophrenia: 50% concordance for monozygotic twins, little or no shared environmental effect; multiple candidate genes involved

**RISK FACTORS**
Substance abuse (particularly cannabis or synthetic cannabinoids), family history of psychosis, lower socioeconomic status

**GENERAL PREVENTION**
Community interventions for early detection and treatment of prodromal symptoms show promise; research currently exploring use of omega-3 fatty acids/fish oil and anti-inflammatory drugs which may prevent prodromal progression to schizophrenia

**COMMONLY ASSOCIATED CONDITIONS**
- Serious mental illness is associated with metabolic syndrome, autonomic dysfunction, sudden cardiac death, and cancer mortality: particularly breast and lung cancer
- Substance abuse disorders, including nicotine dependence

**DIAGNOSIS**
First, rule out delirium: Psychosis should not have fluctuating consciousness/reduced clarity of awareness.

**HISTORY**
- Delusions (fixed false beliefs): persecutory (being monitored), bizarre (involving impossible states), somatic (fixed belief in nonexistent serious illness), referential (getting messages from TV, radio, or thoughts inserted/deleted by others), grandiose (belief that one has special powers)
- Hallucinations: auditory, visual, tactile, gustatory, olfactory
- Bipolar, unipolar depression, and dementia are all associated with psychosis, so screen for symptoms of depression, mania, and memory loss.
Screen for toxidromes of drugs of abuse.
Screen for history of epileptiform activity.
Suicidality: higher risk with comorbid depression/mania, previous suicide attempts, drug abuse, agitation/akathisia, poor compliance

PHYSICAL EXAM
- Mental status exam: disorganized speech, behavior, and/or thought process, thought blocking, latency to respond, blunted or flat affect. Patients often have negative symptoms including social withdrawal, lack of initiative, poverty of thought, and/or positive symptoms such as auditory and visual hallucinations.
- Pay attention to focal neurologic symptoms, antipsychotic-induced parkinsonism, tardive dyskinesia, and akathisia.
- May present with catatonia: ranging from lack of movement to extreme excitement, posturing, mutism, grimacing, waxy flexibility

DIFFERENTIAL DIAGNOSIS
- Schizophrenia: positive symptoms (psychosis) and negative symptoms (flat affect), prodrome of social withdrawal, cognitive impairment; schizophreniform disorder: psychotic/prodromal symptoms in <6 months; schizoaffective disorder: manic/depressive mood disorder with psychosis that persists even when euthymic; schizotypal personality disorder: no true psychosis but distance in relationships and odd beliefs; delusional disorder: nonbizarre delusion (e.g., erotomanic, grandiose, jealous, persecutory, somatic), no negative/mood symptoms
- Mood disorder with psychotic features: can occur in mania or depression. Delusions often mood-congruent; psychosis remits when mood improves.
- Substance-induced psychosis: alcohol and benzodiazepine withdrawal, intoxication with cocaine, bath salts, PCP, cannabis, synthetic cannabinoids, MDMA, amphetamines, hallucinogens, and alcohol; may persist beyond acute intoxication
- Borderline personality disorder: During extreme stress, patients often experience auditory/visual hallucinations (psychosis NOS).
- Posttraumatic stress disorder: psychosis associated with traumatic recollections; often visual hallucinations (vs. more auditory in schizophrenia)
- Psychosis due to general medical condition: delirium, stroke, infection, collagen vascular disease, head injury, tumor, interictal, porphyria, syphilis, etc.
- Medication-induced psychosis: common causes: steroids, L-dopa, anticholinergic medication, antidepressants in bipolar patients, interferon,
digoxin, stimulants

**DIAGNOSTIC TESTS & INTERPRETATION**

- Labs: CBC with differential, CMP, LFTs, thyroid-stimulating hormone (TSH), rapid plasma reagin (RPR), HIV, ANA, ESR, vitamin B₁₂, vitamin D 25 (OH), urinalysis, urine drug screen
- Neuroimaging: not necessary for diagnosis but may consider MRI/CT to evaluate for medical cause of symptoms (especially if new onset or in elderly). Schizophrenia is associated with enlarged lateral ventricles, reduced gray matter and symmetry.
- ECG: especially if patient is on multiple medications or is elderly. Antipsychotics can prolong corrected QT (QTc) interval, particularly ziprasidone and IV haloperidol.

**Follow-Up Tests & Special Considerations**

- Consider Wilson disease, porphyria, metachromatic leukodystrophy, inflammatory conditions.
- Consider lumbar puncture if unable to distinguish from delirium and/or unexplained rapid-onset psychosis.
- Consider electroencephalogram (EEG) for partial complex seizures and psychosis associated with preictal and postictal events.

**TREATMENT**

Before antipsychotic treatment: Screen for metabolic syndrome. Baseline fasting lipid panel and glucose, HgbA1c, CBC, CMP, LFTs, weight, waist circumference, AIMS testing. Continue monitoring with long-term use (1)[B].

**MEDICATION**

- Antipsychotics are the mainstay of treatment (1)[B].
- Classified as typical versus atypical. Dopamine-2 (D₂) antagonists with varied affinity for the receptor. Atypicals also block serotonin 5-HT2A receptors. Help positive symptoms more than negative. Nonspecific effect on agitation begins early; antipsychotic effect takes 1 to 6 weeks.
- For mania with psychotic features, a mood stabilizer may be used with an antipsychotic.
- For major depression with psychotic features, antidepressant and
antipsychotic medications yield better response rate than either medication alone. In delirium, must treat underlying cause; may not require antipsychotic therapy

- **Side Effects**
  - Acute dystonia: Use 1 to 3 mg IM/IV benztropine initially and then 0.5 to 2.0 mg BID–TID or diphenhydramine 50 to 100 mg IM/IV BID–TID max 400 mg/day, NT25 mg/min.
  - Parkinsonism: lower antipsychotic dose; switch to atypical (particularly, quetiapine, olanzapine, or clozapine) or add benztropine 0.5 to 2.0 mg PO BID–TID, diphenhydramine 25 to 50 mg BID–TID.
  - Akathisia: intense restlessness, especially legs. Lower antipsychotic dose; treat with $\beta$-blocker, anticholinergic, or benzodiazepine; may switch to antipsychotic with lower akathisia risk such as quetiapine, olanzapine, iloperidone, or clozapine
  - Tardive dyskinesia: seen in ~32.4% of those treated long-term with typicals, 13.1% treated with atypicals. Switch to clozapine or quetiapine. If cannot, minimize dose. Symptomatic treatment has been tried with low-dose benzodiazepines, botox, anticholinergics, and VMAT-2 inhibitors such as FDA-approved valbenazine and, pending approval, deutetrabenazine. AIMS exam is gold standard for detecting TD.
  - Neuroleptic malignant syndrome: potentially fatal; rigidity, tremor, fever, autonomic instability, mental status changes; discontinue neuroleptic; ICU; volume resuscitation; cooling blankets; no anticholinergics/antihistaminics; consider dantrolene, amantadine, bromocriptine electroconvulsive therapy (ECT).
  - Metabolic syndrome, sudden cardiac death (risk higher IM/IV droperidol, IV haloperidol), stroke, heart failure, PNA (elderly), QTc prolonged, pulmonary embolus

**First Line**

- Benefits of some of the atypical antipsychotics include lower risk of extrapyramidal symptoms (quetiapine, olanzapine, iloperidone, or clozapine) and tardive dyskinesia (clozapine, quetiapine); possibly more effective for negative symptoms
- Greater risk of weight gain, new-onset diabetes, and hyperlipidemia with olanzapine and clozapine compared with typicals and some of the other atypicals (ziprasidone, aripiprazole)
- Acute psychotic agitation: olanzapine 5 to 10 mg IM with up to three 10-mg injections over a 24-hour period, do not administer concurrently with
Psychosis in schizophrenia

- Olanzapine: Start 5 to 10 mg at bedtime, target dose 5 to 20 mg/day within 2 days and up to 40 mg/day in treatment-refractory schizophrenia. More likely weight gain, hyperlipidemia, and hyperglycemia than other oral atypicals except clozapine; may have lower rates of discontinuation and rehospitalization than several other atypicals but likely not more efficacy than clozapine; sedation initially
  - Quetiapine: Start 25 mg BID, 25 to 50 mg BID–TID on days 2 and 3, up to 300 to 400 mg in divided doses by day 4. Within 2 weeks, up to 400 to 800 mg/day divided BID–TID; less risk of parkinsonism, useful in Parkinson disease psychosis; more weight gain than others; sedation, restless legs syndrome; more gradual titration tolerated better. Quetiapine XR can start 300 mg/day. Dose increase ≥1 day and up to 300 mg/day. Slower start and titration may be better; target dose 300 to 800 mg at bedtime
  - Risperidone: Start 1 to 2 mg/day; target dose of 2 to 8 mg/day to be reached over 1 to 2 weeks; doses >6 mg rarely more effective and higher risk of parkinsonism; higher risk of prolactinemia/parkinsonism due to D₂ blockade
  - Paliperidone: Start 3 to 6 mg/day target dose 6 to 12 mg/day; titrate over 1 to 2 weeks. Higher risk of prolactinemia/parkinsonism than others; minimal hepatic metabolism, ideal for hepatic impairment
  - Ziprasidone: Start 20 to 40 mg PO BID, with target dose of 100 to 160 mg/day in divided doses over 2 weeks; prolongs QTc; less likely to cause weight gain than other atypicals; higher risk of akathisia/parkinsonism; requires food (500 kcal, for optimal absorption; activating at lower doses)
  - Aripiprazole: Start 10 to 15 mg/day, may increase up to 30 mg/day over 1 to 2 weeks; less weight gain but higher rates of akathisia/parkinsonism; can lower QTc
  - Asenapine: Start 5 mg at bedtime or BID sublingually, increase to 10 mg BID if needed over a week or 2; less weight gain than some, higher rates of akathisia/parkinsonism; sedation, orthostatic hypotension, numb tongue, nausea, bad taste; comes in black cherry flavor
  - Lurasidone: Start 20 to 40 mg once daily with food (at least 350 calories), increase up to max of 160 mg at bedtime if needed over 2 to 4 weeks. Less
weight gain than some but higher rates of akathisia/parkinsonism; not antihistaminic but α-blocking sedation and serotonergic nausea

– Iloperidone: Start 1 mg BID, may increase by 2 mg each day, but slower can be better due to significant orthostasis. Increase to max 12 mg BID; little akathisia/parkinsonism, less weight gain but slower efficacy due to long titration, orthostasis, sedation

– Brexpiprazole: Start 1 mg daily for first 4 days, 2 mg QD days 5 to 7, can dose up to 4 mg/day based on response and tolerability. Lower rates of akathisia/parkinsonism than aripiprazole but higher rates than others; less weight gain than others

– Cariprazine: Start at 1.5 mg QD, can be increased to 3 mg QD on day 2, dosed up to 6 mg daily based on tolerability and response; in 6-week study, similar to placebo in changes of fasting glucose, cholesterol, triglycerides, and showed 0.8 to 1.0 kg weight increase

**Geriatric Considerations**

Increased risk of death compared to placebo when antipsychotics are used in the elderly with dementia (3)[B]

**Second Line**

Clozapine: more effective for reducing symptoms, preventing relapse, decreasing tardive dyskinesia, and decreasing suicidality than other antipsychotics. Second line given risk of fatal agranulocytosis. Single national registry (clozapine REMS) for all patients on clozapine, updated guidelines in 2015 requiring CBC to monitor absolute neutrophil count weekly for first 6 months, then every 2 weeks for 6 months, and then every 4 weeks. More weight gain, hyperlipidemia, hyperglycemia, seizures, myocarditis, pulmonary embolus, and sedation but low rate of parkinsonism, tardive dyskinesia; useful in treatment-refractory psychosis and in Parkinson disease psychosis. Despite association with more weight gain than other antipsychotics, clozapine and olanzapine do not appear to increase risk of cardiac and all-cause mortality (2,3)[B],(4).

- Maintenance:
  - Consider switching to a long-acting injectable (LAI) medications: available for two typicals (haloperidol and fluphenazine) and five atypical (risperidone, paliperidone, olanzapine, aripiprazole, olanzapine) (requires registration due to rare delirium syndrome). Test tolerability with oral medication first. Long-acting antipsychotics promote adherence.
– Typical: Long-acting haloperidol is administered q4wk, fluphenazine q2wk.
– Atypical: Long-acting paliperidone, administered q4 or q12wk, olanzapine q4wk, aripiprazole q4wk or q8wk, risperidone q2wk

ADDITIONAL THERAPIES
Cognitive-behavioral, vocational, art, group, and individual therapy are effective adjuvants to antipsychotics (1)[B].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Admission criteria/initial stabilization: at risk for harm to self or others; extreme functional impairment; unable to care for self; new-onset psychosis
- Discharge criteria: no longer a danger to self or others and adequate outpatient follow-up treatment in place

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Close follow-up for inpatient discharge (high risk for suicide), use CBT, exercise, teach smoking cessation, AIMS testing q3–q6mo (typicals vs. atypicals)

PATIENT EDUCATION
National Alliance on Mental Illness: www.nami.org

PROGNOSIS
Schizophrenia: Fluctuating course, 70% first-episode psychosis patients improve in 3 to 4 months, 20–40% will attempt suicide, and 7% will die of suicide

REFERENCES

ADDITIONAL READING

CODES

Delirium; Schizophrenia

SEE ALSO

- F29 Unsp psychosis not due to a substance or known physiol cond
- F20.9 Schizophrenia, unspecified
- F39 Unspecified mood [affective] disorder

CLINICAL PEARLS

- Antipsychotics are the mainstay of treatment; lead to decreased all-cause mortality in medication adherent patients
- Clozapine and LAIs may increase adherence, whereas newer atypicals quetiapine, lurasidone, aripiprazole, olanzapine/fluoxetine may help with depressive symptoms in psychosis.
PULMONARY ARTERIAL HYPERTENSION
LK Ferrell, DO • James E. West, MD

BASICS

DESCRIPTION

- Pulmonary arterial hypertension (PAH) is a category of pulmonary hypertension (PH) characterized by abnormalities in the small pulmonary arteries (precapillary PH) that produce increased pulmonary arterial pressure (PAP) and vascular resistance, eventually resulting in right-sided heart failure. PAH is a progressive disorder associated with increased mortality.
  - Previously, PH was classified as primary PH (without cause, now idiopathic IPAH) or secondary PH (with cause or associated condition); now, it is clear that some types of secondary PH closely match primary PH (IPAH) in their histology, natural history, and response to treatment. Therefore, WHO classifies PH into five groups based on mechanism, with PAH as group 1 in this classification.
  - PAH is diagnosed by right-heart catheterization and defined by a mean PAP ≥25 mm Hg at rest when other groups of PH are ruled out; pulmonary capillary wedge pressure ≤15 mm Hg (excludes PH owing to left heart disease; i.e., group 2 PH)
  - Mild or absent chronic lung disease or other causes of hypoxemia (excludes PH owing to lung disease or hypoxemia; i.e., group 3 PH)
  - Absent venous thromboembolic disease (excludes chronic thromboembolic PH [CTEPH]; i.e., group 4 PH)
  - Absent systemic disorder (like sarcoidosis), hematologic disorders (like myeloproliferative disease), and metabolic disorders (like glycogen storage disease) (excludes group 5 PH)
- PAH is divided into following main categories:
  - Idiopathic: sporadic, with no family history or risk factors
  - Heritable: IPAH with mutations or familial cases with or without mutations
  - Drug or toxin induced: mostly associated with anorectics (e.g., fenfluramine), rapeseed oil, L-tryptophan, and illicit drugs such as methamphetamine and cocaine
  - Associated: connective tissue diseases (e.g., systemic lupus erythematosus,
rheumatoid arthritis, scleroderma), HIV infection, portal hypertension, congenital heart disease, schistosomiasis (chronic hemolytic anemia added to group 5 PH—unclear/multifactorial mechanisms) (1)

- Pulmonary veno-occlusive disease (PVOD) and/or pulmonary capillary hemangiomatosis (PCH) and persistent PH of the newborn (PPHN) are classified as separate categories due to more differences than similarities with PAH.
  - PVOD and/or PCH: rare cause of PH characterized by extensive diffuse occlusion of the pulmonary veins (unlike PAH which involves the small muscular pulmonary arterioles)

**Epidemiology**

- Age: can occur at any age; mean age 37 years
- Sex (IPAH): female > male (~4:1)

**Incidence**

- Overall PAH: 5 to 52 cases/million
- IPAH: low, ~2 to 6 per million
- Drug-induced PAH: 1/25,000 with >3 months of anorectic use
- HIV associated: 0.5/100
- Portal hypertension associated: 1 to 6/100
- Scleroderma associated: 6–60%

**Prevalence**

- PAH: ~15 to 50 cases per million
- IPAH: ~6 cases per million

**Etiology and Pathophysiology**

- Pulmonary: Inflammation, vasoconstriction, endothelial dysfunction, and remodeling of pulmonary arteries produced by increased cell proliferation and reduced rates of apoptosis lead to obstruction.
- Cardiovascular: right ventricular hypertrophy (RVH), eventually leading to right-sided heart failure
- IPAH: by definition, unknown. True IPAH is mostly sporadic or sometimes familial in nature.
- Pulmonary arteriolar hyperactivity and vasoconstriction, occult thromboembolism, or autoimmune (high frequency of antinuclear antibodies)
Genetics
- 75% of heritable PAH (HPAH) cases and 25% of IPAH cases have mutations in *BMPR2* (autosomal dominant).
- Mutations in *ALK1* and endoglin (autosomal dominant) also are associated with PAH.

RISK FACTORS
- Female sex
- Previous anorectic drug use
- Recent acute pulmonary embolism
- First-degree relatives of patient with familial PAH

COMMONLY ASSOCIATED CONDITIONS
See associated PAH, earlier discussed.

DIAGNOSIS
Symptoms of PAH are nonspecific, which can lead to missed or delayed diagnosis of this serious disease.

HISTORY
Dyspnea, weakness, syncope, dizziness, chest pain, palpitations, lower extremity edema

PHYSICAL EXAM
- Pulmonary component of S₂ (at apex in >90% of patients)
- Right ventricular (RV) lift
- Early systolic click of pulmonary valve
- Pansystolic murmur of tricuspid regurgitation
- Diastolic murmur of pulmonic insufficiency (Graham Steell murmur)
- RV S₃ or S₄
- Edema as jugular vein distention, ascites, hepatomegaly, or peripheral edema

DIFFERENTIAL DIAGNOSIS
Other causes of dyspnea:
- Pulmonary parenchymal disease such as chronic obstructive pulmonary disease
- Pulmonary vascular disease such as pulmonary thromboembolism
- Cardiac disease such as cardiomyopathy
- Other disorders of respiratory function such as sleep apnea

**DIAGNOSTIC TESTS & INTERPRETATION**

- **ECG:** RVH and right axis deviation
- **Pulmonary function testing:** reduced diffusion capacity
- **Arterial blood gas:** arterial hypoxemia, hypocapnia
- **Ventilation–perfusion (V/Q) scan:** Look for proximal pulmonary artery emboli and CTEPH; rule out group 4 PH.
- **Exercise test:** reduced maximal O$_2$ consumption, high-minute ventilation, low anaerobic threshold, increased PO$_2$ alveolar–arterial gradient; correlation to severity of disease with 6-minute walk distance (6MWD) test
- **Antinuclear antibody positive** (up to 40% of patients)
- **LFTs:** Evaluate for portopulmonary HTN as a complication of chronic liver disease.
- **HIV test,** thyroid function tests, sickle cell disease screening
- **Elevated brain natriuretic peptide (BNP) and N-terminal-proBNP** may be useful for early detection of PAH in young, otherwise healthy patients with mild symptoms. It can also be used to assess disease severity and prognosis.
- **Chest radiograph**
  - Prominent central pulmonary arteries with peripheral hypovascularity of pulmonary arterial branches
  - RV enlargement is a late finding.
- **Echo Doppler**
  - Should be performed with suspicion of PAH; recent studies show some inaccuracy compared with right-sided heart catheterization.
  - Most commonly used screening tool
    - Estimates mean PAP and assesses cardiac structure and function, excludes congenital anomalies
    - Echo suggests, but does not diagnose, PAH. Invasive hemodynamic evaluation confirms PAH diagnosis.
- **Right atrial and ventricular enlargement; tricuspid regurgitation**
- **Important to rule out underlying cardiac disease such as atrial septal defect with secondary PH or mitral stenosis**
- **Cardiac magnetic resonance is not commonly used.**

**Diagnostic Procedures/Other**
Pulmonary angiography
- Should be done if V/Q scan suggests CTEPH
- Use caution; can lead to hemodynamic collapse; use low osmolar agents, subselective angiograms.

Right-sided cardiac catheterization (gold standard for diagnosis of PAH)
- Essential first step to confirm diagnosis and determine severity and prognosis by measuring PAPs and hemodynamics
- Rule out underlying cardiac disease (e.g., left-sided heart disease) and response to vasodilator therapy.

Lung biopsy: not recommended unless primary pulmonary parenchymal disease exists

6MWD: classifies severity of PAH and estimates prognosis

**TREATMENT**

- Treat underlying diseases/conditions that may cause PAH to relieve symptoms and improve quality of life and survival.
- Reasonable goals of therapy include the following:
  - Modified NYHA FC I or II
  - Echocardiography/CMR of normal/near-normal RV size and function
  - Hemodynamic parameters showing normalization of the RV function (RAP <8 mm Hg and CI >2.5 to 3.0 L/min/m²)
  - 6MWD of >380 to 440 m
  - Cardiopulmonary exercise testing, including peak oxygen consumption of >15 mL/min/kg and EqCO2 <45 L/min
  - Normal BNP levels (2)[C]

**GENERAL MEASURES**

- Supervised exercise training (3)[A]
- Psychosocial support (3)[C]
- Avoid strenuous physical activity (3)[C].
- Avoid pregnancy (3)[C].
- Influenza and pneumococcal immunization (3)[C]
- Oxygen—maintain arterial blood O2 pressure >60 mm Hg (3)[C]

**MEDICATION**

- Acute vasodilator test during heart catheterization for all patients who are
potential candidates for long-term oral calcium channel blocker (CCB) therapy (3)[C]
– Screens for pulmonary vasoreactivity/responsiveness using inhaled nitrous oxide; epoprostenol (IV) or adenosine (IV): Positive response may be a prognostic indicator.
– Contraindicated in right-sided heart failure or hemodynamic instability

Chronic vasodilator therapy
– If IPAH with positive response to acute vasodilator test (a fall in mean PAP of ≥10 mm Hg and to a value <40 mm Hg, with unchanged/increased cardiac output), use CCBs.
  o Adequate response confirmed after 3 to 4 months of treatment
  o ~13% will initially respond. Long-term clinical response to CCB therapy is small (~7%) (3)[C].
  o CCBs include nifedipine (long acting), diltiazem, amlodipine.
  o Avoid verapamil due to its significant negative inotropic effect.
– CCBs are contraindicated in patients with a cardiac index of <2 L/min/m² or a right atrial pressure >15 mm Hg if PAH with negative response to acute vasodilator test or worsening on therapy; specific vasodilator choice based on risk stratification (3)[C]
  o Nonresponders to acute vasoreactivity who are in WHO-FC II should be treated with an oral compound (3)[B].
  o Nonresponders who remain or progress to WHO-FC III should be considered for treatment with any approved PAH drugs (3)[B].
  o Continuous IV epoprostenol is recommended as first-line therapy for WHO-FC IV PAH due to survival benefit (NNT = 5) (3)[A].
  o In case of inadequate clinical response, sequential combination therapy should be considered. Therapy includes ERA plus a phosphodiesterase type 5 (PDE5) inhibitor or a prostanoid plus ERA or a prostanoid plus a PDE5 inhibitor (3)[A].
  o WHO-FC II PAH–approved drugs: ambrisentan, bosentan, macitentan, riociguat, sildenafil, tadalafil (3)[B]
  o WHO-FC III PAH–approved drugs: ambrisentan, bosentan, epoprostenol (IV), macitentan, riociguat, sildenafil, tadalafil, treprostinil (SC, inhaled) (3)[B]
  o WHO-FC IV PAH–approved drugs: epoprostenol (IV) (3)[A]
– Drug classes:
  o Prostacyclins: improve exercise capacity, cardiopulmonary hemodynamics: epoprostenol (IV), treprostinil (IV, SC, or inhaled),
iloprost, beraprost
- Prostacyclin IP: receptor agonist—selexipag
- Endothelin receptor antagonists: improve exercise capacity; reducing mortality has been noted (4)[A]: bosentan (PO), ambrisentan (PO), macitentan. Pregnancy Category X; monitor LFTs monthly.
- PDE5 inhibitor: suggested improvement in exercise capacity, cardiopulmonary hemodynamics, and symptoms (3)[C]: sildenafil (PO), tadalafil (PO), vardenafil
- Guanylate cyclase stimulant: stimulators of the nitric oxide receptor, improves exercise capacity: riociguat (PO)

**Anticoagulation**
- Improved survival originally suggested in patients with IPAH only. Newer studies show some evidence for favorable effects of anticoagulation on survival in IPAH, HPAH, or PAH associated with anorexigens (3)[C].
- Warfarin with international normalized ratio of 1.5 to 2.5
  - Contraindications: Avoid in patients with syncope or significant hemoptysis; consider drug interactions.

**Diuretics indicated in patients with RV volume overload (e.g., peripheral edema or ascites) (3)[B]**

- Digoxin has little long-term data in PAH: used in RV failure and/or atrial dysrhythmias, increases cardiac output, and preserves RV contractility

**ISSUES FOR REFERRAL**
Refer to a pulmonologist and/or a cardiologist for further evaluation/treatment if PAH is suspected.

**SURGERY/OTHER PROCEDURES**
- Patients with documented large-vessel thromboembolic disease should be considered for pulmonary thrombectomy.
- Balloon atrial septostomy for severe PAH with right-sided heart failure despite optimized medical therapy to relieve symptoms prior to lung transplant or as a treatment on its own
- Heart–lung or lung transplantation

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Medical therapy is primarily palliative.
- Hospitalization with invasive monitoring is needed to screen vasodilator
responsiveness and initiate vasodilator therapy.
- National registry has been established by the National Heart, Lung, and Blood Institute.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Pneumococcal and influenza vaccines
- Exercise: walking or low-level aerobic activity, as tolerated, once stable; respiratory training

*Patient Monitoring*
Frequently evaluate disease progression and therapeutic efficacy. Tests to measure treatment response include 6-minute walk test and cardiopulmonary exercise test.

**DIET**
Fluid and salt restrictions, especially with RV failure

**PATIENT EDUCATION**
Discuss disease, prognosis, lifestyle changes, and all therapeutic options (including transplant).

**PROGNOSIS**
- Median survival is 2 to 3 years from diagnosis; 5-year survival rate is 34% (NIH registry); newer data show 5-year survival ~70% with new treatment.
- Mode of death: right-sided heart failure (most common), pneumonia, sudden death, cardiac death
- Poor prognostic factors
  - Rapid symptom progression
  - Clinical evidence of RV failure
  - WHO functional PAH class IV (or NYHA functional class III or IV)
  - 6MWD <300 m
  - Peak VO2 during cardiopulmonary exercise testing <10.4 mL/kg/min
  - Echocardiography with pericardial effusion, significant RV enlargement/dysfunction, right atrial enlargement
  - Mean right atrial pressure >20 mm Hg
Cardiac index <2 L/min/m²
- Elevated mean PAP
- Significantly elevated BNP and NT-proBNP; other markers also show promise in predicting survival: RDW, GDF-15, interleukin-6, creatinine.
- Scleroderma spectrum of diseases

COMPlications
- Thromboembolism, heart failure, pleural effusion, and sudden death
- Pregnancy should be avoided due to high maternal mortality (30–50%) and fetal wastage.

REFERENCES

ADDITIONAL READING

CODES

ICD10
- I27.0 Primary pulmonary hypertension
- I27.2 Other secondary pulmonary hypertension

CLINICAL PEARLS
- PAH involves abnormalities in the small pulmonary arteries (precapillary PH) which increase PAP and vascular resistance leading to right heart failure.
- For positive vasodilator test, CCBs are the first-line agents to manage IPAH.
- For nonresponders, treatment depends on WHO-FC.
BASICS

DESCRIPTION

- Pulmonary embolism (PE) is the most serious presentation of venous thromboembolism (VTE).
- Mortality exceeds 15% during the first 3 months. In 25% of patients, first manifestation is sudden death.

EPIDEMIOLOGY

Case fatality rate 1–60%. For patients with intermediate risk, mortality rate is 3–15% if right ventricular (RV) dilation or dysfunction. If hemodynamically unstable, mortality is >15% due to worsening RV failure and cardiogenic shock.

Incidence

- Approximately 60 to 70 per 100,000, with >100,000 cases annually in the United States
- Incidence increases with age, most occurring at 60 to 70 years of age.
- 250,000 hospitalizations per year in the United States, 10–60% in hospitalized patients
  - Highest risk for orthopedic patients
  - 1:1,000 pregnancies (including postpartum)

ETIOLOGY AND PATHOPHYSIOLOGY

- Venous stasis, endothelial damage, and changes in coagulation properties trigger formation of thrombus (1).
- Causes increased pulmonary vascular resistance, impaired gas exchange, and decreased pulmonary compliance. RV failure due to pressure overload is usually the primary cause of death (1).
- DVT in the proximal veins is the most common source of PE, up to 85% of the cases.

Genetics

- Factor V Leiden: Most common thrombophilia. +5.5% in Caucasian, 2.2% in
Hispanics, 1.2% in African American, 0.5% in Asian; associated with 20% of all VTE
- Prothrombin G20210A: 3% of Caucasians, rare in African American, Asian, and Native American; 6% in patients with VTE
- Deficiencies in protein C, S, and antithrombin

RISK FACTORS
- Acquired: age, immobilization, surgery, major trauma, lower limb fractures, joint replacement, spinal cord injury, cancer, hormonal replacement therapy, pregnancy/puerperium, previous thrombosis, paroxysmal nocturnal hemoglobinuria, antiphospholipid syndrome, prolonged travel
- Oral contraceptive is the most frequent medication (1).
- Inherited: antithrombin deficiency, protein C or S deficiency, factor V Leiden, prothrombin gene mutation G20210A (1)

GENERAL PREVENTION
- Mechanical thromboprophylaxis: early ambulation after surgery, compression stockings, and intermittent pneumatic compression
- Intermediate risk: general, gynecologic, or urologic surgery; prophylaxis is recommended with low-molecular-weight heparin (LMWH), unfractionated heparin (UFH), or fondaparinux.
- High risk: 10 or more days prophylaxis in hip or knee arthroplasty, with LMWH, fondaparinux, apixaban, dabigatran, rivaroxaban, or low-dose UFH. 28 to 35 days with LMWH, fondaparinux, UFH, or vitamin K antagonists (VKA) in hip fracture surgery; LMWH or UFH in major trauma, spinal cord injury
- Long-distance travel (>8 hours): hydration, walking, avoidance of constrictive clothing and frequent calf exercises; if additional risk factors, then compression stockings below knee
- Patients with factor V Leiden, prothrombin G20210A with no previous thrombosis do not need long-term daily prophylaxis.

DIAGNOSIS
- Establish a pretest probability based on clinical criteria (2).
  - Wells score
    - Clinical signs and symptoms of DVT +3
    - Alternative diagnosis is less likely than PE +3.
Heart rate >100 +1.5
- Immobilization previous 4 weeks +1.5
- Previous DVT/PE +1.5
- Hemoptysis +1
- Malignancy +1
  - <2 points, low clinical probability; 2 to 6 points, moderate; >7 points, high

Recently, Wells and revised Geneva score were simplified (2).
- Wells score: Each predictor is +1; PE unlikely if 0 to 1, PE likely if >2
- Geneva score: Each predictor is +1 except for heart rate >95 which is +2; PE unlikely if 0 to 2 and PE likely if >3

**HISTORY**
- Determine if the presentation is provoked or idiopathic. Approximately 30% of cases develop without identifiable risk factor.
- Presence of risk factors and family history
- Bleeding risk (previous anticoagulation, history of bleeding, recent interventions/surgeries, liver disease)
- Sudden onset dyspnea (>85%), chest pain (>50%), cough (20%), syncope (14%), hemoptysis (7%)

**PHYSICAL EXAM**
- Dyspnea, syncope, hemoptysis, tachycardia, tachypnea, accentuated S2; pleuritic chest pain, pleural friction rub, rales (1)
- Signs of DVT: leg swelling, tenderness, visible collateral veins (1)
- Signs of RV failure: jugular vein distention, third or fourth sound, systolic murmur at left sternal edge, hepatomegaly (1)

**ALERT**
- Massive PE: mortality rate exceeding 20%; hemodynamic instability with sustained hypotension, pulselessness, or persistent bradycardia, cardiogenic shock, acute manifesting RV failure (1)
- Submassive PE: hemodynamically stable. Mortality rate of 5–25%; no systemic hypotension, but there is either RV dysfunction or myocardial necrosis (1,3)
  - RV dysfunction: RV dilation or systolic dysfunction on echocardiography, RV dilation on CT, elevation of brain natriuretic peptide (BNP) or N-terminal pro-BNP (500 pg/mL), or consistent ECG changes
Low-risk PE: acute and absence of clinical markers of adverse prognosis

DIFFERENTIAL DIAGNOSIS
- Pulmonary: pneumonia, bronchitis, pneumothorax, pneumonitis, chronic obstructive pulmonary disease (COPD) exacerbation, pulmonary edema, pneumothorax
- Cardiac/vascular: myocardial infarction, pericarditis, congestive heart failure (CHF), aortic dissection
- Musculoskeletal: rib fracture(s), musculoskeletal chest wall pain

DIAGNOSTIC TESTS & INTERPRETATION
- D-dimer ELISA: In patients with low pretest probability, it can rule out PE if it is negative (high negative predictive value [NPV]) (1)[A]. It is not diagnostic if positive (low positive predictive value [PPV]), and it is not helpful if pretest probability is intermediate or high (1)[B].
- CBC, creatinine, aPTT and PT, ABG: In young patients with idiopathic, recurrent, or significant family history of VTE, consider testing for hypercoagulable tests.
  - Do not test for protein C, S, factor VIII, or antithrombin in the acute setting or while on treatment, as may be falsely abnormal.
  - Patients with intermediate or high pretest probability and low probability with elevated D-dimer need further diagnostic testing.
- Chest x-ray (CXR): Westermark sign (lack of vessels in an area distal to the embolus), Hampton hump (wedge-shaped opacity with base in pleura), Fleischner sign (enlarged pulmonary arteries), atelectasis, pleural effusion, pulmonary infarct, hemidiaphragm elevation (1)
- ECG: right heart strain, nonspecific rhythm abnormalities, S1Q3T3
- CT pulmonary angiography: sensitivity 96–100%, specificity 86–89%; NPV 99.8%. If normal, it safely excludes PE if low or intermediate clinical probability (1)[A].
- Ventilation/perfusion scintigraphy (V/Q scan): safe with few allergic reactions. Use if CT angiography is not available or contraindicated. A high-probability V/Q scan makes the diagnosis of PE; normal V/Q scan excludes PE (1)[B].
- Pulmonary angiography: gold standard but invasive and technically difficult: 2% morbidity and <0.01 mortality risk (1)[C]
- Echocardiogram: Assess RV function, found in 25% of patients with PE.
- Magnetic resonance angiography: lower sensitivity and specificity than CT
angiography

- Compression venous ultrasound (CUS): noninvasive. Sensitivity >90%, specificity approximately 95%. It confirms the diagnosis of PE in patients with clinical suspicion (1)[B].
- CT venography: can be done at the same time as CT angiography; increases diagnostic yield (1)

**ALERT**
If your preclinical probability is intermediate or high and the patient has a low bleeding risk, start treatment while waiting for the diagnostic results (3)[C].

**Follow-Up Tests & Special Considerations**
Elevated troponin I or T and elevated BNP are markers for higher risk patients.

**TREATMENT**

**MEDICATION**
- If clinical suspicion is high and no contraindications, start treatment immediately.
- Start LMWH, fondaparinux, UFH, as initial therapy for first 5 to 10 days. VKA can be started the 1st day and must overlap with parenteral treatment for minimum of 5 days, until international normalized ratio (INR) is 2 to 3 for 24 hours.
- Following 5 to 10 days of parenteral therapy, dabigatran or edoxaban are also approved (1).
- An oral option for initial and long-term treatment is rivaroxaban or apixaban (1).
- Patients with massive PE with low bleeding risk: Consider systemic thrombolytics if no contraindications. Also in patients <75 years old with submassive PE; greater benefit if initiated within 48 hours of symptoms onset (1)

**First Line**
- UFH (3)[A]:
  - IV bolus of 80 U/kg or 5,000 U followed by continuous infusion (initially 18 U/kg/hr or 1,300 U/hr) with dose adjustments to maintain aPTT that corresponds to anti-Xa levels of 0.3 to 0.7
– SC injection: 2 options:
  o Monitored: 17,500 U or 250 U/kg BID with dose adjustments to maintain an aPTT that corresponds to anti-Xa levels of 0.3 to 0.7 measured 6 hours after a dose
  o Fixed dose: 333 U/kg initial dose, followed by 250 U/kg BID

• LMWH: preferred due to lower risk of major bleeding and heparin-induced thrombocytopenia (HIT) (1),(3)[A]
  – Enoxaparin (Lovenox) 1 mg/kg/dose SC q12h
  – Dalteparin (Fragmin) 200 U/kg SC q24h
  – Fondaparinux (Arixtra): 5 mg (body weight <50 kg), 7.5 mg (body weight 50 to 100 kg), or 10 mg (body weight >100) SC q24h

• Maintenance therapy: Warfarin on day 1, if possible; 5 mg/day for 3 days in hospitalized or older patients, and at a dose of 10 mg in <60 years of aged patients; adjust dose to maintain an INR of 2 to 3; needs to overlap with UFH, LMWH, or fondaparinux: 5 to 7 days, until 2 consecutive days of therapeutic INR (1)

• Rivaroxaban: 15 mg BID for 3 and then 20 mg once daily to complete treatment. Compared to warfarin, it has less major bleeding side effects while having same efficacy (1)[B].

• Edoxaban: 60 mg once daily (reduced to 30 mg once daily if CrCl 30 to 50 mL/min or body weight <60 kg). Patients require initial treatment with LMWH at least 5 days before starting edoxaban; less bleeding risk compared to warfarin (1)[B]

• Apixaban: 10 mg BID for 7 days, followed by 5 mg once daily was compared to conventional therapy; compared to warfarin, noninferior against recurrent symptomatic VTE or death related to VTE, with less frequently major bleeding episodes (1)[B]

• Dabigatran: Require initial treatment with LMWH. Compared to warfarin, 150 mg BID had noninferior efficacy and no differences in major bleeding and fewer episodes of any bleeding (1)[B].

**ALERT**

Contraindications
- Active bleeding
- Heparin: HIT
- LMWH: HIT, renal failure
- Warfarin: pregnancy
- Rivaroxaban and fondaparinux: renal failure (1)[A]
- Edoxaban: severe kidney or liver failure (1) [A]
- Apixaban: renal impairment and nonvalvular atrial fibrillation (1) [A]
- Dabigatran: severe kidney problems. Use of dronedarone or ketoconazole increases risk.

**Pregnancy Considerations**
- Warfarin is teratogenic and should not be used in pregnant patients (especially in 1st trimester); safe while breastfeeding
- **LMWH:** Dalteparin, enoxaparin, and fondaparinux are Category B; heparin is Category C, use if the benefit overweight risks.
- **UFH:** Require aPTT monitoring; can cause osteoporosis if used for prolonged period
- Rivaroxaban is Category C.
- Edoxaban and Apixaban: Category B; increases risk of hemorrhage
- Dabigatran: Category C; use it only if benefit overweighs side effects.

**Second Line**
Massive PE: Consider thrombolytics if the patient has hemodynamic compromise and low bleeding risk, intracranial hemorrhage risk: 0.7–6.4%: (1), (3)[B]
- Tissue plasminogen activator (tPA) 100 mg infused over 2 hours. Absolute contraindications:
  - Intracranial hemorrhage, known intracranial cerebrovascular or malignant disease, ischemic stroke within 3 months, suspected aortic dissection, bleeding diathesis, active bleeding, recent neurosurgery, or major trauma

**SURGERY/OTHER PROCEDURES**
- Inferior vena cava (IVC) filter placement if absolute contraindication for anticoagulation or recurrent PE despite adequate anticoagulation treatment (3) [B]
- PREPIC2 trial showed that retrievable IVC filters at 3 months plus anticoagulation compared to anticoagulation alone among patients with severe PE had no benefit reducing the risk of symptomatic recurrent PE (3%, 95% CI 1.1–6.5% vs. 1.5%, 95% CI 0.3–4.3%) (3)[C].
- Emergency embolectomy can be considered in patients with massive PE with contraindications for thrombolysis (3)[C].
- Consider catheter-based interventions if massive PE and thrombolytic contraindications (3)[C].
Consider ultrasound-assisted catheter-directed thrombolysis (USAT) in patients with intermediate risk of death or submassive PE, superior than heparin alone in reversing RV dilation at 24 hours without increase in bleeding complications.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
ICU-level care if hemodynamically unstable

ONGOING CARE
Duration of anticoagulation

- Provoked PE (trigger no longer present): 3 months (1)[B]
- Unprovoked PE: Minimum of 3 months, consider long-term or prolonged secondary prophylaxis if bleeding risk is low (1)[B].
- Cancer-related PE: LMWH first 3 to 6 months. Consider secondary prophylaxis as long as the patient has active cancer (1)[B].
- Recurrent PE: long-term anticoagulation

FOLLOW-UP RECOMMENDATIONS
- If concomitant DVT, knee-height compression stockings, 30 to 40 mm Hg knee height
- If an IVC filter was placed, follow-up for retrieval.

Patient Monitoring
- INR should be checked regularly; target is 2 to 3 (1).
- aPTT needs to be monitored in SC UFH (1).
- Anti-Xa can be checked in special circumstances if treated with LMWH, including pregnancy, younger patients, renal disease.

Diet
Warfarin use; recommend a vitamin K diet.

PROGNOSIS
- Massive PE 50% versus nonmassive PE 8–14%
- Simplified Pulmonary Embolism Severity Index score predicts acute mortality (any one of the following defines high risk: age >80 years, history of cancer,
chronic cardiopulmonary disease, heart rate 110/min, systolic blood pressure <100 mm Hg, O₂ saturation <90%) (1)[B].

- High early mortality risk: shock or hypotension, +SPESI index >1+ RV dysfunction signs by imaging and cardiac laboratory biomarkers (1)
- Intermediate high early mortality risk: no shock or hypotension + SPESI >1 + RV dysfunction signs by imaging and cardiac laboratory biomarkers (1)
- Intermediate low early mortality risk: no shock or hypotension + SPESI >1 + either RV dysfunction by imaging or cardiac laboratory biomarkers (1)
- Low early mortality risk: no shock or hypotension, no SPESI; imaging is optional (if assessed is negative) (1).

COMPLICATIONS

- 1 in 25 patients will develop chronic thromboembolic pulmonary hypertension, recurrent DVT, or PE.
- Younger age, previous PE, and larger perfusion defect were significantly associated with increased risk of CTPH found in 5.2% of 58 patients with previous DVT and 33.3% of 24 patients with previous PE.
- Incidence of major hemorrhage associated with thrombolytics is 8%; intracerebral bleed is 2% (fatal in 1/2 of cases).

REFERENCES

CODES

ICD10

- I26.99 Other pulmonary embolism without acute cor pulmonale
- I27.82 Chronic pulmonary embolism
CLINICAL PEARLS

- PE can be excluded in patients who have low pretest probability and negative D-dimer testing.
- Perform cancer-oriented review of systems and age/gender-appropriate cancer screening in patients >40, recurrent VTE, upper extremity DVT (not related to catheter or lines), bilateral lower extremity DVT, intra-abdominal DVT, resistance to treatment.
- In patients with prolonged baseline aPTT, adjust heparin dose with anti-Xa levels (therapeutic range 0.3 to 0.7).
PULMONARY FIBROSIS
Azfar S. Syed, DO • Zachary Prather, MD

BASICS
DESCRIPTION
- Characterized by fibrosis of the lung parenchyma
- Chest CT shows reticular pattern and honeycombing, with subpleural and lower lobe predominance.
- Lung biopsy shows “usual interstitial pneumonia” pattern.
- Classified based on etiology
  - Idiopathic
  - Nonidiopathic

EPIDEMIOLOGY
Incidence
- Incidence of IPF is 7 to 16/100,000 person-years.
- Idiopathic pulmonary fibrosis (IPF) is more common in men.
- Most patients with IPF are >60 years.
- Incidence of nonidiopathic pulmonary fibrosis is unknown.

Prevalence
- Prevalence of IPF is 2 to 39 cases/100,000 people.
- Prevalence of nonidiopathic pulmonary fibrosis is unknown.

ETIOLOGY AND PATHOPHYSIOLOGY
- Postulated that microinjury to alveolar epithelial cells causes release of cytokines that activates fibroblasts, which in turn leads to excess production of extracellular matrix
- Causes of the nonidiopathic form include:
  - Occupational exposure
  - Environmental exposure
  - Drugs
  - Systemic connective tissue diseases
  - Granulomatous diseases
**Genetics**
- <5% of IPF is familial and may involve mutations in surfactant protein A2 and C and/or abnormal telomere shortening.
- Most likely mode of transmission is autosomal dominant with variable penetrance.

**RISK FACTORS**
- Family history of pulmonary fibrosis
- Gastroesophageal reflux disease (GERD)
- Smoking
- Exposure to birds, livestock, dust from metals or wood, solvents

**GENERAL PREVENTION**
Avoid the risk factors mentioned earlier, such as smoking, certain occupational exposures, or drugs that induce pulmonary fibrosis.

**COMMONLY ASSOCIATED CONDITIONS**
- Pulmonary hypertension: occurs in 30–80% of patients with IPF, likely as a result of hypoxemic vasoconstriction
- GERD
- Nonidiopathic pulmonary fibrosis may be associated with connective tissue diseases (e.g., rheumatoid arthritis and scleroderma).

**DIAGNOSIS**

**HISTORY**
- Slowly progressive dyspnea
- Dry nonproductive cough

**PHYSICAL EXAM**
- Tachypnea
- Fine inspiratory bibasilar crackles
- Possible clubbing

**DIFFERENTIAL DIAGNOSIS**
- Asbestosis
- Berylliosis
• Coal worker pneumoconiosis
• Chronic hypersensitivity pneumonitis
• Sarcoidosis
• Silicosis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Increased reticular markings on initial chest x-ray, nonspecific finding
• High-resolution chest computed tomography (HRCT) is needed to make diagnosis. Characteristic findings include a reticular pattern, traction bronchiectasis, and honeycombing. There is a subpleural and lower lobe predominance. There is minimal to no evidence of active inflammation (1,2).
• If the patient has characteristic findings of pulmonary fibrosis on chest CT, then lung biopsy may not necessarily be required (1).
• Initial lab work including CBC, CMP, urinalysis to check for other causes of interstitial lung disease

Follow-Up Tests & Special Considerations
• Surgical lung biopsy should be considered if clinical presentation and HRCT are not entirely characteristic of pulmonary fibrosis (1).
• Blood work to rule out associated collagen vascular disease (1)
• Bronchoscopy with bronchoalveolar lavage has limited role but may help rule out other types of interstitial lung disease and concurrent infection (1).

Diagnostic Procedures/Other
• Pulmonary function testing (PFT): initially, may see only decrease in diffusing capacity; later in disease, may develop decrease in lung volumes as well
• Echocardiogram to evaluate for concomitant pulmonary hypertension
• Resting and exercise pulse oximetry to determine need for supplemental oxygen

Test Interpretation
Usual interstitial pneumonitis: shows interstitial scarring, honeycombing, and fibroblastic foci. There is temporal heterogeneity, meaning there may be areas of normal lung adjacent to fibrosed or inflamed lung.
TREATMENT

GENERAL MEASURES

- Pulmonary rehabilitation (1)[C]
- Consider treating for GERD, even if asymptomatic (1)[B].
- Consider lung transplant evaluation.

MEDICATION

First Line

- Supplemental oxygen, if needed (1)[C]
- Treat exacerbation with high-dose glucocorticoids (3)[C].

ISSUES FOR REFERRAL

- Patients should be evaluated and cared for longitudinally by a pulmonologist.
- If any uncertainty in diagnosis, then consider referral to thoracic surgery for lung biopsy (4).
- Depending on patient age, comorbidities, and preference, may consider referral for lung transplant

ADDITIONAL THERAPIES

- Recent studies have shown a benefit with the antifibrotic agent pirfenidone and the tyrosine kinase inhibitor nintedanib for slowing the progression of IPF (4,5). These drugs were approved by the FDA in 2014.
- Pirfenidone and nintedanib slowed decline in fixed volume capacity (FVC) more so than N-acetylcysteine (6).
- Many other clinical trials are currently under way. Some of the targets being studied include TGF-β; connective tissue growth factor; IL-13; CCL2; CXCR4; and CXCL12, ACE, and angiotensin II (7).

SURGERY/OTHER PROCEDURES

Lung transplant carries a 5-year survival rate of 40–50%.

COMPLEMENTARY & ALTERNATIVE MEDICINE

Recommend pneumococcal vaccine and yearly influenza vaccine.
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Worsening shortness of breath and/or increased oxygen requirements:
- Provide adequate supplemental oxygen.
- Workup for other possible causes of respiratory decompensation
- If no other cause for respiratory decompensation is found, then consider administration of high-dose steroids.
- Supplemental oxygen to keep saturations >90%

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Patient should follow-up with a pulmonologist.

Patient Monitoring
Disease progression can be monitored by periodic PFTs and HRCT.

DIET
No specific dietary requirements

PATIENT EDUCATION
- Patients should be counseled extensively regarding the prognosis of this diagnosis and given as much support as possible. Information about support groups in the local community and online may be helpful.
- Pulmonary Fibrosis Foundation: http://www.pulmonaryfibrosis.org/ which includes information about active pulmonary fibrosis clinical trials

PROGNOSIS
- Median survival time was thought to be 2 to 3 years from time of diagnosis. However, recent data from clinical trials suggest that this may be an underestimate.
- Some patients may deteriorate quickly, whereas others can remain stable for an extended period of time. Acute exacerbations carry a high mortality, and ICU treatment (mechanical ventilation) is mostly unsuccessful.
A higher extent of fibrosis increases the risk of death, whereas a higher percentage-predicted diffusing capacity of lung for carbon monoxide reduced the risk of death.

COMPICATIONS

- Respiratory failure
- Infection
- Pulmonary hypertension
- Rib fractures secondary to prolonged coughing (especially in elderly patients with decreased bone density)

REFERENCES

ADDITIONAL READING

- Castriotta RJ, Eldadah BA, Foster WM, et al. Workshop on idiopathic

**CODES**

**ICD10**

- J84.10 Pulmonary fibrosis, unspecified
- J84.112 Idiopathic pulmonary fibrosis

**CLINICAL PEARLS**

- Pulmonary fibrosis can usually be diagnosed based on characteristic chest CT findings, which include a reticular pattern, traction bronchiectasis, and honeycombing with a peripheral and basilar predominance.
- There are idiopathic and nonidiopathic forms of pulmonary fibrosis.
- Treatment options for pulmonary fibrosis are very limited and, at best, serve to slow the progression of disease.
PYELONEPHRITIS

Katelin M. Lisenby, PharmD, BCPS • Dana G. Carroll, PharmD, BCPS, CDE, CGP • Catherine Scarbrough, MD, MSc, FAAFP

BASICS

DESCRIPTION

- A syndrome caused by infection of the renal parenchyma and/or renal pelvis, often producing localized flank/back pain combined with systemic symptoms, such as fever, chills, and nausea. It has a wide spectrum of presentation, from mild illness to septic shock.
- Chronic pyelonephritis is the result of progressive inflammation of the renal interstitium and tubules, due to recurrent infection, vesicoureteral reflux, or both.
- Pyelonephritis is considered uncomplicated if the infection is caused by a typical pathogen in an immunocompetent patient with normal urinary tract anatomy and renal function.
- System(s) affected: renal; urologic
- Synonym: acute upper urinary tract infection (UTI)

Geriatric Considerations

- May present as altered mental status; absence of fever is common in this age group.
- Elderly patients with diabetes and pyelonephritis are at higher risk of bacteremia, longer hospitalization, and mortality.
- The high prevalence of asymptomatic bacteriuria in the elderly makes the use of urine dipstick less reliable for diagnosing UTI in this population (1)[A].

Pregnancy Considerations

- Most common medical complication requiring hospitalization
- Affects 1–2% of all pregnancies. Morbidity does not differ between trimesters.
- Urine culture as test of cure 1 to 2 weeks after therapy

Pediatric Considerations
UTI is present in ~5% of patients age 2 months to 2 years with fever and no apparent source on history and physical exam. Treatment (oral or IV; inpatient or outpatient) should be based on the clinical situation and patient toxicity.

EPIDEMIOLOGY

Incidence
Community-acquired acute pyelonephritis: 28/10,000/year

Prevalence
Adult cases: 250,000/year, with 200,000 hospitalizations

ETIOLOGY AND PATHOPHYSIOLOGY

- *Escherichia coli* (>80%)
- Other gram-negative pathogens: *Proteus, Klebsiella, Serratia, Clostridium, Pseudomonas, and Enterobacter*
- *Enterococcus*
- *Staphylococcus: Staphylococcus epidermidis, Staphylococcus saprophyticus* (number 2 cause in young women), and *Staphylococcus aureus*
- *Candida*

RISK FACTORS

- Underlying urinary tract abnormalities
- Indwelling catheter/recent urinary tract instrumentation
- Nephrolithiasis
- Immunocompromised, including diabetes
- Elderly, institutionalized patients (particularly women)
- Prostatic enlargement
- Childhood UTI
- Acute pyelonephritis within the prior year
- Frequency of recent sexual intercourse; spermicide use; new sex partner within the prior year
- Stress incontinence in the previous 30 days
- Pregnancy
- Hospital-acquired infection
- Symptoms >7 days at time of presentation

COMMONLY ASSOCIATED CONDITIONS
• Indwelling catheters
• Renal calculi
• Benign prostatic hyperplasia

DIAGNOSIS

HISTORY

• In adults
  – Fever; flank pain
  – Nausea ± vomiting
  – Malaise, anorexia
  – Myalgia
  – Dysuria, urinary frequency, urgency
  – Suprapubic discomfort
  – Mental status changes (elderly)

• In infants and children
  – Fever
  – Irritability and poor feeding
  – GI symptoms

PHYSICAL EXAM

• In adults
  – Fever: ≥38°C (100.4°F)
  – Costovertebral angle tenderness
  – Presentation ranges from no physical findings to septic shock.
  – Mental status changes common in the elderly
  – A pelvic exam may be necessary in female patients to exclude pelvic inflammatory disease.

• In infants and children
  – Sepsis
  – Fever
  – Poor skin perfusion
  – Inadequate weight gain/weight loss
  – Jaundice to gray skin color

DIFFERENTIAL DIAGNOSIS

• Obstructive uropathy
• Acute bacterial pneumonia (lower lobe)
• Cholecystitis
• Acute pancreatitis
• Appendicitis
• Perforated viscus; aortic dissection
• Pelvic inflammatory disease; ectopic pregnancy
• Kidney stone
• Diverticulitis

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Urinalysis: pyuria ± leukocyte casts, hematuria, nitrites (sensitivity 35–85%; specificity 92–100%), and mild proteinuria
- Urine leukocyte esterase positive (sensitivity 74–96%; specificity 94–98%)
- Urine Gram stain; urine culture (>100,000 colony-forming units/mL or >100 colony forming units/mL + symptoms) and sensitivities
- CBC, BUN, Cr, GFR, and pregnancy test (if indicated)
- C-reactive protein levels have been shown to correlate with prolonged hospitalization and recurrence; serum albumin <3.3 g/dL also associated with risk for hospital admission
- Imaging not necessary in routine cases
- Pediatrics: Recent guidelines recommend renal/bladder US (not voiding cystourethrogram), after first UTI.

**Follow-Up Tests & Special Considerations**

- Catheterization/suprapubic aspirate to obtain samples from non–toilet-trained children
- Catheterization may also be necessary for some geriatric patients.
- Blood culture(s): if diagnostic uncertainty, immunosuppression, or a suspected hematogenous source
- Recent antibiotic use may alter lab results.
- If patient’s condition does not improve within 72 hours, if obstruction/anatomic abnormality suspected, or if certain lab abnormalities are present (urine pH >7, GFR <40, 50% decline in renal function), consider:
  - CT scan of abdomen and pelvis ± contrast
  - US of kidneys, ureter, bladder
  - Cystoscopy with ureteral catheterization
**Test Interpretation**
- Acute: abscess formation with neutrophil response
- Chronic: fibrosis with reduction in renal tissue

**TREATMENT**
- \( \leq 7 \) days of treatment is equivalent to longer regimens in adults (including those with bacteremia) without urogenital abnormalities\(^{(2)}\)[A].
- IV antibiotics are indicated for inpatients who are toxic appearing or unable to tolerate oral antibiotics.

**GENERAL MEASURES**
- Broad-spectrum antibiotics initially; tailor therapy to culture and sensitivity results.
- Analgesics and antipyretics
- Consider urinary analgesics (e.g., phenazopyridine 200 mg q8h) for dysuria.

**MEDICATION**
- For empiric oral therapy, a fluoroquinolone is recommended. Should fluoroquinolone resistance exceed 10% or the patient has nausea/vomiting, a single initial IV dose of a long-acting antibiotic such as ceftriaxone 1 g is additionally recommended.
- For parenteral therapy, fluoroquinolone, aminoglycoside ± ampicillin, an extended-spectrum cephalosporin with or without a \( \beta \)-lactamase inhibitor, an extended-spectrum penicillin with or without an aminoglycoside, or a carbapenem are recommended.
- Contraindications:
  - Known drug allergy
  - Fluoroquinolones are not recommended in children, adolescents, and pregnant women unless other alternatives are not available.
  - Nitrofurantoin does not achieve reliable tissue levels for treatment of pyelonephritis.
- Precautions
  - Most antibiotics require adjustments in dosage for patients with renal insufficiency.
  - Monitor aminoglycoside levels and renal function.
  - If *Enterococcus* is suspected based on Gram stain, ampicillin ± gentamicin
is a reasonable empiric choice; unless patient is penicillin-allergic, then use vancomycin. If outpatient, add amoxicillin to fluoroquinolone, pending culture results and sensitivity. Do not use a 3rd-generation cephalosporin for suspected/proven enterococcal infections.

- >20% E. coli strains are resistant to ampicillin and trimethoprim-sulfamethoxazole (TMP-SMX) in community-acquired infections.
- Extended-spectrum beta-lactamase (ESBL)-producing strains should be treated with a carbapenem or ceftolozane–tazobactam.

**First Line**

- **Adults**
  - Oral (initial outpatient treatment)
    - Ciprofloxacin: 500 mg q12h for 7 days
    - Ciprofloxacin XR: 1,000 mg/day for 7 days
    - Levofloxacin: 750 mg/day for 5 days
    - TMP-SMX (160/800 mg): 1 tab q12h for 14 days provided uropathogen known to be susceptible ± ceftriaxone 1 g initial IM/IV dose
  - Intravenous (initial inpatient treatment)
    - Ciprofloxacin: 400 mg q12h
    - Levofloxacin: 750 mg/day
    - Cefotaxime: 1 g q8–12h up to 2 g q4h
    - Ceftriaxone: 1 to 2 g/day
    - Cefepime: 1 to 2 g q12h
    - Gentamicin: 5 to 7 mg/kg of body weight daily
    - Ampicillin: 2 g q6h ± gentamicin for *Enterococcus*
    - Ceftolozane–tazobactam: 1.5 g q8h (Although superiority was demonstrated in the ASPECT-cUTI trial, option should be reserved and therapy deescalated when causative pathogen is known.)
  - Severe illness: IV therapy until afebrile 24 to 48 hours and tolerating oral hydration and medications and then oral agents to complete up to a 2-week course

- **Pediatric**
  - Oral: cefdinir: 14 mg/kg/day for 10 to 14 days; ceftibuten 9 mg/kg/day for 10 to 14 days; cefixime 8 mg/kg/day for 10 to 14 days
  - IV (general indication for IV therapy is age <2 months or clinical concern in other ages)
    - Ceftriaxone: 75 mg/kg/day (also can be used IM in outpatient setting)
    - Cefotaxime: 150 mg/kg/day divided in 3 to 4 doses
    - Ampicillin: 100 mg/kg/day divided in 4 doses + gentamicin 7.5
mg/kg/day divided in 3 doses

**Second Line**

Adults
- **Oral**
  - Oral β-lactams should be used with caution due to inferior efficacy and higher relapse rates; if used, provide an initial IV dose of ceftriaxone or a consolidated 24-hour dose of an aminoglycoside; longer courses of therapy (10 to 14 days) recommended
  - Cefpodoxime (Proxetil): 200 mg q12h
  - Amoxicillin–clavulanate: 875/125 mg q12h or 500/125 mg q8h
- **IV**
  - Piperacillin–tazobactam: 3.375 g q6–8h
  - Ticarcillin–clavulanate: 3.1 g q4–6h
  - Meropenem: 500 mg q12h

**Pediatric Considerations**
- Treat children <2 years of age and children with febrile or recurrent UTI for 10 to 14 days.
- Initial empiric antibiotic choice should cover *E. coli*. Add ampicillin if *Enterococcus* is suspected.
  - Oral antibiotics (ceftibuten, cefixime, and amoxicillin/clavulanic acid) may be used alone, or
  - IV antibiotics (single daily dosing if an aminoglycoside is chosen) for 2 to 4 days, followed by oral antibiotics for a total of 10 to 14 days (3)[A]
- Complete outpatient antibiotic course in entirety

**ISSUES FOR REFERRAL**
- Acute pyelonephritis unresponsive to therapy
- Chronic pyelonephritis
- Abnormal urogenital anatomy

**SURGERY/OTHER PROCEDURES**
Perinephric abscess may require surgical drainage.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Inpatient therapy for severe illness (e.g., high fevers, severe pain, marked
debility, intractable vomiting, inability to tolerate oral intake, possible sepsis), risk factors for complicated pyelonephritis, pregnancy, or extremes of age

- Outpatient therapy if mild to moderate illness (not pregnant, no nausea/vomiting; fever and pain not severe), uncomplicated, and tolerating oral hydration and medications. Many patients can be treated as outpatients.
- IV fluids as indicated for dehydration or renal calculi
- Discharge on oral agent after patient is afebrile 24 to 48 hours to complete up to 2 weeks of therapy.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

- Women: routine follow-up cultures not recommended unless symptoms recur after 2 weeks and then urologic evaluation is necessary
- Men, children, adolescents, patients with recurrent infections, patients with risk factors: Repeat cultures 1 to 2 weeks after completing therapy; urologic evaluation after first episode of pyelonephritis and with recurrences

**Patient Monitoring**

- No response within 48 hours (5% of patients): Reevaluate and review cultures, CT scan, or US to review anatomy; adjust therapy as needed; urologic consult. The two most common causes of failure to respond are a resistant organism and nephrolithiasis.
- Work with parents to monitor response in children.

**DIET**

Encourage fluid intake.

**PROGNOSIS**

95% of treated patients respond within 48 hours.

**COMPLICATIONS**

- Kidney abscess
- Metastatic infection: skeletal system, endocardium, eye, meningitis with subsequent seizures
- Septic shock and death
- Acute/chronic renal failure
REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- N12 Tubulo-interstitial nephritis, not spcf as acute or chronic
- N10 Acute tubulo-interstitial nephritis
- N11.9 Chronic tubulo-interstitial nephritis, unspecified

CLINICAL PEARLS
• Pyelonephritis can present with isolated confusion or mental status changes (no fever) in the elderly.
• The most common causes of poor response to treatment are antibiotic resistance and coexisting nephrolithiasis.
• Fluoroquinolones are generally the initial drugs of choice for treating pyelonephritis. Oral \( \beta \)-lactams are less effective. Parental \( \beta \)-lactams, however, may be used in cases of complicated urinary tract infections.
PYLORIC STENOSIS
Jennifer M. Cornwell, DO

BASICS

DESCRIPTION
- Progressive narrowing of the pyloric canal, occurring in infancy
- Synonym(s): infantile hypertrophic pyloric stenosis (IHPS)

EPIDEMIOLOGY
- Predominant age: infancy
  - Onset usually at 3 to 6 weeks of age; rarely in the newborn period or as late as 5 months of age
- Considered the most common condition requiring surgical intervention in the 1st year of life
- A recent decline in incidence has been reported in a number of countries.
- Predominant sex: male > female (4 to 5:1)

Incidence
In Caucasian population, 2 to 5:1,000 babies; less common in African American and Asian populations

Prevalence
National prevalence level is 1 to 2:1,000 infants, ranging from 0.5 to 4.21:1,000 live births.

ETIOLOGY AND PATHOPHYSIOLOGY
- Abnormal relaxation of the pyloric muscles leads to hypertrophy.
- Redundant mucosa fills the pyloric canal.
- Gastric outflow is obstructed, leading to gastric distension and vomiting.
- The exact cause remains unknown, but multiple genetic and environmental factors have been implicated.
- Breast versus bottlefeeding—increased vasoactive intestinal peptide in breast milk may mediate pyloric relaxation and increase gastric emptying, whereas bottlefeeding may cause higher serum levels associated with pylorospasm (1) [C].
**Genetics**
Recent studies have identified linkage to chromosomes 3, 5, 11 and 19.

**RISK FACTORS**
- 5 times increased risk with affected first-degree relative
- Strong familial aggregation and >80% heritability
- Multiple gestation—200-fold increased risk if monozygotic twin diagnosed and 20-fold increased risk if dizygotic twin diagnosed
- Breastfeeding protective versus bottlefeeding where risk is increased
- Postnatal macrolide use (i.e., erythromycin, azithromycin)—erythromycin agonist of motilin which might cause continuous contraction of the pyloric muscle (1)[C]
- A recent surveillance study of a population-based birth defects registry identified association between pyloric stenosis and the use of fluoxetine in the 1st trimester, even after adjustment for maternal age and smoking. The adjusted odds ratio was 9.8 (95% CI 1.5–62) (2)[B].

**COMMONLY ASSOCIATED CONDITIONS**
Associated anomalies present in ~4–7% of infants with pyloric stenosis
- Hiatal and inguinal hernias (most commonly)
- Other anomalies include the following:
  - Congenital heart disease
  - Esophageal atresia
  - Tracheoesophageal fistula
  - Renal abnormalities
  - Turner syndrome and trisomy 18
  - Cornelia de Lange syndrome
  - Smith-Lemli-Opitz syndrome
- A common proposed genetic link between breast cancer, endometriosis, and pyloric stenosis has been observed in families.

**DIAGNOSIS**

**HISTORY**
- Nonbilious projectile vomiting after feeding, increasing in frequency and severity
- Emesis may become blood-tinged from vomiting-induced gastric irritation.
Hunger due to inadequate nutrition
Decrease in bowel movements
Weight loss

**PHYSICAL EXAM**
- Firm, mobile (“olivelike”) mass palpable in the right upper quadrant (historically 70–90% of the time)
- However, this finding has decreased in occurrence to about 13% due to earlier diagnosis with US (1)[C].
- Epigastric distention
- Visible gastric peristalsis after feeding
- Late signs: dehydration, weight loss
- Rarely, jaundice when starvation leads to decreased glucuronyl transferase activity resulting in indirect hyperbilirubinemia

**DIFFERENTIAL DIAGNOSIS**
- Inexperienced or inappropriate feeding
- GERD
- Gastritis
- Congenital adrenal hyperplasia, salt-wasting
- Pylorospasm
- Gastric volvulus
- Antral or gastric web

**DIAGNOSTIC TESTS & INTERPRETATION**
Metabolic disturbances are late findings and are uncommon in present era of early diagnosis and intervention.
- If prolonged vomiting, check electrolytes for the following:
  - Hypokalemia
  - Hypochloremia
  - Metabolic alkalosis
- Elevated unconjugated bilirubin level (rare)
- Paradoxical aciduria: The kidney tubules excrete hydrogen to preserve potassium in face of hypokalemic alkalosis.
- Abdominal US is the study of choice.
  - US shows thickened and elongated pyloric muscle and redundant mucosa.
  - Pathologic limits are 3-mm pyloric muscle thickness, 15-mm pyloric length, 11-mm pyloric diameter, and 12-mL pyloric volume with muscle
thickness being the key factor. However, current studies are showing a correlation between pyloric muscle thickness being directly related to age and weight which should be taken into consideration in smaller, younger infants who do not meet current US criteria for IHPS but may still be diagnosed appropriately with IHPS by clinical symptoms (3)[B].

- Upper GI series reveal strong gastric contractions; elongated, narrow pyloric canal (string sign); and parallel lines of barium in the narrow channel (double-tract sign or railroad track sign).

**Test Interpretation**
Concentric hypertrophy of pyloric muscle

---

**TREATMENT**

**SURGERY/OTHER PROCEDURES**

- Ramstedt pyloromyotomy is curative. The entire length of hypertrophied muscle is divided, with preservation of the underlying mucosa.
- Surgical approaches include open (traditional right upper quadrant transverse) incision, more contemporary circumumbilical incision, and laparoscopic techniques.
- Recent reviews have concluded that the laparoscopic approach results in less postoperative pain, shorter hospital stays, shorter postoperative recovery, lower complication rates, improved cosmesis, and can be performed with no increase in operative time or complications (4)[A],[5][B].
- Conservative approach
  - Conservative management of IHPS with atropine can be effective in approximately six out of seven cases but has a lower success rate and longer duration of therapy than surgery (6)[B].
  - Atropine therapy may be considered as an alternative to pyloromyotomy for patients unsuitable or at high risk for surgery and in areas of the world where surgery on small infants is unavailable or unsafe (6)[B].

---

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Prompt treatment to avoid dehydration and malnutrition
- Correct acid–base and electrolyte disturbances. Surgery should be delayed until alkalosis is corrected.
- Patients need pre- and postoperative apnea monitoring due to a tendency toward apnea to compensate with respiratory acidosis for their metabolic alkalosis.
- IV fluids to correct dehydration and metabolic abnormalities. For optimal resuscitation in infants, use D5 1/2NS with 20 mEq of KCl (1)[C].

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Routine pediatric health maintenance
- Postoperative monitoring, including monitoring for pain, emesis, apnea
- If significant emesis present after 1 to 2 weeks, then upper GI studies needed to rule out incomplete pyloromyotomy or duodenal leak (1)[C]

**DIET**
- No preoperative feeding
- Adlib feedings are recommended after pyloromyotomy which can decrease length of stay versus structured feedings. However, if a provider prefers structured feedings, a rapid feeding regimen is recommended although increased emesis will likely occur but with no negative outcomes reported. Timing of first feed is not significant, but early feeding is associated with increased potential for emesis (7)[A].

**PROGNOSIS**
Surgery is curative.

**COMPlications**
- No long-term morbidity
- Incomplete pyloromyotomy
- Mucosal perforation
- Wound infections
- Delayed feeding due to postoperative vomiting
- Serosal tear
- Subcutaneous emphysema
- 4.6–12% complication rate (3)[C]
REFERENCES

ADDITIONAL READING

- Georgoula C, Gardiner M. Pyloric stenosis a 100 years after Ramstedt. *Arch

**CODES**

**ICD10**

Q40.0 Congenital hypertrophic pyloric stenosis

**CLINICAL PEARLS**

- Pyloric stenosis is the most common condition requiring surgical intervention in the 1st year of life.
- The condition classically presents between 1 and 5 months of life, with projectile vomiting after feeds and a firm, mobile mass in the right upper quadrant.
- Abdominal US is the study of choice.
- Surgery (laparoscopic Ramstedt pyloromyotomy is the preferred method) is curative.
RABIES

Alan M. Ehrlich, MD

BASICS

DESCRIPTION
- A rapidly progressive CNS infection caused by a ribonucleic acid (RNA) rhabdovirus affecting mammals, including humans
- Generally considered to be 100% fatal once symptoms develop
- System(s) affected: nervous
- Synonym(s): hydrophobia (inability to swallow water)

EPIDEMIOLOGY

Incidence
- Most cases are in developing countries.
- Estimated 55,000 deaths worldwide per year
- Typically only 1 to 3 cases per year in the United States, with 1/3 of those being due to exposure outside of the United States
- Predominant age: any
- Predominant sex: male = female

ETIOLOGY AND PATHOPHYSIOLOGY

Lyssavirus, an RNA virus in the family Rhabdoviridae
- Rabies virus is a neurotropic virus present in saliva of infected animals.
- Transmission occurs via bites from infected animals or when saliva from an infected animal comes in contact with an open wound or mucous membranes.
- Bats are most common reservoir in the United States.

RISK FACTORS
- Professions or activities with exposure to potentially infected (wild or domestic) animals (e.g., animal handlers, lab workers, veterinarians, cave explorers)
- Most U.S. cases are associated with bat exposure.
- Internationally, rabies is widespread in both domestic and feral dogs.
- Human-to-human transmission has occurred through transplantation of
cornea, solid organs, and other tissues.
- Travel to countries where canine rabies is endemic.

**GENERAL PREVENTION**
- Preexposure vaccination for high-risk groups (veterinarians, animal handlers, and certain laboratory workers)
- Consider preexposure vaccination for travelers to areas (such as North Africa) that have increased risk of rabies from domestic animals.
- Immunization of dogs and cats
- Contact animal control and avoid approaching or handling wild (or domestic) animals exhibiting strange behaviors.
- Avoid wild and unknown domestic animals.
- Seek treatment promptly if bitten, scratched, or in contact with saliva from potentially infected animal.
- Prevent infection by prompt postexposure treatment.
- Consider postexposure prophylaxis for individuals in direct contact with bats, unless it is known that an exposure did not occur.
- Hospital contacts of patients infected with rabies do not require postexposure prophylaxis unless there has been exposure through mucous membranes or an open wound (including a bite) to saliva, CSF, or brain tissue from the infected patient.

**DIAGNOSIS**

**HISTORY**
- History of animal exposure
- Most patients do not recall exposure.
- Five stages (may overlap)
  - Incubation period: time between bite and first symptoms; usually 10 days to 1 year (average of 20 to 60 days). Incubation is shortest in patients with extensive bites in the head or trunk.
  - Prodrome: lasts 1 to 14 days; symptoms include pain or paresthesia at bite site and nonspecific flulike symptoms, including fever and headache.
  - Acute neurologic period: lasts 2 to 10 days. CNS symptoms dominate; generally 1 of 2 forms: (i) furious rabies: brief (~5 minute) episodes of hyperactivity with hydrophobia, aerophobia, hyperventilation, hypersalivation, and autonomic instability; (ii) paralytic rabies: Paralysis
dominates; may be ascending (as in Guillain-Barré syndrome) or may affect ≥1 limbs differentially
– Coma: lasts hours to days; may evolve over several days following acute neurologic period; may be sudden, with respiratory arrest
– Death: usually occurs within 3 weeks of onset as result of complications

PHYSICAL EXAM
Findings range from normal exam to severe neurologic findings, including paralysis and coma, depending on the stage of rabies at the time of presentation.

DIFFERENTIAL DIAGNOSIS
● Any rapidly progressive encephalitis; important to exclude treatable causes of encephalitis, especially herpes
● Transverse myelitis

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
● Lumbar puncture. WBC count is normal or shows moderate pleocytosis; protein normal or moderately elevated
● Skin biopsy to detect rabies antigen in hair follicles
  – Available through state and federal reference labs
● Rabies antibody titer of serum and CSF
● Skin biopsy from nape of neck for direct fluorescent antibody examination
● Viral isolation from saliva or CSF
● Corneal smear stains are positive by immunofluorescence in 50% of patients.
● Hyponatremia is common.
● Head CT scan: normal or nonspecific findings consistent with encephalitis
● MRI can help rule out other forms of encephalitis.

Follow-Up Tests & Special Considerations
Submit brain of the biting animal for testing if possible.

Test Interpretation
Encephalitis may be found on brain biopsy. Other abnormal findings (e.g., brainstem, midbrain, cerebellum) often found only postmortem.
TREATMENT

Thorough wound cleansing with soap and water is first line of treatment. Irrigate wound with virucidal agent, such as povidone-iodine, if available.

GENERAL MEASURES

- Evaluate risk based on exposure and consult public health officials about the need for rabies prophylaxis.
- In the United States, raccoons, skunks, bats, foxes, and coyotes are the animals most likely to be infected. Any carnivore can carry the disease.
- Before initiating antirabies treatment, consider:
  - Type of exposure (bite or nonbite)
  - Epidemiology of rabies in species involved
  - Circumstances surrounding exposure (provoked vs. unprovoked bite)
  - Vaccination status of offending animal

MEDICATION

ALERT

- Immunosuppression alters immunity after vaccination. Immunosuppressive drugs should be avoided during postexposure prophylaxis if possible. If postexposure prophylaxis is given to an immunosuppressed patient, check serum samples for the presence of rabies virus–neutralizing antibody to assess response to vaccination (1)[C].
- Clean wounds thoroughly, regardless of postexposure prophylaxis status.
- Assess need for postexposure prophylaxis based on circumstances of possible exposure.
- Increased risk:
  - Bites involving skin puncture are high risk; saliva exposure is a risk only if it comes in contact with an open wound or mucous membranes.
  - Wild or domestic animals unavailable for quarantine
  - Bat exposure
  - Hybrid animals of wild and domestic species (e.g., wolf-dog)
  - Unprovoked attack (Feeding a wild animal is considered a provoked attack.)
- Management:
  - Bites from cats, dogs, and ferrets that can be watched for 10 days do not require prophylaxis unless animal shows signs of illness.
– Skunks, foxes, bats, raccoons, and most carnivores are high risk, and prophylaxis should begin promptly unless animal can be captured and euthanized for pathologic evaluation.
– For rodents or livestock, consult local public health authorities before initiating prophylaxis.

○ Postexposure prophylaxis (2)[B]
  – Passive vaccination: rabies immunoglobulin (RIG, HyperRAB) 20 IU/kg administered once. Infiltrate RIG around the wound if possible. Administer remaining RIG IM. Do not administer RIG using the same syringe or into the same anatomic site as vaccine.
  – Active vaccination: rabies vaccine, human diploid cell vaccine (HDCV) or rabies vaccine adsorbed (RVA) or purified chick embryo cell vaccine IM in the deltoid. Give the first dose, 1 mL, as soon as possible after exposure. The day of the first dose is designated day 0. Give additional 1-mL doses on days 3, 7, and 14. If immunocompromised, give fifth dose on day 28. For children, use the anterolateral aspect of the thigh and avoid the gluteal area.

○ For previously vaccinated patients, administer an initial 1-mL IM dose of vaccine immediately and an additional 1-mL dose 3 days later. RIG is not necessary in these patients (2)[B].

○ Preexposure vaccination: for people in high-risk groups, such as veterinarians, animal handlers, certain laboratory workers, and those spending time in foreign countries where rabies is enzootic (3)[B]:
  – Primary preexposure: three IM 1-mL injections of HDCV or RVA in deltoid area on days 0, 7, and 21, or 28
  – Preexposure boosters: For people at risk of exposure to rabies, test serum every 2 years. Administer preexposure booster of 1-mL IM if immunity is waning. If titer cannot be obtained, a booster can be administered instead.

○ Contraindications: none for postexposure treatment

**Pregnancy Considerations**

– Pregnancy is not a contraindication to postexposure prophylaxis.
– Rabies vaccination is not associated with a higher incidence of spontaneous abortion, premature births, or fetal abnormalities.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

Clinical rabies
- Comfort care and sedation for all patients
- Milwaukee protocol: experimental treatment using ketamine, midazolam, and amantadine (originally included ribavirin but no longer recommended) (1,4) [C]. One patient who did not receive pre- or postexposure prophylaxis recovered from clinical rabies in 2004 after being treated with medically induced coma and amantadine l (1)[C].
- Control cerebral artery vasospasm (with an agent such as nimodipine) (4,5) [C].
- Fludrocortisone and hypertonic saline if needed to maintain normal sodium level (5)[C]

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
After primary vaccination, serologic testing is necessary only if the patient has a disease or takes immunosuppressive medication.

PATIENT EDUCATION
Use screens over ventilation areas in the roof to secure from bats. Avoid exposure to wild mammalian species known to carry rabies and report potential exposures immediately.

PROGNOSIS
- No postexposure failures in the United States since the 1970s
- If untreated, rabies has the highest case fatality rate of any infectious disease; generally considered to be 100% fatal once symptoms develop
- There have only been a small number of cases of successful recovery from rabies. Almost all received some form of pre- or postexposure immunization.

COMPLICATIONS
0.6% of people develop mild serum sickness reaction following HDCV boosters. Mild local and systemic reactions are common following vaccination. Do not interrupt immunization series with mild reactions.

SEE ALSO
Bites, Animal and Human

CODES

ICD10
- A82.9 Rabies, unspecified
- Z20.3 Contact with and (suspected) exposure to rabies

CLINICAL PEARLS
- Rabies is rare in the United States but more common in other areas of the world.
- Seek immediate treatment if exposed to scratch, bite, or saliva of potentially infected animal (e.g., feral dog, bat, fox, raccoon, or other wild mammals).
- Postexposure prophylaxis consists of three steps: local wound cleansing, passive immunization with rabies immunoglobulin, and active immunization with HDCV.
- Consider postexposure prophylaxis for those reporting direct contact with bats, unless it can be verified that an exposure did not occur.
RAPE CRISIS SYNDROME
An-Hoa Giang, MD, MPH • Virginia J. Van Duyne, MD

BASICS
DESCRIPTION

- Definitions (legal definitions vary from state to state)
  - Sexual contact: intentional touching of a person’s intimate parts (including thighs) or the clothing covering such areas, if it is construed as being for the purpose of sexual gratification
  - Sexual conduct: vaginal intercourse between a male and female, or anal intercourse, fellatio, or cunnilingus between persons, regardless of sex
  - Rape (which is a legal term, physician should use the phrase “alleged sexual assault”): any sexual penetration, however slight, using force or coercion against the person’s will
  - Sexual imposition: similar to rape but without penetration or the use of force (i.e., nonconsensual sexual contact, stalking)
  - Gross sexual imposition: nonconsensual sexual contact with the use of force
  - Corruption of a minor: sexual conduct by an individual age ≥18 years with an individual <16 years of age

- Most states have expanded rape statutes to include marital rape, date rape, and shield laws.
- System(s) affected: nervous; reproductive; GI

EPIDEMIOLOGY

- In the United States, 25% of women and 7.6% of men report being target of the definition of rape crisis syndrome listed above. The cost of this is estimated to exceed $5.8 billion annually.
- Anyone can be sexually assaulted, but some populations are especially vulnerable.
  - Adolescents and young children
  - People with disabilities
  - Elderly
  - Low socioeconomic status and homeless people
  - Sex workers
  - Those living in institutions/areas of conflict
• Predominant age
  – The incidence of sexual assault peaks in those 16 to 19 years of age, with the mean occurring at 20 years of age.
    o Adolescent sexual assault has a greater frequency of anogenital injuries.
• Predominant sex: female > male
  – For males
    o 69% of male victims were first raped before age 18 years.
    o 41% of male victims were raped before age 12 years.

**Incidence**

• In the United States, approximately 1.5 million women and 834,700 men are sexually assaulted annually.
• Estimated that only a fraction of sexual assaults are reported to law enforcement.
• Almost 1 in 5 women (18%) in the United States have experienced rape or attempted rape.
  – 20–25% of undergraduate women indicated that they’ve been a victim of sexual violence since starting college.
• 2–3% of American men will be sexually assaulted during their lifetime.
• Most rape victims either know or have some acquaintance with their attacker.

**RISK FACTORS**

• Children living in household of sexual assault are in increased risk of maltreatment and lifelong poor health.
• Early sexual initiation
• Sexual risk-taking behavior
• Exposure to parental violence
• Alcohol consumption is estimated to be involved in 1/2 of sexual assault.
• Illicit drug may also contribute to sexual assault.

**GENERAL PREVENTION**

• Primary prevention: Evidence suggests that promotion of gender equality decreases sexual violence perpetration—strategies include mobilizing men and boys as allies and empowering/supporting girls and women through economic supports and increasing leadership opportunities.

• Secondary prevention: The USPSTF recommends screening women of childbearing age for intimate partner violence and refer women who screen positive to intervention services; HARK screening tool is 81% sensitive and
95% specific (1)[B].

- Tertiary prevention: Support survivors through victim-centered services (refer to patient education section) and medical treatment.

**DIAGNOSIS**

- In adults
  - History of sexual penetration
  - Sexual contact/conduct without consent and/or with the use of force
- In children
  - Actual observation/suspicion of sexual penetration, sexual contact, or sexual conduct
  - Signs include evidence of the use of force and/or evidence of sexual contact (e.g., presence of semen and/or blood).

**HISTORY**

- Note that some states require specific forms for documenting the history.
- Avoid questioning that implies the patient is at fault.
- Record answers in patient’s own words. Include date, approximate time, and general location.
- Document physical abuse other than sexual. Describe all types of sexual contact, whether actual/attempted.
- Take history of alcohol and/or drug use before or after alleged incident.
- Document time of last activity that could possibly alter specimens (e.g., bath, shower, douche).
- Thorough gynecologic history is mandatory, including last menstrual period, last consenting sexual contact, contraceptive practice, and prior gynecologic surgery.

**PHYSICAL EXAM**

- Note that some states require specific forms for documenting physical exam.
- Document all signs of trauma/unusual marks.
- Document mental status and emotional state.
- Use UV light (Wood lamp) to detect seminal stains on clothing/skin.
- Obtaining the patient’s consent at each step of examination helps the patient regain a sense of control.

**ALERT**
A forensic kit or “rape kit” contains swabs that are collected from the vagina and rectum, and instructions are given with the kit regarding proper collection.

Many states and emergency departments across the country are using a Sexual Assault Nurse Examiner (SANE) when available. This has led to more consistent and more accurate collection of evidence in alleged rape cases.

Complete genital–rectal exam, including evidence of trauma, secretions, or discharge.
- Use of a nonlubricated, water-moistened speculum is mandatory because commonly used lubricants may destroy evidence.
- Testing and/or specimen collection, as indicated, and in compliance with state requirements (2)

DIFFERENTIAL DIAGNOSIS
Consenting sex among adults

DIAGNOSTIC TESTS & INTERPRETATION
- In females, obtain a serum or urine pregnancy test.
- Record results of wet mount, screening for vaginitis, but also note the presence/absence of sperm and, if present, whether it is motile/immotile.
- Drug/alcohol testing as indicated by history and/or physical findings
- Diagnosis tests for STIs is indicated but not necessary for treatment; NAAT for chlamydia, gonorrhea, and trichomoniasis; HIV, HepB, and Syphilis testing

TREATMENT
GENERAL MEASURES
- Providing health care to victims of sexual assault/abuse requires special sensitivity and privacy.
- All such cases must be reported immediately to the appropriate law enforcement agency.
- With the victim’s permission, enlist the help of personnel from local support agencies (e.g., rape crisis center) and in-house social services.
- SANE programs have been shown to be beneficial, especially in large cities and metropolitan areas with multiple emergency departments of varying
capability and staff training/experience.
- Give sedation and tetanus prophylaxis when indicated.
- Discuss suspected STI exposure with the victim and test/treat in accordance with the hospital, regional, and state policies/protocols (see below for recommended guidelines of testing/treatment).
- Discuss possible pregnancy and pregnancy termination with the victim. If hospital policy precludes such as discussion, then information about this option should be offered to the victim via follow-up mechanisms.
- Evaluate for psychological sequelae and refer to treatment.

MEDICATION

First Line
- The Centers for Disease Control and Prevention (CDC) recommends empiric prophylaxis treatment of sexually transmitted infections (specifically, gonorrhea, chlamydia, trichomoniasis, bacterial vaginosis, HepB, and HPV), and recommends consideration of treatment for HIV and syphilis depending on level of risk (3). Empiric treatment of these STI's is based on the finding that sexual assault victims have poor follow-up compliance.
- Cultures are not required before initiating treatment but can be considered as part of routine evidence collection.
- Gonorrhea: ceftriaxone 250 mg IM once
- Chlamydia: azithromycin 1 g PO single dose, or doxycycline 100 mg PO BID for 7 days
- Trichomoniasis and bacterial vaginosis: metronidazole 2 g PO once
- HIV: There is a low likelihood of HIV transmittance, but nonoccupational postexposure prophylaxis (nPEP) for victims of sexual assault is recommended for patients evaluated to be at high risk (HIV status of assailant is known, method of penetration, IVDU status of assailant).
  - 28-day starter pack is recommended over the 3- to 7-day pack as it’s been shown to increase likelihood of adherence and due to concerns of patient inability to keep 1-week follow-up appointment (4).
  - Most effective if started within 4 hours and could reduce transmission by as much as 80%; unlikely to be beneficial if started after 72 hours
- Hepatitis B: hepatitis B immunoglobulin 0.06 mL/kg IM, single dose, and initiate 3-dose hepatitis B virus immunization series; no treatment if the victim has had a complete hepatitis B vaccine series, with documented levels of immunity
- HPV vaccination is recommended for women who have been sexually
assaulted from age 9 to 26 years and for males age 9 to 21 years.

- There is no evidence for empiric treatment of syphilis; however, screening with serology tests (nontreponemal and treponemal) is recommended.

SSRIs are the first-line treatment for posttraumatic stress disorder (PTSD), one of the most common sequelae of sexual assault (5)[A].

**Second Line**

**Pregnancy Considerations**

Conduct baseline pregnancy test; discuss pregnancy prevention and termination with patient (6)[A].

- Ulipristal acetate is more effective than levonorgestrel-only, effective for up to 5 days.
- Levonorgestrel-only regimen is more effective than combined hormonal regimen, less nausea/vomiting side effects.
- Copper IUD is the most effective emergency contraceptive method.

**Pediatric Considerations**

Assure the child that she or he is a good person and was not the cause of the incident.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Contact appropriate social services agency.
- Most adult victims can be treated as outpatients, unless associated trauma (physical/mental) requires admission.
- Most pediatric sexual assault/abuse victims will require admission/outside placement until appropriate social agency can evaluate home environment.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Patient should be seen in 7 to 10 days for follow-up care, including pregnancy testing and counseling.
- Close exam for vaginitis and treatment if necessary.
Follow-up test for gonorrhea should occur in 1 to 2 weeks.
Follow-up testing for syphilis and HIV should occur at 6 weeks, 3 months, and 6 months.
Follow-up evaluation for HPV anogenital warts should occur 1 to 2 months after the assault.
Provide telephone numbers of counseling agencies that can give counseling/legal services to the patient.
Use SANE, if available.

PATIENT EDUCATION
- Local rape crisis support organizations
- National Sexual Violence Resource Center, 123 Enola Drive, Enola, PA 17025; (877) 739-3895; www.nsvrc.org
- National Domestic Violence Hotline at (800) 799-SAFE (7233) or TTY (800) 787-3224 or www.thehotline.org
- National Sexual Assault Hotline: (800) 656-HOPE (4673)

PROGNOSIS
- Acute phase (usually 1 to 3 weeks following rape): shaking, pain, wound healing, mood swings, appetite loss, crying, feelings of grief, shame, anger, fear, revenge, or guilt
- Late/chronic phase (also called “reorganization”): Female victim may develop fear of intercourse, fear of men, anxiety or increase discomfort during Pap smears, nightmares, sleep disorders, daytime flashbacks, fear of being alone, loss of self-esteem, anxiety, depression, posttraumatic stress syndrome, and somatic complaints (e.g., nonspecific abdominal pain).
- Recovery may be prolonged. Patients who talk about their feelings seem to have a faster recovery. It is unclear if pharmaco- or psychotherapy results in better outcomes.

COMPLICATIONS
Sequelae include the following:
- Trauma (physical and/or mental)
- STIs, including HIV
- Unwanted pregnancy
  - In the United States, rape-related pregnancy accounts for >32,000 unwanted pregnancies each year.
  - Adolescents are at highest risk of pregnancy.
Medical: chronic pain, fibromyalgia, headaches, irritable bowel syndrome, sexual dysfunction
Psychological: anxiety, depression, PTSD, eating disorder, substance abuse
Sexual assault is the most common type of trauma in women with PTSD. Of women with PTSD, 32% had been raped and 31% had experienced sexual assault.

CODES

ICD10
- T74.21XA Adult sexual abuse, confirmed, initial encounter
- T74.22XA Child sexual abuse, confirmed, initial encounter
- Z04.41 Encounter for exam and obs following alleged adult rape

CLINICAL PEARLS
- Rape is a legal term; the examining physician is encouraged to use terminology such as alleged rape or alleged sexual conduct.
- Use of a protocol is encouraged to assure every victim a uniform, comprehensive evaluation, regardless of the expertise of the examiner. The protocol must ensure that all evidence is properly collected and labeled; chain of custody is maintained, and evidence is sent to the appropriate forensic laboratory.
- Medical personnel must be willing and able to testify on behalf of the patient.
- Treatment of patients undergoing a rape crisis includes prophylactic treatment of STIs, pregnancy testing and discussion of termination options, pharmacotherapy/psychotherapy for psychological sequelae (anxiety, depression, PTSD), and providing patients with support lines/organizations.
RAYNAUD PHENOMENON

Kelsey E. Phelps, MD

BASICS

DESCRIPTION

• Idiopathic intermittent episodes of vasoconstriction of digital arteries, precapillary arterioles, and cutaneous arteriovenous shunts in response to cold, emotional stress, or blunt trauma
  – A triphasic color change of the fingers (occasionally the toes, rarely nipples) is the principal physical manifestation.
    o The initial color is white from extreme pallor, then blue from cyanosis, and finally with warming/vasodilatation, the skin appears red.
    o Thumbs are rarely involved.
  – Swelling, throbbing, and paresthesias are associated symptoms.
  – Primary
    o 80% of patients have primary disease.
    o Episodes are bilateral and nonprogressive.
    o Diagnosis confirmed if after 2 years of symptoms, no underlying connective tissue disease develops.
  – Secondary
    o Progressive and asymmetric
      o Vascular spasm is more frequent and more severe over time. Ulceration is rare; gangrene does not develop; 13% progress to digital fat pad atrophy and ischemic fingertip changes.
      o Typically associated with an underlying connective tissue disorder
• System(s) affected: hematologic, lymphatic, immunologic, musculoskeletal, dermatologic, exocrine

Pregnancy Considerations

• Raynaud phenomenon can appear as breast pain in lactating women (1).
• Positive breast milk bacterial culture distinguishes mastitis from Raynaud phenomenon.

Geriatric Considerations

Initial appearance of Raynaud phenomenon after age 40 years often indicates
underlying connective tissue disease.

**Pediatric Considerations**
Associated with systemic lupus erythematosus (SLE) and scleroderma

**EPIDEMIOLOGY**

**Incidence**
- Primary
  - Predominant age: 14 years; ~1/4 begin >40 years
  - Predominant sex: female > male (4:1)
- Secondary
  - Predominant age: >40 years
  - Predominant sex: no gender predilection

**Prevalence**
- Primary: 3–12.5% of men; 6–20% of women (based on clinical history)
- Secondary: ~1% of population

**ETIOLOGY AND PATHOPHYSIOLOGY**
Unknown. Dysregulation of vascular control mechanisms leads to imbalance between vasodilation and vasoconstriction. There is a reduced endothelin-dependent vasodilation activity and an increased vasoconstriction in peripheral vessels by overproduction of endothelin-1. 5-HT₂ serotonin receptors may be involved in secondary Raynaud phenomenon. Platelet and blood viscosity abnormalities in secondary disease contribute to ischemic pathology.

**Genetics**
Some studies suggest dominant inheritance pattern. ~1/4 of primary patients have a first-degree relative with Raynaud phenomenon.

**RISK FACTORS**
- Existing autoimmune or connective tissue disorder
- End-stage renal disease with hemodialysis may increase risk if a steal phenomenon associated with the arterial-venous shunt develops.
- Primary and secondary disease associated with elevated homocysteine levels
- Smoking is not associated with increased risk of Raynaud phenomenon but may worsen symptoms.
GENERAL PREVENTION

- Avoid cold exposure.
- Tobacco cessation
- No relationship has been established between Raynaud phenomenon and vibratory tool use.

COMMONLY ASSOCIATED CONDITIONS

Secondary Raynaud

- Scleroderma; SLE; polymyositis
- Sjögren syndrome; occlusive vascular disease
- Cryoglobulinemia

DIAGNOSIS

HISTORY

Primary
- Symmetric attacks involving fingers
- Family history of connective tissue disorder
- Absence of tissue necrosis, ulceration, or gangrene
- If after ≥2 years of symptoms, no abnormal clinical or laboratory signs have developed, secondary disease is highly unlikely.

Secondary
- Onset typically after 40 years of age
- Asymmetric episodes more intense and painful
- Arthritis, myalgias, fever, dry eyes and/or mouth, rash, or cardiopulmonary symptoms
- History of medication and/or recreational drug use
- Exposure to toxic agents
- Repetitive trauma

PHYSICAL EXAM

Pallor (whiteness) of fingertips with cold exposure, then cyanosis (blue) and then redness and pain with warming

- Ischemic attacks evidenced by demarcated or cyanotic skin limited to digits; usually starts on one digit and spreads symmetrically to remaining fingers of both hands. The thumb is typically spared.
Rarely involves other tissues (e.g., tongue) (2)

Beau lines: transverse linear depressions in nail plate on most or all fingernails that occurs after exposure to cold or any insult that disrupts normal nail growth

Livedo reticularis: mottling of the skin of the arms and legs; benign and reverses with warming

Primary
  – Normal physical exam
  – Nail bed capillaries have normal appearance: Place 1 drop of grade B immersion oil on skin at base of fingernail and view capillaries with handheld ophthalmoscope at 10 to 40 diopters.

Secondary
  – Skin changes, arthritis, and abnormal lung findings suggest connective tissue disease.
  – Ischemic skin lesions: ulceration of finger pads (autoamputation in severe, prolonged cases)
  – Nail bed capillary distortion including giant loops, avascular areas, and increased tortuosity
  – Abnormal Allen test: conducted by having the patient open and close his or her hand several times and then squeezing his or her hand tightly into a fist. The examiner sequentially occludes the ulnar and radial arteries while the patient opens his or her hand to reveal the return of color as a measure of circulation.

DIFFERENTIAL DIAGNOSIS

- Thromboangiitis obliterans (Buerger disease): primarily affects men; smoking-related
- Rheumatoid arthritis (RA)
- Progressive systemic sclerosis (scleroderma): Raynaud phenomenon precedes other symptoms.
- SLE
- Carpal tunnel syndrome; thoracic outlet syndrome
- Hypothyroidism
- CREST syndrome (calcinosis cutis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, and telangiectasias)
- Cryoglobulinemia; Waldenström macroglobulinemia
- Acrocyanosis
- Polycythemia
- Occupational (e.g., especially from vibrating tools, masonry work, exposure to
polyvinyl chloride

Drug-induced (e.g., clonidine, ergotamine, methysergide, amphetamines, bromocriptine, bleomycin, vinblastine, cisplatin, cyclosporine)

**DIAGNOSTIC TESTS & INTERPRETATION**

Provocative test (e.g., ice water immersion) unnecessary

- Primary
  - Antinuclear antibody: negative
  - ESR: normal

- Secondary
  - Tests for secondary causes (e.g., CBC, ESR)
  - Positive autoantibody has low positive predictive value for connective tissue disease (30%).
  - Antibodies to specific autoantigens (e.g., scleroderma with anticentromere or anti-topoisomerase antibodies)
  - Videocapillaroscopy is gold standard (200 times magnification).

**Follow-Up Tests & Special Considerations**

Periodic assessments for a connective tissue disorder

**Diagnostic Procedures/Other**

Diagnosis is determined by history and physical exam.

**TREATMENT**

Assess using a Raynaud Condition Score.

**GENERAL MEASURES**

- Dress warmly, wear gloves, and avoid cold temperatures.
- During attacks, rotate the arms in a windmill pattern or placing the hands under warm water or in a warm body fold to alleviate symptoms.
- Tobacco cessation
- Avoid β-blockers, amphetamines, ergot alkaloids, and sumatriptan.
- Temperature-related biofeedback may help patients increase hand temperature. 1-year follow-up is no better than control.
- Finger guards to protect ulcerated fingertips
**MEDICATION**

**First Line**
- Calcium channel blockers (CCBs). Nifedipine is the best studied and most frequently used.
- Nifedipine: 30 to 180 mg/day (sustained-release form); seasonal (winter) use is effective with up to 75% of patients experiencing improvement.
- Is compatible with breastfeeding
- Contraindications: allergy to drug, pregnancy, CHF
- Precautions: may cause headache, dizziness, lightheadedness, edema, or hypotension
- Significant possible interactions
  - Increases serum level of digoxin

**Second Line**
- Amlodipine (5 to 10 mg/day) and nicardipine are effective and may have fewer adverse effects.
- No data exist to support switching CCB if initial drug is ineffective.
- Small studies support benefit from losartan and fluoxetine.
- Phosphodiesterase type-5 inhibitors (sildenafil, vardenafil) may reduce symptoms without increasing blood flow.
- Parenteral iloprost, a prostacyclin, in low doses (0.5 ng/kg/min over 6 hours), has improved ulcerations with severe Raynaud phenomenon when CCBs failed. Oral prostacyclin has not proven useful.
- Nitroglycerin patches may be helpful, but use is limited by the incidence of severe headache. Nitroglycerin gel has shown promise as a topical therapy.
- Prazosin (1 to 2 mg TID) is the only well-studied α₁-adrenergic receptor blocker with modest effect, but adverse effects may outweigh any benefit.
- ACE inhibitors are no longer recommended.

**ISSUES FOR REFERRAL**
If an underlying disease is suspected, consider rheumatology consultation for evaluation and treatment.

**ADDITIONAL THERAPIES**
- Botulinum toxin has shown some effect in reducing vasospastic episodes, frequency of attacks, rest pain, and helping to promote digital ulcer healing (3)[C].
Aspirin
Digital or wrist block with lidocaine or bupivacaine (without epinephrine) for pain control
Short-term anticoagulation with heparin if persistent critical ischemia, evidence of large-artery occlusive disease, or both

SURGERY/OTHER PROCEDURES
Surgical intervention is rarely indicated or used for Raynaud phenomenon. Effect of cervical sympathectomy is transient; symptoms return in 1 to 2 years. Digital fat grafting is a novel modality that has shown improved symptomatology and evidence of measurably increased perfusion in several cases; further study is needed (4)[C].

COMPLEMENTARY & ALTERNATIVE MEDICINE
- *Ginkgo biloba* may reduce the frequency of attacks.
  Well-designed studies have not been done yet (5)[B].
- Fish oil supplements may increase digital systolic pressure and time to onset of symptoms after exposure to cold; not proven in controlled trials
- Vitamin D supplementation led to improvement in self-reported symptoms in vitamin D–deficient patients with Raynaud phenomenon (6)[B].
- Evening primrose oil reduced severity of attacks in one study.
- Oral arginine is no better than placebo.
- Biofeedback is not helpful.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Avoid exposure to cold; reassess for secondary causes.

*Patient Monitoring*
Manage fingertip ulcers and rapidly treat infection.

DIET
No special diet
PATIENT EDUCATION

- Tobacco cessation.
- Avoid triggers (e.g., trauma, vibration, cold).
- Dress warmly; wear gloves.
- Warm hands when experiencing vasospasm.

PROGNOSIS

- Attacks may last from several minutes to a few hours.
- 2/3 of attacks resolve spontaneously.
- ~13% of Raynaud patients develop a secondary disorder, typically connective tissue diseases.

COMPLICATIONS

- Primary: very rare
- Secondary: gangrene, autoamputation of fingertips

REFERENCES

ADDITIONAL READING

- Herrick AL. Contemporary management of Raynaud’s phenomenon and

**SEE ALSO**

Algorithm: Raynaud Phenomenon

**CODES**

**ICD10**
- I73.00 Raynaud’s syndrome without gangrene
- I73.01 Raynaud’s syndrome with gangrene

**CLINICAL PEARLS**

- Raynaud phenomenon is a clinical diagnosis.
- Provocative testing is not recommended.
- Initial presentation of Raynaud phenomenon after age 40 years suggests underlying (secondary) disease.
- Raynaud phenomenon is a cause of breast pain in lactating women.
- Primary Raynaud phenomenon is symmetric; secondary Raynaud phenomenon is asymmetric.
- Primary Raynaud phenomenon is treated with handwarming and avoiding cold exposure.
- Digital ulcers are not normal and always merit a workup for secondary disease.
- Acute digital ischemia is a medical emergency.
REACTIVE ARTHRITIS (REITER SYNDROME)

Douglas W. MacPherson, MD, MSc–CTM, FRCPC

BASICS

Reiter syndrome is a seronegative, multisystem, inflammatory disorder classically involving joints, the eye, and the lower genitourinary (GU) tract. Axial joint (e.g., spine, sacroiliac joints) and dermatologic manifestations are common (1).[C]

DESCRIPTION

The classic triad includes arthritis, conjunctivitis/iritis, and either urethritis or cervicitis (‘can’t see; can’t pee; can’t bend my knee’).

- The epidemiology is similar to other reactive arthritides, characterized by sterile joint inflammation associated with infections originating at nonarticular sites. A fourth feature (dermatologic involvement) may include buccal ulceration, balanitis, or a psoriasiform skin eruption. (Having only two features does not rule out the diagnosis.)

- Two forms of Reiter syndrome:
  - Sexually transmitted: Symptoms emerge 7 to 14 days after exposure to *Chlamydia trachomatis* and other sexually acquired pathogens.
  - Postenteric infection (including traveler’s diarrhea)

- In individuals with new or frequent sexual partners, the triggering infection is likely sexually transmitted (rather than enteric).

- In individuals with a history of recent enteric illness, the triggering event is more likely to be a bacterial enteric infection than sexual transmission.

- System(s) affected: musculoskeletal, renal/urologic, dermatologic/exocrine

- Synonym(s): idiopathic blennorrheal arthritis; arthritis urethritica; urethroc-oculo-synovial syndrome; Fiessinger-Leroy-Reiter disease; reactive arthritis

Pediatric Considerations

Juvenile rheumatoid arthritis (RA) has many of the same clinical features as Reiter syndrome.

Pregnancy Considerations
No special considerations; usual drug precautions

**EPIDEMIOLOGY**

**Incidence**
- Predominant age: 20 to 40 years
- Predominant sex: male > female
- 0.2–1% incidence after bacterial dysentery outbreaks
- Complicates 1–2% of nongonococcal urethritis cases

**ETIOLOGY AND PATHOPHYSIOLOGY**
- The pathophysiology of all the seronegative reactive arthritis syndromes and the immunologic role of infectious diseases as precipitants for clinical illness are incompletely understood.
- Avoiding precipitant infections and early management of multiorgan inflammation is important. Antibiotic treatment following onset of syndrome does not appear to benefit inflammatory joint, eye, or urinary tract symptoms.
- *C. trachomatis* is the most common sexually transmitted infection associated with Reiter syndrome.
- Dysentery-associated Reiter syndrome follows infection with *Shigella*, *Salmonella*, *Yersinia*, and *Campylobacter* spp. Enteric-associated Reiter syndrome is more common in women, children, and the elderly than the postvenereal form.

**Genetics**
HLA-B27 tissue antigen present in 60–80% of patients, suggesting a genetic predisposition

**RISK FACTORS**
- New or high-risk sexual contacts 7 to 14 days before the onset of clinical presentation; the primary infection may be subclinical and undiagnosed.
- Food poisoning or bacterial dysentery

**GENERAL PREVENTION**
- The immune-response characteristics of this syndrome make avoidance of infectious precipitants the most important general precaution (and potentially the most difficult to achieve).
- Safe sexual practices; proper food and water hygiene
COMMONLY ASSOCIATED CONDITIONS

- Enteric disease
  - Shigellosis; Salmonellosis; Campylobacteriosis
  - Enteric infection with *Yersinia* spp.
- Urogenital infection
  - *Chlamydia* urethritis/cervicitis (2)[C]
  - *Mycoplasma* or *Ureaplasma* spp.
- HIV/AIDS

DIAGNOSIS

- Clinical presentation with joint, eye, and GU inflammation ("classic triad") and negative serologic testing for rheumatoid factor
- Classic symptoms not always present
- HLA-B27 testing is not required for diagnosis.

HISTORY

The presence of the clinical syndrome plus

- Diarrhea, dysentery, urethritis, or genital discharge and appropriate exposure history
- Exposure risks, including travel or migration history and potential infectious exposure
- Arthritis associated with urethritis for >1 month (84% sensitive; 98% specific for diagnosis)
- Urethritis occurs 1 to 15 days after sexual exposure.
- Reiter syndrome onset within 10 to 30 days of either enteric infection or STI
- Mean duration of symptoms is 19 weeks.

PHYSICAL EXAM

- Musculoskeletal
  - Asymmetric arthritis (especially knees, ankles, and metatarsophalangeal joints)
  - Enthesopathy (inflammation at tendinous insertion into bone, such as plantar fasciitis, digital periostitis, and Achilles tendinitis)
  - Spondyloarthropathy (spine and sacroiliac joint involvement)
- Urogenital tract
  - Urethritis; prostatitis; cystitis (rare)
– Balanitis
– Cervicitis: usually asymptomatic

● Eye
  – Conjunctivitis of one or both eyes
  – Occasionally, scleritis, keratitis, and corneal ulceration
  – Rarely, uveitis and iritis

● Skin
  – Mucocutaneous lesions (small, painless superficial ulcers on oral mucosa, tongue, or glans penis)
  – Keratoderma blennorrhagica (hyperkeratotic skin lesions of palms and soles and around nails—can be mistaken for psoriasis)

● Cardiovascular: occasionally, pericarditis, murmur, conduction defects, and aortic incompetence

● Nervous system: rarely, peripheral neuropathy, cranial neuropathy, meningoencephalitis, and neuropsychiatric changes

● Constitutional
  – Fever, malaise, anorexia, and weight loss
  – Patient can appear seriously ill (e.g., fever, rigors, tachycardia, and exquisitely tender joints).

DIFFERENTIAL DIAGNOSIS

● RA
● Ankylosing spondylitis
● Arthritis associated with inflammatory bowel disease
● Psoriatic arthritis
● Juvenile RA
● Bacterial arthritis, including gonococcal

DIAGNOSTIC TESTS & INTERPRETATION

● Blood
  – Negative rheumatoid factor
  – Leukocyte count: 10,000 to 20,000 cells/mm³
  – Neutrophil predominance
  – Elevated ESR and/or CRP
  – Moderate normochromic anemia
  – Hypergammaglobulinemia

● Synovial fluid
  – Leukocyte count: 1,000 to 8,000 cells/mm³
– Bacterial culture negative

- Supportive tests
  – Cultures, antigens, or PCR positive for *C. trachomatis* or stool test positive for *Salmonella, Shigella, Yersinia,* or *Campylobacter* species
  – HIV serology positive (acute retroviral syndrome)
  – HLA-B27-positive (*not required for diagnosis*)
  – Drugs that may alter lab results: Antibiotics may affect isolation of the bacterial pathogens.
  – Rheumatoid factor is negative.

- X-ray
  – Periosteal proliferation, thickening
  – Articular bony spurs; erosions at articular margins
  – Residual joint destruction
  – Syndesmophytes (spine); sacroiliitis

**Diagnostic Procedures/Other**

HLA-B27 histocompatibility antigen: positive in 60–80% of cases in non–HIV-related Reiter syndrome; HLA testing is not required or recommended for diagnosis.

- Screen for STI if clinically indicated.
- Screening for enteric infections is rarely useful and generally not indicated.

**Test Interpretation**

- Seronegative spondyloarthropathy (similar to ankylosing spondylitis, enteric arthritis, and psoriatic arthritis)
- Villous formation within joints; hyperemia, and inflammation
- Prostatitis and seminal vesiculitis
- Skin biopsy similar to psoriasis

---

**TREATMENT**

**GENERAL MEASURES**

Treatment is determined by symptoms.

- Conjunctivitis does not require specific treatment.
- Iritis requires treatment.
- Mucocutaneous lesions do not require treatment.
- Physical therapy (PT) aids recovery.
• Arthritis may become prominent and disabling during the acute phase.

**MEDICATION**

**First Line**

• Symptomatic management: NSAIDs, including indomethacin, naproxen, and others; intra-articular or systemic corticosteroids for refractory arthritis and enteritis
  – Contraindications
    • GI bleeding
    • Peptic ulcer, gastritis, or ulcerative colitis
    • Renal insufficiency
  
• Specific treatment of isolated microorganism (3)[A]:
  – *C. trachomatis*: doxycycline 100 mg PO BID for 7 to 14 days (Note: All STIs should be treated whether associated with Reiter syndrome or not.)
  – *Salmonella, Shigella, Yersinia, and Campylobacter* infections: ciprofloxacin 500 mg PO BID for 5 to 10 days (Note: Emerging antimicrobial resistance may limit the effectiveness of ciprofloxacin. Antibiotic treatment does not reduce GI symptoms or duration of infection or prevent carrier state.)
  – Trials of antibiotic treatment for reactive arthritis have produced mixed results, rendering the efficacy of antibiotics uncertain.

• GI upset: antacids
• Iritis: intraocular steroids
• Keratitis: topical steroids

**Second Line**

• Aspirin or other NSAIDs
• Sulfasalazine is promising but not FDA-approved.
• Methotrexate or azathioprine in severe cases (experimental, not approved or known to be effective); immunosuppressive therapy is relatively contraindicated in HIV-related Reiter syndrome.
• Specialty consultation is recommended, particularly if considering immunomodulatory agents such as sulfasalazine, methotrexate, or azathioprine or for treatment with anti-TNF medications (etanercept and infliximab) which have shown benefit in isolated case reports.
• Role of antibiotics under investigation—currently unproven effectiveness in seronegative arthritides
• No published evidence supports the beneficial effect of antibiotics on the long-term outcome in patients with Reiter syndrome.
ISSUES FOR REFERRAL
Joint and eye complications; complex cases—consider consultation with rheumatology; ophthalmology

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Based on severity of disease and associated complications
- Inpatient care may be needed during acute phase.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Activity modification until joint inflammation subsides

Patient Monitoring
Monitor clinical response to anti-inflammatory drugs. Observe for complications, particularly with sulfasalazine and immunosuppressive drugs.

PATIENT EDUCATION
- Educate on risk factors for exposure and recurrence.
- Home PT
- National Institute of Arthritis and Musculoskeletal and Skin Diseases: http://www.niams.nih.gov/

PROGNOSIS
Prognosis is poor in cases involving the heel, eye, or heart.

COMPLICATIONS
- Chronic or recurrent disease in 5–50% of patients
- Ankylosing spondylitis develops in 30–50% of patients who test positive for HLA-B27 antigen.
- Urethral strictures
- Cataracts and blindness
- Aortic root necrosis

REFERENCES

ADDITIONAL READING

SEE ALSO

- Ankylosing Spondylitis; Arthritis, Psoriatic; Behçet Syndrome

CODES

**ICD10**
- M02.30 Reiter’s disease, unspecified site
- M02.39 Reiter’s disease, multiple sites
CLINICAL PEARLS

- Diagnosis of Reiter syndrome is based on the clinical presentation of the classic triad of joint, eye, and GU inflammation and negative serologic testing for rheumatoid factor (signs and symptoms may not all be present at the same time).
- Screen for STI (including HIV) if sexually acquired. Enteric studies are rarely clinically indicated.
- Refer patients with a chronic or recurrent course and those who have clinical complications.
RENAL TUBULAR ACIDOSIS
Jason Kurland, MD

BASICS

DESCRIPTION

- Renal tubular acidosis (RTA) is composed of a group of disorders characterized by an inability of the kidney to resorb bicarbonate/secrete hydrogen ions, resulting in normal anion gap metabolic acidosis. Renal function (glomerular filtration rate [GFR]) must be normal or near normal.
- Several types have been identified:
  - Type I (distal) RTA: inability of the distal tubule to acidify the urine due to impaired hydrogen ion secretion, increased back leak of secreted hydrogen ions, or impaired sodium reabsorption (interfering with the generation of negative luminal charge required for hydrogen/potassium secretion); urine pH >5.5
  - Type II (proximal) RTA: defect of the proximal tubule in bicarbonate (HCO₃⁻) reabsorption. Proximal tubular HCO₃⁻ reabsorption is absent; plasma HCO₃⁻ concentration stabilizes at 12 to 18 mEq/L due to compensatory distal HCO₃⁻ reabsorption; urine pH <5.5 unless plasma HCO₃⁻ brought above reabsorptive threshold
  - Type III RTA: extremely rare autosomal recessive syndrome due to carbonic anhydrase II deficiency; causes mixed type I and type II RTA, osteopetrosis, cerebral calcification, intellectual disability
  - Type IV RTA (hypoaldosteronism): due to aldosterone resistance/deficiency that results in hyperkalemia. Urine pH usually is <5.5.

EPIDEMIOLOGY

Incidence
- Predominant age: all ages
- Predominant sex: male > female (with regard to type II RTA with isolated defect in bicarbonate reabsorption)

ETIOLOGY AND PATHOPHYSIOLOGY

- Type I RTA
– Autoimmune diseases: Sjögren syndrome, rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), thyroiditis (1)
– Medications: amphotericin B, lithium, ifosfamide, foscarnet, amiloride, triamterene, trimethoprim, pentamidine
– Obstructive uropathy (hyperkalemic)
– Genetic: autosomal dominant, autosomal recessive associated with sensorineural deafness
– Sporadic
– Other familial disorders: Ehlers-Danlos syndrome, glycogenosis type III, Fabry disease, Wilson disease
– Hematologic diseases: sickle cell disease (hyperkalemic), hereditary elliptocytosis
– Toxins: toluene, glue
– Hypercalciuria, diseases causing nephrocalcinosis
– Vitamin D intoxication
– Medullary cystic disease
– Hypergammaglobulinemic syndrome
– Chronic pyelonephritis
– Chronic renal transplant rejection
– Leprosy
– Chronic active hepatitis, primary biliary cirrhosis
– Malnutrition

• Type II RTA
  – Multiple myeloma, other dysproteinemic states
  – Amyloidosis
  – Medications: acetazolamide, ifosfamide, tenofovir, sulfanilamide, outdated tetracycline, topiramate (2), aminoglycosides
  – Familial (cystinosis, tyrosinemia, hereditary fructose intolerance, galactosemia, glycogen storage disease type I, Wilson disease, Lowe syndrome, inherited carbonic anhydrase deficiency)
  – Sporadic
  – Heavy metal poisoning (e.g., cadmium, lead, mercury, copper)
  – Interstitial renal disease
  – Paroxysmal nocturnal hemoglobinuria
  – Defects in calcium metabolism (hyperparathyroidism)

• Type IV RTA
  – Medications: NSAIDs, ACE inhibitors, ARBs, heparin/low-molecular-weight heparin (hyperkalemia in 5–10% of patients), ketoconazole, calcineurin inhibitors (tacrolimus, cyclosporine)
– Diabetic nephropathy
– Tubulointerstitial nephropathies
– Primary adrenal insufficiency
– Markedly decreased distal Na\(^+\) delivery
– Pseudohypoaldosteronism (PHA) (end-organ resistance to aldosterone)
  o PHA type 1
  o PHA type 2 (Gordon syndrome)

**Genetics**

- **Type I RTA**: hereditary forms due to mutations affecting intercalated cells in collecting tubules (3). May occur in association with other genetic diseases (e.g., Ehlers-Danlos syndrome, hereditary elliptocytosis, or sickle cell nephropathy). The autosomal recessive form is associated with sensorineural deafness.
- **Type II RTA**: Autosomal dominant form is rare. Autosomal recessive form is associated with ophthalmologic abnormalities and mental retardation. Occurs in Fanconi syndrome, which is associated with several genetic diseases (e.g., cystinosis, Wilson disease, tyrosinemia, hereditary fructose intolerance, Lowe syndrome, galactosemia, glycogen storage disease, metachromatic leukodystrophy)
- **Type IV RTA**: Some cases are familial, such as PHA type I (autosomal dominant).

**GENERAL PREVENTION**

Careful use/avoidance of causative agents

**COMMONLY ASSOCIATED CONDITIONS**

- **Type I RTA** in children: hypercalciuria leading to rickets, nephrocalcinosis
- **Type I RTA** in adults: autoimmune diseases (Sjögren syndrome, RA, SLE), obstructive uropathy, hypercalciuria
- **Type II RTA**: Fanconi syndrome (generalized proximal tubular dysfunction resulting in glycosuria, aminoaciduria, hyperuricosuria, phosphaturia, bicarbonaturia)
- **Type II RTA** in adults: multiple myeloma, carbonic anhydrase inhibitors (acetazolamide) (4)
- **Type IV RTA**: diabetic nephropathy, solid-organ transplant (due to calcineurin inhibitors)
DIAGNOSIS

HISTORY
- Often asymptomatic (particularly type IV)
- In children: failure to thrive, rickets
- Anorexia, nausea/vomiting, constipation
- Weakness or polyuria (due to hypokalemia)
- Polydipsia
- Osteomalacia in adults

DIFFERENTIAL DIAGNOSIS
- Plasma anion gap should be normal. If not, evaluate for causes of anion-gap metabolic acidosis. (MUDPILES: methanol, uremia, diabetic ketoacidosis, propylene glycol/paraldehyde, iron/isoniazid ingestion, lactic acidosis, ethylene glycol, salicylates)
- Extrarenal HCO₃ losses
  - Diarrhea
  - Small bowel, pancreatic, or biliary fistulas
  - Urinary diversion (e.g., ureterosigmoidostomy, ileal conduit)
- Acidosis of chronic renal failure (develops when GFR ≤20 to 30 mL/min)
- Excessive administration of acid load via chloride salts- including dilutional acidosis via normal saline (NaCl, HCl, NH₄Cl, lysine HCl, CaCl₂, MgCl₂)

DIAGNOSTIC TESTS & INTERPRETATION
- Electrolytes reveal hyperchloremic metabolic acidosis.
- Plasma anion gap normal (anion gap = Na − [Cl + HCO₃]). Normal values (in mEq/L) depend on analyzer used: infants/children 5 to 15; adolescents/adults 4 to 12 (5); must increase calculated anion gap by 2.5 mEq/L for each 1 g/dL decrease in albumin <4 g/dL
- Plasma K⁺: Low in type I (if due to impaired distal H⁺ secretion/increased H⁺ back leak), type II; high in type IV, type I (if due to impaired distal Na⁺ reabsorption)
- Plasma HCO₃ (in untreated RTA): type I: <10 to 20 mEq/L; type II: 12 to 18 mEq/L (1); type IV: >17 mEq/L
- BUN/Cr normal or near normal (rules out renal failure as cause of acidosis)
- Urinalysis: Urine pH inappropriately alkaline (>5.5) despite metabolic acidosis in type I; also in type II if HCO₃ above reabsorptive threshold (12 to
18 mEq/L

- Urine culture: Rule out UTI with urea-splitting organism (may elevate pH) and chronic infection.
- Urine anion gap (UAG; urine [Na⁺ + K⁺] − Cl⁻ on a random specimen): reflects unmeasured urine anions, so inversely related to urine NH₄⁺ (or acid) excretion. Positive UAG in an acidemic patient indicates impaired renal acid excretion. Urine Na⁺ >25 mEq/L required for accurate interpretation of UAG. Results tend to be
  - Negative in HCO₃⁻ losses due to diarrhea, UTI caused by urea-splitting organisms, and other extrarenal causes of nonanion gap metabolic acidosis
  - Variable in type II RTA
  - Positive in type I RTA, type IV RTA
  - Positive in impaired acid excretion due to renal failure
- Urine calcium
  - High in type I
  - Typically normal in type II
- Drugs that may alter lab results
  - Diuretics
  - Sodium bicarbonate (and other alkali)
  - Cholestyramine

**Initial Tests (lab, imaging)**
Serum electrolytes; consider urinalysis, urine culture

**Diagnostic Procedures/Other**
- Helpful to measure urine pH on fresh sample with pH meter for increased accuracy instead of dipstick. Pour film of oil over urine to avoid loss of CO₂ if pH cannot be measured quickly.
- Urine NH₄⁺ excretion (anion gap only provides a qualitative estimate)
- Urinary acidification (impaired in type I RTA) can be assessed by oral administration of furosemide and fludrocortisone; patients with type I RTA unable to reduce urine pH to <5.3
- Fractional excretion of HCO₃⁻ >15% during HCO₃⁻ infusion (type II RTA) (1)

**Test Interpretation**
- Nephrocalcinosis
- Nephrolithiasis
Rickets
Osteomalacia, osteopenia
Findings of an underlying disease causing RTA

**TREATMENT**

**MEDICATION**

**First Line**

- Provide oral alkali to raise serum HCO₃⁻ to normal. Start at a low dose and increase until HCO₃⁻ is normal. Give as sodium bicarbonate (7.7 mEq NaHCO₃/650 mg tab), sodium citrate (oral solution, 1 mEq HCO₃⁻ equivalent/mL), sodium/potassium citrate (oral solution), or potassium citrate (tablet, powder, or oral solution: 2 mEq K/mL, 2 mEq HCO₃⁻/mL), depending on need for potassium.

- Type I RTA: Typical doses 1 to 2 mEq/kg/day (in adults), 3 to 4 mEq/kg/day (in children) HCO₃⁻ equivalent divided 3 to 4 times per day (require much higher doses if HCO₃⁻ wasting is present); may require K⁺ supplementation

- Type II RTA: Typical doses 10 to 15 mEq/kg/day HCO₃⁻ equivalent, divided 4 to 6 times per day. Very difficult to restore plasma HCO₃⁻ to normal, as renal HCO₃⁻ losses increase once plasma HCO₃⁻ is corrected above resorptive threshold. Exogenous HCO₃⁻ increases K⁺ losses, requiring supplemental K⁺. Often need supplemental PO₄³⁻ and vitamin D due to proximal PO₄³⁻ losses; may add thiazide diuretic to induce mild hypovolemia, which increases proximal Na⁺/HCO₃⁻ reabsorption

- Type IV RTA: Avoid inciting medications; restrict dietary K⁺. May augment K⁺ excretion with loop diuretic, thiazide diuretic, or Kayexalate. Correcting hyperkalemia increases activity of the urea cycle, augmenting renal ammoniagenesis and adding substrate for renal acid excretion. If necessary, 1 to 5 mEq/kg/day alkali divided 2 to 3 times per day. If mineralocorticoid deficiency, fludrocortisone: 0.1 to 0.3 mg/day

**Precautions**

- Sodium-containing compounds will increase urinary calcium excretion, potentially increasing the risk of nephrolithiasis.
- Mineralocorticoids and sodium-based alkali may lead to hypertension
and/or edema.
- Aluminum-containing medications (antacids, sucralfate) should be avoided if solutions containing citric acid are prescribed because citric acid increases aluminum absorption.
- Sodium bicarbonate may cause flatulence because CO$_2$ is formed, whereas citrate is metabolized to HCO$_3$ in the liver, avoiding gas production.

**Second Line**
Thiazide diuretics may be used as adjunctive therapy in type II RTA (after maximal alkali replacement) but are likely to further increase urinary K$^+$ losses.

**SURGERY/OTHER PROCEDURES**
If distal RTA is due to obstructive uropathy, surgical intervention may be required.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Generally managed as outpatient; inpatient if acidosis severe, patient unreliable, emesis persistent, or infant with severe failure to thrive

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
- Electrolytes 1 to 2 weeks following initiation of therapy, monthly until serum HCO$_3$ corrected to desired range, and then as clinically indicated
- Monitor underlying disease as indicated.
- Poor compliance common due to 3 to 6 times per day alkali dosing schedule

**DIET**
Varies based on serum K$^+$ level and volume status

**PATIENT EDUCATION**
- National Kidney & Urologic Diseases Information Clearinghouse, Box NKUDIC, Bethesda, MD 20893, 301-468-6345:
PROGNOSIS

- Depends on associated disease; otherwise, good with therapy
- Transient forms of all types of RTA may occur.

COMPlications

- Nephrocalcinosis, nephrolithiasis (type I)
- Hypercalciuria (type I)
- Hypokalemia (type I, type II if given bicarbonate)
- Hyperkalemia (type IV, some causes of type I)
- Osteomalacia (type II due to phosphate wasting), osteopenia (due to buffering of acid in bone)

REFERENCES

CODES

**ICD10**

N25.89 Oth disorders resulting from impaired renal tubular function

CLINICAL PEARLS

- Consider RTA in cases of normal anion gap metabolic acidosis with
normal/near-normal renal function.

- **Type I RTA:** urine pH >5.5 in setting of acidemia; positive urine anion gap; acidemia can be severe.

- **Type II RTA:** urine pH <5.5 unless HCO₃ raised above reabsorptive threshold (12 to 18 mEq/L)

- **Type IV RTA:** most common subtype; hyperkalemia; urine pH <5.5; acidemia usually mild

- **Treatment** includes avoidance of inciting causes, provision of oral alkali (HCO₃ or citrate), and measures to supplement (type II, many type I) or restrict (type IV) potassium.
RESPIRATORY DISTRESS SYNDROME, ACUTE (ARDS)
Ahmed Munir, MBBS • Carrie Valenta, MD, FACP • Robert W. Plambeck, MD

BASICS
DESCRIPTION
- Acute respiratory distress syndrome is defined as onset of acute hypoxemia within 7 days of known clinical insult or new or worsening respiratory symptoms. On imaging, it appears as bilateral opacities consistent with pulmonary edema not fully explained by effusions, lung collapse or nodules. The respiratory failure is not explained by cardiac failure or fluid overload.
- Severity of ARDS depends on oxygenation of the blood. It is measured with ratio of partial pressure of arterial oxygen (PaO₂) to fraction of inspired oxygen (FiO₂) at positive end-expiratory pressure (PEEP) or continuous positive airway pressure (CPAP) of at least 5 centimeter of water (cm H₂O).
  - Mild—200 mm Hg < PaO₂/FiO₂ ≤300 millimeter of mercury (mm Hg)
  - Moderate—100 mm Hg < PaO₂/FiO₂ ≤200 mm Hg
  - Severe—PaO₂/FiO₂ ≤100 mm Hg
- Synonym(s): acute lung injury; increased-permeability pulmonary edema; noncardiac pulmonary edema
- Systems affected—pulmonary, cardiovascular

EPIDEMIOLOGY
Incidence
Incidence of ARDS is very variable. Highest incidence rate was in United States of 78.9 per 100,000 person-years.

ETIOLOGY AND PATHOPHYSIOLOGY
- ARDS is a response to an injury to lung which can be direct or indirect.
  - Direct
    o Aspiration of gastric contents
- Pneumonia (bacterial, viral, fungal or opportunistic infections)
- Air, fat, or amniotic fluid emboli
- Near-drowning
- Pulmonary contusion
- Inhalation injury
- Indirect
  - Sepsis (nonpulmonary source)
  - Shock
  - Transfusion
  - Major burn injury
  - Nonthoracic trauma
  - Drug overdose
  - Pancreatitis, severe
  - Cardiopulmonary bypass
  - Reperfusion edema after lung transplant or embolectomy
  - Eclampsia

- Progression of ARDS is divided into 3 phases.
  - Exudative phase—It is the initial phase where alveolar macrophages are activated in high inflammatory stage due to lung injury which leads to complement activation, release of pro-inflammatory mediators, and activation of neutrophils. It causes epithelial–endothelial barrier disruption, leading to intra-alveolar and extra-alveolar flooding with fluid. It is followed by hyaline membrane formation leading to alveolar collapse.
  - Proliferative phase—Fibroblasts, myofibroblasts, and alveolar epithelial cell (ACE) II mediate repair in this phase. Formation of new matrix, differentiation into ACE I, and formation of cellular junctions begin which leads to expression of aquaporin and ion channels. These help in reabsorption of fluid.
  - Fibrotic phase—not seen in everyone; related to prolonged mechanical ventilation and increased mortality.

**GENERAL PREVENTION**

Good ICU practices like low tidal volumes in all mechanically ventilated patients, early resuscitation and antibiotics for sepsis, restrictive use of blood products, and intensivist involvement may help prevent nosocomial ARDS.

**COMMONLY ASSOCIATED CONDITIONS**

Pneumonia, sepsis, and aspiration of gastric contents lead to 85% cases of ARDS.
DIAGNOSIS

HISTORY
Precipitating event (see “Etiology and Pathophysiology”) followed by abrupt onset of respiratory distress

PHYSICAL EXAM
- Tachypnea and tachycardia during the first 12 to 24 hours; increase in oxygen requirements
- Manifestations of underlying disease
- Decrease breath sound along with rales
- Absence of exam findings of cardiac failure

DIFFERENTIAL DIAGNOSIS
- Congestive heart failure
- Interstitial and airway diseases
- Hypersensitivity pneumonitis
- Endobronchial tuberculosis
- Diffuse alveolar hemorrhage
- Venoocclusive disease
- Mitral stenosis: intravascular volume overload
- Drug-induced lung disease especially vascular leak syndrome with immunotherapy

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Arterial blood gases (ABGs) show evidence of severe hypoxemia.
- ECG: sinus tachycardia; nonspecific ST-T–wave changes
- Chest x-ray (CXR): normal heart size; fluffy, bilateral infiltrates; air bronchograms common
- Chest CT scan: diffuse interstitial opacities

Follow-Up Tests & Special Considerations
- Serial blood gases and CXRs
- Decrease in oxygen requirements and improving respiratory status will indicate improvement.
- Different biomarkers are being studied to help identify subtypes of ARDS.

mebooksfree.com
future, they may be in use to help guide therapy.

**Diagnostic Procedures/Other**

- Invasive monitoring of pulmonary artery wedge pressure (PAWP) has fallen out of favor after clinical trials have shown no increased benefit and more catheter-related complication (1)[A].
- Measuring esophageal pressure with a manometer to estimate pleural pressure allows for adjustment of PEEP to achieve a positive end-expiratory transpulmonary pressure gradient, an approach that is increasingly used in clinical care and especially useful in the morbidly obese (2)[C].

**Test Interpretation**

With introduction of Berlin criteria, using ABG to calculate PaO₂/FiO₂ and if, it is <300 with radiologic evidence, after ruling out other causes of acute changes in respiratory status, we can diagnose ARDS.

---

**TREATMENT**

**GENERAL MEASURES**

- Identify the cause of ARDS and treat the cause.
- Central venous line and arterial line insertion
- Ventilatory support generally requires endotracheal intubation and use of PEEP with lung protective ventilation.
  - Using tidal volumes of 6 milliliter per kilogram (ml/kg) of predicted body weight have shown decrease in mortality in comparison to higher volumes. For plateau pressure, the aim is to keep it below 30 cm H₂O (3)[A].
  - Tidal volumes can be reduced to 4 ml/kg if plateau pressures exceed 30 cm H₂O (2)[A].
  - Respiratory rate can be set to maintain adequate minute ventilation. Permissive hypercapnia allowed so long as pH > 7.30 (3)[A]. Recent data supports lower respiratory rates (2)[C].
- No clear guideline for PEEP has been established. No clinical trial has shown consistent benefit of high PEEP. There is possible benefit of reduced mortality in subgroup of patients with moderate to severe ARDS with high PEEP (2) [C].
- In patients with early moderate-to-severe ARDS (PaO₂/FiO₂ <150 mm Hg),
use of neuromuscular blockade with sedation compared with placebo resulted in decrease in mortality. This possibly prevents breath stacking and patient-ventilator dyssynchrony and increase efficacy of lung protective ventilation (4)[A].

- Also in patients with moderate to severe ARDS (PaO₂/FiO₂ <150 mm Hg and PEEP >5 cm H₂O) who had been intubated for <36 hours, prone positioning has shown decrease in mortality and early extubation in comparison to supine. In prone positioning group, patients were placed in prone position for 16 consecutive hours/day for up to 28 days or until PaO₂/FiO₂ ratio of ≥150 mm Hg, with a PEEP of ≤10 cm H₂O and an FiO₂ of ≤0.6 for >4 hours while in the supine position. The benefit of prone position is due to reduction in deleterious effects of positive pressure ventilation on nondependent and less injured airspaces (5)[A].

**MEDICATION**

No single medication or combination of medications prevents or improves clinical outcomes in ARDS. Treatment is supportive while addressing the underlying cause.

**ISSUES FOR REFERRAL**

- All patients with ARDS should be cared for in an ICU with appropriately trained staff.
- Pregnant patients with ARDS also should be followed by a high-risk perinatologist or obstetrician.

**ADDITIONAL THERAPIES**

- For fluid management, central venous pressure (CVP) can be used to estimate fluid status. Liberal fluid management strategy targeting CVP of 10 to 14 cm H₂O was compared to conservative fluid management strategy targeting CVP of 4 cm H₂O. Conservation approach led to increased ventilator free days and decreased stay in ICU with no change in mortality (1)[A].
- High-frequency oscillation ventilation showed increased mortality in a clinical trial, although a meta-analysis suggested some benefit when patients with PaO₂/FiO₂ <60 mm Hg (2)[C].
- Airway pressure release ventilation may improve oxygenation but no mortality benefit (2)[C].
- Noninvasive ventilation in patients with severe hypoxemia may increase the
risk of ventilation-induced lung injury in ARDS (2)[C].

- Extracorporeal membrane oxygenation (ECMO) is reserved for severe ARDS after standard supportive measure have failed. One randomized controlled trial suggested improved mortality in properly selected individuals with ARDS referred to an ECMO center (2)[C].
- Corticosteroids may improve airway pressures, oxygenation, and especially in pneumonia, infiltrates on radiography, but there is not a consistent mortality benefit in ARDS. There is likely potential harm when started later in course after 14 days (2)[C].
- Inhaled nitric oxide, surfactant, statins, nonsteroidal anti-inflammatory agents, antioxidants, albuterol and neutrophil elastase inhibitor have not shown any benefit in clinical trials (2)[C].
- Clinical trials are underway for dexamethasone, vitamin D, aspirin, mesenchymal stem cells, and other therapies.
- Focus of research is now to identify different subtypes of ARDS and treat according to pathophysiology.

**Pregnancy Considerations**

Supportive care while identifying the underlying cause of ARDS continues to be important in the management of pregnant women with ARDS. However, fetal well-being, possible need for delivery, and physiologic changes associated with pregnancy must be considered.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

All patients with ARDS should be managed in an ICU setting.

- Lung protective ventilation while providing adequate PEEP
- Consider prone positioning and paralysis if PaO₂/FiO₂ <120 to 150 mm Hg.
- If failing initial supportive measures, consider early referral to an ECMO center.
- Monitoring blood gases especially after changing ventilator settings
- If perfusion is inadequate after restoration of intravascular volume (e.g., septic shock), vasopressor therapy is indicated.
- Early physical therapy
- Nursing may include any or all of the following:
  - Skin, eye, and mouth care
  - Deep vein thrombosis (DVT) prophylaxis
  - Stress ulcer prophylaxis
– Suctioning of endotracheal tube
– Adequate care while changing position of patient from supine to prone and vice versa
– Ensure adequate level of sedation and/or paralysis while on mechanical ventilation.
– Tracheostomy care
– Explain all procedures to patient and family; reduce anxiety.

- Discharge criteria
  – Resolution or improvement of underlying precipitant, improving respiratory status and return to baseline oxygen status
  – Nutrition counseling

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**

- Driving pressure and static lung compliance are important measures of lung mechanics.
- Daily labs are needed until the patient is no longer critical.
- Daily CXRs are not needed but should be ordered when evaluating for endotracheal tube placement, the presence of progressing infiltrates, catheter placement, and complications of mechanical ventilation (e.g., air leaks).

**DIET**

For nutrition, trophic and full-calorie enteral nutrition have shown no difference in mortality, whereas early parenteral nutrition might be harmful \(^2\)[C].

**PATIENT EDUCATION**

ARDS support center and brochure titled *Learn About ARDS*: [www.ards.org](http://www.ards.org)

**PROGNOSIS**

- Mortality rate is 40% with significant increase across the severity categories.
- Mortality is 34.9% in mild ARDS, 40.3% in moderate, and 46.1% in severe ARDS.

**COMPLICATIONS**
Following are short-term complications:
- Barotrauma
- Nosocomial infection
- Delirium
- Catheter-related infection
- DVT
- Gastrointestinal bleeding due to stress ulcer
- Poor nutrition
- Multiple organ dysfunction syndrome
- Death

ARDS can have long-term complications which is not dependent on severity of ARDS but on age and comorbidities of patients.

Following can be long-term sequelae:
- Pulmonary dysfunction
- Reduced health-related quality of life
- Reticular pattern/ground glass opacities on radiographic imaging
- Neuropsychological disability

REFERENCES

ADDITIONAL READING

**CODES**

**ICD10**

J80 Acute respiratory distress syndrome

**CLINICAL PEARLS**

- ARDS is onset of hypoxemia secondary to an injury to the lung which appears as bilateral infiltrates on imaging and divided in severity with measurement of \(\text{PaO}_2/\text{FiO}_2\).
- Treatment is treating the cause along with lung protective approach to mechanical ventilation.
- Low tidal volume (6 ml/kg with plateau pressure 30 cm H\(_2\)O), adequate PEEP and respiratory rate along with fluid conservative approach. Prone positioning and paralytics can be considered in \(\text{PaO}_2/\text{FiO}_2 <150\) mm Hg.
RESPIRATORY DISTRESS SYNDROME, NEONATAL

Mary Cataletto, MD, FAAP, FCCP • Margaret J. McCormick, MS, RN, CNE

BASICS

DESCRIPTION
- Neonatal respiratory distress syndrome (NRDS) is a disorder primarily of prematurity manifest by respiratory distress.
- System(s) affected: respiratory
- Synonym(s): hyaline membrane disease; surfactant deficiency

ALERT
A disorder of the neonatal period

EPIDEMIOLOGY

Incidence
- >90% incidence in infants born ≤28 weeks’ gestation
- Inversely proportional to gestational age
- Gender: slight male predominance
- Eighth leading cause of infant death in United States in 2013: 13.3 infant deaths per 100,000 live births (1)

ETIOLOGY AND PATHOPHYSIOLOGY
- Impaired surfactant synthesis and secretion
- High oxygen exposure and barotrauma can cause further damage to alveolar epithelium.

Genetics
No known genetic pattern

RISK FACTORS
- Premature birth
Infants of diabetic mothers
Perinatal asphyxia
History of RDS in a sibling

GENERAL PREVENTION
- Prevention of premature birth:
  - Education
  - Regular prenatal care
  - Management of maternal medical conditions
- Promote healthy behaviors during pregnancy focusing on:
  - Diet
  - Exercise
  - Avoidance of exposure to tobacco smoke, alcohol, and illegal drugs
- Antenatal corticosteroids for women at risk for premature birth between 24 and 33 6/7 weeks’ gestation including those with ruptured membranes and multiple gestations (2)[C]

DIAGNOSIS

HISTORY
- Preterm neonates with worsening respiratory distress beginning at or shortly after birth and progressing over first few hours of life
- Early interventions can modify classic course.

PHYSICAL EXAM
- Tachypnea
- Grunting
- Nasal flaring
- Subcostal and intercostal retractions
- Decreased breath sounds
- Cyanosis

DIFFERENTIAL DIAGNOSIS
- Bacterial pneumonia
- Transient tachypnea of newborn
- Interstitial lung disease
DIAGNOSTIC TESTS & INTERPRETATION
- Arterial blood gases (ABGs)
  - Evaluate for evidence of acid-base abnormalities, hypoxemia, and hypercarbia.
- Chest x-ray (CXR):
  - Diffuse reticulogranular pattern (ground-glass appearance)
  - Air bronchograms
  - Low lung volumes

Diagnostic Procedures/Other
- Complete blood count
- Blood culture
- Echocardiogram: Consider if murmur is present to evaluate for patent ductus arteriosus (PDA) and contribution to lung disease due to L → R shunting.
- Lung pathology (autopsy findings)
  - Macroscopically: uniformly ruddy, airless appearance of lungs
  - Microscopically: diffuse atelectasis and hyaline membranes (eosinophilic and fibrinous membrane lining air spaces)

TREATMENT
GENERAL MEASURES
- Supportive care:
  - Thermoneutral environment
  - Support ventilation and ensure adequate oxygenation (3)[C].
  - If no respiratory failure: early initiation of continuous positive airway pressure (CPAP) and consider surfactant therapy
- If respiratory failure: Intubate, ventilate as needed, and administer pulmonary surfactant.
  - Maintain adequate perfusion.
  - Optimize fluid and electrolyte balance (avoid overhydration).
  - Routine use of diuretics is not indicated.
  - Provide for nutritional needs.
  - Empiric antibiotic therapy with ampicillin and gentamycin pending evaluation of blood cultures
- Respiratory monitoring options
  - Noninvasive respiratory monitoring
o Transcutaneous monitor or end tidal CO₂ monitor
  o Pulse oximetry
  – Invasive respiratory monitoring
    o Umbilical artery catheter placement for ABG sampling
    o Direct sampling of ABGs

MEDICATION
• Pulmonary surfactant (4)[A]
  • Side effects: bradycardia, hypotension, airway obstruction/ endotracheal tube blockage with administration; rapid changes in tidal volume due to increased compliance can cause a pneumothorax and small risk of pulmonary hemorrhage.
  • Precautions: Transient adverse effects seen with the administration of surfactant may require stopping administration and alleviating situation; may proceed with dosing when stable
  • Contraindications: presence of congenital anomalies incompatible with life beyond neonatal period; infant with laboratory evidence of lung maturity

ISSUES FOR REFERRAL
Comorbid conditions associated with prematurity may require consultation during the course of the infant’s NICU admission, including PDA (cardiology consult), necrotizing enterocolitis (NEC) (gastroenterology), retinopathy of prematurity (ROP) (ophthalmology), and so forth.

ADDITIONAL THERAPIES
Treat associated problems of prematurity.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• All neonates with respiratory distress require immediate evaluation, monitoring, and treatment in the delivery room with transfer to a NICU.
  • Supportive care
    – Thermoneutral environment
    – Respiratory monitoring
    – Establish relationship with family to provide education and emotional support.
  • Discharge Criteria
    – Should have stable vital signs and pulse oximetry before discharge
– Medical home and support services should be in place.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Following discharge, infants should be followed closely by their physicians to monitor growth and respiratory symptomatology.

**DIET**
As clinically indicated

**PATIENT EDUCATION**
- Educate parents regarding the risks in subsequent pregnancies.
- Advise parents regarding potential issues with chronic lung disease.
- For patient education materials favorably reviewed on this topic, go to Boston Children’s Hospital Web site ([www.childrenshospital.org](http://www.childrenshospital.org)) and search for respiratory distress syndrome in the “My Child Has” window.

**PROGNOSIS**
- Prognosis and outcome are highly dependent on gestational age; significant neurodevelopmental delays in almost half infants ≤25 weeks’ gestation (5)
- Survival rare in infants <25 weeks’ gestation (6)

**COMPPLICATIONS**
- Complications specific to NRDS
  – Pneumothorax
  – Chronic lung disease, bronchopulmonary dysplasia (BPD)
  – Pulmonary interstitial edema (PIE)
- Additional complications may occur related to therapeutic interventions and comorbid conditions.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**

P22.0 Respiratory distress syndrome of newborn
CLINICAL PEARLS

- Early treatment with CPAP or pulmonary surfactant can modify clinical course.
- Prognosis and outcome are highly dependent on gestational age.
RESPIRATORY SYNCYTIAL VIRUS (RSV) INFECTION

Elizabeth C. McKeen, MD, FAAP

BASICS
Respiratory syncytial virus (RSV) is a medium-sized, membrane-bound ribonucleic acid (RNA) virus that causes acute respiratory tract illness in patients of all ages. The most clinically significant disease occurs in infants and children <3 years old.

DESCRIPTION
A major cause of upper respiratory tract (URT) or lower respiratory tract (LRT/bronchiolitis) illness
- In adults, RSV causes URT infections (URTIs).
- In infants and children, RSV causes URTIs and LRT infections (bronchiolitis and pneumonia-LRTI).

Pediatric Considerations
- 90–95% of children are infected by the age of 24 months; reinfection is common.
- Leading cause of pediatric bronchiolitis (50–90%)
- Premature infants are at increased risk for severe acute RSV infection.

EPIDEMIOLOGY
- Seasonality: Highest incidence of RSV in the United States occurs between December and March.
- Morbidity: RSV infection leads to over 100,000 annual hospitalizations.
- Mortality: Deaths associated with RSV are uncommon. Children with complex chronic conditions account for the majority of deaths, and the relative contribution of RSV infection to their deaths is unclear (1)[B].

ETIOLOGY AND PATHOPHYSIOLOGY
- RSV-induced bronchiolitis causes acute inflammation, edema, and necrosis of small airway epithelium, air trapping, bronchospasm, and increased mucus production.
RSV develops in the cytoplasm of infected cells and matures by budding from the plasma membrane.
Infection spreads through droplets, either airborne or personal contact, that inoculate the nose of a susceptible individual.

**Genetics**
- A genetic predisposition to severe RSV infections may be associated with polymorphisms in cytokine- and chemokine-related genes, including CCR5; IL4; and affiliated receptors, IL8, IL10, and IL13.
- Infants with transplacentally acquired antibody against RSV are not fully protected against infection but may have milder symptoms.

**RISK FACTORS**
- Risk factors for severe disease
  - Prematurity
  - Age <12 weeks
  - Underlying cardiopulmonary disease
  - Immunodeficiency
- Other risk factors
  - Low socioeconomic status
  - Exposure to environmental air pollutants
  - Child care attendance
  - Severe neuromuscular disease
  - Adults: occupational exposure to young children, hospital staff, teachers, and daycare workers

**GENERAL PREVENTION**
- Hand hygiene is the most important step to prevent the spread of RSV.
  - Alcohol-based rubs are preferred. Hand washing with soap and water is acceptable but less effective (2)[B].
- Avoid passive smoke exposure, especially in infants and children (3)[A].
- Isolate patients with proven or suspected RSV.
- Palivizumab (Synagis) is a monoclonal antibody directed against the fusion (F) protein of RSV; indicated for prophylaxis for:
  - Infants and children <24 months of age with
    - Chronic lung disease of prematurity requiring medical therapy within 6 months of the start of RSV season
    - Hemodynamically significant congenital heart disease
o Congenital abnormalities of the airway or neuromuscular disease that compromises handling airway secretions
  – Infants born at ≤29 weeks’ gestation if they are <12 months of age at the start of the RSV season; prophylaxis should be maintained through the end of the RSV season.
  – Infants born at 29 to 32 weeks’ gestation if they are <6 months of age at the start of the RSV season; prophylaxis should be maintained through the end of the RSV season.
  – Infants born at 32 to 35 weeks’ gestation who are <3 months of age at the start of the RSV season or who are born during the RSV season if they have one of the following two risk factors:
    o Infant attends child care
    o ≥1 more siblings or other children <5 years of age living permanently in the child’s household

• Dosage: maximum of 5 monthly doses beginning in November or December at 15 mg/kg per dose IM
• Current palivizumab guidelines in the Red Book

COMMONLY ASSOCIATED CONDITIONS
• Asthma
• Otitis media
• Serious bacterial infection (SBI) in infants and children with concurrent RSV infection is rare.

DIAGNOSIS

ALERT
In most cases, the diagnosis is clinical. Laboratory and radiologic studies are not routinely necessary (2)[B].

HISTORY
• Rhinorrhea and upper respiratory congestion
• Difficulty feeding in infants (due to respiratory effort)
• Increased respiratory rate or signs of increased work of breathing (grunting, flaring, retracting)
• Cough; fever; wheezing
• History of prematurity, secondhand tobacco exposure, daycare, number and
age of siblings
● Immunization history
● Family history of respiratory disease

PHYSICAL EXAM
● Vital signs: fever, signs of increased work of breathing (tachypnea, grunting, flaring, retracting), pulse rate; pulse oximetry (“5th vital sign”) to assess oxygenation
● Rhinorrhea
● Dry mucous membranes; skin turgor (dehydration)
● Serous otitis or acute otitis
● Pulmonary: wheezing, crackles
● Serial examinations to assess status

Pediatric Considerations
Young infants with bronchiolitis may develop apnea with increased risk of prolonged hospitalization, ICU admission, and mechanical ventilation.

DIFFERENTIAL DIAGNOSIS
● Mild illness/URTI
  – Other respiratory viral infections: rhinovirus, human metapneumovirus, influenza virus, human bocavirus
  – Allergic rhinitis
  – Sinusitis
● Severe illness/LRTI
  – Bronchiolitis
  – Asthma
  – Pneumonia
  – Foreign body aspiration

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
● Routine laboratory testing is not necessary.
  – If obtained, WBC count normal or elevated
  – Virologic tests for RSV, despite high predictive value, rarely change management decisions or outcomes for patients with clinical bronchiolitis.
● Given the low risk of systemic bacterial infection, full septic workups are not necessary unless child appears toxic.
● Chest x-ray (CXR) does not predict disease severity or change patient outcomes but may be helpful if a patient does not improve as expected, if the severity of the disease requires further investigation, or if another diagnosis is suspected.
● When obtained, typical CXR findings include:
   – Hyperinflation and peribronchiolar thickening
   – Atelectasis
   – Interstitial infiltrates
   – Segmental or lobar consolidation

**TREATMENT**

**GENERAL MEASURES**

● Assess hydration status and ability to take fluids orally. Treat dehydration (oral or IV), particularly in infants.
● Supplemental oxygen if pulse oximetry persistently <90% in previously healthy patients

**MEDICATION**

*First Line*
No first-line medication for RSV infections; treatment is usually supportive; oxygen as needed

*Second Line*

● Bronchodilators do not improve oxygen saturation, reduce hospital admission after outpatient treatment, shorten the duration of hospitalization, or reduce the time to resolution of illness at home; routine use not recommended (2)[B]
● Nebulized epinephrine is superior to placebo for short-term outcomes in the outpatient setting, particularly in the first 24 hours.
● Glucocorticoids do not alter admissions or length of hospitalization (4)[A].
   – Some data suggest that the combination of dexamethasone and epinephrine may reduce outpatient admissions.
● Montelukast (Singulair) has no effect on the clinical course of acute bronchiolitis.
● Ribavirin, a nucleoside analogue and antiviral agent, has not been shown to be efficacious, particularly in immunocompromised patients.
● There is no current evidence that nebulized rhDNase changes clinical
outcomes in children <24 months of age hospitalized with acute RSV bronchiolitis.

- Reserve antibiotic use for patients who have specific findings suggesting a coexisting SBI.
- Nebulized 3% saline may reduce the length of stay and improve the clinical severity score in infants hospitalized with acute viral bronchiolitis.
- Heliox therapy may significantly reduce a clinical score evaluating respiratory distress in the first hour after starting treatment for infants with acute bronchiolitis, but there does not seem to be a reduction in the rate of intubation, in the rate of emergency department discharge, or in the length of treatment for respiratory distress (4)[A].

**ADDITIONAL THERAPIES**

- Bulb suctioning of the nares may provide some comfort to infants and allow for easier feeding.
- Efforts are underway to develop an RSV vaccine (5)[C].

**Pediatric Considerations**

Over-the-counter (OTC) cough and cold medications should not be used in children <6 years due to lack of efficacy and the risk of life-threatening side effects.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**

No complementary, alternative, or integrative therapies are of proven benefit in the prevention or treatment of RSV bronchiolitis.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Clinical evaluation of the patient’s respiratory status is critical. Ill-appearing infants should be hospitalized.
- Significant respiratory distress, an oxygen requirement to keep $\text{SpO}_2 > 90\%$, and the inability to hydrate orally are indications for admission.
- Mechanical ventilation is required in about 5% of infants hospitalized with RSV and 20% of children with underlying congenital heart disease, chronic lung disease, or immunosuppression.
- Universal precautions with gown and glove use are necessary to prevent
transmission of RSV in the inpatient setting. RSV airborne transmission is inefficient; masks/goggles are not necessary (6)[B].

- No set criteria for discharge; patients should be recovering and demonstrate:
  - Stable respiratory status with no oxygen requirement
  - Ability to maintain oral intake and hydration
  - Home resources adequate to support necessary home therapies, including caretaker ability to clear the infant’s airway with bulb suctioning if needed
  - Adequate follow-up and patient education

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Primary care follow-up to ensure resolution

PATIENT EDUCATION

PROGNOSIS
Most patients with RSV infection recover fully within 7 to 10 days. Reinfection is common.

COMPLICATIONS
- Infants hospitalized for RSV may be at increased risk for recurrent wheezing and reduced pulmonary function, particularly during the 1st decade of life.
- Overall mortality for infants and children <24 months of age is <1%.
- Although the relationship between RSV and asthma is unclear, RSV bronchiolitis in infancy has been linked to subsequent asthma.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- B97.4 Respiratory syncytial virus causing diseases classd elswhr
- J06.9 Acute upper respiratory infection, unspecified
- J21.0 Acute bronchiolitis due to respiratory syncytial virus

**CLINICAL PEARLS**

- RSV causes 50–90% of pediatric bronchiolitis.
- Hand sanitation (alcohol-based rubs are preferred) is the primary step for RSV prevention.
● The diagnosis of RSV is typically clinical. Routine laboratory or radiology studies are not necessary.
● Treatment of RSV is usually supportive.
● Palivizumab should be used to prevent RSV in high-risk patients.
RESTLESS LEGS SYNDROME

Denise Sharon, MD, PhD, FAASM • John R. Burk, MD

BASICS

DESCRIPTION

• Sensorimotor disorder consisting of a strong, nearly irresistible urge to move the limbs (1)[A]
• The urge usually affects the legs at least initially but may involve arms or other body parts (2)[C].
• The urge might be accompanied by uncomfortable and unpleasant sensations.
• The symptoms:
  – Begin or worsen during rest or inactivity
  – Are relieved by movement but recur with inactivity. Relief by movement may not be noticeable but has been previously reported.
  – Occur preferentially in the evening/night. Circadian aspect may not be noticeable but must have been previously reported.
  – Are not solely accounted for by “mimics” or another medical or behavioral condition
    o Mimics include leg cramps, positional discomfort, habitual foot tapping, arthralgias/arthritis, myalgias, leg edema, peripheral neuropathy, radiculopathy; even though some may coexist
    – Cause concern, distress, sleep disturbance
• Patient may also report involuntary leg jerks during wake or sleep (1)[A].
• System(s) affected: nervous; musculoskeletal
• Early, <45 years versus late >45 years onset (1)[A]
  – Early onset: 40–92% familial, stable or slow progression of symptoms
  – Late onset: more aggravating factors; rapid progression is common.
• Synonym(s): Willis-Ekbom disease

EPIDEMIOLOGY

Incidence

• 0.8–2.2% annually
• Onset at any age
• Predominant sex: male = female (nulliparous); parous females are twice > male.
Might be affected by temperature (cold weather) and other environmental factors

**Prevalence**
- 4–15% in Caucasian adults, underdiagnosed
- 2–3% are clinically significant.
- 1–3% in children and adolescents
- Increases with age up to 70 years
- Lower in non-Caucasians (except Koreans)

**Pregnancy Considerations**
- 10–30% prevalence; triggers or exacerbates RLS
- Predictors: family history, past history, iron deficiency, Hgb < or = 11 g/dL (3)
- Peaks in 3rd trimester
- Most are relieved by 1-month postpartum.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Brain iron deficiency and impaired iron transport into the brain
  - Iron deficiency and associated conditions
- CNS dopamine regulation:
  - Fast dopamine turnover consistent with increased dopamine production
  - Circadian changes in dopamine (> evening)
  - Decreased dopamine transporter
- Genetics: heterogeneous
  - Susceptibility loci: 2p14, 2q, 6p21.2, 9p, 12q, 14q, 15q23, and 20p
  - Genes: MEIS1, MAP2K5/LBX1COR1, BTBD9
- Changes in substantia nigra, striatum, putamen (reduced iron, less myelin, less D2 receptors)
- Sensorimotor pathways abnormalities:
  - Bilateral activation of the cerebellum and contralateral activation of the thalamus
  - Increased activation of the prefrontal and anterior cingulate cortex
  - Decreased gray matter volume which correlates with disease severity and duration
- Cortical excitability: increased thalamic glutamate
- Increased endogenous opioids, possibly
- Triggering and exacerbating factors:
– Prolonged immobility
– Medications:
  o Most antidepressants (except bupropion)
  o Dopamine-blocking antiemetics (e.g., metoclopramide, prochlorperazine)
  o Some antiepileptic agents (e.g., phenytoin)
  o Phenothiazine antipsychotics (risperidone, clozapine, olanzapine, quetiapine) possible exception: aripiprazole (partial D2 agonist)
  o Cognition-enhancing medications donepezil
  o Theophylline and other xanthines
  o Antihistamines/over-the-counter (OTC) cold preparations (e.g., pseudoephedrine)
  o Adrenergics, stimulants, anti-inflammatory
  o Anti-inflammatory medications

RISK FACTORS
● Iron deficiency
● Family history
● Increased with every pregnancy
● Chronic renal failure—11–58% affecting dialysis compliance
● Sleep deprivation, alcohol, caffeine—limited data

GENERAL PREVENTION
● Regular physical activity/exercise during the day, low impact such as stretches and evening walks
● Adequate sleep; delay wake time if possible.
● Avoid evening caffeine, alcohol, nicotine.
● Avoid use of medications that trigger RLS (4)[C].

COMMONLY ASSOCIATED CONDITIONS
● Periodic limb movements in sleep (PLMS), insomnia, sleep walking, delayed sleep phase
● Iron deficiency, renal disease/uremia/dialysis, gastric surgery, IBS, liver disease
● Parkinson disease, multiple sclerosis, peripheral neuropathy, Machado-Joseph disease, migraine
● Cardiovascular disease, including coronary artery disease and stroke
● Orthopedic problems, arthritis, fibromyalgia
● Venous insufficiency/peripheral vascular disease
- Pulmonary hypertension, lung transplantation, chronic obstructive pulmonary disease (COPD)
- Anxiety, depression, ADHD

**DIAGNOSIS**
- Depends on history, often “difficult to describe”
- All criteria must be met for RLS diagnosis (2)[C]:
  - An urge to move the legs, usually accompanied by or thought to be caused by uncomfortable and unpleasant sensations in the legs. The urge must:
    - Begin or worsen during periods of rest or inactivity such as lying down or sitting
    - Be partially or totally relieved by movement such as walking or stretching at least as long as the activity continues
    - Occur exclusively or predominantly in the evening or night rather than during the day
  - The above features are not solely accounted for as symptoms of another medical or a behavioral condition.
  - The symptoms of RLS cause concern/distress, sleep disturbance, or impairment in mental, physical, social, occupational, educational, behavioral, or other area of functioning.

**HISTORY**
- Signs/symptoms (see also “Description”) (1)[A]
  - Painful in ~35% of patients
  - Example descriptions: burning, achy, itching, antsy, “can’t get comfortable”
  - Urge to move may be the only “discomfort.”
  - Some patients must get up and walk.
  - PLMS in ~80% of patients
  - Insomnia, fatigue, anxiety, depression
- Severity range: from rare, minor problem to daily life, to severe impact on quality of life

**Pediatric Considerations**
Symptoms described in child’s own words and additional supportive findings (1,2)[A]:
- Insomnia or sleep disturbance
- RLS in immediate biologic relative
- PLMS

**Geriatric Considerations**
For diagnosis in the cognitively impaired
- Rubbing or kneading the legs in the evening
- Evening hyperactivity (foot tapping, pacing, fidgeting, tossing/turning in bed)

**Differential Diagnosis**
- Claudication: Movement does not relieve pain.
- Motor neuron disease fasciculation/tremor: no discomfort or circadian pattern
- Peripheral neuropathy: usually no circadian pattern; unresponsive to dopamine agonists
- Dermatitis/pruritus: movement only to scratch; no circadian pattern
- Sleep-related leg cramps: isolated and very painful muscle contracture
- PLMD: no wakeful movements
- Sleep starts: isolated involuntary events
- Rhythmic movement sleep disorder: movement periodicity faster than RLS
- Growing pains: no urge to move or relief by movement; circadian pattern opposite RLS
- ADHD: no sleep complaints or disorders

**Diagnostic Tests & Interpretation**
Assessment of serum iron stores: ferritin, transferrin saturation, iron-binding capacity, serum iron (see also “General Measures”) (5)[C]

**Diagnostic Procedures/Other**
Sleep study helpful but not required
- Frequent, PLM during wake, prior to sleep
- Suggested immobilization test (SIT) or multiple SIT (m-SIT)
  - Conducted before or without nocturnal PSG
  - Patient attempts to sit still in bed for 1 hour (SIT) or four 1-hour periods, every 2 hours (m-SIT) while completing every 10 minutes a visual analogue scale (VAS) or m-SIT disturbance scale.
  - >40 movements per hour suggest RLS.
TREATMENT

GENERAL MEASURES

- If iron deficient, supplement (4)[C]:
  - 325 mg FeSO₄ TID combined with vitamin C
  - Repletion requires months till serum ferritin >75 ng/ml and transferrin saturation >16%.
- Daily exercise; avoid activities that may exacerbate symptoms.
- Regular and replete sleep (6)[C]
- Hot bath and leg massage
- Warm the legs (long socks, electric blanket).
- Intense mental activity (games, puzzles, etc.)
- Avoid exacerbating factors.
- Consider not initiating medications in mild to moderate cases until general measures applied.

MEDICATION

- Titrate to minimum dose necessary to control symptoms, including sleep disturbance (consider weekly assessment rather than single day/dose).
- Preferentially use longer acting or extended-release options (4–6)[C].
- Refractory RLS may require combination therapy.

First Line

- α₂δ Ligands—less risk for augmentation and more effective in DA-naive patients (4–6)[C]:
  - Gabapentin enacarbil (Horizant): 300 to 1,200 mg every day ~5:00 PM (4,5)[C]
  - Pregabalin (Lyrica): 50 to 450 mg/day (off-label)
  - Gabapentin (Neurontin): 100 to 2,400 mg/day (off-label)
- Dopamine agonists—assess for augmentation and impulse-control disorders (ICD) at every encounter (4–6)[C]:
  - Pramipexole (Mirapex): 0.125 to 0.500 mg 1 hour before symptoms; titrate by 0.125 mg; pramipexole ER 0.375 tablet.
  - Ropinirole (Requip): 0.25 to 4.00 mg 1 hour before symptoms; titrate by 0.25 mg; ropinirole XL 2 mg tablet.
  - Transdermal rotigotine (Neupro): 1 to 3 mg/24-hr patch; initiate with 1 mg/day; titrate by 1 mg weekly.
– Avoid dopamine agonists in psychotic patients, particularly if taking dopamine antagonists.

- Add a different class of medication before exceeding DA-recommended dose.

**Second Line**

*Off-label (4–6)[C]*

- Iron: ferrous sulfate 325 mg 2 to 3/day PO + vitamin C 100 or ferric carboxymaltose 1,000 mg IV
- Benzodiazepines and agonists (for associated insomnia or anxiety)
  - Clonazepam (Klonopin): 0.5 to 3.0 mg/day
  - Temazepam, triazolam, alprazolam, zaleplon, zolpidem, and diazepam
- Other anticonvulsants (for comorbid neuropathy)
  - Carbamazepine: 200 to 800 mg/day
- Short-acting dopamine agonists
  - Carbidopa and levodopa (Sinemet or Sinemet CR): 10/100 to 25/250; PRN for sporadic symptoms

**Pregnancy Considerations**

- Initial approach: nonpharmacologic therapies, assess/correct iron deficiency
- Avoid medications class C or D.
  - In 3rd trimester, may consider low-dose clonazepam, clonidine, or opioids (3) [B]

**Pediatric Considerations**

- First-line treatment: nonpharmacologic therapies, assess/correct iron deficiency
- Consider low-dose clonidine or clonazepam.

**Geriatric Considerations**

- Avoid medications that cause dizziness or unsteadiness.
- Many medications given to elderly trigger/exacerbate RLS.

**ISSUES FOR REFERRAL**

- Severe, intractable symptoms
- Augmentation response to dopaminergic therapy
- Intransigent iron deficiency

**ADDITIONAL THERAPIES**
• Vitamin, mineral supplements: Ca, Mg, vitamin B\textsubscript{12}, folate
• Clonidine: 0.05 to 0.10 mg/day
• Baclofen: 20 to 80 mg/day
• Prescription or OTC hypnotics

SURGERY/OTHER PROCEDURES
For orthopedic, neuropathic, or lower extremities vein disease (laser ablation, sclerotherapy, etc.)

COMPLEMENTARY & ALTERNATIVE MEDICINE
• Relaxis leg vibration device (FDA-approved)
• Sequential pneumatic leg compression
• Enhanced external counterpulsation
• Compression stockings
• Acupuncture
• MicroVas therapy

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
• Can prolong hospitalization and/or compromise outcomes
• Addition/withdrawal of medications exacerbating/treating RLS
• Control RLS especially after orthopedic procedures.
• Changes in medical status may require medication changes (e.g., Mirapex contraindicated in renal failure, Requip contraindicated in liver disease).
• Iron infusion when oral iron fails or contraindicated
• When NPO, consider IV opiates.
• Sleep interruption risks prolonged wakefulness.

ONGOING CARE
FOLLOW UP RECOMMENDATIONS

Patient Monitoring
• At 1 to 2-week intervals until stable and then annually
• If taking iron, reassess iron stores, at least ferritin.
• If status changes, assess for augmentation, associated conditions and medications.

**DIET**
Avoid evening caffeine and alcohol.

**PATIENT EDUCATION**
• Restless Legs Syndrome Foundation: [www.rls.org](http://www.rls.org)
• National Sleep Foundation: [sleepfoundation.org](http://sleepfoundation.org)
• American Academy of Sleep Medicine: [http://sleepeducation.com/](http://sleepeducation.com/)

**PROGNOSIS**
• Early-onset: lifelong condition with no current cure
• Late-onset/secondary: may subside with resolution of precipitating factors
• Current therapies usually control symptoms.

**COMPLICATIONS**
• Augmentation of symptoms following DA therapy to be assessed at every visit (5)[C]:
  – 4-hour time advance of symptoms or 2 to 4 hours advance of symptoms together with shorter latency at rest; symptoms spread to other body parts, or have greater intensity.
  – Higher doses increase risk and increasing the dose makes symptoms worse.
  – Highest risk from daily levodopa or Sinemet
  – Iron deficiency increases risk.
  – Discontinue dopaminergics or add alternative medication and then slowly down-titrate DA.
• Obsessive-compulsive or ICD following dopaminergic therapy to be assessed at every visit (5)[C]
• Iatrogenic RLS (following blood loss or donation)

**REFERENCES**

ADDITIONAL READING

SEE ALSO
Periodic Limb Movement Disorder (PLMD)

CODES
ICD10
G25.81 Restless legs syndrome

CLINICAL PEARLS
- Insomnia is often a symptom of RLS.
- Iron supplement is frequently the best, well tolerated, easily available treatment for RLS.
- Antidepressants, antipsychotics, antiemetics, and antihistamines can trigger or exacerbate RLS.
- Titrate dopaminergics, only up to the minimum dose necessary to control symptoms.
- RLS may interfere with use of positive airway pressure in obstructive sleep apnea.
- RLS is associated with depression, anxiety ADHD.
RETINAL DETACHMENT
Richard W. Allinson, MD

BASICS

DESCRIPTION
- Separation of the sensory retina from the underlying retinal pigment epithelium
- Rhegmatogenous retinal detachment (RRD): most common type; occurs when the fluid vitreous gains access to the subretinal space through a break in the retina (Greek rhexma, “rent”)
- Exudative or serous detachment: occurs in the absence of a retinal break, usually in association with inflammation or a tumor
- Traction detachment: Vitreoretinal adhesions mechanically pull the retina from the retinal pigment epithelium. The most common cause is proliferative diabetic retinopathy.
- System(s) affected: nervous

EPIDEMIOLOGY

Incidence
- Predominant age: Incidence increases with age.
- Predominant sex: male > female (3:2)
- Per year: 1/10,000 in patients who have not had cataract surgery

Prevalence
After cataract surgery, 1–3% of patients will develop a retinal detachment.

ETIOLOGY AND PATHOPHYSIOLOGY
- Traction from a posterior vitreous detachment (PVD) causes most retinal tears. With aging, vitreous gel liquefies, leading to separation of the vitreous from the retina. The vitreous gel remains attached at the vitreous base, in the retinal periphery, resulting in vitreous traction that produces tears in the retinal periphery. There is an ~15% chance of developing a retinal tear from a PVD.
- PVD associated with vitreous hemorrhage has a high incidence of retinal tears.
- Exudative detachment
- Tumors
- Inflammatory diseases (Vogt-Koyanagi-Harada disease, posterior scleritis)
- Miscellaneous (central serous retinopathy, uveal effusion syndrome, malignant hypertension, drugs—ipilimumab)

- Traction detachment
  - Proliferative diabetic retinopathy
  - Cicatricial retinopathy of prematurity
  - Proliferative sickle-cell retinopathy

- Penetrating trauma

**Genetics**
- Most cases are sporadic.
- There is an increased risk of RRD if a sibling has been affected by this condition. The risk increases with higher levels of myopia in the family history.

**RISK FACTORS**
- Myopia (>5 diopters)
- Aphakia or pseudophakia
  - In patients undergoing small-incision coaxial phacoemulsification with high myopia (axial length ≥26 mm), the incidence of retinal detachment is 2.7%.
- PVD and associated conditions (e.g., aphakia, inflammatory disease, and trauma)
- Trauma
- Retinal detachment in fellow eye
- Lattice degeneration: a vitreoretinal abnormality found in 6–10% of the general population
- Glaucoma: 4–7% of patients with retinal detachment have chronic open-angle glaucoma.
- Vitreoretinal tufts: Peripheral retinal tufts are caused by focal areas of vitreous traction.
- Meridional folds: Redundant retina usually is found in the supranasal quadrant.

**GENERAL PREVENTION**
Patients at risk for retinal detachment should have regular ophthalmologic exams.
Geriatric Considerations
- PVD
- Cataract surgery

Pediatric Considerations
Usually associated with underlying vitreoretinal disorders and/or retinopathy of prematurity

COMMONLY ASSOCIATED CONDITIONS
- Lattice degeneration
- High myopia
- Cataract surgery
- Glaucoma
- History of retinal detachment in the fellow eye
- Trauma

Pregnancy Considerations
Preeclampsia/eclampsia may be associated with exudative retinal detachment. No intervention is indicated, provided hypertension is controlled. Prognosis is usually good.

DIAGNOSIS

HISTORY
- Sudden flashes (photopsia)
- Shower of floaters
- Visual field loss: “curtain coming across vision”
- Central vision will be preserved if the macula is not detached.
- Poor visual acuity (20/200 or worse), with loss of central vision when macula is detached

PHYSICAL EXAM
- Slit-lamp exam
- Dilated fundus exam with binocular indirect ophthalmoscopy

DIFFERENTIAL DIAGNOSIS
Retinoschisis (splitting of the retina)
Vitreous cells and vitreous hemorrhage are found rarely in the vitreous with retinoschisis, whereas they are seen commonly in RRD.
Retinoschisis usually has a smooth surface and is dome-shaped, whereas RRD often has a corrugated, irregular surface.

DIAGNOSTIC TESTS & INTERPRETATION
Visual field testing: differentiates RRD from retinoschisis. An absolute scotoma is seen in retinoschisis, whereas RRD causes a relative scotoma.

Initial Tests (lab, imaging)
Ultrasound (US) can demonstrate a detached retina and may be helpful when the retina cannot be visualized directly (e.g., with cataracts or vitreous hemorrhage).
Fluorescein dye leakage can be seen in exudative retinal detachment; caused by central serous retinopathy and other inflammatory conditions.
Optical coherence tomography (OCT)

Test Interpretation
Elevation of the neurosensory retina from the underlying retinal pigment epithelium.
Elevation of retina associated with ≥1 retinal tears in RRD or elevation of the retina without tears in exudative detachment.
In 3–10% of patients with presumed RRD, no definite retinal break is found.
Tenting of the retina without retinal tears in traction detachment.
Pigmented cells within the vitreous (“tobacco dust”)

TREATMENT
GENERAL MEASURES
Not all retinal tears or breaks need to be treated:
– Flap or horseshoe tears in symptomatic patients (e.g., patients with flashes or floaters) are treated frequently.
– Operculated holes in symptomatic patients are treated sometimes.
– Atrophic holes in symptomatic patients are treated rarely.
Lattice degeneration with or without holes within the lattice in an asymptomatic patient with prior retinal detachment in the fellow eye may be treated prophylactically.
Flap retinal tears in asymptomatic patients frequently are treated prophylactically.
Exudative detachments usually are managed by treating underlying disorder.
Traction detachments usually are managed by observation. If the fovea is involved, a vitrectomy is needed.

MEDICATION

First Line
- Intraocular gases
  - Air
  - Perfluoropropane (C₃F₈)
  - Sulfur hexafluoride (SF₆)
- Perfluorocarbon liquids
- Silicone oil
- Contraindications to intraocular gas: patients with poorly controlled glaucoma
- Precautions with intraocular gas: Expanding intraocular gas bubble increases intraocular pressure; therefore, avoid higher altitudes.
- Significant possible interactions with intraocular gas: Nitrous oxide used in general anesthesia can expand an intraocular gas bubble.

Second Line
Steroids may cause worsening of central serous retinopathy.

SURGERY/OTHER PROCEDURES
- Timing of repairs
  - Macula attached: within 24 hours if possible. If the detachment is peripheral and does not have features suggestive of rapid progression (e.g., large and/or superior tears), repair can be performed within a few days.
    - Preoperative posturing consisting of bed rest and positioning is frequently prescribed to patients with macula-on retinal detachment. Preoperative posturing can reduce the progression of macula-on retinal detachments (1)[B].
  - Macula recently detached: within 10 days of development of a macula-off retinal detachment (2)[B]
    - Old macular detachment: elective repair within 2 weeks
- If a retinal break has led to the development of a retinal detachment, surgery is needed. Surgical options (and combinations) include the following:
  - Demarcation laser treatment
– Pneumatic retinopexy: Head positioning is required postoperatively.
– Scleral buckle
– Vitrectomy
– Perfluorocarbon liquids for giant tears (circumferential tears ≥90 degrees)
– Silicone oil for complex repairs

- Anesthesia: local or general
- RRD may have >1 break. If any retinal break is not closed at the time of surgery, the surgery will fail.
- Additional surgery may be required if the retina redetaches secondary to a new retinal break or because of proliferative vitreoretinopathy (PVR).
- If a vitreous hemorrhage is present, presumably from a retinal tear and the fundus cannot be well visualized, consideration can be given for early vitrectomy (3)[C].
- Patients who underwent pars plana vitrectomy (PPV) within the first week of presentation had a significantly lower risk of having a macula-off RD.
- Both phakic and pseudophakic patients had a similar chance of developing a retinal detachment. Phakic patients who underwent PPV had a higher chance of requiring subsequent cataract surgery.

There is a trend toward primary vitrectomy in the management of RRD. Eyes undergoing PPV for primary RRD repair may not need the addition of a scleral buckle.

- There is no statistical difference in the primary reattachment rate between eyes treated with PPV and scleral buckle for RRD in both phakic and pseudophakic/aphakic eyes (4)[A].
- Patients with RRD who are at high risk for PVR (retinal detachment in two or more quadrants, retinal tears >1 clock hour, preoperative PVR, or vitreous hemorrhage). PPV-scleral buckle was associated with higher rates of anatomical success compared to PPV alone (5)[B].

- There is a reduced incidence of intraoperative retinal tear formation using a transconjunctival cannulated PPV system compared to the standard 20-gauge system requiring suture closure.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Recognition of condition is key (see “Diagnosis”).
- Refer to an ophthalmologist for exam and treatment, if indicated.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Bed rest prior to surgery
- Postoperatively, if intraocular gas has been used, the patient may need specific head positioning and should not travel to high altitudes.

Patient Monitoring

- Alert ophthalmologist if there is new onset of floaters or flashes, increase in floaters or flashes, sudden shower of floaters, curtain or shadow in the peripheral visual field, or reduced vision.
- Patients with acute symptomatic PVD should be reexamined by the ophthalmologist in 3 to 4 weeks. The development of a retinal detachment is unlikely if no retinal tears are present on reexamination in 3 to 4 weeks.
- If acute symptomatic PVD is associated with gross vitreous hemorrhage that interferes with complete visualization of the retinal periphery by indirect ophthalmoscopy, the patient should be reexamined at short intervals with indirect ophthalmoscopy until the entire retinal periphery can be observed. Early PPV can be considered.
- If the examiner is not certain whether the retina is detached in the presence of opaque medium, US should be performed.

DIET

NPO if surgery is imminent

PATIENT EDUCATION

American Academy of Ophthalmology, 655 E. Beach Street, San Francisco, CA 94109-1336

PROGNOSIS

- RRD
  - 90% of retinal detachments can be reattached successfully after ≥1 surgical procedure. Postoperative visual acuity depends primarily on the status of the macula preoperatively. Also important is the length of time between the detachment and the repair (75% of eyes with macular detachments of <1 week will obtain a final visual acuity of 20/70 or better).
  - 87% of eyes with a retinal detachment not involving the macula attain a
visual acuity of 20/50 or better postoperatively. 37% of eyes with a detached macula preoperatively attain 20/50 or better vision postoperatively.

– In 10–15% of successfully repaired retinal detachments not involving the macula preoperatively, visual acuity does not return to the preoperative level. This decrease is secondary to complications such as macular edema and macular pucker.

– Failed primary pneumatic retinopexy selects for RDs that are inherently more difficult to reattach.

Risk factors associated with primary RRD repair failure include choroidal detachment, significant hypotony, grade C-1 PVR, four detached quadrants, and large or giant retinal breaks. Additional risk factors associated with primary RRD repair failure include increased number of breaks and inferior location of retinal breaks.

• Tractional retinal detachment
  – When not involving the fovea, the patient usually can be observed because it is uncommon for these to extend into the fovea.

• Exudative retinal detachment
  – Management is usually nonsurgical.
  – The presence of shifting fluid is highly suggestive of an exudative retinal detachment. Fixed retinal folds, which are indicative of PVR, are seen rarely in exudative retinal detachment. If the underlying condition is treated, the prognosis generally is good.

COMPICATIONS

• PVR is the most common cause of failed retinal detachment repair; 10–15% of retinas that reattach initially after retinal surgery will redetach subsequently, usually within 6 weeks, as a result of cellular proliferation and contraction on the retinal surface.

• Partial or total loss of vision due to macular detachment and/or PVR

• Moderate to severe forms of PVR usually are treated with PPV and fluid–gas exchange. If a segmental scleral buckle was placed at the initial procedure, it may need to be revised.

• Primary retinectomy can be used in cases of PVR without a scleral buckle (6) [C].

• Scleral buckles may erode the overlying conjunctiva and lead to an infection.

• Optic neuropathy after PPV for macula-sparing primary RRD

SEE ALSO

Retinopathy, Diabetic

CODES

ICD10
- H33.001 Unspecified retinal detachment with retinal break, right eye
- H33.019 Retinal detachment with single break, unspecified eye
- H33.20 Serous retinal detachment, unspecified eye

CLINICAL PEARLS
- If a patient complains of the new onset of floaters or flashes of light, the patient should undergo a dilated eye exam to rule out a retinal tear or retinal detachment.
- There is an increased risk of retinal detachment after cataract surgery.
- PVR can result in redetachment of the retina after an initially successful repair.
RETINOPATHY, DIABETIC
Richard W. Allinson, MD

BASICS

DESCRIPTION
- Noninflammatory retinal disorder characterized by retinal capillary closure and microaneurysms. Retinal ischemia leads to release of a vasoproliferative factor, stimulating neovascularization on retina, optic nerve, or iris.
- Most patients with diabetes mellitus (DM) will develop diabetic retinopathy (DR). It is the leading cause of new cases of legal blindness among residents in the United States between the ages of 20 and 64 years.
- DR can be divided into three stages.
  - Nonproliferative (background)
  - Severe nonproliferative (preproliferative)
  - Proliferative
- System(s) affected: nervous

Geriatric Considerations
Prevalence will increase, as population generally ages and patients with diabetes live longer.

Pregnancy Considerations
- Pregnancy can exacerbate condition.
- Pregnant diabetic women should be examined in 1st trimester and then every 3 months until delivery.

EPIDEMIOLOGY

Incidence
- Peak incidence of type 1, juvenile-onset DM is between the ages of 12 and 15 years. In type 1 DM (T1DM), there is beta cell destruction, leading to insulin deficiency.
- Peak incidence of type 2, adult-onset DM is between the ages of 50 and 70 years. Type 2 DM (T2DM) ranges from a condition characterized by insulin resistance with relative insulin deficiency to one that is predominantly an insulin secretory defect with insulin resistance.
Incidence of DR is directly related to the duration of diabetes.
<10 years of age, it is unusual to see DR, regardless of DM duration.

**Prevalence**
- 6.6% of the U.S. population between ages of 20 and 74 years has DM.
- ~25% of the diabetic population has some form of DR.
- Predominant age
  - Risk increases after puberty.
  - 2/3 of juvenile-onset diabetics who have had DM for at least 35 years will develop proliferative DR (PDR), and 1/3 will develop macular edema.
    Proportions are reversed for adult-onset diabetes.
- Predominant sex: male = female (type 1, juvenile-onset DM); female > male (type 2)

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Related to development of diabetic microaneurysms and microvascular abnormalities
- Reduction in perifoveal capillary blood flow velocity, perifoveal capillary occlusion, and increased retinal thickness at the central fovea in diabetic patients are associated with visual impairment in patients with diabetic macular edema (DME).
- Vascular endothelial growth factor (VEGF) is elevated in patients with hypoxic retina. Intraocular levels of VEGF are elevated in patients with retinal or iris neovascularization. Retinal hypoxia also contributes to DME, and VEGF is a major contributor to DME.

**RISK FACTORS**
- Duration of DM (usually >10 years)
- Poor glycemic control
- Pregnancy
- Renal disease
- Systemic hypertension (HTN)
- Smoking
- Elevated lipid levels associated with increased risk of retinal lipid deposits (hard exudates)
- Myopic eyes (eyes with longer axial length) have a lower risk of DR.

**GENERAL PREVENTION**
● See “General Measures.”
● Monitor and control of blood glucose.
● Schedule yearly ophthalmologic eye exams.

COMMONLY ASSOCIATED CONDITIONS
● Glaucoma
● Cataracts
● Retinal detachment
● Vitreous hemorrhage (VH)
● Disc edema (diabetic papillopathy); may occur in T1DM and T2DM

DIAGNOSIS

HISTORY
Diabetic patients should be encouraged to have an annual ophthalmologic exam because early eye changes may be asymptomatic.

PHYSICAL EXAM
● Eye exam: measurement of visual acuity and documentation of the status of the iris, lens, vitreous, and fundus
● Nonproliferative (background) DR
  – Microaneurysms
  – Intraretinal hemorrhage
  – Macular edema causing decrease in central vision
  – Lipid deposits
● Severe nonproliferative (preproliferative) DR
  – Nerve fiber layer infarctions (“cotton wool spots”)
  – Venous beading
  – Venous dilatation
  – Intraretinal microvascular abnormalities (IRMA)
  – Extensive retinal hemorrhage
  – The Early Treatment Diabetic Retinopathy Study (ETDRS) developed the 4:2:1 rule for severe nonproliferative diabetic retinopathy (NPDR). Severe NPDR was defined as having any one of the following features:
    o Severe intraretinal hemorrhages and microaneurysms in 4 quadrants
    o Venous beading in 2 or more quadrants
    o IRMAs in 1 or more quadrants
PDR
- New blood vessel proliferation (neovascularization) on the retinal surface, optic nerve, and iris
- Visual loss caused by VH, traction retinal detachment. Neovascularization can result in contracting fibrovascular tissue on a vitreous scaffold, which can lead to VH and traction retinal detachment.

GENERAL MEASURES
- The Diabetes Control and Complications Trial (DCCT) recommended that for most patients with insulin-dependent DM, blood glucose levels should be as close to the nondiabetic range as is safe to reduce the risk and rate of progression of DR.
  - In the DCCT, insulin-dependent DM patients were randomly assigned into either conventional or intensive insulin treatment. Conventional treatment consisted of 1 to 2 daily insulin injections, with daily self-monitoring of urine/blood glucose. Intensive treatment consisted of insulin administered ≥3 times daily by injection/an external pump, with self-monitored blood glucose levels measured at least 4 times per day.
  - The DCCT demonstrated that intensive insulin therapy reduced the risk of DME and retinal neovascularization. The benefit of intensive insulin therapy with the reduced risk of DR-associated microvascular complications persists for at least 10 years.
- In the DCCT, intensive insulin therapy was more effective in reducing the risk of progression of DR in the less advanced stages. However, advanced DR also benefited from the intensive insulin therapy.
- Intensive therapy in patients with T1DM is associated with a substantial reduction in the long-term risk of ocular surgery.
- The ETDRS demonstrated that aspirin therapy did not prevent the development of PDR or reduce the risk of visual loss associated with DR.
- Microvascular complications, including PDR, are increased when blood sugar levels are ≥200 mg/dL.
- Cataracts are more common among those with DM. Try to delay cataract surgery in DM patients with retinopathy until the symptoms are more severe. Cataract surgery can cause retinopathy to worsen and increase the risk for development of DME.
- HTN has a detrimental effect on DR and must be controlled.

DIFFERENTIAL DIAGNOSIS
Other causes of retinopathy (e.g., radiation, retinal venous obstruction, HTN)
DIAGNOSTIC TESTS & INTERPRETATION

Diagnostic Procedures/Other
- Fluorescein angiography demonstrates retinal nonperfusion, retinal leakage, and PDR.
- Optical coherence tomography (OCT) can be used to help detect DME by measuring retinal thickness.
- Optical coherence tomography angiography (OCTA)
  - Poor responders to anti-VEGF treatment for DME show significant damage to the deep capillary plexuses (DCP) but not the superficial capillary plexuses (SCP). The extent of the DCP loss and the corresponding outer plexiform layer disruption as seen on spectral-domain OCT (SD OCT) could be useful predictors of responsiveness to anti-VEGF treatment.

Test Interpretation
- Increased capillary permeability
- Microaneurysms
- Hemorrhages in retina
- Exudates in retina
- Capillary nonperfusion

TREATMENT

MEDICATION
- Treatment with the angiotensin-receptor blocker candesartan has been shown to result in regression of DR in some patients.
- Nutritional antioxidant intake of vitamins C and E and of β-carotene has no protective effect on DR.
- Atorvastatin may reduce the severity of lipid deposits with clinically significant diabetic macular edema (CSDME) in T2DM and dyslipidemia.
- Aspirin
  - Does not alter progression of DR
  - Does not increase the risk of VH

SURGERY/OTHER PROCEDURES
Treatment for DME
- Intravitreal anti-VEGF is first-line treatment for DME:
– Ranibizumab, an antibody fragment that binds vascular VEGF, can be used to treat DME when injected intravitreally. Ranibizumab 0.3 mg given monthly resulted in improved vision and reduced central foveal thickness.
  o Anti-VEGF treatment results in superior clinical outcomes compared to laser photocoagulation for DME.
  o Intravitreal ranibizumab treatment for DME may also improve DR severity and reduce the risk of DR progression.
  o Treat and extend dosing for intravitreal ranibizumab injections (IRI) decreased the number of injections while giving similar visual and anatomic outcomes compared with monthly dosing at 1 year.
  o As-needed treatment after a loading dose of 3 monthly injections has been shown to result in comparable results to more frequent treatments.
– Bevacizumab, a full-length antibody that binds VEGF, can be used to treat DME when injected intravitreally. This is an off-label use.
– Aflibercept, a decoy receptor for VEGF that inhibits all isoforms of VEGF-A and placental growth factor. Aflibercept 2 mg (0.05 mL) injected intravitreally every 4 weeks for the first 5 injections followed by 2 mg (0.05 mL) intravitreally once every 8 weeks. It is indicated for patients with DME and for DR in patients with DME.
  o Intravitreal aflibercept injection (IAI) has demonstrated significant superiority in functional and anatomic end points over macular laser photocoagulation.
  o At worse levels of initial visual acuity (20/50 or worse) in patients with DME, IAI was more effective in improving vision than ranibizumab or bevacizumab with 1-year follow-up. When the initial vision loss was mild (20/32 to 20/40) in patients with DME, there was no significant difference between aflibercept, ranibizumab, and bevacizumab (1)[A].
    ■ Aflibercept had superior 2-year visual acuity outcomes compared with bevacizumab. The superiority of aflibercept over ranibizumab, noted at 1 year, was no longer seen (2)[A].
  o As-needed IAI has been shown to maintain vision and reduce treatment frequency.
  • Topical povidone-iodine prophylaxis is important to help prevent endophthalmitis from intravitreous injections from anti-VEGF treatment.
  • Vitrectomy may benefit some with diffuse macular edema. This may apply especially to eyes with vitreomacular traction found on OCT and with persistent DME.
  • Intravitreal triamcinolone may be used for DM-related macular edema that fails laser treatment. No long-term benefit of intravitreal triamcinolone
relative to focal/grid photocoagulation in patients with DME. This is an off-label use.

- **Intraocular steroid implants for DME.** Either a dexamethasone implant and a fluocinolone acetonide implant. Complications of these implants include cataract and glaucoma.
- **Activated Tie2 stabilizes the retinal vasculature.**
  - Vascular endothelial-protein tyrosine phosphatase (VE-PTP) is increased in retinal hypoxia and inactivates Tie2. AKB-9778 is an antagonist of VE-PTP.
  - Activation of Tie2 by subcutaneous injections of AKB-9778 combined with IRI results in a significantly greater reduction in DME that is seen with IRI alone (3)[B]. This is an investigational drug.

- **Treatment for PDR:**
  - Thermal laser photocoagulation in a panretinal pattern is the primary form of treatment for PDR. The goal of panretinal photocoagulation (PRP) is regression or involution of neovascularization. PRP destroys ischemic retina and decreases the neovascular stimulus.
    - The Diabetic Retinopathy Study demonstrated that when PRP was used to treat PDR or severe NPDR, eyes treated with PRP had a reduction of 50% or more in the rates of severe vision loss compared with untreated control eyes. In certain subgroups, the incidence of severe visual loss in untreated eyes was as high as 36.9% at 2 years.
    - Patients with DME and high-risk proliferative disease can have simultaneous focal and PRP without adversely affecting the visual outcome.
  - **IRI is an alternative therapy to PRP for PDR.**
    - Intravitreal bevacizumab injection (IBI) may be of benefit in the treatment of VH due to PDR and may help to avoid the need for a pars plana vitrectomy (PPV) (4)[C].
  - **PPV recommended for patients with severe PDR, traction retinal detachment involving the macula, and nonclearing VH**
    - The Diabetic Retinopathy Vitrectomy Study (DRVS) demonstrated the benefits of early PPV (1 to 6 months after onset of VH) in T1DM and for eyes with very severe PDR.
    - Immediate PPV with endolaser may be considered for PDR-associated VH (<30 days) (5)[C].
    - Preoperative bevacizumab can be used as an adjuvant to vitrectomy for complications of PDR. This is an off-label use.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Scheduled ophthalmologic eye exams
- Yearly follow-up if no retinopathy
- Every 6 months with background DR
- At least every 3 to 4 months with pre-PDR
- Every 2 to 3 months with active PDR
- Patients with DME should be followed every 4 to 6 weeks.
- Young people with either T1DM or T2DM are at risk for developing DR and need to have regular eye examinations.

DIET
- Follow prescribed diet for patients with diabetes.
- In middle-aged and older individuals with T2DM, intake of at least 500 mg/day of dietary long-chain omega-3 polyunsaturated fatty acids, achievable with 2 weekly servings of oily fish, is associated with a decreased risk of visual loss from DR (6)[A].

PATIENT EDUCATION
- Advise regular ophthalmic exams.
- Stress importance of glucose control through diet, exercise, drugs/insulin.

PROGNOSIS
If the condition is diagnosed and treated early in development, outlook is good. If treatment is delayed, blindness may result.

COMPLICATIONS
- Repeated intravitreal injection of anti-VEGF therapy may increase the risk of sustained intraocular pressure elevation and the possible need for ocular hypotensive treatment.
- Blindness
- Patients with T2DM and DME or PDR have an increased risk of cardiovascular disease.

**CLINICAL PEARLS**

Options for the treatment of diffuse macular edema include focal laser treatment, intravitreal triamcinolone, intravitreal ranibizumab, intravitreal bevacizumab, intravitreal aflibercept, intraocular steroid implants, and vitrectomy.
RH INCOMPATIBILITY
Kirsten A. Winnie, MD • Jennifer G. Chang, MD

BASICS

DESCRIPTION
• Antibody-mediated destruction of red blood cells (RBCs) that bear Rh surface antigens in individuals who lack the antigens and have become isoimmunized (sensitized) to them
• System(s) affected: hematologic/lymphatic/immunologic
• Synonym(s): Rh isoimmunization; Rh alloimmunization; Rh sensitization

EPIDEMIOLOGY

Incidence
Predominantly affects fetuses/neonates of isoimmunized, childbearing females; varies by race and ethnicity

ETIOLOGY AND PATHOPHYSIOLOGY
• Circulating antibodies to Rh antigens (transplacentally transferred antibodies in the case of a fetus/newborn) attach to Rh antigens on RBCs
• Immune-mediated destruction of RBCs leads to hemolysis, anemia, and increased bilirubin production.
• Transplacental fetomaternal hemorrhage (most common etiology) during pregnancy or at delivery
• Transfusion of Rh-positive blood to Rh-negative recipient; exposure to needles contaminated with Rh-positive blood
• Most commonly seen in the Rh-positive fetus of an Rh-negative mother

Genetics
• Complex autosomal inheritance of polypeptide Rh antigens; three genetic loci with closely related genes carry an assortment of alleles: Dd, Cc, and Ee.
• Individuals who express the D antigen (also called Rho or Rho[D]) are considered Rh-positive. Individuals lacking the D antigen are Rh-negative.
• Variant D alleles (weak D and partial D) are heterogeneous, altered forms of the D antigen. Some D variants are at risk of formation of anti-D antibodies, whereas others are not. With current blood typing procedures, certain D
variants likely to produce alloimmunization are typed as D-negative, although this does not include all genetic subtypes at risk of isoimmunization.

- Another variant D antigen, DEL, has been identified in some individuals (predominantly Asians). Those with partial DEL expression are at risk for alloimmunization and should be considered clinically Rh-negative. Women with complete DEL are not likely to be sensitized by exposure to Rh-D antigens through pregnancy or transfusion and should be considered clinically Rh-positive and do not need RhD prophylaxis.
- Antibodies may be produced to C, c, D, E, or e in individuals lacking the specific antigen; only D is strongly immunogenic.
- Isoimmunization to Rh antigens in susceptible individuals is acquired, not inherited.

**RISK FACTORS**

- ~15% of the white population and smaller fractions of other races are Rh-negative and susceptible to sensitization.
- Any Rh-positive pregnancy in an Rh-negative woman can result in sensitization.
- Weak D and partial D women are a heterogeneous group. Although previously reported to be Rh-positive and treated as such, alloimmunization has been reported and can result in HDFN or fatal hydrops fetalis.
- Native risk of isoimmunization after Rh-positive pregnancy had been estimated at ≤15% but seems to be decreasing.
- The risk of isoimmunization antepartum is only 1–2%.
- The risk of isoimmunization is 1–2% after spontaneous abortion and 4–5% after induced abortion.
- Use of Rho(D) immunoglobulin prophylaxis has reduced incidence of isoimmunization to <1% of susceptible pregnancies (1).

**GENERAL PREVENTION**

- Blood typing (ABO and Rh) on all pregnant women and prior to blood transfusions
- Antibody screening early in pregnancy
- Rh immunoglobulin prevents only sensitization to the D antigen.
- For prophylaxis, Rho(D) immunoglobulin (RhIG, RhGAM, HyperRHO, Rhophylac) given to unsensitized, Rh-negative women after the following:
  - Spontaneous abortion
  - Induced abortion
  - Ectopic pregnancy
– Antepartum hemorrhage
– Trauma to abdomen
– Amniocentesis
– Chorionic villus sampling
– Within 72 hours of delivery of an Rh-positive infant
– Given routinely at 28 weeks’ gestation

- Prophylaxis is to prevent sensitization affecting a subsequent pregnancy and has little effect on the current pregnancy.
- Dose for prophylaxis
  – 50-μg dose for events up to 12 weeks’ gestation
  – 300-μg dose for events after 12 weeks’ gestation
  – Higher doses may be required in the event of a large fetal–maternal hemorrhage (>30 mL of whole blood).

COMMONLY ASSOCIATED CONDITIONS
- Hemolytic disease of newborn
- Hydrops fetalis
- Neonatal jaundice
- Kernicterus
- See “Erythroblastosis Fetalis” topic.

DIAGNOSIS

PHYSICAL EXAM
- Jaundice of newborn
- Kernicterus
- Fetal hydrops or fetal death in utero if severe (see “Erythroblastosis Fetalis” topic)

DIFFERENTIAL DIAGNOSIS
- ABO incompatibility
- Other blood group (non-Rh) isoimmunization
- Nonimmune fetal hydrops
- Hereditary spherocytosis
- RBC enzyme defects

DIAGNOSTIC TESTS & INTERPRETATION
Initial Tests (lab, imaging)
- Positive indirect Coombs test (antibody screen) during pregnancy
- Paternal blood type
- Kleihauer-Betke (fetal hemoglobin acid elution, Hb F slide elution) test to quantify an acute fetal–maternal bleed
- Congenital or fetal anemia
- Blood type, direct Coombs test in newborn
- Cell-free fetal DNA (Cff DNA) test: standard practice in many European countries; available in the United States but is not a widely covered benefit. It allows detection of fetal Rh genotype with accuracy of 97.1%, sensitivity of 97.2%, and specificity of 96.8%.
- Cff DNA testing with selective administration of Rh immunoglobulin when the fetus tests Rh-positive has been shown to be as effective at preventing new Rh sensitization when compared to routine administration of Rh-immunoglobulin to all Rh-negative women. Such an approach avoids unnecessary use of Rh immunoglobulin (2)[B].
- Currently, routine administration of Rh immune globulin is more cost effective than use of Cff DNA testing in the United States.

Follow-Up Tests & Special Considerations
Prior administration of Rho(D) may lead to weakly (false-) positive indirect Coombs test in mother and direct Coombs test in infant.

TREATMENT
GENERAL MEASURES
- Depending on severity of involvement, treatment of fetus may include the following:
  - Intrauterine transfusion (3)[B],(4)[A]
  - Early delivery—typically no later than 37 to 38 weeks’ gestation (5)[C]
- Treatment of newborn may include the following:
  - Exchange transfusion
  - Transfusion after delivery
  - Phototherapy
- Inconclusive evidence on efficacy of IVIG to reduce need for exchange transfusion (6)[A]
ISSUES FOR REFERRAL
Because of the specialized, somewhat hazardous treatment measures involved, pregnancies in Rh-sensitized women are usually managed at tertiary-care facilities with maternal–fetal medicine specialists.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Initial monitoring of the newborn is inpatient or in special care nursery if treatment interventions are needed.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- In most cases, outpatient ambulatory management is appropriate during the antepartum period.
- Antibody titer measured monthly until 24 weeks and every 2 weeks thereafter during first affected pregnancy; a titer of ≥1:16 indicates the need for further testing (4)[A].
- If the patient had a previously affected infant, an Rh-positive fetus in the current pregnancy should be considered at risk regardless of antibody titers (4)[A].
  - Fetal heart rate testing/US to assess fetal status
  - Doppler US measurement of cerebral blood flow. If peak MCA velocity >1.5 multiples of the median, further testing is needed (cordocentesis) for diagnosing fetal anemia (4)[A].
  - Umbilical blood sampling (cordocentesis) for fetal blood type, hematocrit, reticulocyte count, and presence of erythroblasts (5)[C]
  - Amniocentesis for amniotic fluid bilirubin levels (5)[C]
  - Amniocentesis for fetal lung maturity if early delivery is a treatment option (5)[C].

PROGNOSIS
- With appropriate monitoring and treatment, infants born of severely affected pregnancies have a survival rate of >80% (4)[A].
- Even with severe disease, the neurologic outcome of survivors is generally
Fetuses with hydrops have a higher mortality rate and higher risk of neurologic impairment (6)[B].
Disease is likely to be more severe in affected subsequent pregnancies.

COMPPLICATIONS
- Pregnancy loss from umbilical blood sampling
- Pregnancy loss from intrauterine transfusion
- Fetal distress requiring emergent delivery

REFERENCES

ADDITIONAL READING

**SEE ALSO**

- Anemia, Autoimmune Hemolytic; Erythroblastosis Fetalis
- Algorithm: Jaundice

**CODES**

**ICD10**

- P55.0 Rh isoimmunization of newborn
- O36.0990 Maternal care for other rhesus isoimmunization, unspecified trimester, not applicable or unspecified
- T80.40XA Rh incompat react due to tranfs of bld/bld prod, unsp, init

**CLINICAL PEARLS**

- If paternity is certain, determining that the father does not carry the Rh(D) blood group antigen eliminates the need to give RhIG prophylaxis during pregnancy or the need for special fetal surveillance if the mother is already sensitized.
- The dose of RhIG for prophylaxis is affected by gestational age. The fetal blood volume is only a few milliliters at 12 weeks’ gestation. Therefore, a 50-μg dose of RhIG may be used for threatened, spontaneous, or induced
abortions up to 12 weeks’ gestation, instead of the standard 300-μg dose.

- Diagnosis is made by antibody titer. Affected pregnancies will require maternal–fetal medicine consultations and monitoring of antibody levels; if titer >1:16, will also require serial monitoring of MCA peak velocity. This will determine the need for invasive testing and transfusions.

- If the patient had a previously affected infant, an Rh-positive fetus in the current pregnancy should be considered at risk regardless of antibody titers—proceed to MCA peak velocity monitoring.

- The current standard in the United States is to provide prophylaxis to all unsensitized Rh-negative mothers; however, determination of the fetal Rh status by Cff DNA testing is reliable and could allow for targeted, rather than universal prophylaxis. Currently routine prophylaxis is more cost effective in the United States.
RHABDOMYOLYSIS

Caroline Tschibelu, MD • Chirag N. Shah, MD, FACEP

BASICS

DESCRIPTION

- Breakdown of skeletal muscle with release of intracellular contents into the circulation
- Rhabdomyolysis typically manifests with muscle aches, pains and weakness, and reddish brown (tea-colored) urine. Up to 50% of patients are asymptomatic.

EPIDEMIOLOGY

Incidence

26,000 hospitalizations annually in United States

ETIOLOGY, PATHOPHYSIOLOGY, AND RISK FACTORS

- Direct muscle trauma (most common cause)
  - Crush injuries
  - Extended periods of muscle pressure (during surgery, unconscious from alcohol ingestion)
  - Burns, electrocution, lightning strike
- Muscle exertion
  - Intense and/or prolonged physical exercise (marathon runners, athletes, contact sports)
  - Seizures
  - Delirium tremens
- Drugs and toxins
  - Alcohol
  - Cocaine (most common recreational drug), methamphetamine, phencyclidine, heroin, bath salts (1)[B], synthetic marijuana has been associated with severe rhabdomyolysis (2)[A].
  - Antipsychotics (due to neuroleptic malignant syndrome, malignant hyperthermia, and severe dystonia)
- Zidovudine
- Antimalarials
- HMG-CoA reductase inhibitors (statins) (risk <0.01%), higher with high dose and in combination with fibrates
- Colchicine
- Corticosteroids
- Carbon monoxide
- Snake envenomation
- Muscle ischemia
  - Thrombosis, embolism, sickle cell disease
  - Compartment syndrome
  - Tourniquets
- Infections
  - Viral: influenza A and B, coxsackievirus, HIV, varicella
  - Bacterial: *Streptococcus* or *Staphylococcus* sepsis, gas gangrene, necrotizing fasciitis, *Salmonella*, *Legionella*
  - Malaria
- Hypothermia
- Hyperthermia
- Autoimmune and genetic disorders
  - Polymyositis, dermatomyositis
  - Muscular dystrophies
  - Disorders of lipid metabolism (e.g., carnitine palmitoyltransferase deficiency)
  - Disorders of carbohydrate metabolism (i.e., phosphofructokinase deficiency, phosphoglycerate mutase, myophosphorylase deficiency, aka McArdle disease/deficiency)
  - Glycogen storage diseases (e.g., phosphorylase B kinase deficiency) and others (e.g., lactate dehydrogenase A deficiency)
- Metabolic and endocrinologic:
  - Hypothyroidism or thyrotoxicosis
  - Electrolyte imbalances (e.g., hyponatremia, hypernatremia, hypokalemia, hypocalcemia, hypophosphatemia)
  - Diabetic ketoacidosis
  - Hyperosmolar state

**Genetics**
Hereditary causes of rhabdomyolysis are rare but should be suspected for children, patients with recurrent attacks, or patients who have attacks after
minimal exertion, mild illness, or starvation.

**GENERAL PREVENTION**
- Avoid excessive exertional muscle injury; adequate hydration to prevent renal hypoperfusion, acidemia, and subsequent renal failure.
- Avoid precipitating drugs, metabolic and electrolyte abnormalities.

**DIAGNOSIS**

**HISTORY**
- Crush injury: direct trauma, prolonged compression/immobility. Causes include motor vehicle accidents (MVA) and entrapment in collapsed buildings. The elderly are more susceptible to crush injury due to immobility and falls. Rhabdomyolysis usually occurs after 1 hour of immobilization, but cases reported with compression lasting <20 minutes.
- Possible history of overexertion or use of drug/toxin (e.g., cocaine, amphetamine, statins), particularly in warm environments.
- Patient may complain of muscle aches, cramps, or fatigue.
- Agitation while patients are in restraints.
- Prolonged periods of lying on a hard surface (e.g., intoxicated or obtunded individuals).

**PHYSICAL EXAM**
- May have obvious muscle tenderness/injury and swelling on exam, or muscle exam may be completely normal.
- Tea-colored urine is indicative of myoglobinuria.
- Decreased urine output may indicate renal failure.

**DIFFERENTIAL DIAGNOSIS**
- Any disease that causes acute tubular injury may be confused with rhabdomyolysis.
- Renal pigment injury from hemoglobin resembles pigment injury from myoglobin.

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Creatine kinase (CK) is the most important diagnostic test: Elevated >5 times
the upper limit of normal or >1,000 U/L. CK levels >5,000 U/L are causally related to acute renal failure (ARF) (2,3)[A] and should prompt aggressive fluid resuscitation.

- CK levels peak at ~24 hours and return to normal after 3 to 5 days, making it a more sensitive marker than myoglobin. Myoglobin is responsible for kidney failure (2,3)[A].
- Serum myoglobin levels peak within a few hours and return to normal after ~24 hours. Normal myoglobin levels do not rule out rhabdomyolysis due to its rapid clearance.
- Urinalysis: Dipstick test positive for blood without erythrocytes in sediment suggests injury from either hemoglobin or myoglobin.
- Elevations of serum potassium from muscle injury can be compounded by ARF.
- Initial hypocalcemia: Calcium enters the injured muscle cells and precipitates as calcium phosphate, leading to calcification of ischemic muscle cells. Only correct initial hypocalcemia if patient is symptomatic or has ECG changes; resolves during the renal recovery phase.
- Hypercalcemia during renal recovery phase: Unique to rhabdomyolysis-induced ARF for 20–30% of patients (3)[A]. As renal function improves, there is mobilization of the precipitated calcium, increase in calcitriol, and hyperphosphatemia resolves.
- Extreme hyperuricemia may be present and can cause acute uric acid nephropathy.
- Elevations in BUN and creatinine suggest ARF.
- Reversible hepatic dysfunction can occur. However, elevations in alanine aminotransferase (ALT), aspartate aminotransferase (AST), and lactic dehydrogenase may be due to muscle injury rather than hepatic injury.
- Disseminated intravascular coagulation (DIC) suggested by increase in coagulation times, fibrin degradation products, and D-dimer with decreases in platelets and fibrinogen.
- 12-lead ECG as hyperkalemia can induce fatal arrhythmias.

**Follow-Up Tests & Special Considerations**

- Delayed renal failure/electrolyte abnormalities despite normal initial levels.
- Ongoing muscle injury is manifested by rising creatine phosphokinase (CPK).
- Renal imaging shows findings similar to other mechanisms of ARF.

**Diagnostic Procedures/Other**
Muscle compartment pressures if compartment syndrome is suspected

**Test Interpretation**
- Muscle necrosis
- Myoglobin-related renal injury may resemble acute tubular injury from other causes.

**TREATMENT**

**GENERAL MEASURES**
- Address underlying cause (e.g., medications cessation, temperature control, trauma, infection)
- Aggressive hydration is often necessary. With severe muscle trauma (crush injuries), up to 12 L of fluid may be sequestered in the muscles.
- Monitor CK levels, renal function, and electrolytes.
- Follow potassium levels due to potential for arrhythmias.
- Treat DIC or hepatic dysfunction appropriately.

**MEDICATION**

**First Line**
- Aggressive fluid resuscitation is the most important intervention: normal saline (NS) and 5% glucose solution with a target urine output of 200 to 300 mL/hr. Alternating NS and 5% glucose is recommended to prevent volume overload. Infusion rate should be 500 mL/hr (4)[C],(5)[A].
- Alkalization of the urine may decrease myoglobin-induced nephrotoxicity in the tubules (sodium bicarbonate to increase urine pH >6.5):
  - Use is controversial.
  - Side effects include worsening hypocalcemia.
  - Sodium bicarbonate may be of use in patients with very high CK levels, acidosis, or coexisting hyperkalemia.
  - Place 150 mEq (3 ampules) NaHCO$_3$ in 1 L of D5W and infuse at 200 mL/hr.

**Second Line**
- IV mannitol as a bolus if urine output remains low, 1 to 2 g/kg, not to exceed 200 g in 24 hours with a cumulative dose of 800 g. It is used to prevent ARF
only if diuresis is not adequate (<200 mL/hr) despite fluid therapy (5)[A].

- Increases prostaglandin production leading to renal vasodilation and diuresis, reducing susceptibility to myoglobin injury. As an osmotic agent, filtered but not reabsorbed by the tubules, mannitol increases sodium delivery and diuresis. This may remove necrotic cell debris and prevent rise in compartment pressures.
- Use of mannitol is controversial. No good evidence that it improves outcomes more than aggressive IV hydration. As a free-radical scavenger, mannitol has renal protective effects if used before tubular occlusion.
- Consider adding furosemide to force diuresis if necessary (40 to 120 mg/day).
- Do not diurese in anuric renal failure; caution also in the elderly and patients with heart disease

- Hyperkalemia can result from massive release of intracellular potassium stores or ARF. Severe hyperkalemia may be life-threatening. Treatment when ECG changes are present (tall, thin T waves; PR prolongation; QRS widening; P wave flattening).
  - Calcium gluconate: to stabilize the cardiac membrane. IV 1 to 2 ampules (0.5 mL 10% calcium gluconate = 4 mg elemental calcium; give 4 mg/kg/hr for 4 hours.)
  - If acidosis is present: 1 to 2 ampules (2 to 3 mL/kg) sodium bicarbonate IV. Sodium bicarbonate can worsen hypocalcemia.
  - If tolerated: Oral sodium polystyrene sulfonate (Kayexalate) as much as 20 g (1 g/kg) can be given via enema.
  - Insulin and albuterol transiently drive potassium into the cells. Administration of glucose can prevent the hypoglycemic effects of insulin.
  - Precautions: Continuous monitoring of potassium levels to prevent overcorrecting with potential hypokalemia and arrhythmias.
  - Indications for dialysis include resistant and symptomatic hyperkalemia (ECG), oliguria (<0.5 mL/kg over 12-hour period), anuria, volume overload, or persistent acidosis (pH <7.1).

ISSUES FOR REFERRAL
- Usually managed as an inpatient
- Diagnosis of compartment syndrome merits surgical consultation for consideration of fasciotomy.
- Renal dialysis may be indicated in ARF.

ADDITIONAL THERAPIES
During the oliguric phase, symptomatic hypocalcemia (rare) may benefit from IV calcium gluconate.

**SURGERY/OTHER PROCEDURES**
For muscle entrapment/compartment syndrome

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Patients with significant elevations of CK should be admitted for IV hydration and clinical monitoring.
- Volume expansion with NS to increase urine output to at least 150 mL/hr
- CK usually peaks 24 to 36 hours after muscle injury, so monitoring should confirm that the CK is trending down. Renal function should be stable/improving. Electrolytes should be normal.
- Patients with mild CK elevation and normal renal function may be discharged after observation phase if CK is trending down.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Follow-up within a few days to recheck CK, electrolytes, and renal function

*Patient Monitoring*
- Contingent on disease: essential for metabolic myopathies
- Myotoxic drugs should be discontinued/monitored closely.

**DIET**
- With renal failure, restrict protein intake to lower BUN level.
- Limit potassium intake.
- With anuria, essential to restrict volume intake

**PROGNOSIS**
Contingent on primary cause of rhabdomyolysis and on recovery from ARF without complications

**COMPLICATIONS**
Death, especially from hyperkalemia/renal failure

With dialysis and supportive care, the prognosis is very good.

CODES

ICD10

- M62.82 Rhabdomyolysis
- T79.6XXA Traumatic ischemia of muscle, initial encounter
• T79.6XXD Traumatic ischemia of muscle, subsequent encounter

**CLINICAL PEARLS**

• The cornerstone of treatment of rhabdomyolysis is aggressive fluid administration.
• Frequent monitoring of potassium, calcium, and creatinine is necessary in the acute period.
Rhabdomyosarcoma (RMS) is a malignancy of primitive mesenchymal cells with myogenesis capacity, which are in skeletal muscle tissues. It occurs mainly as primary malignancy, but can also be a component of heterogeneous neoplasias, like malignant teratoma.

- **Common anatomic sites:**
  - Head and neck (common primary site in young children and are almost always of the embryonal type)
  - Genitourinary (mostly of the embryonal type)
  - Musculoskeletal (extremities are the most common primary sites in adolescents and adults)

- The International Classification of RMS describes four major subtypes:
  - Embryonal RMS (ERMS): corresponds to 60–70% of pediatric cases. It is of early onset and the most common subtype in children. It is also more likely to occur in the head, neck, and genitourinary areas. ERMS is subdivided into:
    - Classic: groups most of the cases
    - Botryoid: is typically seen in infants, although can happen in children <4 years of age
    - Spindle cell: corresponds to 3% of cases and affects mostly young children
    - Both botryoid and spindle cell variants have better prognosis than the classical one.
  - Alveolar RMS (ARMS): represents 30% of pediatric cases. It is more common in the trunk, perineum/perianal area, and extremities. It is very aggressive.
  - Anaplastic (children)/pleomorphic (adults) is usually seen in patients aged 30 to 50 years, rarely in children.

**EPIDEMIOLOGY**
**Incidence**
- 4.5 cases of RMS per 1 million children per year
- 50% of pediatric cases occur before the age of 10 years.
- RMS accounts for 60% of sarcomas in children and adolescents.
- In adults, RMS represents 3% of all soft tissue sarcomas in adults.

**Prevalence**
- RMS comprises 3.5% of all childhood cancers.
- The embryonal subtype is more frequent in males (male:female ratio, 1.5)

**Genetics**
Genetic characteristics vary according to the RMS subtype (1,2):
- Alveolar:
  - t(2;13)(q35;q14); causing PAX3-FOXO1 fusion
  - t(1;13)(p36;q14); causing PAX7-FOXO1 fusion
  - t(X:2)(q13;q35); causing PAX3-FOXO4 fusion
  - t(2;2)(q35;p23); causing PAX3-NCOA1 fusion
  - t(2;8)(q35;q13); causing PAX3-NCOA2 fusion
  - t(8;13)(p12;q13); causing FOXO1-FGFR1 fusion
- Embryonal:
  - Complex genetic aberrations affecting multiple genes; among them, MYOD1 mutations
  - Loss or uniparental disomy of 11p15.5 +2,+8,+11,+12,+13,+20 affecting the genes IGF-2, H19, CDKN1C, and/or HOTS
- Spindle cell RMS:
  - 8q13 rearrangements involving SRF-NCOA2 and TEAD1-NCOA2

**RISK FACTORS**
RMS is associated with high birth weight, large gestational size for age, and the genetic conditions described below.

**COMMONLY ASSOCIATED CONDITIONS**
- Beckwith-Wiedemann syndrome (11p15 mutations)
- Costello syndrome (germline HRAS mutations)
- Li-Fraumeni (germline TP53; also known as p53 mutations)
- Neurofibromatosis type I (NF1 mutations)
- Noonan syndrome (PTPN11 mutations)
- Pleuropulmonary blastoma (DICER1 mutations)
**DIAGNOSIS**

**HISTORY**
- Presents as a progressive painless mass of the head and neck, genitourinary tissue, trunk, or extremities
- RMS of genitourinary tissue may present as vaginal bleeding in females.
- Other symptoms may be noted due to mass effect of the primary or metastatic lesions.
- Personal or family history of genetic syndromes (i.e., NF1, Li-Fraumeni, etc.)

**PHYSICAL EXAM**
- Painless, enlarging mass
- Polypoid mass protruding from vagina (botryoid)
- Exophthalmos and chemosis (orbital involvement)
- Abdominal pain
- Compression symptoms (i.e., seizures, visual field defects, nerve palsy, headaches)

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- MRI with and without contrast or CT with contrast of the primary tumor: provides details about the size of the tumor and infiltration to nearby structures
- Basic staging tests:
  - Chest x-ray or CT chest without contrast (preferred). The most common site of metastasis is the lungs. PET/CT scans may be useful to detect lymph node or distant metastases; not readily evident on CT or MRI scans. It is also helpful in monitoring the response to treatment for deep, firm lesions >3 cm.

*Diagnostic Procedures/Other*
- Pathology:
  - Core needle biopsy, incisional biopsy, or excisional biopsy (based on the size of the mass). The histologic morphology is similar to that of other small, blue, round-cell tumors which raises the need for advanced immunohistochemical and genetic tests.
    - Alveolar: Rhabdomyoblasts arranged in what grossly appears to mimic
pulmonary alveoli. The alveolar component must be ≥50%.

- Embryonal:
  - Classic: rhabdomyoblasts configured in sheets without alveolar pattern
  - Botryoid: “grape-like” appearance of rhabdomyoblasts with notable clustering in the subepithelium forming the cambium layer. These are seen in the vagina and bladder.
  - Spindle cell: rhabdomyoblasts with a spindle-like appearance

- Anaplastic (children)/pleomorphic (adults): rhabdomyoblast with large hyperchromatic nuclei and strange mitotic morphologies

- Immunohistochemical markers:
  - Muscle-specific actin, myosin, desmin, myoglobin, Z-band protein, and MyoD

- Molecular testing for PAX/FOXO1 fusion

- Currently both PCR and fluorescence in situ hybridization (FISH) were used to determine PAX3-FOXO1 rearrangements with good concordance (94.9%). Although both have similar sensitivity (85.7% vs. 83.3%), PCR seems to have a slightly higher specificity (100% vs. 96%) (3).

- The perspective is that extensive genetic profiling will become the gold standard for diagnosis and prognosis (2).

- Staging:
  - Based on site, size, regional nodal involvement, and distance spread
  - See “Table 1.”

T1, confined to organ of origin; T2, extends outside the organ of origin; a, ≤5 cm in diameter; b, >5 cm in diameter; N0, regional nodes not clinically involved; N1, regional nodes clinically involved by neoplasm; NX, clinical status of regional nodes unknown; M0, no distant metastasis; M1, distant metastasis.
TREATMENT
The three tenets of treatment for adults and children are composed of surgical resection, radiation therapy, and chemotherapy. Patients should be referred to a multidisciplinary team with expertise in oncology for definitive treatment.

SURGERY/OTHER PROCEDURES
- Surgery:
  - Local resection of tumor. If possible, resect metastasis as well. However, wide resection may not be feasible in cases where grossly impaired functionality results.
- Chemotherapy:
  - Chemotherapy schemes depend on the risk stratification assessment (i.e., low, intermediate, high). For nonmetastatic RMS, this stratification is made based on the TNM staging as well as the surgical/pathologic clinical grouping system. The latter is determined after the surgical resection based on histopathologic features and extent of residual tumor. In other words, in nonmetastatic RMS, the risk stratification cannot be fully determined before the initial surgery (2).
    - All children receive chemotherapy.
    - Chemotherapy regimens may vary but the gold standard is VAC (vincristine, dactinomycin [also known as actinomycin D], and cyclophosphamide) (4)[A]. In low-risk patients, sometimes VA can be given instead (just vincristine and dactinomycin) (4)[A].
      - Most characteristic effects of these medications are:
        - Vincristine: peripheral neuropathy
        - Dactinomycin: myelosuppression and hepatotoxicity
        - Cyclophosphamide: hemorrhagic cystitis (mesna is used for prophylaxis), transitional cell carcinoma, myelosuppression with leukopenia, and infertility
    - In addition, ifosfamide, topotecan, doxorubicin, etoposide, and irinotecan may also be used in alternative regimens.
    - Chemotherapy duration depends on risk stratification but in general terms ranges from 12 to 24 months given in separate cycles (usually 14 to 15 cycles) (5).
    - Given low frequency of RMS in adults, there has been no large trials to set appropriate regimen; therefore, standard VAC is used empirically from ages 19 to 50 years, base in children studies. Although this practice showed low
efficacy in some case series and has led to recommend alternative regimen as mentioned priorly (doxorubicin, ifosfamide, and vincristine) which has demonstrated improve in short-term (2 years) overall survival and disease-free survival.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

All patients should follow up with their multidisciplinary treatment team, a necessary practice for treatment response, early detection of locoregional relapse, metastatic disease, or development of secondary malignancies. During follow-up besides physical exam, imaging surveillance should be included for the first 5 years as the following recommendation: chest x-ray or CT chest and MRI or CT of primary site every 3 months for the 1st year after diagnosis and then every 4 months for the following 2 years and finally every 6 months for next 2 years. After the first 5 years, no more imaging surveillance is recommended as it has not showed further benefits. Other imaging techniques such as bone scan/PET scan should be considered based on clinical decisions, and echocardiograms are recommended if patient received anthracycline therapy (5,6).

**PROGNOSIS**

- RMS (overall): 70% 5-year survival (5)
- In orbital RMS, survival can be as high as 95%.
- Prognosis as in other tumors depends on size, presence or not of metastasis, and location of the tumor which help to risk-stratify patients into low, intermediate, and high risk.
- Favorable site: orbit/eyelid, head and neck (with no parameningeal involvement), genitourinary (without bladder or prostate involvement), and biliary tract
- Unfavorable site: bladder, prostate, extremity, parameningeal, trunk, retroperitoneal, pelvis (5)
- 5-year survival outcome by *PAX/FOXO1* fusion status and risk stratification status: low risk + fusion negative 90%; intermediate risk + fusion negative 78%; intermediate risk + fusion positive 56%; high risk + fusion negative 41%; high risk + fusion positive 11% (5)
- Prognosis in adults is worse when compared to children not only due to lower
rates of treatment adherence and lack of clinical trials identifying best treatment but also due to less favorable location and histopathology at presentation. Risk factors associated with the poorest outcomes at the time of relapse are metastatic disease at relapse, prior RT treatment, initial tumor size $>5$ cm, and relapse within 18 months of diagnosis (6).

**COMPLICATIONS**

- Relapse
- Secondary neoplasm
- Growth abnormalities
- Treatment side effects

**REFERENCES**

**ADDITIONAL READING**

The references 1 and 4 are excellent additional resources.
CODES

ICD10
- C49.9 Malignant neoplasm of connective and soft tissue, unsp
- C49.0 Malignant neoplasm of connective and soft tissue of head, face and neck
- C49.5 Malignant neoplasm of connective and soft tissue of pelvis

CLINICAL PEARLS
- RMS are more common in children but can develop in adults.
- Epidemiology and prognosis of each subtype of RMS can vary significantly.
- Several genetic disorders and congenital syndromes are associated to a higher risk of developing RMS.
RHEUMATIC FEVER

Anum Abbas, MD • Renuga Vivekanandan, MD

BASICS

DESCRIPTION

- Acute rheumatic fever (ARF) is a delayed inflammatory sequela of group A Streptococcus (GAS) tonsillopharyngitis that affects multiple organ systems.
- Can lead to rheumatic heart disease (RHD)
- Recurrence in adults and children is common if antibiotic prophylaxis is withheld.
- Systems affected: cardiovascular, nervous, hematologic/lymphatic/immunologic, skin/exocrine, musculoskeletal

Pediatric Considerations

Can affect any age but most common ages 5 to 15 years

EPIDEMIOLOGY

- ARF and RHD are now largely restricted to developing countries and some poor populations of wealthy countries.
- Largely disease of poverty and economic disadvantage
- Male = female, but females more likely to develop chorea
- Can occur as an epidemic

Incidence

- Worldwide, incidence (new cases) has been declining for decades, attributed to increasing antibiotic use and improved living conditions. Most new cases are in developing countries.
- In early studies, ARF developed in 3% of children with untreated GAS pharyngitis.
- Incidence of ARF in the United States in the 1960s was 13.3/100,000 and is currently <1/100,000.
- Mean incidence of ARF is 19/100,000 school aged children worldwide.
- 95% of cases currently occur in developing countries.

Prevalence
Worldwide, >15 million people have RHD, and prevalence has been rising due to improved medical care and longer survival (despite decreasing incidence of ARF).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Preceded by tonsillopharyngitis of GAS, also known as *Streptococcus pyogenes*, a gram–positive organism
- Molecular mimicry: Antibodies against M protein on GAS cross-reacts with cardiac and vessel endothelial proteins, leading to an inflammatory cascade.

**Genetics**
- Susceptibility is associated with certain genetic polymorphisms, including toll-like receptors, cytokines, and human leukocyte antigen genes; not fully understood
- ARF appears to be a heritable disease and susceptibility is most likely polygenic.
- Increased susceptibility in certain populations, including Australian aborigines, New Zealand Maori, and Pacific Islanders

**RISK FACTORS**
Genetic susceptibility and possible increased risk with iron deficiency or low serum albumin

**GENERAL PREVENTION**
- Primary prevention: Antibiotics are effective at reducing incidence of ARF after known or suspected GAS pharyngitis. Number needed to treat is 100 (1). Appropriate treatment of streptococcal pharyngitis prevents ARF in most cases.
- Secondary prevention: long-term antibiotic prophylaxis to prevent recurrence which can lead to RHD

**DIAGNOSIS**
- Requires laboratory evidence of preceding GAS infection (See “Initial Tests [lab, imaging].”)
- Revised 2015 Jones criteria
- Initial ARF: 2 major OR 1 major + 2 minor
- Recurrent ARF: 2 major OR 1 major + 2 minor OR 3 minor
### Major Criteria
- Carditis/valvulitis
- Low risk: polyarthritis
- Moderate to high risk: mono/polyarthritis
- Sydenham chorea
- Erythema marginatum
- Subcutaneous nodules

### Minor Criteria
- Low risk: fever ≥38.5°C
- Moderate to high risk: fever ≥38°C
- Low risk: polyarthralgia
- Moderate to high risk: monoarthralgia
- ↑PR interval
- CRP ≥3 mg/dL, and/or
- Low risk: ESR ≥60 mm/hr
- Moderate to high risk: ESR ≥30 mm/hr

The revised criteria distinguish between patients with low risk versus moderate-high risk of having ARF. Patients can be considered low risk if they are from and among a low-incidence group (2)[C].

### HISTORY
- ARF presents 1 to 4 weeks following GAS tonsillopharyngitis.
- Polyarthritis is often first, affecting the knees, ankles, elbows, and wrists. Each resolves in days, thus seems to “migrate.” Usually self-limited <1 month. Moderate- to high-risk patients may develop monoarthritis. Use of NSAID or aspirin may mask the arthritis.
- Fever
- Erythema marginatum rash
- Pancarditis or valvulitis (50–70%) can be subclinical (asymptomatic without auscultatory findings) or clinically apparent (symptomatic or auscultatory findings).
- Sydenham chorea (clinical diagnosis, in 10–30%)
- Neurologic disorder consisting of abrupt, nonrhythmic, involuntary movements
  - 1 to 6 months after infection, so lab evidence of preceding infection may be absent.
  - More common in 5 to 15 years old, more common in females
  - Improves or ceases during sleep
  - Psychiatric symptoms may have onset prior to chorea, with emotional lability and obsessive-compulsive symptoms.
  - Usually self-resolves over several months and can relapse

### PHYSICAL EXAM
- Neuro: Sydenham chorea: Involuntary movements may be general or unilateral and may involve the face. “Milkmaid grip” is intermittent hypotonia
appreciated on test of grip strength.

- Cardiac: pericardial friction rub, blowing holosystolic murmur, rarely diastolic, or new or changing murmur; rarely evidence of heart failure
- Skin
  - Subcutaneous nodules (<10%): firm, painless, up to 2 cm, over bony surfaces or tendons, usually extensor surfaces; more common in severe ARF, persists up to several weeks
  - Erythema marginatum (5–13%): nonpruritic, blanching, evanescent, pale pink macular transitions to central clearing, found on trunk and occasionally limbs, accentuated by warming the skin

**DIFFERENTIAL DIAGNOSIS**

- Systemic lupus erythematosus
- Poststreptococcal reactive arthritis
- Juvenile rheumatoid arthritis
- Infectious arthritis
- Viral myocarditis
- Innocent cardiac murmur
- Tourette syndrome
- Kawasaki syndrome
- Pediatric autoimmune neuropsychiatric disorders associated with streptococcal infections (PANDAS)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Bacteriologic/serologic evidence of GAS infection, helpful but not necessary to make the diagnosis of ARF (2)[B]:
  - Rapid streptococcal antigen test with high pretest probability
  - Throat culture (sensitivity 25% by time of ARF)
  - Elevated or rising antistreptolysin O (ASO) titer; peaks ~1 month postinfection
- If ASO negative, check anti-DNAse B (peaks ~2.5 months, remains elevated up to 9 months), streptokinase, and antihyaluronidase.
- Bacteriologic/serologic evidence may be negative in chorea or chronic indolent rheumatic carditis.
- ESR and CRP are acute-phase reactants that almost always increase in ARF.
- CBC with differential: leukocytosis, possible normocytic anemia
- Complement levels normal (do not need to check)
- ECG: PR prolongation, AV block, signs of pericarditis
- Arthrocentesis of affected joints shows sterile inflammatory fluid with 10 to 100,000 WBC/mm³.
- Chest x-ray: may have cardiomegaly from myocarditis
- Echocardiogram: Assess chamber size and function, pericardial effusion, and valve disease.
- All cases of confirmed or suspected ARF should have an echocardiogram (2) [B] due to the 18% prevalence of subclinical carditis.
- Antimyosin scintigraphy can detect carditis (nonspecific).

**Follow-Up Tests & Special Considerations**
- ESR and CRP are useful to monitor rebound inflammation.
- Repeat echocardiograms to monitor evolution of carditis, even if not initially present (2)[C].
- Household contacts should be screened with throat culture even if asymptomatic and treated with antibiotics if positive.

**Test Interpretation**
Prior treatment with aspirin or steroids may lead to falsely normal lab results.

**TREATMENT**

**GENERAL MEASURES**
- Antibiotic
- Anti-inflammatory agent (aspirin or naproxen)
- Manage cardiac manifestations as needed in addition to standard ARF treatment (e.g., dysrhythmia, pericarditis, myocarditis, valvular disease, or heart failure).

**MEDICATION**

**First Line**
- Eradication: Treat initially as if active GAS infection, then begin prophylaxis.
- If no penicillin allergy
  - Penicillin VK PO BID for 10 days, or benzathine penicillin G IM for 1 day, or amoxicillin PO for 10 days (preferred in children) (3)[A]
- If penicillin allergy
– 1st-generation cephalosporin PO for 10 days (3)[A], azithromycin PO for 5 days, or clindamycin PO for 10 days, or clarithromycin PO for 10 days (3) [B]

- If there is heart failure, AV block third degree, or other severe manifestations of carditis, appropriate traditional management should be initiated.

- Aspirin high-dose is effective for treatment of arthritis and fever (4)[B] but has not been shown to reduce or improve cardiac manifestations (5)[B]. High-dose aspirin for prolonged periods risks salicylate toxicity and if used, consider following salicylate levels.

- If severe carditis is present, consider prednisone, although not shown to prevent or reduce cardiac manifestations (5)[B].

- Chorea generally self-resolves and does not require treatment, but if symptoms are severe, can use valproic acid, carbamazepine, or an antipsychotic if still resistant. If symptoms persist, consider prednisone, which unlike cardiac disease, has been shown effective for Sydenham chorea.

**Second Line**

- If penicillin allergy is present, erythromycin is preferred by the New Zealand guidelines but not by the Infectious Diseases Society of America.

- Naproxen is a reasonable alternative to aspirin (see “Pediatric Considerations”).

**ISSUES FOR REFERRAL**

A cardiologist should be involved in management of ARF.

**SURGERY/OTHER PROCEDURES**

Valve stenosis is a late sequela that can result from fibrosis and calcification; it may require surgical correction (valve repair preferred over replacement) (6).

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Initial hospitalization may be helpful for diagnosis and to ensure stability.

- Heart failure requires prompt hospitalization.

- IV fluids
  - Only if signs of dehydration or to augment preload; use caution if heart failure present.

- Nursing
  - Consider bedrest if severe symptoms, with gradual return to ambulation as
ARF patients should be on a prophylactic antibiotic throughout childhood until age 21 years and possibly indefinitely depending on cardiac damage because recurrence can worsen prognosis (7)[C].
- First-line prophylaxis is long-acting benzathine penicillin G monthly IM injections (7)[A].
- Penicillin V PO 250 mg BID is an alternative but has risk of nonadherence (7)[B].
- If penicillin allergy, treat with sulfadiazine (7)[B].
- If penicillin and sulfa drug allergy, treat with azithromycin (7)[C].
- Patients on penicillin prophylaxis who develop GAS pharyngitis on penicillin should be treated with an alternative agent such as clindamycin.
- If diagnostic uncertainty exists, consider 1 year of secondary antibiotic prophylaxis followed by reassessment and echocardiogram (2)[C].
- Routine antibiotic prophylaxis for dental procedures is no longer recommended by the American Heart Association for patients with RHD (6).
- Have low threshold to test and treat episodes of acute tonsillopharyngitis.

Patient Monitoring
Initially weekly and then every 6 months

Pediatric Considerations
- Use aspirin with caution in children given the risk of Reye syndrome.
- Naproxen (10 to 20 mg/kg/day) has been found noninferior to aspirin with fewer risks in ARF, in a small study (4)[B].

Pregnancy Considerations
May exacerbate valve disease, particularly mitral stenosis. Refer pregnant patients to a cardiologist.

DIET
Regular diet or low-sodium if heart failure present
PATIENT EDUCATION
American Heart Association: http://www.heart.org

PROGNOSIS
Sequelae are generally limited to the heart and depend on the severity of carditis during an acute attack.

COMPLICATIONS
- Recurrence of ARF due to GAS reinfection
- RHD can occur 10 to 20 years after ARF, with mitral more common than aortic regurgitation, can lead to stenosis. Heart failure is worst complication.
- Jaccoud arthropathy is chronic and involves painless deformities of hands/feet.

REFERENCES

CODES

ICD10

- I00 Rheumatic fever without heart involvement
- I01.9 Acute rheumatic heart disease, unspecified
- I01.0 Acute rheumatic pericarditis

CLINICAL PEARLS

- ARF is an inflammatory disease that affects multiple organ systems including the heart.
- Modified Jones criteria for diagnosis include two major or one major plus two minor manifestation in the context of a preceding documented GAS infection.
- Treatment involves aspirin and antibiotic eradication followed immediately by long-term antibiotic prophylaxis.
**RHINITIS, ALLERGIC**

*Naureen Rafiq, MBBS • Krista E. Goins, MD*

---

**BASICS**

Allergic rhinitis is the collection of symptoms involving mucous membranes of nose, eyes, ears, and throat after an exposure to allergens such as pollen, dust, or dander.

**DESCRIPTION**

- IgE-mediated inflammation of the nasal mucosa following exposure to an extrinsic protein; an immediate symptomatic response is characterized by sneezing, congestion, and rhinorrhea followed by a persistent late phase dominated by congestion and mucosal hyperreactivity.
- Allergic rhinitis can be classified into seasonal or perennial and can be intermittent or persistent.
- Seasonal responses are usually due to outdoor allergens such as tree pollen, flowering shrubs in spring, grasses and flowering plants in summer, and ragweed and mold in fall.
- Perennial responses, or year-round symptoms, are usually associated with indoor allergens like dust mites, mold, and animal dander.
- Occupational allergic rhinitis is caused by allergens at the workplace and can be sporadic or year-round.
- Nonallergic rhinitis (e.g., vasomotor, rhinitis of pregnancy, and rhinitis medicamentosa) can occur.

**Pediatric Considerations**

Chronic nasal obstruction can result in facial deformities, dental malocclusions, and sleep disorders.

**Pregnancy Considerations**

Physiologic changes during pregnancy may aggravate all types of rhinitis, frequently in the 2nd trimester.

**EPIDEMIOLOGY**

- Onset usually in first 2 decades, rarely before 6 months of age, with tendency declining with advancing age
The mean age of onset is 8 to 11 years, and about 80% of cases have established allergic rhinitis by age 20 years.

**Prevalence**
- ~10–25% of the U.S. adult population and 9–42% of the U.S. pediatric population are affected.
- 44–87% of patients with allergic rhinitis have mixed allergic and nonallergic rhinitis, which is more common than either pure form (1).
- Scandinavian studies have demonstrated cumulative prevalence rate of 14% in men and 15% in women.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Aeroallergen-driven mucosal inflammation due to resident and infiltrating inflammatory cells as well as vasoactive and proinflammatory mediators (e.g., cytokines)
- Inhalant allergens:
  - Perennial: house dust mites, indoor molds, animal dander, cockroach/insect detritus
  - Seasonal: tree, grass, and weed pollens; outdoor molds
  - Occupational: latex, plant products (e.g., baking flour), sensitizing chemicals, and certain animals for people working in farms and vet clinics

**Genetics**
Complex but strong genetic predilection present (80% have family history of allergic disorders)

**RISK FACTORS**
- Family history of atopy, with a greater risk if both parents have atopy
- Higher socioeconomic status
- Tobacco smoke can exacerbate symptoms and increase risk of developing asthma in patients with allergic rhinitis.
- Having other allergies such as asthma
- Unclear evidence regarding risk due to early, repeated exposure to offending allergen and early introduction of solid food
- Pets in house and houses infested with cockroaches can cause perennial allergic rhinitis.

**GENERAL PREVENTION**
● Primary prevention of atopic disease has not been proven effective by maternal diet or maternal allergen avoidance (2).
● Exclusive breastfeeding to 6 months of age lowers risk of some atopic disorders.
● Symptomatic control by environmental avoidance is the “first-line treatment.”
● No evidence to support use of acaricides with mite-proof mattress and pillow covers, carpet and drape removal, removal of plants in the home, and pet control (2,3)[B]
● Air conditioning and limited outside exposure during allergy season (1)[B]
● HEPA air cleaners and vacuum bags of unclear efficacy
● Close doors and windows during allergy season.
● Use a dehumidifier to reduce indoor humidity.

COMMONLY ASSOCIATED CONDITIONS
Other IgE-mediated conditions: asthma, atopic dermatitis, allergic conjunctivitis, food allergy

DIAGNOSIS
Diagnosis is made primarily by history and physical exam.

HISTORY
● Evaluation of nature, duration, and time course of symptoms
● History of atopic dermatitis and/or food allergies
● History of nasal congestion; rhinorrhea; pruritus of nose, eyes, ears, and/or palate; sneezing; itching; and watering eyes
● Family history of allergic diseases
● History of environmental and occupational exposure and various nasal stimuli can help differentiate between allergic and vasomotor rhinitis.

PHYSICAL EXAM
Many findings are suggestive of but not specific for allergic rhinitis:
● Dark circles under eyes, “allergic shiners” (infraorbital venous congestion)
● Transverse nasal crease from rubbing nose upward; typically seen in children
● Rhinorrhea, usually with clear discharge
● Pale, boggy, blue-gray nasal mucosa
● Postnasal mucus discharge
Oropharyngeal lymphoid tissue hypertrophy

**DIFFERENTIAL DIAGNOSIS**
- Infectious rhinitis: usually viral, commonly with secondary bacterial infection
  - Usually associated with sinusitis and is known as rhinosinusitis
  - Viral rhinitis averages 6 episodes/year from ages 2 to 6 years.
  - IgA deficiency with recurrent sinusitis
- Rhinitis medicamentosa:
  - Rebound effect associated with continued use of topical decongestant drops and sprays
  - ACE inhibitors, reserpine, β-blockers, oral contraceptive pills (OCPs), guanethidine, methyldopa
  - Aspirin, NSAIDs
- Vasomotor (idiopathic) rhinitis caused by numerous nasal stimuli such as warm or cold air, scents and odors, light or particulate matter
- Hormonal: pregnancy, thyroid, OCPs
- Nonallergic rhinitis with eosinophilia syndrome (NARES)
- Gustatory: watery rhinorrhea in response to alcohol or food
- “Skier’s nose”: watery rhinorrhea in response to cold air
- Conditions associated with rhinitis:
  - Nasal polyps, tumor
  - Septal/anatomic obstruction
    - Adenoidal hypertrophy, particularly in children
    - Septal abnormality or deflected nasal septum (DNS) in adults

**DIAGNOSTIC TESTS & INTERPRETATION**
- Lab tests rarely needed
- Skin testing is done to identify the allergen for immunotherapy.

**Initial Tests (lab, imaging)**
- Testing is rarely indicated.
- If diagnosis implies other causes, consider the following:
  - CBC with differential may show elevated eosinophils.
  - Increased total serum IgE level
  - Nasal probe smear may show elevated eosinophils.
- Medications that may alter lab results
  - Corticosteroids may decrease eosinophilia.
  - Antihistamines suppress reactivity to skin tests; stop antihistamines 7 days
before testing.

- CT scan of sinuses is not routinely done but can be used to check for complete opacity, fluid level, and mucosal thickening.

**Diagnostic Procedures/Other**

- Consider testing in only those cases where allergic symptoms do not respond to treatment and/or considering immunotherapy.
- Specific allergen sensitivity with allergen skin testing or radioallergosorbent test (RAST); clinical correlation based on history is essential in interpreting results.
- Diagnostic allergen prick tests are used to select agent to determine appropriate environmental control measures as well as to direct immunotherapy:
  - Prick or puncture: superficial injury to epidermis with application of test antigen
  - Intradermal
- RAST: more expensive and less sensitive than skin testing; typically used in patients in whom skin testing is not practical or a severe reaction is possible
- Rhinoscopy: useful to visualize intranasal anatomy and posterior pharyngeal structures, including adenoids, polyps, and larynx

**Test Interpretation**

- Nasal washing/scraping: Eosinophils predominate but may see basophils, mast cells.
- Nasal mucosa: submucosal edema but without destruction; eosinophilic infiltration; congested mucous glands and goblet cells

**TREATMENT**

There are three mainstays of treatment of allergic rhinitis:

- Allergen avoidance
- Medication
- Allergy immunotherapy

**GENERAL MEASURES**

- Establish specific cause(s) by history and appropriate testing.
- Limit exposure to offending allergen.
* Allergen immunotherapy (desensitization)
  - Reserved when symptoms are uncontrollable with medical therapy or have a comorbidity (e.g., asthma)
  - Specific allergen extract is injected SC in increasing doses to induce patient tolerance.

**MEDICATION**
Oral medication and intranasal sprays are commonly used.

**First Line**
- Mild symptoms: 2nd-generation nonsedating antihistamines are the first-line therapy for mild to moderate allergic rhinitis (1,4).
- Adverse effects: mild sedation, mild anticholinergic effects
- Generic (cetirizine, fexofenadine, loratadine; most to least effective)
  - Levocetirizine is a 2nd-generation nonsedating antihistamine that is effective but costly.

- Intranasal corticosteroids are first-line therapy for moderate to severe allergic rhinitis (1,4)[A]:
  - Most effective drug class for symptoms of allergic rhinitis
  - Use nasal sprays after showering and direct spray away from septum to improve deposition on mucosal surface.
  - May be used as needed; however, more effective with daily use (1)
  - Adverse effects: nosebleed, nasal septal perforation, and systemic corticosteroid effects
- Systemic steroids should be considered only in urgent cases and only for short-term use.

**Second Line**
- Nasal antihistamines effective but may be systemically absorbed and may cause sedation: azelastine, olopatadine
- 1st-generation antihistamines, such as the following:
  - Brompheniramine: 12 to 24 mg PO BID
  - Chlorpheniramine: 4 mg PO q4–6h PRN
  - Clemastine: 1 to 2 mg PO BID PRN
  - Diphenhydramine: 25 to 50 mg PO q4–6h PRN:
    - May precipitate urinary retention in men with prostatism and/or hypertrophy
    - Adverse effects: sedation, prolonged QT interval, performance
impairment, and anticholinergic effect

- Decongestants
  - Phenylephrine: 10 mg PO q4h PRN
  - Pseudoephedrine: 60 mg PO q4–6h PRN
  - Oxymetazoline nasal spray (Afrin): 2 to 3 sprays per nostril q10–12h PRN (max 3 days). Intranasal agents should not be used for >3 days due to rebound rhinitis. Discourage use in patients with hypertension (HTN) or cardiac arrhythmia.
  - Intranasal anticholinergics such as ipratropium nasal spray 2 sprays per nostril BID to TID
    - Intranasal anticholinergics can increase efficacy in combination with steroid use.
  - Leukotriene antagonists such as montelukast 10 mg/day PO
    - Should generally be used as an adjunct, not monotherapy
    - May be first line in those with concomitant asthma
  - Mast cell stabilizers such as cromolyn nasal spray 1 spray per nostril TID to QID
    - May take 2 to 4 weeks of therapy for optimal efficacy
    - May be ineffective in patients with nonallergic rhinitis and nasal polyps

**ISSUES FOR REFERRAL**
Refer to allergist for consideration of immunotherapy.

**ADDITIONAL THERAPIES**
- Nasal saline use has evidence of efficacy as sole agent or as adjunctive treatment (1,5)[A].
- Other treatment strategies
  - When initiating intranasal steroids, consider starting with a “burst,” using 2 sprays in each nostril daily for 2 weeks and then decreasing to 1 spray in each nostril daily thereafter (6).
  - To mitigate long-term side effects of intranasal steroids, consider a “5 days on, 2 days off” strategy, with the days off being the days of lowest exposure to allergens (6).

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
No specific restrictions on activity; emphasize avoiding activity where exposure to the allergen is likely.

**Patient Monitoring**
Initiation of patient education is critical.

**DIET**
- No special diet unless concomitant food reactions are suspected and evaluated.
- Some patients with severe sensitivity to seasonal pollens may have oral allergy syndrome, which is associated with itching in the mouth with the ingestion of fresh fruits that may cross-react with the allergens.

**PATIENT EDUCATION**
- Asthma & Allergy Foundation of America, 1717 Massachusetts Ave., Suite 305, Washington, DC 20036; (800) 7-ASTHMA: http://www.aafa.org/

**PROGNOSIS**
- Acceptable control of symptoms is the goal.
- Treatment is helpful to reduce the risk of comorbidities, such as sinusitis and asthma.

**COMPLICATIONS**
- Secondary infection such as otitis media or sinusitis
- Epistaxis
- Nasopharyngeal lymphoid hyperplasia
- Airway hyperreactivity with allergen exposure
- Asthma
- Facial changes, especially in children who are mouth breathers
- Sleep disturbance

**REFERENCES**

**SEE ALSO**

Conjunctivitis, Acute

**CODES**

**ICD10**

- J30.9 Allergic rhinitis, unspecified
- J30.1 Allergic rhinitis due to pollen
- J30.2 Other seasonal allergic rhinitis

**CLINICAL PEARLS**

- Nasal saline irrigation (flushing 6 to 8 oz) may be very helpful in clearing upper airway of secretions and may precede the use of nasal corticosteroids.
- 2nd-generation antihistamines and intranasal corticosteroids are first-line therapies for allergic rhinitis.
ROCKY MOUNTAIN SPOTTED FEVER

Eugene Y. Wang, MD • Lloyd A. Runser, MD, MPH • Christopher A. Zagar, MD

BASICS

Rocky Mountain spotted fever (RMSF) is one of the spotted fever rickettsioses (SFR) and is associated with the highest rates of severe and fatal outcomes of all reportable rickettsial diseases in the United States.

DESCRIPTION

- RMSF is a potentially fatal tick-borne systemic small vessel vasculitis caused by the bacterium Rickettsia rickettsii.
- Symptoms include fever, headache, and myalgia followed by a macular rash; begins at wrists and ankles, spreading toward palms, soles, and the trunk.
- System(s) affected: cardiovascular, musculoskeletal, skin, CNS, renal, hepatic, and pulmonary.

EPIDEMIOLOGY

In the United States, ticks are both vectors and main reservoirs; the American dog tick, Dermacentor variabilis in the eastern two-thirds of the states; the Rocky Mountain wood tick, Dermacentor andersoni in the western states; and the Brown dog tick, Rhipicephalus sanguineus is distributed throughout all states (1,2)[A].

Incidence

- In the United States, incidence of SFR was 8.9 cases per million from 2008 to 2012. Cases have been reported in all states except Hawaii and Alaska. RMSF also seen in Canada, Mexico, and throughout Central and South America (1,2)[A],(3)[B].
- North Carolina, Arkansas, Missouri, Oklahoma, and Tennessee account for over 60% of cases (1,2)[A].
- Cases occur year round. Most are reported during April to September during the peak of outdoor activity (1,2)[A],(3)[B].
- All ages are susceptible; highest incidence occurs in age 60 to 69 years. Highest case-fatality rate is in children <10 years (1)[A].
Prevalence
In the United States, 4,470 cases were reported in 2012. <0.1% of ticks carry virulent rickettsial species.

ETIOLOGY AND PATHOPHYSIOLOGY
- An adult tick releases *R. rickettsii*, an obligate intracellular gram-negative coccobacilli, from its salivary glands after 6 to 10 hours of feeding.
- Pathogens infect vascular endothelial cells, causing small-vessel injury, microhemorrhages, and local consumption of platelets resulting in characteristic petechial rash.
- Damage leads to progressively increased vascular permeability, pulmonary and cerebral edema, hypovolemia, and hyponatremia in late-stage disease.
- Subsequent end-organ injury may also result in meningoencephalitis, ARF, ARDS, shock, arrhythmia, and seizure (1)[A].
- Symptoms appear 3 to 12 days after bite or between 4 to 8 days after discovery of an attached tick. Incubation period is typically 5 days or less.
- Transplacental transmission has not been reported.
- RMSF can rarely be caused by direct inoculation of tick blood into open wounds or conjunctivae.

Genetics
*R. rickettsii* has one of the smallest bacterial genomes (1.1 to 1.6 Mb), making the organism highly adapted to the intracellular environment.

RISK FACTORS
- Known tick bite, engorged tick, or presence of tick for >20 hours; likelihood of infection increases with duration of tick attachment.
- Tick crushed during removal
- Accumulated outdoor exposure or residence in wooded areas
- Contact with outdoor pets or wild animals

GENERAL PREVENTION
- Limit tick exposure when possible in endemic areas, highest tick exposure with time spent in tall grasses, open areas of low bushy vegetation or wooded areas.
- Wear light-colored clothing, long sleeves, pants, socks, and closed-toed shoes.
- Use DEET-containing insect repellents.
- Permethrin spray on clothing
- Regular tick checks
- Prompt tick removal.
- Wash hands and site of bite with soap and water after tick removal to avoid potential mucosal inoculation.
- Nail polish, petrolatum jelly, and heat do not aid in tick removal. Do not use bare hands to remove ticks.
- Protect pets with ectoparasite control (1,2)[A].
- Prophylactic antibiotic treatment is not recommended.

**DIAGNOSIS**
Delay of empirical therapy increases risk of long-term sequelae and mortality.

**HISTORY**
Consider RMSF in acute febrile illness and rash, particularly with a history of potential tick exposure within previous 14 days; outdoor activities or travels to an endemic area, during late spring or summer months. *The tick bite goes unnoticed 30–50% of the time.*

- Typically presents like a viral illness with sudden onset of fever, frontal headache, malaise, and myalgia (1,2)[A]
- Nausea, vomiting, abdominal pain, anorexia, and photophobia may also be present.
- RMSF is easily mistaken for gastroenteritis, pharyngitis, or mononucleosis.
- Rash typically appears 2 to 4 days after onset of fever; starts as a small blanching, pink macules on wrist and ankles before spreading to the trunk where rash may become maculopapular in appearance
- Involvement of palms and soles usually present by 5th to 6th day, along with generalized petechial rash; a sign of advanced disease
- Although children <15 years more frequently (>90%) have a rash, the classic triad of fever, rash and tick bite occurs in <60% of children with RMSF. A small number of patients never develop rash (1,2)[A].
- Other symptoms include conjunctival injection, mental status impairments, restlessness, arthralgia, peripheral or periorbital edema, calf pain, and hearing loss (1,2)[A].

**PHYSICAL EXAM**
- Fever is typically >102°F.
The rash typically starts as an erythematous, macular, or maculopapular exanthema (1 to 5 mm in diameter); 50% become petechial or purpuric; blanchable

- 20% never develop the “classic” rash. Do not rely solely on the presence or absence of the typical rash for diagnosis.
- Rash can be difficult to visualize on dark-skin.
- In severe cases, the rash can involve the entire body (including mucous membranes) and may progress to necrotic or gangrenous lesions.
- The rash is not associated with pruritus or urticaria; if present, this makes RMSF less likely.
- Lymphadenopathy and hepatosplenomegaly

**DIFFERENTIAL DIAGNOSIS**

- Viral exanthema (e.g., hand-foot-mouth disease, measles, rubella, roseola)
- Viral gastroenteritis, mononucleosis
- URI, UTI, TTP/ITP, idiopathic vasculitides, toxic shock syndrome
- Meningoencephalitis, meningococcemia
- Other tick-borne infections: typhus, ehrlichiosis, Lyme disease
- Leptospirosis
- Drug reaction or serum sickness
- Kawasaki disease

**DIAGNOSTIC TESTS & INTERPRETATION**

Diagnosis is often clinical based on symptoms and exposure history. Confirm with serology. Do not delay therapy awaiting results.

**Initial Tests (lab, imaging)**

- Specific laboratory diagnosis
  - Indirect fluorescent antibody (IFA) testing is gold-standard for serology.
  - Sensitivity of IFA 2 weeks after onset of illness is 94–100%: A 4-fold increase in titers of IgG from paired acute-phase and convalescent-phase sera confirms diagnosis (4)[A].
  - Detectable antibody response develops 7 to 10 days after exposure; optimal time for testing is 14 to 21 days after symptom onset.
- Nonspecific laboratory tests
  - WBC count: variable, frequently normal
  - Platelet: thrombocytopenia (<150,000 cells/μL) 60% of kids
  - Hyponatremia <135 mEq/dL, and elevated hepatic transaminases in 50% of
patients

– Anemia, increase in BUN/creatinine, PT/PTT, hyperbilirubinemia, and hypoalbuminemia may also be present.

– CSF may have mononuclear pleocytosis and elevated protein (1,2)[A].

- Other than occasional nonspecific pneumonic infiltrates on chest radiograph, imaging procedures are rarely helpful.

### Diagnostic Procedures/Other

- Skin biopsy can also offer definitive diagnosis; a 3-mm punch biopsy to perform a rapid direct fluorescent antibody (DFA) test (sensitivity 70%, specificity 100%)

- Rickettsial DNA detection using PCR of skin biopsy samples is a new approach to diagnosis of up to 60–70% of suspected rickettsial infections during the acute-phase of illness (4)[A].

- Qualitative ELISA

### Test Interpretation

- Test acute and convalescent phase sera in tandem.

- Early treatment may limit antibody formation.

- Seropositivity increases with age in endemic states. Positive spotted fever group *Rickettsia* antibody does not necessarily signify an acute infection.

- Petechiae due to the vasculitis may be seen on organ surfaces (e.g., liver, brain, or epicardium).

### TREATMENT

### MEDICATION

#### First Line

Doxycycline is the treatment of choice in both adults and children (1,2,4)[A],(3)[B].

- Untreated rickettsial infections have a high rate of morbidity and mortality. Other antibiotics are considerably less effective.

- Adults: 100 mg PO or IV q12h for 5 to 10 days; children weighing <45 kg (100 lb): 2.2 mg/kg/dose PO or IV q12h for 5 to 10 days

- Treat all patients for at least 3 days after defervescence (1,2)[A],(3)[B],(4)[A].

- Fever typically subsides within 24 to 48 hours with early treatment; longer if
patient is severely ill. If promptly treated, and patient lack response to
doxycycline in 48 hours, consider an alternate diagnosis.

- RMSF resistance to doxycycline has not been documented.
- Adverse effects may include
  - Dyspepsia. Take medication with food and water. Avoid dairy, iron, or
    antacids, as they may inhibit drug absorption.
  - Photosensitivity may occur. Minimize sun exposure and use sunscreen.
  - No risk of dental staining in children <8 years old (1,2,3)[A]
- Severe allergy is a contraindication to doxycycline; rapid desensitization may
  be considered for life-threatening disease in severe illness.

**Second Line**

- Chloramphenicol is the alternative to treat RMSF; associated with adverse
  hematologic effects (e.g., aplastic anemia) and increased case mortality (1,2)
  [A]
- Fluoroquinolones have in vitro activity against rickettsiae but no human
  efficacy data. They are not currently recommended for treatment (1)[A].
- Sulfa-containing drugs may increase disease severity/fatality and are
  contraindicated.

**Pregnancy Considerations**

- Doxycycline is appropriate for this life-threatening infection in pregnancy if
  suspicion is high, despite the potential risk to fetal bones/teeth along with
  maternal hepatotoxicity and pancreatitis (4)[A].
- Short-term doxycycline is compatible with breastfeeding (1)[A].
- Chloramphenicol may be considered but should be avoided in the 3rd
  trimester due to risk for gray baby syndrome.

**ISSUES FOR REFERRAL**

- Consider infectious disease consult along with immunology/allergist if patient
  is severely allergic to doxycycline.
- Report cases of RMSF to public health authorities.

**ADDITIONAL THERAPIES**

Patients with neurologic injury may require prolonged physical and cognitive
therapy.

**ADMISSION, INPATIENT, AND NURSING**
CONSIDERATIONS

- Admission criteria/initial stabilization
  - CNS dysfunction
  - Nausea/vomiting preventing oral antibiotic therapy
  - Immunocompromised patients
  - Specific acute organ failure
  - Failure of oral pain management
  - ICU for patients with shock

- Discharge criteria
  - Resolution of fever
  - Ability to take oral therapy and nutrition

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Patients with mild disease may be treated as outpatients if close follow-up is available.
- Hospitalize patients with moderate to severe disease.
- Infection does not confer lifelong immunity.

Patient Monitoring

- Follow patients treated as outpatients every 2 to 3 days until symptoms resolve.
- Follow up CBC, electrolytes, LFTs if clinically indicated.

DIET

Consider nutritional supplementation if intake is poor.

PATIENT EDUCATION

General prevention and caution regarding tick avoidance during outside activities in endemic areas

PROGNOSIS

- Prognosis is closely related to timely administration of appropriate antibiotics.
- Delay in treatment may increase mortality by 3-fold if delayed to 5th day of illness (2)[A].
When treated promptly, prognosis is excellent with resolution of symptoms and no sequelae.

Children aged <10 years and elderly >70 years are at higher risk of morbidity and/or mortality.

Patients with G6PD deficiency are at highest risk for fulminant RMSF, in which death can occur ≤5 days.

COMPLICATIONS

- Encephalopathy, most commonly transient impaired level of consciousness or meningismus
- Seizures, focal neurologic deficit
- Renal injury leading to acute renal failure
- Hepatitis, congestive heart failure (CHF), respiratory failure
- Proximal muscle weakness, changes in personality, paresthesias, deafness, secondary thromboses, and tissue necrosis may also be seen.

REFERENCES

CODES

**ICD10**

A77.0 Spotted fever due to Rickettsia rickettsii

CLINICAL PEARLS

- Diagnosis of RMSF requires a high index of clinical suspicion.
- Tick bites are often unnoticed, and some patients may never develop a rash.
- Begin treatment immediately in suspected cases. Doxycycline is drug of choice for RMSF in both adults and children. The only absolute contraindication is severe allergy to the drug.
- Do not wait for laboratory testing prior to beginning treatment of suspected cases.
ROSEOLA

Jeffrey D. Quinlan, MD, FAAFP

BASICS

Omnipresent infection occurring in infancy and childhood. Majority of cases are caused by human herpesvirus 6 (HHV-6); may be associated with other diseases including encephalitis.

DESCRIPTION

- Acute infection of infants or very young children (1)
- Causes a high fever followed by a skin eruption as the fever resolves (1)
- Transmission via contact with salivary secretions or respiratory droplet (1)
- Incubation period of 9 to 10 days (1)
- System(s) affected: skin/exocrine, metabolic, gastrointestinal, respiratory, neurologic
- Synonym(s): roseola infantum, exanthem subitum; pseudorubella; sixth disease; 3-day fever (1)

Pediatric Considerations

A disease of infants and very young children (2)

EPIDEMIOLOGY

- Predominant age
  - HHV-6
    - Infants and very young children (<2 years old) (3)
    - Peak age infection 6 to 9 months, rarely congenital or perinatal infection (1)
    - 95% of children have been infected with HHV-6 by 2 years of life.
  - HHV-7
    - Later childhood
      - Mean age of infection 26 months
      - >90% population with HHV-7 by 10 years (1)
- Predominant sex: male = female (1)
- No seasonal variance

Incidence
Common—accounts for 20% ED visits for febrile illness among children 6 to 8 months (4)

**Prevalence**
- Peak prevalence is between 9 and 21 months (3).
- Nearly 100% population carrying HHV-6 by 3 years (1)
- Approximately 20% patients with primary HHV-6 have roseola (4).

**ETIOLOGY AND PATHOPHYSIOLOGY**
- HHV-6 and HHV-7 (2)
- Majority of cases (60–74%) due to HHV-6
  - HHV-6B > HHV-6A (2)
  - HHV-6A seen in children in Africa
  - HHV-6 binds to CD46 receptors on all nucleated cells (2).
- Primary infection typically through respiratory droplets or saliva
- Congenital infection/vertical transmission occurs in 1% of cases (1).
  - Transplacental transmission
  - Chromosomal integration (clinical significance unknown)
- Lifelong latent or persistent asymptomatic infection occurs after primary infection (1).
  - 80–90% of population intermittently sheds HHV-6/HHV-7 in saliva (2).
  - Patients are viremic from 2 days prior to fever until defervescence and onset of rash.
  - HHV-6 latency is also implicated in CSF (4).

**Genetics**
HHV-6 is integrated into the chromosomes of 0.2–3.0% of the population. This leads to vertical transmission of the virus. Clinical significance of this is unknown (1).

**RISK FACTORS**
- Female gender (3)
- Having older siblings (3)
- At-risk adults: immunocompromised (5)
  - Renal, liver, other solid organ, and bone marrow transplant (BMT) (3)
  - HHV-6 reactivation can occur in 1st week posttransplant (5). HHV-6 viremia occurs in 30–45% of BMT within the first several weeks after transplantation (4).
Usually asymptomatic (4)
- Up to 82% of HHV-6 reactivation/reinfection in solid organ transplant (5)

Nonrisk factors (3)
- Child care attendance
- Method of delivery
- Breastfeeding (HHV does not appear to pass through breast milk)
- Maternal age
- Season

**DIAGNOSIS**

**HISTORY**
- 3 to 5 days abrupt fever 102.2–104.0°F (39–40°C) not associated with a rash (1)
- The child may be fussy during this prodrome (1,6).
- Sudden drop of fever associated with appearance of rash (1)
  - Rash on trunk then spreads centrifugally mainly to neck, possibly also to peripheral extremities, and face
- Diarrhea (3)
- Mild upper respiratory symptoms (3)
- Rhinorrhea (3)
- Febrile seizure occurs in 13% of cases (1).

**PHYSICAL EXAM**
- Rash (exanthem subitum) (1)
  - Rose-pink macules and/or papules that blanch
  - First appears on the trunk then peripherally
  - May occur up to 3 days after fever resolves (1)
  - Fades within 2 days
  - Occurs in approximately 20% of patients in the United States (1)
- Mild inflammation of tympanic membrane, pharynx, and/or conjunctiva (1,6)
- Ulcers on soft palate and uvula (Nagayama spots) (1)
- Cervical lymphadenopathy (1)
- Periorbital edema (2)

**DIFFERENTIAL DIAGNOSIS**
- Enterovirus infection
- Adenovirus infection (1)
- Epstein-Barr virus
- Fifth disease—parvovirus B19
- Rubella (1)
- Scarlet fever (1)
- Drug eruption (1)
- Measles (1)

**DIAGNOSTIC TESTS & INTERPRETATION**

- Primarily a clinical diagnosis not requiring laboratory or radiologic testing (1)
- Tests often cannot differentiate latent or active disease (1).
- Specific diagnosis only necessary in severe cases, unclear diagnosis where more serious disease needs to be ruled out, or if considering antiviral therapy (1).

**Initial Tests (lab, imaging)**

- HHV-6 and HHV-7 by PCR (1, 5)
  - Serum, whole blood, CSF, or saliva
  - Becoming more widely available
- HHV-6 IgM immunofluorescence (1)
  - Diagnostic for acute infection
  - Spike seen in 1st week of illness
- HHV-6 IgG immunofluorescence (1)
  - Check at diagnosis and then 2 weeks later.
  - Use with IgM to show primary infection.
  - Negative initial test and rise on follow-up suggests primary infection.
- Viral culture (5)
  - Rarely done
  - No clinical use (very time consuming)
- Other laboratory findings (1)
  - Decreased total leukocytes, lymphocytes, and neutrophils
  - Elevated transaminases
  - Thrombocytopenia

**Diagnostic Procedures/Other**

- Urine culture: to rule out UTI as source of fever (2)
- Chest x-ray (CXR): if a child has respiratory symptoms
TREATMENT
No treatment necessary, resolves without sequelae (1) [C]

GENERAL MEASURES
- Symptomatic relief including antipyretics (1) [C]
- Hydration (1) [C]

MEDICATION
**First Line**
- No specific first-line treatment in immunocompetent hosts beyond supportive measures (2) [C]
  - Antivirals are not recommended in immunocompetent.
- No approved antiviral treatment in immunocompromised (2)
- Second-line IV ganciclovir, cidofovir, foscarnet tested in vitro studies in stem cell transplant patients
  - HHV-6B susceptible: ganciclovir and foscarnet (5) [C]
  - HHV-6A and HHV-7 are more resistant to ganciclovir (5).
- Antivirals suggested in individual cases of encephalitis (associated with reactivation of HHV-6) (5)
- In bone marrow and stem cell transplant recipients receiving immunosuppression, ganciclovir prophylaxis is effective in preventing reactivation of HHV-6 (6) [B].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
**Patient Monitoring**
- During febrile prodrome, monitor for dehydration.
- None after typical rash appears and fever resolves
- Mean duration of illness is 6 days (4).
- If febrile seizures occur, they will cease after fever subsides and will not likely recur (4).
- Symptomatic reactivation in immunocompromised (1)
**DIET**
Encourage fluids.

**PATIENT EDUCATION**
- Parental reassurance that this is usually a benign, self-limited disease (1)
- There is no specific recommended period of exclusion from out-of-home care for affected children.
- Patient is viremic a few days prior to fever until time of defervescence and rash onset.

**PROGNOSIS**
- Course: acute, complete recovery without sequelae (1)
- Reactivation in immunocompromised patients is common (4).

**COMPLICATIONS**
- Febrile seizures
  - 13% patients with roseola (1,6)
  - Accounts for 1/3 of primary seizures in children <2 years old (1)
- Medication hypersensitivity syndromes (drug reaction with eosinophilia and systemic symptoms) (2)
- Reactivation can occur in transplant patients, HIV-1 infection, and other immunocompromised individuals (4).
- Meningoencephalitis occurs in immunocompetent and in immunosuppressed patients (4); poor association with multiple sclerosis (4)
- Pityriasis rosea (1)
- Possible association with progressive multifocal leukoencephalopathy (4)

**REFERENCES**
5. Le J, Gantt S; for AST Infectious Diseases Community of Practice. Human herpesvirus 6, 7 and 8 in solid organ transplantation. *Am J Transplant.*

ADDITIONAL READING

CODES

ICD10

- B08.20 Exanthema subitum [sixth disease], unspecified
- B08.21 Exanthema subitum [sixth disease] due to human herpesvirus 6
**B08.22 Exanthema subitum [sixth disease] due to human herpesvirus 7**

**CLINICAL PEARLS**

- Roseola infection should be suspected if an infant or young child presents with a high temperature without other clinical findings.
- As the fever abates, a macular rash will be seen on the trunk, with eventual spread to the face and extremities in 20% of patients.
- Roseola is a clinical diagnosis, and laboratory testing is not necessary for most children with classic presentation.
- For atypical presentations, complications, and immunocompromised hosts, several laboratory tools are available, including serologic testing for antibody, viral PCR testing, and viral culture.
- Infection is typically self-limiting and without sequelae.
- Usually only symptomatic treatment is needed.
- Consider prophylaxis in patients undergoing bone marrow or stem cell transplant and receiving immunosuppressive therapy.
ROTATOR CUFF IMPINGEMENT SYNDROME

Faren H. Williams, MD, MS • Minjin Fromm, MD

BASICS

DESCRIPTION

- Compression of rotator cuff tendons and subacromial bursa between the humeral head and the structures comprising the coracoacromial arch and proximal humerus
- Most common cause of atraumatic shoulder pain in patients >25 years of age
- Primary symptom is pain that is most severe when the arm is abducted between 60 and 120 degrees (the “painful arc”).
- Classically divided into three stages
  - Stage I: acute inflammation, edema, or hemorrhage of the underlying tendons due to overuse (typically in those age <25 years)
  - Stage II: progressive tendinosis that leads to partial rotator cuff tear along with underlying thickening or fibrosis of surrounding structures (commonly, ages 25 to 40 years)
  - Stage III: full-thickness tear (typically in patients age >40 years)

EPIDEMIOLOGY

Incidence

- Shoulder pain accounts for 1% of all primary care visits.
- Peak incidence of 25/1,000 patients/year occurs in patients aged 42 to 46 years.
- Impingement responsible for 18–74% of shoulder pain diagnoses

Prevalence

Prevalence of shoulder pain in general population ranges from ~7% to 30%.

RISK FACTORS

- Repetitive overhead motions (throwing, swimming)
- Glenohumeral joint instability or muscle imbalance
- Acromioclavicular arthritis or osteophytes
• Thickened coracoacromial ligament
• Shoulder trauma
• Increasing age
• Smoking

GENERAL PREVENTION
• Proper throwing and lifting techniques
• Proper strengthening to balance rotator cuff and scapula stabilizer muscles

DIAGNOSIS

HISTORY
• Gradual increase in shoulder pain with overhead activities (Sudden onset of sharp pain suggests a tear.)
• Night pain is common, exacerbated by lying on the affected shoulder or sleeping with the affected arm above the head.
• Anterolateral shoulder pain with overhead activities
• May progress to weakness and decreased range of motion if shoulder is not used through full range of motion

PHYSICAL EXAM
• Examine patient for atrophy/asymmetry. Observe how the patient takes off his or her shirt during exam.

Neer impingement test: Examiner stabilizes the scapula and moves the affected upper extremity through a flexion arc. Positive is pain with flexion of the shoulder. Sensitivity: 78%. Specificity: 58% (1)[A].

Hawkins-Kennedy impingement test: Examiner places the arm in 90 degrees of forward flexion and then gently internally rotates the arm. End point for internal rotation is when the patient feels pain or when the rotation of the scapula is felt or observed by the examiner. Test is positive when patient experiences pain during the maneuver. Sensitivity: 74%. Specificity: 57% (1)[A].

Empty can test (supraspinatus): Examiner asks the patient to elevate and internally rotate the arm with thumbs pointing downward in the scapular plane. Elbow should be fully extended. Examiner applies downward pressure on upper surface of the arm. Test is positive when patient complains of pain with resistance. Sensitivity: 69%. Specificity: 62% (1)[A].
Lift-off test (subscapularis): Patient internally rotates the shoulder, placing the hand on ipsilateral buttock, then lifts hand off buttock against resistance. A tear in the subscapularis muscle produces weakness of this action. Sensitivity: 42%. Specificity: 97% (1)[A].

Drop-arm test: Patient fully elevates arm and then slowly reverses the motion. If the arm is dropped suddenly or the patient has extreme pain, the test is positive for a possible rotator cuff tear. Sensitivity: 21%. Specificity: 92% (1) [A].

Resisted external rotation: weakness suggestive of infraspinatus and/or teres minor tendon involvement
Examine cervical spine to rule out cervical pathology as source of shoulder pain.
Neurovascular exam of the upper extremity

DIFFERENTIAL DIAGNOSIS

- Labral injury
- Acromioclavicular arthritis (more common in older patients; positive cross-arm test—pain when affected arm is fully adducted across the chest in the horizontal plane)
- Adhesive capsulitis (rotator cuff tendonitis leads to decreased use and atrophy of rotator cuff muscles, followed by contracture; linked to diabetes and potentially prior trauma)
- Anterior shoulder instability (prior trauma; more common in patients <25 years old)
- Multidirectional instability
- Biceps tendonitis or rupture (Perform Speed and Yergason tests and look for visible or palpable defect of biceps—“Popeye sign.”)
- Calcific tendonitis
- Cervical radiculopathy (spinal or foraminal stenosis, can test with Spurling maneuver)
- Glenohumeral arthritis (Evaluate with plain films.)
- Suprascapular nerve entrapment (Look for focal muscle atrophy of supra- or infraspinatus.)
- Traumatic rotator cuff tear

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)

- Plain-film radiographs of the shoulder (three views): anteroposterior, axillary,
scapular Y views

- Plain films may reveal:
  - Osteoarthritis of the acromioclavicular and glenohumeral joints
  - Superior migration of the humeral head (indicative of a large rotator cuff tear)
  - Cystic change of the humeral head and sclerosis of the inferior acromion (indicative of chronic rotator cuff disease)
  - Calcific tendonitis

- MRI is used to definitively assess rotator cuff tendinopathy, partial tears, and complete tears.
- MR arthrogram is preferred for labral pathology.
- Ultrasound is sensitive and specific for rotator cuff tears but is highly operator-dependent.
- CT scan is preferred for bony pathology or for those unable to undergo MRI.

### Diagnostic Procedures/Other

- Lidocaine injection test
  - Inject lidocaine into the subacromial space:
    - Repeat impingement tests; if pain is completely relieved and range of motion is improved, likely impingement syndrome (rather than cuff tear)
    - Allows for more accurate strength testing on physical examination:
      - If strength is intact, rule out rotator cuff tear.
      - If range of motion does not improve in any plane, more likely adhesive capsulitis
    - Some pain relief and improved range of motion occurs after lidocaine injection with
      - Glenoid labral tear
      - Capsular strain
      - Glenohumeral osteoarthritis
      - Glenohumeral instability
  - A lack of any pain relief suggests other sources or inappropriate placement of injection.

### Test Interpretation

May have tendinosis, tendonitis, or muscle/tendon tear
Pain control in combination with aggressive rehabilitation improves and fully resolves rotator cuff tendonitis in most patients.

GENERAL MEASURES
- Rest
- Ice or heat for symptom relief
- Activity modification, with avoidance of aggravating activities, particularly overhead motions
- Range-of-motion exercises
- Rotator-cuff and adjacent muscle strengthening to enhance stability and prevent further injuries

MEDICATION

*First Line*
NSAIDs or other analgesic, often for 6 to 12 weeks

ISSUES FOR REFERRAL
Failure of conservative treatment, persistent pain, weakness, or complete tear of rotator cuff

ADDITIONAL THERAPIES
- Supervised- or home-exercise regimens provide significant pain reduction and improve function (2)[A].
- Physical therapy is effective for short-term and long-term recovery of function (3)[A]:
  - Initial goal is to restore range of motion.
  - After pain resolves, gradually strengthen rotator cuff muscles in internal rotation, external rotation, and abduction.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture is potentially beneficial for reducing pain and improving function, particularly when used with physical therapy (4)[A].

SURGERY/OTHER PROCEDURES
- Steroid injections may have a significant benefit on pain and function in the short term but do not appear to have a significant long-term effect (5)[A].
• No evidence that surgery is superior to conservative management or that one surgical technique is superior to another for impingement syndrome (6)[A]
• Platelet-rich therapies for musculoskeletal soft tissue injuries are increasingly common.
  – No apparent effect of platelet-rich plasma injection during arthroscopic rotator cuff repair on overall retear rates or shoulder-specific outcomes
• Extracorporeal shock wave therapy is currently under study as an emerging treatment for calcific tendonitis.

ONGOING CARE

PATIENT EDUCATION
• Physical rehabilitation is necessary, both in conservative course of treatment (i.e., NSAIDs, physical therapy, home exercises) and in surgical intervention. An aggressive trial of rehabilitation should be encouraged prior to extensive testing or surgical intervention. Providing pain relief prior to beginning a program of physical therapy improves adherence and outcomes.
• Symptoms often recur if not fully addressed.

PROGNOSIS
• Variable, depends on underlying pathology
• Most patients improve with conservative management. Recovery can be slow.
• Patients with more severe symptoms—those with symptoms for >1 year—are less likely to respond well with conservative therapies.

COMPPLICATIONS
• Progression of injury
• Tendon retraction in complete rotator cuff tear

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- M75.40 Impingement syndrome of unspecified shoulder
- M75.110 Incomplete rotator-cuff tear/rupture of unspecified shoulder, not trauma
- M75.120 Complete rotator-cuff tear/rupture of unspecified shoulder, not trauma

**CLINICAL PEARLS**

- Consider impingement syndrome in patients who engage in activities with repetitive overhead motions (e.g., swimming, throwing) who present with shoulder pain.
- Atraumatic shoulder pain in middle age often represents rotator cuff
tendonitis.
- The supraspinatus tendon is most commonly affected in impingement syndrome.
- Neer and Hawkins tests specifically check for shoulder impingement.
- The empty can maneuver tests for weakness of supraspinatus muscle.
- The drop-arm test is specific for rotator cuff tear.
- Physical therapy over 6 to 12 weeks promotes return to function.
- Most patients with shoulder impingement respond well to conservative management.
BASICS

DESCRIPTION

- Inflammation and/or infection involving one or more salivary gland
- Sialolithiasis is the cause of ~90% of all obstructive salivary gland diseases.
- Salivary obstruction is usually characterized by a painful swelling of the affected gland when eating, known as “mealtime syndrome.”
- The submandibular gland is more commonly affected (80–90% of cases) by sialolithiasis and infection than the parotid gland. Submandibular stones occur more commonly due to higher mucinous content of saliva, longer course of Wharton duct, slow salivary flow, and saliva flow against gravity.
- Can be acute or chronic
  - Types: infectious, obstructive (sialolithiasis), and autoimmune

EPIDEMIOLOGY

Incidence

- Predominant age: Peak incidence is 30 to 60 years.
- Most common in debilitated and dehydrated patients
- 49% men and 51% women, average age 47.5 years; 82% submandibular stones and 18% parotid stones; 44% had a positive smoking history, and 20% of patients were taking diuretics.

Prevalence

- Salivary calculi can be found in 1.2% of the adult population.
- Only 5% of all cases occur in the pediatric population.
- In those with sialographic evidence of benign intraductal obstruction, the obstruction is caused by salivary calculi in >73% of cases.

ETIOLOGY AND PATHOPHYSIOLOGY
Decreased salivary outflow from anticholinergics, dehydration, or radiation is thought to allow bacterial infection of salivary glands.

Salivary calculi form by deposition of calcium phosphate. Predisposing factors include salivary stasis, retrograde bacterial contamination from the oral cavity, increased alkalinity of saliva, and physical trauma to salivary duct or gland.

Gout is a systemic disease known to be associated with salivary stone development. In gout, sialoliths are composed of uric acid.

Sialadenitis occurs by recurrent inflammatory reactions that result in progressive acinar destruction with fibrous replacement and sialectasis.

Bacterial sialadenitis: *Staphylococcus aureus*, *Streptococcus viridans*, *Streptococcus pyogenes*, *Haemophilus influenzae*, *Escherichia coli*, *Pseudomonas aeruginosa*, and group B streptococci (neonates and prepubescent children)

Viral sialadenitis: mumps, cytomegalovirus (CMV), Epstein-Barr virus (EBV), HIV, and enteroviruses

**Pediatric Considerations**
The two most common causes of sialadenitis in children are mumps and idiopathic juvenile recurrent parotitis.

**Genetics**
Polygenic cause, with several loci under investigation

**RISK FACTORS**
- Dehydration
- Anticholinergic use
- Antihistamine use
- Diuretic use
- Poor oral hygiene
- Malnutrition
- Head/neck radiation
- Tuberculosis (TB)
- HIV
- Failure to immunize (mumps)
- Gout
- Diabetes mellitus
- Hypothyroidism
Renal failure
Duct strictures
Previous intraoral procedures

**GENERAL PREVENTION**
- Adequate hydration
- Maintain proper oral care and hygiene.
- Avoid antihistamines, anticholinergics, and other causes of xerostomia, especially if other risk factors are present.

**COMMONLY ASSOCIATED CONDITIONS**
- Postoperative dehydration
- Radiation-induced xerostomia
- Drug-induced xerostomia
- Sjögren syndrome
- Hypercalcemia

**DIAGNOSIS**

**HISTORY**
- Review immunization history.
- History of:
  - Alcoholism, bulimia, malnutrition
  - Recent dental work, oral surgery
  - Radiation therapy
  - TB or HIV exposure
- Acute onset of pain and swelling over the affected salivary gland, especially postprandial
- Dental pain, discharge, foul breath (halitosis), and pain with chewing
- Fever, unintentional weight loss
- Xerostomia

**PHYSICAL EXAM**
- Palpate all salivary glands, floor of mouth, tongue, and neck to assess symmetry, tenderness, induration, edema, presence of stones, and lymphadenopathy.
- Examine duct openings for purulent discharge and saliva.
Palpate gland gently to express purulent material.
Examine eyes for interstitial keratitis.
Note lingual papillary atrophy and/or loss of tooth enamel.

**Pediatric Considerations**
Stones in children are traditionally smaller in size, within the duct distally, and present with a shorter symptom duration.

**DIFFERENTIAL DIAGNOSIS**
- Acute bacterial parotitis
- Chronic bacterial parotitis
- Idiopathic juvenile recurrent parotitis
- Dental abscess
- Mumps
- TB
- HIV (in pediatric populations)
- EBV, CMV, enteroviruses
- Tularemia
- Cystic fibrosis
- Lupus
- Sjögren syndrome
- Alcoholism
- Bulimia
- Hypothyroidism
- Pleomorphic adenoma
- Lymphoma
- Sarcoidosis
- Collagen vascular disease
- Metal poisoning

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Consider CBC, rarely electrolytes.
- Culture and sensitivity of any expressed pus
- CT scan with IV contrast is the preferred imaging modality, if needed (1)[C].
- Ultrasound can localize abscesses as well as stones. Stones appear hyperechoic with posterior shadowing.
- Sonopalpation (concurrent ultrasound with transoral palpation) proved to have
a sensitivity and specificity of 96.6% and 90% in finding a calculus (1)[B].

**Follow-Up Tests & Special Considerations**
- If autoimmune process is suspected, consider ordering appropriate labs, such as autoantibody titers: Sjögren syndrome A (SS-A) and Sjögren syndrome B (SS-B), rheumatoid factor (RF), and antinuclear antibodies (ANAs). Erythrocyte sedimentation rate (ESR) may also be conducted (2)[C].
- Salivary gland biopsy
- Consider serial CT scans with contrast to evaluate disease resolution.
- Ultrasound can identify indicators of persistent obstruction in patients undergoing sialolithotomy.

**Diagnostic Procedures/Other**
- Sialography to evaluate sialolithiasis and other obstructive lesions
- Sialendoscopy to find and remove sialoliths. In one study, sialendoscopy confirmed 221 (79%) parotid and 812 (93%) submandibular stones (3)[A].
- One study revealed that sonography, cone beam CT, and sialendoscopy all had excellent specificity and positive predictive value in diagnosing stones. However, sialendoscopy was superior in sensitivity and negative predictive value (1)[B].
- When sialendoscopy fails, a novel ultrasound-guided needle localization approach has been proposed.
- Technetium-99m pertechnetate scintigraphy showed decreased gland excretion and decreased uptake in patients with sialolithiasis.

**Test Interpretation**
In chronic sialadenitis, loss of acini, fibrosis, and periductal lymphocytosis are evident; degree indicates chronicity.

**TREATMENT**

**GENERAL MEASURES**
- Maintain hydration.
- Apply warm compresses with massage.
- Maintain good oral hygiene.
- Antibiotics if indicated by diagnosis
MEDICATION

**First Line**
- Antistaphylococcal penicillins (nafcillin, dicloxacillin) are indicated in areas where methicillin-resistant *S. aureus* (MRSA) is not predominant.
- Penicillin-allergic: Use clindamycin 300 mg PO q8h.
- Gram negative: 3rd-generation cephalosporin or fluoroquinolone
- Anaerobic: metronidazole or clindamycin
- Antibiotic coverage should be narrowed once culture and sensitivity are available.
- Continue antibiotic therapy for 10 to 14 days.

**Second Line**
- 1st-generation cephalosporin (cephalexin or cefazolin) or clindamycin is also indicated for empiric coverage.
- If MRSA than vancomycin

**ISSUES FOR REFERRAL**
In the case of poor dentition and dental abscess, refer patient to a dentist.

**ADDITIONAL THERAPIES**
In the case of chronic sialadenitis with strictures, consider sialostent placement.

**SURGERY/OTHER PROCEDURES**
- Submandibular stones found in the anterior floor of the mouth can be excised intraorally (sialodochoplasty), whereas those in the hilum require gland excision. Parotid stones usually require parotidectomy (2)[A].
- Good results in patient symptom relief, quality of life, and safety have been reported in sialadenitis and sialolithiasis using sialendoscopy (2–4)[A]. However, one study revealed a complication rate of 3.23%. Complications include strictures, ranulas, and lingual nerve injury.
- A combined approach using limited intraoral incision with sialendoscopy has shown an 87% success rate.
- Incision and drainage of parotid abscess is indicated after failing 3 to 5 days of medical management.
- Sialoliths and stenoses can be successfully treated by radiologically or fluoroscopically controlled or sialendoscopically based methods in ~80% of cases. Extracorporeal shock wave lithotripsy (ESWL) is successful in up to
50% of cases.

- Transoral duct slitting is an important method for extraparenchymal submandibular submandibular stones, with a success rate of 90%.

- Sialolithotomy with sialendoscopy can now be successfully performed robotically (5)[B].

- Recent evidence shows that larger stones can be successfully and safely treated with holmium: YAG laser lithotripsy.

**Pediatric Considerations**
The most effective diagnostic and therapeutic modality for children with sialadenitis is sialendoscopy with stone retrieval (6)[B].

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
Consider lemon drops or other sialogogues to promote salivation. In one study, postoperative use of sialogogues nearly halved rates of sialadenitis (2)[C].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Parotid abscess
- Sepsis
- Inability to tolerate PO intake
- Airway, breathing, circulation
- Check vital signs, with particular attention to blood pressure, as patient may be septic secondary to abscess formation.
- Evaluate airway patency.
- Nursing responsibilities may include ensuring excellent oral hygiene and avoiding administration of drugs that cause decreased production or flow of saliva.
- Discharge criteria
  - Exclude abscess or sepsis.
  - Ensure ability to tolerate PO intake.
  - Stable vital signs

**ONGOING CARE**
FOLLOW-UP RECOMMENDATIONS

- Provide regular follow-up visits for patients with chronic sialadenitis.
- Avoid prescribing medications that cause xerostomia.

Patient Monitoring
Continue to monitor patients with chronic sialadenitis, as decreased salivary gland function due to fibrosis and loss of acini can lead to acute exacerbations.

DIET

- Avoid sialogogues during acute attacks.
- Maintain adequate hydration on an outpatient basis.

PATIENT EDUCATION

- Educate patients on maintaining excellent oral hygiene.
- Educate patients on maintaining good hydration.

PROGNOSIS

- Generally excellent, with acute symptoms resolving in about a week with appropriate treatment
- Patients with autoimmune etiology may have prolonged course due to systemic involvement.

COMPLICATIONS

Abscess, dental caries, recurrent sialadenitis, facial nerve impingement, Ludwig angina

REFERENCES

4. Meier BA, Holst R, Schousboe LP. Patient-perceived benefit of sialendoscopy as measured by the Glasgow Benefit Inventory. Laryngoscope.

**ADDITIONAL READING**

**CODES**

**ICD10**
- K11.5 Sialolithiasis
- K11.20 Sialoadenitis, unspecified
- K11.21 Acute sialoadenitis

**CLINICAL PEARLS**
- Sialadenitis is associated with conditions that predispose patient to xerostomia.
- Sialadenitis occurs in debilitated patients who lack ability to control hydration.
- Mainstay of treatment is hydration, good oral hygiene, sialogogues, and possible surgical excision.
- Many cases are now being successfully and safely treated with sialendoscopy.
**SALMONELLA INFECTION**

Matthew E. Tick, DO • Marie L. Borum, MD, EdD, MPH

---

**BASICS**

**DESCRIPTION**

- Infection caused by any serotype of the bacterial genus *Salmonella*, a gram-negative anaerobic bacillus
- Nontyphoidal *Salmonella* typically causes gastroenteritis via foodborne infection and sporadic outbreaks; less commonly causes infection outside the gastrointestinal tract
- Clinical syndromes
  - Enteric fever (see “Typhoid Fever”)
  - Nontyphoidal gastroenteritis
    - Chronic carrier state (>1 year)
  - Nontyphoidal invasive disease
    - Bacteremia
      - Endovascular complications
      - Localized infection outside GI tract

**Geriatric Considerations**

Patients >65 years have increased risk of invasive disease with bacteremia and endovascular complications due to higher prevalence of comorbidities (atherosclerotic endovascular lesions, prostheses, etc.).

**Pediatric Considerations**

Neonates (<3 months) are more susceptible to invasive disease and complications.

**EPIDEMIOLOGY**

**Incidence**

- Global incidence of nontyphoidal *Salmonella* enteritidis ~94 million/year
  - Wide variation by region from 40 to 3,980 estimated cases per 100,000
- Global incidence of invasive nontyphoidal *Salmonella* infection estimated to be 2.1 to 6.5 million
  - Wide variation by region from ~0.8 to 227 estimated cases per 100,000

mebooksfree.com
• Most commonly identified foodborne illness in the United States and a common cause of traveler’s diarrhea; annual incidence in the United States—15 illnesses per 100,000 individuals
• Second most common bacteria (following *Campylobacter*) isolated from diarrheal stool cultures in the United States
• Highest incidence in children <5 years old
• Hospitalization rates higher in patients >50 years old
• Peak frequency from July to November

**ETIOLOGY AND PATHOPHYSIOLOGY**

**Salmonella enterica**
- Most pathogenic species in humans
- 2,500 different serotypes

**Etiology**
- ~95% of cases are foodborne.
- Most other cases are from direct or indirect fecal–oral contact human (or animal) carriers.
- Iatrogenic seeding (e.g., blood transfusion, endoscopy) is rare.

**Pathophysiology**
- Typical infectious dose in immunocompetent patients is 1 million bacteria.
- Ingested bacteria invade the distal ileum and proximal colon to produce an inflammatory and cytotoxic mucosal response.
- Bacteria enter the mesenteric lymphatic system and systemic circulation to cause disseminated disease.

**RISK FACTORS**

• Recent travel
• Consumption of undercooked meat, egg, or unpasteurized dairy products. Nonanimal products have been implicated in outbreaks.
• Contact with live reptiles or poultry
• Contact with human carrier (*Salmonella* fecal shedding)
• Impaired gastric acidity: H$_2$ receptor blockers, antacids, proton pump inhibitors (PPIs), gastrectomy, achlorhydria, pernicious anemia, infants
• Recent antibiotic use
• Reticuloendothelial blockage: sickle cell disease, malaria, bartonellosis
• Immunosuppression: HIV, diabetes, corticosteroid or other immunosuppressant use, chemotherapy
• Iron overload, chronic granulomatous disease
Age <5 years or >50 years

GENERAL PREVENTION
- Proper food hygiene production, transport, and storage (e.g., refrigeration during food storage and thorough cooking prior to consumption)
- Control of animal reservoirs: Avoid contact with high-risk animals, animal feces, and polluted waters.
- Hand hygiene
- CDC Web site (http://www.cdc.gov/salmonella/): outbreak tracking

COMMONLY ASSOCIATED CONDITIONS
- Gastroenteritis
- Bacteremia: immunocompromised patients or those with underlying comorbidities that predispose to *Salmonella* (e.g., cholelithiasis, prostheses)
- Osteomyelitis: higher incidence in sickle cell disease
- Abscesses: higher incidence with malignant tumors
- Reactive arthritis

DIAGNOSIS

HISTORY
- *Salmonella* infections are typically asymptomatic or result in mild, self-limited gastroenteritis.
- Exposure history: travel; contact with infected human, reptile, or poultry; improper food preparation
- Host factors: age, immune status, other risk factors
- Symptoms typically begin 12 to 72 hours after ingestion and resolve within 4 to 10 days.
- Acute uncomplicated illness
  - Sudden onset of nausea, vomiting, diarrhea
  - Abdominal cramping
  - Headache
  - Myalgias
  - Fever

PHYSICAL EXAM
- Fever
- Evidence of hypovolemia
- Abdominal tenderness
- Heme-positive stool in some patients
- Hepatosplenomegaly in some patients

**DIFFERENTIAL DIAGNOSIS**
- Viral gastroenteritis
- Bacterial enteritis due to other organisms
- Pseudomembranous colitis
- Inflammatory bowel disease

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*
- Gastroenteritis
  - Stool culture for *Salmonella, Escherichia coli, Shigella,* and *Campylobacter* (1)[C]
  - Indications for stool culture:
    - Severe diarrhea (≥6 loose stools daily) (1)[C]
    - Diarrhea >1 week in duration (1)[C]
    - Fever (1)[C]
    - Diarrhea containing blood or mucous (1)[C]
    - Multiple cases suggesting an outbreak (1)[C]
  - Fecal leukocytes: positive
- Bacteremia
  - Blood cultures if febrile (1)[C]
  - Stool cultures (1)[C]
- Endovascular infection
  - Consider angiography in bacteremic patients >50 years if aortic or vascular source is suspected (2)[A].

- Local infections
  - Wound culture
  - CT or MRI for soft tissue or bone infections (3)[C].
- Chronic carrier state
  - Stool culture positive for >1 year (3)[C]
  - Urine culture may be positive in chronic carriers.

*Follow-Up Tests & Special Considerations*
- Investigate for other causes in diarrhea lasting >10 days.
Asymptomatic excretion of *Salmonella* may occur for weeks after infection; follow-up fecal cultures are generally not indicated for patients with uncomplicated gastroenteritis (2,3)[C].

Follow-up blood cultures suggested for bacteremic patients (3)[C]

**Test Interpretation**

Intestinal biopsies (if taken) may show mucosal ulceration, hemorrhage, necrosis, and reticuloendothelial hypertrophy/hyperplasia.

**TREATMENT**

- Treatment for nonsevere nontyphoidal *Salmonella* gastroenteritis in immunocompetent patients is supportive. The illness is typically self-limited. There is no proven benefit for treatment of mild disease. Treatment can suppress the host immunologic response, resulting in higher rates of relapse (1)[C].
- Consider antibiotics in immunocompetent hosts with severe diarrhea, high fever, or if hospitalization is required (1)[C].
- Some patients are at increased risk of bacteremia and benefit from antibiotics:
  - Infants <3 months of age (1)[C]
  - Patients age >50 years; (particularly those age >65 years) (1,3)[C]
  - Patients with hemoglobinopathies, atherosclerosis, and prosthetic valves, grafts, or joints; any immunosuppressed state (1,3)[C],(2)[A]
- Chronic carriage of nontyphoidal *Salmonella*
  - 4 to 6 weeks of antimicrobial therapy
  - Prophylactic therapy in immunocompromised patients (2)[A]

**GENERAL MEASURES**

- Hydration and electrolyte replacement
- Hand washing and barrier precautions for inpatients
- Avoid antimitility drugs in patients with fever or dysentery. Antimitility drugs may increase enteropathogen contact time with gut mucosa (1)[C].

**MEDICATION**

*First Line*

- Gastroenteritis, uncomplicated: supportive care (1)[A]
- Gastroenteritis, complicated (due to illness severity or host risk factors such as
immunocompromised)

- Adults (treat for 14 days if immunocompromised)
  - Levofloxacin (or other fluoroquinolone) 500 mg/day PO for 7 to 10 days (1)[C] or
  - Trimethoprim-sulfamethoxazole: 160/800 mg PO BID for 7 to 10 days or
  - Amoxicillin: 500 mg PO TID for 7 to 10 days or
  - Ceftriaxone: 1 to 2 g/day IV for 7 to 10 days or
  - Azithromycin: 500 mg/day PO for 7 days (1)[C]

- Children
  - Ceftriaxone: 100 mg/kg/day IV or IM in 2 equally divided doses for 7 to 10 days (1)[C] or
  - Azithromycin: 20 mg/kg/day PO daily for 7 days (1)[C]

- HIV patients
  - Increased duration of antimicrobial therapy and/or the use of zidovudine may decrease relapse (2)[C].

**Bacteremia:** Due to resistance trends, treat life-threatening infections in adults with a fluoroquinolone and a 3rd-generation cephalosporin until susceptibilities are determined (2)[A].

- Adults
  - Ciprofloxacin (or other fluoroquinolone): 400 mg IV BID for 10 to 14 days; *plus*
    - Ceftriaxone: 1 to 2 g/day IV for 10 to 14 days; *or*
    - Cefotaxime: 2 g IV q8h for 10 to 14 days

- Children
  - Ampicillin: 200 mg/kg/day in 4 divided doses for 10 to 14 days; *or*
  - Trimethoprim-sulfamethoxazole: 8 to 12 mg/kg/day of trimethoprim component in 2 divided doses for 10 to 14 days; *or*
  - Ceftriaxone: 50 to 75 mg/kg/day (max 1 g) once per day for 10 to 14 days

**Localized infection (e.g., septic arthritis, osteomyelitis, cholangitis, and pneumonia)**

- Same treatment as for bacteremia
- In sustained bacteremia, prolonged local infection, or immunocompromised patients, give antibiotics PO for 4 to 6 weeks (2)[A].

**Chronic carrier state (shedding >1 year duration)**

- Amoxicillin: 1 g PO TID for 12 weeks; *or*
- Trimethoprim-sulfamethoxazole 160 mg/800 mg PO BID for 12 weeks; *or*
- Ciprofloxacin: 500 mg PO BID for 4 weeks, *or*
- Levofloxacin 500 mg/day for 4 weeks; *or*
- Norfloxacin 400 mg PO BID for 4 weeks if gallstones are present
ALERT

Antimicrobial resistance

- Strains resistant to ampicillin, chloramphenicol, and trimethoprim-sulfamethoxazole have been reported.
- Fluoroquinolone resistance is increasing, perhaps due to increasing use in livestock.
- Extended-spectrum cephalosporin resistance has been reported with increasing frequency.

Second Line

- Aztreonam is a useful alternative in patients with multiple allergies or if organisms demonstrate unusual resistance patterns \(^2\)[A].
- Fluoroquinolones are routinely given to children for 5 to 7 days in areas where multidrug-resistant *Salmonella typhi* is common \(^2\)[A].

SURGERY/OTHER PROCEDURES

- Surgical excision and drainage of infected tissue, followed by at least 2 weeks of antibiotic therapy
- If biliary tract disease is present, 10 to 14 days of parenteral antibiotics are recommended prior to cholecystectomy.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring

- Asymptomatic shedding of *Salmonella* may occur for weeks after infection. Follow-up fecal cultures are generally not indicated for patients with uncomplicated gastroenteritis. Requirements may differ during a *Salmonella* outbreak.
- Criteria vary by state. Some public health departments require negative stool cultures for health workers and food handlers prior to returning to work. Shedding may last 4 to 8 weeks.
- Serotyping of isolates can be performed at public health laboratories.

DIET
Easily digestible foods

PATIENT EDUCATION
- Hand hygiene; caution handling raw meat, poultry, and eggs
- Wash fruits and vegetables prior to consumption.
- Thoroughly cooking meats eliminates *Salmonella*.
- Caution when handling animals with high fecal carriage rates
- [www.cdc.gov/salmonella/general/prevention.html](http://www.cdc.gov/salmonella/general/prevention.html)

PROGNOSIS
- Most cases of *Salmonella* gastroenteritis are self-limited and have an excellent prognosis.
- Increased mortality is seen in the young (<3 months), elderly (>65 years), and immunocompromised.
- Increased mortality is seen with bacteremia and other invasive infections.
- Mortality is increased in multidrug-resistant strains.

COMPLICATIONS
- Toxic megacolon, hypovolemic shock, metastatic abscess formation, endocarditis, infectious endarteritis, meningitis, septic arthritis, reactive arthritis, osteomyelitis, pneumonia, appendicitis, cholecystitis

SEE ALSO
Gastroenteritis; Typhoid Fever

CODES

ICD10
- A02.9 Salmonella infection, unspecified
- A02.0 Salmonella enteritis
- A02.1 Salmonella sepsis

CLINICAL PEARLS

- Nontyphoidal Salmonella infection is typically a foodborne infection associated with a self-limited gastroenteritis.
- Clinical syndromes include gastroenteritis, bacteremia, endovascular infection, localized infection outside the GI tract, and a chronic carrier state.
- Very young, elderly, and immunocompromised patients are at the greatest risk of complications from *Salmonella* infection.
- Uncomplicated gastroenteritis in healthy patients is generally treated with supportive care.
- Antibiotics are useful for disease affecting infants, the elderly, immunocompromised patients, and for invasive infections such as bacteremia outside the GI tract.
SARCOIDOSIS
Donnah Mathews, MD, FACP

BASICS
DESCRIPTION
- Sarcoidosis is a noninfectious, multisystem, granulomatous disease of unknown cause, commonly affecting young and middle-aged adults.
  - Frequently presents with hilar adenopathy, pulmonary infiltrates, ocular or skin lesions
  - In ~50% of cases, it is diagnosed in asymptomatic patients with abnormal chest x-rays (CXRs).
  - Almost any organ may be involved.
- System(s) affected: primarily pulmonary but also cardiovascular, gastrointestinal, hematologic/lymphatic, endocrine, renal, neurologic, dermatologic, ophthalmologic, musculoskeletal
- Synonym(s): Löfgren syndrome (erythema nodosum [EN], hilar adenopathy, fever, arthralgias); Heerfordt syndrome (uveitis, parotid enlargement, facial palsy, fever); Besnier-Boeck disease; Boeck sarcoid; Scheuermann disease (1)[C],(2)[B],(3)[C]

EPIDEMIOLOGY
Incidence
Estimated 6/100 person-years (3)[C]

Prevalence
- Estimated 10 to 20/100,000 persons
- 11/100,000 annual incidence rate for women (4)[C]
- Usually occurs in younger persons, peak age 20 to 39 years
- Rare in children (2)[B],(3)[C]
- In the United States, the highest prevalence is in the Northeast (4)[C].

ETIOLOGY AND PATHOPHYSIOLOGY
- Despite extensive research, mostly unknown
- Thought to be due to exaggerated cell-mediated immune response to unknown antigen(s)
In the lungs, the initial lesion is CD4+ T-cell alveolitis, causing noncaseating granulomata, which may resolve or may undergo fibrosis. “Immune paradox” with affected organs showing an intense immune response and yet anergy exists elsewhere (1)[C]

**Genetics**
- Reports of familial clustering, with genetic linkage to a section within MHC on short arm of chromosome 6
- 3 to 4 times more common in African Americans
- Although worldwide in distribution, increased prevalence in Scandinavians, Japanese, African Americans, and women
- In Northern Europe, 5 to 40 cases/100,000 persons. In Black Americans, 35 cases/100,000 persons; in Caucasian Americans, 11 cases/100,000 persons (3)[C]

**RISK FACTORS**
Exact etiology and pathogenesis remain unknown.

**GENERAL PREVENTION**
None

**COMMONLY ASSOCIATED CONDITIONS**
None

**DIAGNOSIS**

**HISTORY**
- Patients may be asymptomatic.
- Patients may have nonspecific complaints, such as the following:
  - Nonproductive cough
  - Shortness of breath
  - Fever
  - Night sweats
  - Weight loss
  - General fatigue
  - Eye pain
  - Chest pain/palpitations
– Skin lesions
– Polyarthritis
– Renal calculi
– Facial droop due to Bell palsy
– Encephalopathy, seizures, hydrocephalus (rare)
– Patients >70 years old more likely to have systemic symptoms

**PHYSICAL EXAM**

- Many patients have a normal physical exam.
- Lungs may reveal wheezing/fine interstitial crackles in advanced disease.
- ~30% of patients have extrapulmonary manifestations (1)[C], which may include the following:
  - Uveitis
  - Other eye findings: conjunctival nodules, lacrimal gland enlargement, cataracts, glaucoma, papilledema
  - Cranial nerve palsies
  - Salivary gland swelling
  - Lymphadenopathy
  - Arrhythmias
  - Hepatosplenomegaly
  - Polyarthritis
  - Rashes (1)[C]
    - Maculopapular of nares, eyelids, forehead, base of neck at hairline, and previous trauma sites
    - Waxy nodular of face, trunk, and extensor surfaces of extremities
    - Plaques (lupus pernio) of nose, cheeks, chin, and ears
    - EN (component of Löfgren syndrome)
    - Atypical lesions

**DIFFERENTIAL DIAGNOSIS**

- Sarcoidosis is a diagnosis of exclusion.
- Infectious granulomatous disease, such as tuberculosis and fungal infections
- Hypersensitivity pneumonitis
- Lymphoma
- Other malignancies associated with lymphadenopathy
- Berylliosis (1)[C]

**DIAGNOSTIC TESTS & INTERPRETATION**
No definitive test for diagnosis, but diagnosis is suggested by the following:

- Clinical and radiographic manifestations
- Exclusion of other diagnoses
- Histopathologic detection of noncaseating granulomas

**Initial Tests (lab, imaging)**

- CBC: Anemia/leukopenia ± eosinophilia can be seen.
- Hypergammaglobulinemia can exist.
- LFTs: Abnormal liver function and increased alkaline phosphatase can be encountered with hepatic involvement.
- Calcium: Hypercalciuria occurs in up to 10% of patients, with hypercalcemia less frequent.
- Serum ACE elevated in >75% of patients but is not diagnostic or exclusionary
  - Drugs may alter lab results: Prednisone will lower serum ACE and normalize gallium scan. ACE inhibitors will lower serum ACE level.
  - Disorders may alter lab results: Hyperthyroidism and diabetes will increase serum ACE level.
- CXR or CT scan may reveal granulomas/hilar adenopathy. Routine CXRs are staged using Scadding classification.
  - Stage 0 = normal
  - Stage 1 = bilateral hilar adenopathy alone
  - Stage 2 = bilateral hilar adenopathy + parenchymal infiltrates
  - Stage 3 = parenchymal infiltrates alone (primarily upper lobes)
  - Stage 4 = pulmonary fibrosis (1,2)[C]
- Chest CT scan may enhance appreciation of lymph nodes.
- High-resolution chest CT scan may reveal peribronchial disease.
- Gallium scan will be positive in areas of acute disease/inflammation but is not specific.
- Positron emission tomography (PET) scan can indicate areas of disease activity in lungs, lymph nodes, and other areas of the body but does not differentiate between malignancy and sarcoidosis.
- Cardiac PET scan may detect cardiac sarcoidosis (2,3)[C].
- Serum amyloid A or adenosine deaminase have been found to be elevated with sarcoidosis but are not clinically used due to low sensitivity and specificity (5)[C].

**Diagnostic Procedures/Other**

- Pulmonary function tests (PFTs) may reveal restrictive pattern with decreased
carbon monoxide diffusing capacity (DLCO).

- Characteristically in active disease, bronchioalveolar lavage fluid has an increased CD4-to-CD8 ratio.
- Ophthalmologic examination may reveal uveitis, retinal vasculitis, or conjunctivitis.
- ECG
- Tuberculin skin test
- Biopsy of lesions should reveal noncaseating granulomas.
- If lungs are affected, bronchoscopy with biopsy of central and peripheral airways is helpful. Endobronchial US (EBUS)–guided transbronchial needle aspiration may potentially have a better diagnostic yield (2)[C].
- Kveim test (ongoing research): Suspension of sterilized splenic cells from a patient with sarcoidosis is injected in an intradermal skin test to evoke a sarcoïd granulomatous response over 3 weeks, similar to a tuberculin skin test.

**ALERT**
If signs indicate Löfgren syndrome (acute sarcoid with bilateral hilar lymphadenopathy, EN, and diffuse arthritis/arthralgias), it is not necessary to perform a biopsy because prognosis is good with observation alone, and biopsy would not change management.

**Test Interpretation**
Noncaseating epithelioid granulomas without evidence of fungal/mycobacterial infection

**TREATMENT**
- Many patients undergo spontaneous remission. It is difficult to assess disease activity and severity, however, making it challenging to develop guidelines.
- No treatment may be necessary in asymptomatic individuals, but treatment may be needed for specific indications, such as cardiac, CNS, renal, or ocular involvement.
- No treatment is indicated for asymptomatic patients with stage I to III radiographic changes with normal/mildly abnormal lung function, although close follow-up is recommended.
- Treatment of pulmonary and skin manifestations is done on the basis of impairment. The symptoms that necessitate systemic therapy remain
controversial.
- Worsening pulmonary symptoms
- Deteriorating lung function
- Worsening radiographic findings (6)[B]

**MEDICATION**

Systemic therapy is clearly indicated for hypercalcemia, cardiac disease, neurologic disease, and eye disease not responding to topical therapy. Most patients with pulmonary sarcoidosis do not require treatment with medications, as many are asymptomatic or have a spontaneous remission.

**First Line**

- There is no FDA-approved treatment specifically for sarcoidosis.
- Systemic corticosteroids in the symptomatic individual (dyspnea, cough, hemoptysis) or in the individual with worsening lung function or radiographic findings
  - The optimal dose of glucocorticoids is not known.
  - Usually prednisone initially, 0.3 to 0.6 mg/kg ideal body weight (20 to 40 mg/day) for 4 to 6 weeks
  - If stable, taper by 5 mg/week to 10 to 20 mg/day over the next 6 weeks.
  - If no relapse, 10 to 20 mg/day for 8 to 12 months
  - Relapse is common.
  - Higher doses (80 to 100 mg/day) may be warranted in patients with acute respiratory failure, cardiac, neurologic, or ocular disease.
- In patients with skin disease, topical steroids may be effective.
- Inhaled steroids (budesonide 800 to 1,600 μg BID) may be of some clinical benefit in early disease with mild pulmonary symptoms.
  - Contraindications: patients with known problems with corticosteroids
  - Precautions: careful monitoring in patients with diabetes mellitus and/or hypertension
  - Significant possible interactions: Refer to the manufacturer’s profile of each drug (1,3,6)[C].

**Second Line**

- All alternative agents to glucocorticoids carry substantial risk for toxicity, including myelosuppression, hepatotoxicity, and opportunistic infection. Prior to utilizing these medications, it is important to assess for steroid compliance, comorbid disease, or other complicating factors contributing to steroid failure.
Methotrexate: initially 7.5 mg/week, increasing gradually to 10 to 15 mg/week
Azathioprine: generally a supplement to prednisone in an attempt to lower steroid doses
Leflunomide
Mycophenolate
Use of immunosuppressants, such as methotrexate or azathioprine, will require regular monitoring of CBC and LFTs.
Antimalarial agents, such as chloroquine or hydroxychloroquine
Tumor necrosis factor antagonists, such as infliximab, have been useful in refractory cases (3,6)[C].

ISSUES FOR REFERRAL
May be followed by a pulmonologist, with referrals to other specialists as dictated by involvement of other organ systems; if requiring a second-line therapy, should be followed by a specialist

SURGERY/OTHER PROCEDURES
Lung transplantation in severe, refractory cases; long-term outcomes are unknown.

COMPLEMENTARY & ALTERNATIVE MEDICINE
None known to be effective

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
There is limited data on indications for the specific tests and optimal frequency of monitoring of disease activity. Suggestions follow.

Patient Monitoring
- Patients on prednisone for symptoms should be seen q1–2mo while on therapy.
- Patients not requiring therapy should be seen regularly (q3mo) for at least the first 2 years after diagnosis, obtaining a thorough history and physical exam, laboratory testing tailored to sites of disease activity, PFTs, and ambulatory pulse oximetry.
- If active disease
  - Every 6 to 12 months, obtain ophthalmologic exam if on hydroxychloroquine.
  - Annually, CBC, creatinine, calcium, LFTs, ECG, 25-hydroxy vitamin D and 1,25 dihydroxy vitamin D, CXR, ophthalmologic examination
- Other testing per individual patient’s symptoms, including HRCT, echocardiogram, Holter monitoring, urinalysis (UA), thyroid-stimulating hormone (TSH), bone density, MRI of brain
- The serum ACE level is used by some physicians to follow the disease activity. In patients with an initially elevated ACE level, it should fall toward normal while on the therapy or when the disease resolves.
- If inactive disease, follow annually with history and physical exam, PFTs, ambulatory pulse oximetry, CBC, creatinine, calcium, liver enzymes, 1,25 dihydroxy vitamin D, ECG, ophthalmologic exam.

**DIET**
No special diet

**PATIENT EDUCATION**
- The American Lung Association: [www.lungusa.org/lung-disease/sarcoidosis/?gclid=CPX6zuipm6MCFQxW2godISFepQ](www.lungusa.org/lung-disease/sarcoidosis/?gclid=CPX6zuipm6MCFQxW2godISFepQ)

**PROGNOSIS**
- 50% of patients will have spontaneous resolution within 2 years.
- 25% of patients will have significant fibrosis, but no further worsening of the disease after 2 years.
- 25% of patients (higher in some populations, including African Americans) will have chronic disease.
- Patients on corticosteroids for >6 months have a greater chance of having chronic disease.
- Overall death rate: <5%

**COMPLICATIONS**
- Patients may develop significant respiratory involvement, including cor pulmonale.
- Pulmonary hemorrhage from infection with aspergillosis in the damaged lung is possible.
Other organs, especially the heart (congestive heart failure, arrhythmias), eyes (rarely blindness), and CNS, can be involved with serious consequences. Cardiac, ocular, and CNS involvement usually manifests early on in patients with these complications of the disease.

REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- D86.9 Sarcoidosis, unspecified
- D86.0 Sarcoidosis of lung
- D86.86 Sarcoid arthropathy

**CLINICAL PEARLS**

- Sarcoidosis is a noninfectious, multisystem, granulomatous disease of
unknown cause, typically affecting young and middle-aged adults.

- Any organ can be affected.
- Diagnosis is based on clinical findings, exclusion of other disorders, and pathologic detection of noncaseating granulomas.
- Most patients do not need systemic treatment, and the disease resolves spontaneously; a few will have life-threatening progressive organ dysfunction.
SCABIES
Kaelen C. Dunican, PharmD • Brandi Hoag, DO

BASICS

DESCRIPTION
- A contagious parasitic infection of the skin caused by the mite Sarcoptes scabiei, var. hominis
- System(s) affected: skin/exocrine
- Synonym(s): sarcoptic mange

EPIDEMIOLOGY

Incidence
Predominant age: children and young adults

Prevalence
Prevalence varies substantially worldwide but is more common in resource-poor settings (1):
- May be more prevalent in urban areas and areas of overcrowding
- Common in developing countries particularly tropical climates; 2013 added to World Health Organization list of neglected tropical diseases

ETIOLOGY AND PATHOPHYSIOLOGY
- Itching is a delayed hypersensitivity reaction to the mite saliva, eggs, or excrement.
- S. scabiei, var. hominis
  - An obligate human parasite
  - Female mite lays eggs in burrows in the stratum corneum and epidermis.
  - Primarily transmitted by prolonged human-to-human direct skin contact
  - Infrequently transmitted via fomites (e.g., bedding, clothing, or furnishings)

RISK FACTORS
- Personal skin-to-skin contact (e.g., sexual promiscuity, crowding, nosocomial infection)
- Poor nutritional status, poverty, and homelessness
- Hot, tropical climates
- Seasonal variation: Incidence may be higher in the winter than in the summer (may be due to overcrowding).
- Immunocompromised patients, including those with HIV/AIDS, are at increased risk of developing severe (crusted/Norwegian) scabies.

**GENERAL PREVENTION**

Prevent outbreaks by prompt treatment and cleansing of fomites (see “Additional Therapies”).

**DIAGNOSIS**

**HISTORY**
- Generalized itching is often severe and worse at night.
- Determine any contact with infected individuals.
- Initial infection may be asymptomatic.
- Symptoms may develop after 3 to 6 weeks.

**PHYSICAL EXAM**
- Lesions (inflammatory, erythematous, pruritic papules) most commonly located in the finger webs, flexor surfaces of the wrists, elbows, axillae, buttocks, genitalia, feet, and ankles
- Burrows (thin, curvy, elevated lines in the upper epidermis that measure 1 to 10 mm in length) may be seen in involved areas—a pathognomonic sign of scabies.
- Secondary erosions or excoriations from scratching
- Pustules (if secondarily infected)
- Pruritic nodules in covered areas (buttocks, groin, axillae) resulting from an exaggerated hypersensitivity reaction
- Crusted scabies (Norwegian scabies) is a psoriasiform dermatosis occurring with hyperinfestation with thousands of mites (more common in immunosuppressed patients).

**Geriatric Considerations**

The elderly often itch more severely despite fewer cutaneous lesions and are at risk for extensive infestations, perhaps related to a decline in cell-mediated immunity. There may be back involvement in those who are bedridden.
**Pediatric Considerations**
Infants and very young children often present with vesicles, papules, and pustules and have more widespread involvement, including the hands, palms, feet, soles, body folds, and head (rare for adults).

**DIFFERENTIAL DIAGNOSIS**
- Atopic dermatitis
- Contact dermatitis
- Folliculitis/impetigo
- Tinea corporis
- Dermatitis herpetiformis
- Eczema
- Insect bites
- Papular urticaria
- Pediculosis corporis
- Pityriasis rosea
- Prurigo
- Psoriasis (crusted scabies)
- Pyoderma
- Seborrheic dermatitis
- Syphilis

**DIAGNOSTIC TESTS & INTERPRETATION**
- Definitive diagnosis is based on microscopic identification of mites, eggs, or fecal pellets (scybalae), but diagnosis may be based on history and physical exam (2–4)[C].
- A failure to find mites does not rule out scabies.

**Initial Tests (lab, imaging)**
CBC is rarely needed but may show eosinophilia.

**Diagnostic Procedures/Other**
- Examination of skin with magnifying lens
  - Look for typical burrows in finger webs and on flexor aspect of the wrists and on the penis.
  - Look for a dark point at the end of the burrow (the mite).
  - Presumptive diagnosis based on clinical presentation, skin lesions, and identification of burrow (2,3)
- Skin scraping
  - Place a drop of mineral oil over a nonexcoriated lesion or burrow.
  - Scrape the lesion with a surgical blade.
  - Examine under a microscope for mites, eggs, egg casings, or feces (2)[C].
  - Scraping from under fingernails often may be positive.
  - When mite is not found with scraping, biopsy may reveal mite, eggs, or feces (3).
- Potassium hydroxide (KOH) wet mount not recommended because it can dissolve mite pellets
- Burrow ink test
  - If burrows are not obvious, apply gentian violet or India ink to an area of rash. Wash off the ink with alcohol. A burrow should remain stained and become more evident.
  - Then apply mineral oil, scrape, and observe microscopically, as noted previously (3)[C].

**Test Interpretation**
Skin biopsy of a nodule (although performed rarely) will reveal portions of the mite in the corneal layer.

**TREATMENT**

**GENERAL MEASURES**
- Treat all intimate contacts and close household and family members.
- Wash all clothing, bed linens, and towels in hot (60°C) water and dry in hot dryer.
- Personal items that cannot be washed should be sealed in a plastic bag for at least 3 to 5 days.
- Some itching and dermatitis may persist for up to 6 weeks and can be treated with oral antihistamines and/or topical or oral corticosteroids.

**MEDICATION**

**First Line**
Permethrin 5% cream (Elimite) is generally accepted as first-line therapy (5)[A].
- After bathing or showering, apply cream from the neck to the soles of the feet paying particular attention to areas that are most involved and then wash off
after 8 to 14 hours and repeat in 1 week.

- The adult dose is usually 30 g per treatment.
- Side effects include itching and stinging (minimal absorption).
- Crusted scabies may require more frequent application (q2–3d for 1 to 2 weeks) in combination with repeated doses of PO ivermectin on days 1, 2, 8, 9, and 15 (2,3,5)[C].

**Pediatric Considerations**

Permethrin may be used on infants >2 months of age. In children <5 years of age, the cream should be applied to the head and neck as well as to the entire body.

**Second Line**

- **Ivermectin (Stromectol) (5)[A]**
  - Not FDA-approved for scabies
  - 200 to 250 μg/kg PO as single dose; repeated in 1 week
  - Take with food to improve bioavailability and enhance penetration into the epidermis.
  - May need higher doses or may need to use in combination with topical scabicide for HIV-positive patients
- **Crotamiton (Eurax) 10% cream**
  - Apply from the neck down for 24 hours, rinse off, then reapply for an additional 24 hours and then thoroughly wash off.
  - Nodular scabies: Apply to nodules for 24 hours, rinse off, reapply for an additional 24 hours and then thoroughly wash off.
- **Precipitated sulfur 2–10% in petrolatum**
  - Not FDA-approved for scabies
  - Apply to the entire body from the neck down for 24 hours, rinse by bathing and then repeat for 2 more days (3 days total). It is malodorous and messy but is thought to be safer than lindane, especially in infants <6 months of age and safer than permethrin in infants <2 months of age.
- **Lindane (γ-benzene hexachloride, Kwell) 1% lotion**
  - Apply to all skin surfaces from the neck down and wash off 6 to 8 hours later.
  - Two applications 1 week apart are recommended but may increase the risk of toxicity.
  - 2 oz is usually adequate for an adult.
  - Side effects: neurotoxicity (seizures, muscle spasms), aplastic anemia
Contraindications: uncontrolled seizure disorder, premature infants
Precautions: Do not use on excoriated skin, on immunocompromised patients, in conditions that may increase risk of seizures, or with medications that decrease seizure threshold.
Possible interactions: concomitant use with medications that lower the seizure threshold

**Alert**
Lindane: FDA black box warning of severe neurologic toxicity; use only when all other agents have failed.

**Pediatric Considerations**
- The FDA recommends caution when using lindane in patients who weigh <50 kg. It is not recommended for infants and is contraindicated in premature infants.
- PO ivermectin should be avoided in children <5 years and in those weighing <15 kg.

**Pregnancy Considerations**
- Permethrin is pregnancy Category B, and lindane, ivermectin, and crotamiton are Category C.
- Permethrin is considered compatible with lactation, but if permethrin is used while breastfeeding, the infant should be bottlefed until the cream has been thoroughly washed off.

**Additional Therapies**
- Crusted scabies may require use of keratolytics to improve penetration of permethrin.
- Benzyl benzoate lotion (not available in the United States but used widely in developing countries)
  - Not FDA-approved for scabies
  - Dose for adults is 25–28%; dilute to 12.5% for children and 6.25% for infants.
  - After bathing, apply lotion from the neck to soles of feet for 24 hours.
- Topical ivermectin 1% lotion (investigational) (4)
  - Not FDA-approved for scabies
  - Apply to affected sites and wash off 8 hours later.
COMPLEMENTARY & ALTERNATIVE MEDICINE
Herbal products such as tea tree oil, clove oil, neem oil, and aloe vera require additional evidence to establish efficacy (4).

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
Recheck patient at weekly intervals only if rash or itching persists. Scrape new lesions and retreat if mites or products are found.

PATIENT EDUCATION
- Patients should be instructed on proper application and cautioned not to overuse the medication when applying it to the skin.
- A patient fact sheet is available from the CDC: http://www.cdc.gov/parasites/scabies/.

PROGNOSIS
- Lesions begin to regress in 1 to 2 days, along with the worst itching, but eczema and itching may persist for up to 6 weeks after treatment.
- Nodular lesions may persist for several weeks, perhaps necessitating intralesional or systemic steroids.
- Some instances of lindane-resistant scabies have now been reported. These cases do respond to permethrin.

COMPLICATIONS
- Poor sleep due to pruritus
- Social stigma
- Secondary bacterial infection (more common in developing countries): Impetigo due to group A streptococci and Staphylococcus aureus may lead to sepsis, glomerulonephritis, and rheumatic heart disease.
- Eczema
- Pyoderma
- Postscabetic pruritus
- Nodules (nodular scabies) may persist for weeks to months after treatment.
REFERENCES

SEE ALSO
Arthropod Bites and Stings; Pediculosis (Lice)

CODES

ICD10
B86 Scabies

CLINICAL PEARLS

- Prior to diagnosis, use of a topical steroid to treat pruritic symptoms may mask symptoms and is termed *scabies incognito*.
- Environmental control is recommended. All linens, towels, and clothing used in the previous 4 days should be washed in hot water or dry-cleaned. Personal items that cannot be washed or dry-cleaned should be sealed in a plastic bag for 3 to 5 days.
- All members of the affected household may require treatment.
- Close contacts (those sharing the same bed or who have intimate contact) may not show signs and symptoms immediately but recommend treating simultaneously to avoid reinfection.
- Eczema and itching may persist for up to 6 weeks after treatment, causing many patients to falsely believe that they have failed treatment or are being reinfected.
- In patients with actual reinfection, either the patient has not applied the
medication properly or, more likely, the index patient has not been identified and treated.
SCARLET FEVER

John C. Huscher, MD

BASICS

DESCRIPTION
- A disease (typically in childhood) characterized by fever, pharyngitis, and rash caused by group A β-hemolytic Streptococcus pyogenes (GAS) that produces erythrogenic toxin
- Incubation period: 1 to 7 days
- Duration of illness: 4 to 10 days
- Rash usually appears on the second day of illness.
- Rash first appears on the upper chest and flexural creases and then spreads rapidly all over the body.
- Rash clears at the end of the 1st week and is followed by several weeks of desquamation.
- System(s) affected: head, eyes, ears, nose, throat, skin/exocrine
- Synonym(s): scarlatina

EPIDEMIOLOGY

Incidence
- In developed countries, 15% of school age children and 4–10% of adults have an episode of GAS pharyngitis each year.
- Scarlet fever is rare in infancy because of maternal antitoxin antibodies.
- Predominant age: 6 to 12 years
- Peak age: 4 to 8 years
- Predominant sex: male = female
- Rare in the United States in persons >12 years because of high rates (>80%) of lifelong protective antibodies to erythrogenic toxins

Prevalence
- 15–30% of cases of pharyngitis in children are due to GAS; 5–15% in adults
- <10% of children with streptococcal pharyngitis develop scarlet fever.

ETIOLOGY AND PATHOPHYSIOLOGY
- Erythrogenic toxin production is necessary to develop scarlet fever.
Three toxin types: A, B, C
Toxins damage capillaries (producing rash) and act as superantigens, stimulating cytokine release.
Antibodies to toxins prevent development of rash but do not protect against underlying infection.
Primary site of streptococcal infection is usually within the tonsils, but scarlet fever may also occur with infection of skin, surgical wounds, or uterus (puerperal scarlet fever).

RISK FACTORS
- Winter/spring seasonal increase
- More common in school-aged children
- Contact with infected individual(s)
- Crowded living conditions (e.g., lower socioeconomic status, barracks, child care, schools)

GENERAL PREVENTION
- Spread by contact with airborne respiratory droplets
- Asymptomatic contacts do not require cultures/prophylaxis.
- Symptomatic contacts may be treated with or without culture.
- Children should not return to school/daycare until they have received 24 hours of antibiotic therapy.

COMMONLY ASSOCIATED CONDITIONS
- Pharyngitis
- Impetigo
- Rheumatic fever
- Glomerulonephritis

DIAGNOSIS

HISTORY
Prodrome 1 to 2 days
- Sore throat
- Headache
- Myalgias
- Malaise
• Fever (>38°C [100.4°F])
• Vomiting
• Abdominal pain (may mimic acute abdomen)
• Rash—scarlatiniform erythematous punctate eruption
• Cough, conjunctivitis, hoarseness, and rhinorrhea are more commonly associated with viral infections.

PHYSICAL EXAM
• Oral exam
  – Beefy red tonsils and pharynx with/without exudate
  – Petechiae on palate
  – White coating on tongue: White strawberry tongue appears on days 1 to 2. This sheds by days 4 to 5, leaving a red strawberry tongue, which is shiny and erythematous with prominent papillae.
• Exanthem (appears within 1 to 5 days)
  – Scarlet macules with generalized erythema; blanches when pressed
  – Orange-red punctate skin eruption with sandpaper-like texture, “sunburn with goose pimples”
  – Coarse “sandpaper” rash, initially appearing on chest and axillae, and then spreading to abdomen and extremities; prominent in skin folds, flexural surfaces (e.g., axillae, groin, buttocks), with sparing of palms and soles
  – Flushed face with circumoral pallor, red lips
  – Pastia lines: transverse red streaks in skin folds of abdomen, antecubital space, and axillae
  – Desquamation begins on face after 7 to 10 days and proceeds over trunk to hands and feet; may persist for 6 weeks
  – In severe cases, small vesicular lesions (miliary sudamina) may appear on abdomen, hands, and feet.

DIFFERENTIAL DIAGNOSIS
• Viral exanthem: measles; rubella; roseola
• Infectious mononucleosis
• Mycoplasma pneumonia
• Secondary syphilis
• Toxic shock syndrome
• Staphylococcal scalded-skin syndrome
• Kawasaki disease
• Drug hypersensitivity
• Severe sunburn
DIAGNOSTIC TESTS & INTERPRETATION

- Use results from rapid antigen detection testing (RADT) in conjunction with validated clinical decision rules such as the modified Centor score.

- Modified Centor clinical decision rule
  - Absence of cough 1 point
  - Swollen, tender anterior cervical nodes 1 point
  - Temperature 100.4°F (38°C) 1 point
  - Tonsillar exudate or swelling 1 point
  - Age:
    - 3 to 14 years ........................................ 1 point
    - 15 to 44 years ........................................ 0 point
    - 45 years or older ..................................... -1 point

- Cumulative score:
  - 0 Risk of GAS pharyngitis 1–2.5%—no further testing or antibiotics indicated
  - 1 Risk of GAS pharyngitis 5–10%—no further testing or antibiotics indicated—option to perform throat culture or RADT—treat if positive.
  - 2 Risk of GAS pharyngitis 11–17%—perform throat culture or RADT—treat if positive.
  - 3 Risk of GAS pharyngitis 28–35%—perform throat culture or RADT—treat if positive.
  - 4+ Risk of GAS pharyngitis 51–53%—consider empiric treatment with antibiotics.

- Testing for GAS pharyngitis is not recommended for patients with symptoms suggesting a viral etiology (e.g., cough, rhinorrhea, hoarseness, oral ulcers).

Initial Tests (lab, imaging)

- RADT: diagnostic if positive, 95% specific; sensitivity approaches that of culture. In children, negative RADT should be confirmed by throat culture (not necessary in adults). Positive RADT does not require confirmatory culture (1)(C).

- Throat culture is the gold standard to confirm streptococcal infection (99% specific, 90–97% sensitive; 5–10% of healthy individuals are carriers) (1).

- Serologic tests (antistreptolysin O titer and streptozyme tests, antihyaluronidase): Confirm recent GAS infection; not helpful or recommended for diagnosis of acute disease

- Gram stain: gram-positive cocci in chains
CBC may show elevated WBC count (12,000 to 16,000/mm$^3$); eosinophilia later (second week)

Follow-up (posttreatment) throat cultures or RADT not routinely recommended

Diagnostic testing and empiric treatment of asymptomatic household contacts of patients with acute streptococcal pharyngitis is not routinely recommended (2)[B].

Appropriately symptomatic patients >3 years old with a family member recently diagnosed with laboratory-confirmed GAS pharyngitis may be treated without screening or confirmatory testing (3)[C].

Follow-Up Tests & Special Considerations

- Recent antibiotic therapy may impact culture results.
- Within 5 days of symptoms, antibiotics can delay/abolish antistreptolysin O response.

Test Interpretation
Skin lesions reveal characteristic inflammatory reaction, specifically hyperemia, edema, and polymorphonuclear cell infiltration.

TREATMENT

GENERAL MEASURES
Supportive care; analgesic/antipyretic such as acetaminophen or NSAID, for moderate to severe symptoms or to control fever. Symptomatic treatment can include medicated throat lozenges and topical anesthetics.

MEDICATION

First Line
The primary reason for treating GAS is to decrease the risk of acute rheumatic fever. Early treatment decreases duration of symptoms by 1 to 2 days and decreases the period of contagiousness (3)[B]. Penicillin is the drug of choice for GAS pharyngitis given its proven efficacy, safety, narrow spectrum, and low cost.

- Penicillin (PO; penicillin V and others) for 10 days
  - 250 mg PO BID or TID for <27 kg (60 lb); 250 mg QID or 500 mg BID for
>27 kg (60 lb) adolescents and adults([1,4,5][A])
  – If compliance is questionable, use penicillin G benzathine: single IM dose 600,000 U for <27 kg (60 lb); 1.2 mU for those >27 kg
  • Amoxicillin (PO) 50 mg/kg (max dose 1,000 mg) once daily or 25 mg/kg (max dose 500 mg) twice daily for 10 days (use only for definitive GAS because it can induce rash with some viral infections)
  – Contraindications: penicillin allergy
  • Precautions: Avoid in patients with penicillin allergy (anaphylaxis).

**Second Line**
  • For patients allergic to penicillin
  • Type IV hypersensitivity to penicillin:
    – Oral cephalosporins: Many are effective, but 1st-generation cephalosporins are less expensive:
      o Cephalexin 20 mg/kg dose twice daily for 10 days; max 500 mg every 12 hours ([1][A])
      o Cefadroxil 30 mg/kg once daily; max 1,000 mg for 10 days ([1])
  • Type I hypersensitivity to penicillin:
    – Azithromycin (Zithromax, Z pack): 12 mg/kg/day (max 500 mg) for 5 days ([4][A])
    – Clarithromycin (Biaxin): children >6 months: 7.5 mg/kg BID for 10 days; adults: 250 mg BID for 10 days
  • Clindamycin 7 mg/kg (max 300 mg/dose) TID for 10 days ([4][B])
  • Tetracyclines and sulfonamides should not be used.

**ALERT**
Avoid aspirin in children due to risk of Reye syndrome.

**ISSUES FOR REFERRAL**
Peritonsillar abscess; shock symptoms: hypotension, disseminated intravascular coagulation (DIC), cardiac, liver, renal dysfunction

**SURGERY/OTHER PROCEDURES**
  • Tonsillectomy is recommended with recurrent bouts of pharyngitis (≥6 positive strep cultures in 1 year).
  • Although children still may get streptococcal pharyngitis (“strep throat”) after a tonsillectomy, the procedure reduces the frequency and severity of infections.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Follow-up throat culture not needed unless symptomatic

**Patient Monitoring**
GAS is uniformly susceptible to penicillin, treatment failures are typically due to:
- Poor adherence to recommended antibiotic therapy
- β-Lactamase oral flora hydrolyzing penicillin
- GAS carrier state and concurrent viral rash (requires no treatment)
- Repeat exposure to carriers in family: Streptococci persist on unrinsed toothbrushes and orthodontic appliances for up to 15 days.
- Retreat recurrent GAS pharyngitis with the same agent, an alternative oral agent, or IM penicillin G.

**DIET**
No special diet

**PATIENT EDUCATION**
- Delay in treatment awaiting culture results does not increase the risk of rheumatic fever.
- Complete the entire course of antibiotics.
- Children should not return to school/daycare until they have received >24 hours of antibiotic therapy.
- Can spread person to person. Personal hygiene is important (wash hands, don‘t share utensils).
- “Recurring strep throat: When is tonsillectomy useful?”
  (http://www.mayoclinic.org/diseasesconditions/strep-throat/expert-answers/recurringstrep-throat/faq-20058360)

**PROGNOSIS**
- Treatment shortens symptoms by 12 to 24 hours.
- Recurrent attacks are possible (different erythrogenic toxins).

**COMPLICATIONS**
- Suppurative
– Sinusitis
– Otitis media/mastoiditis
– Cervical adenitis
– Peritonsillar abscess/retropharyngeal abscess
– Pneumonia
– Bacteremia with metastatic infectious foci: meningitis, brain abscess, osteomyelitis, septic arthritis, endocarditis, intracranial venous sinus thrombosis, necrotizing fasciitis

• Nonsuppurative
  – Rheumatic fever: Therapy prevents rheumatic fever when started as long as 10 days after onset of acute GAS infection.
  – Glomerulonephritis: due to nephritogenic strain of Streptococcus; prevention even after adequate treatment of GAS is less certain.
  – Streptococcal toxic shock syndrome: fever; hypotension; DIC; and cardiac, liver, and/or kidney dysfunction due to other toxin-mediated sequelae
  – Cellulitis
  – Weeks to months later, may develop transverse grooves in nail plates and hair loss (telogen effluvium)
  – Pediatric autoimmune neuropsychiatric disorder associated with GAS (PANDAS). A subset of children has been recognized whose symptoms of obsessive-compulsive disorder (OCD) or tic disorders are exacerbated by GAS infection.

REFERENCES

SEE ALSO
- Pharyngitis
- Algorithm: Pharyngitis

CODES

**ICD10**
- A38.9 Scarlet fever, uncomplicated
- J02.0 Streptococcal pharyngitis
- A38.0 Scarlet fever with otitis media

CLINICAL PEARLS
- Consider scarlet fever in the differential diagnosis of children with fever and an exanthematous rash.
- Key clinical findings include strawberry tongue, circumoral pallor, and a coarse sandpaper rash.
- Desquamation (7 to 10 days after symptom onset) may last for several weeks following scarlet fever.
- Diagnose GAS pharyngitis using a validated clinical decision rule (modified Centor score) and selective use of RADT.
- Penicillin remains the drug of choice.
BASICS
Schizophrenia is a persistent and severe psychiatric condition characterized by neurocognitive decline and impairment in reality testing.

DESCRIPTION
- Major psychiatric disorder characterized by prodrome, active, and residual psychotic symptoms involving disturbances in appearance, speech, behavior, perception, and thought that last for at least 6 months
- *DSM-5* eliminated subcategories of schizophrenia (1).
- System(s) affected: central nervous system (CNS)

EPIDEMIOLOGY

**Incidence**
- 7.7 to 43/100,000
- Predominant sex: male-to-female ratio = 1.4:1.0
- Age of onset: typically <30 years, earlier in males (early to mid-20s) than females (late 20s), with a smaller peak that occurs in women >45 years

**Prevalence**
- Lifetime (1%): highest prevalence in lower socioeconomic classes and urban settings (2-fold higher risk)
- 1.1% of the population >18 years old; similar rates in all countries

ETIOLOGY AND PATHOPHYSIOLOGY
- Stems from a complex interaction between genetic and environmental factors; higher incidence if prenatal infection or hypoxia, winter births, first-generation immigrants, advanced paternal age, drug use, and genetic (velocardiofacial) syndromes
- Overstimulation of mesolimbic dopamine D<sub>2</sub> receptors, deficient prefrontal dopamine, and aberrant prefrontal glutamate (NMDA) activity results in perceptual disturbances, disordered thought process, and cognitive impairments
Genetics
If first-degree biologic relative has schizophrenia, risk is 8–10% (a 10-fold increase).

GENERAL PREVENTION
- Currently, no known preventive measures decrease the incidence of schizophrenia.
- Interventions to improve long-term outcome and associated comorbid conditions are employed during management.

COMMONLY ASSOCIATED CONDITIONS
- Nicotine dependence (>50%) (1) and substance use disorders are common and lead to significant long-term medical and social complications.
- Metabolic syndrome, diabetes mellitus, obesity, and certain infectious diseases, including HIV, hepatitis B, and hepatitis C all occur in higher-than-expected rates in individuals with schizophrenia.

DIAGNOSIS
Focus on identifying an insidious social and functional decline per history with the onset of ≥2 of the following characteristic symptoms on mental status exam:
- Delusions (fixed, false beliefs)
- Hallucinations (auditory > visual disturbances)
- Disorganized thought (derailed or incoherent speech)
- Grossly disorganized/catatonic behavior (hyper- or hypoactive movements that are often repetitive)
- Negative symptoms (affective flattening, avolition, asociality, alogia, anhedonia) (1)

PHYSICAL EXAM
No physical findings characterize the illness; however, chronic treatment with neuroleptic agents may result in parkinsonism, tardive dyskinesia, and other extrapyramidal symptoms.

DIFFERENTIAL DIAGNOSIS
- Brief psychotic disorder (symptom duration <1 month)
- Schizophreniform disorder (symptom duration 1 month to 6 months)
Psychotic disorder due to another medical condition
  - Disorientation, in particular, indicates delirium
  - Possible medical illnesses include porphyria, TBI, infection, tumor, metabolic, endocrine, and intoxication, including withdrawal states and disorders that affect the CNS (i.e., epilepsy, Huntington disease, Wilson disease, lupus cerebritis, anti-NMDA limbic encephalitis, metachromatic leukodystrophy).

Substance-induced psychosis: secondary to substance use/abuse, such as cocaine, hallucinogens (amphetamines, LSD, phencyclidine), cannabis (including synthetic), bath salts, alcohol, or prescribed medications including steroids, anticholinergics, and opiates

Personality disorders: paranoid, schizotypal, schizoid, borderline personality disorder

Mood disorders: bipolar disorder, major depressive disorders with psychotic features or catatonia

Other thought disorders: delusional disorder, schizoaffective disorder

Posttraumatic stress disorder

Cultural belief system

Autism spectrum disorder or neurodevelopmental disorders

**DIAGNOSTIC TESTS & INTERPRETATION**

No tests are available to indicate schizophrenia.

Imaging (MRI), EEG, LP, and laboratory tests may be needed to rule out other causes and may be used as clinical presentation warrants.

**Initial Tests (lab, imaging)**

The following labs are often used to rule out a medical etiology of a patient experiencing their first episode of psychotic symptoms:
  - TSH, CBC, blood chemistries
  - Vitamin levels (thiamine, vitamin D, methylmalonic acid/vitamin B_{12})
  - Drug/alcohol screen of blood and urine, urinalysis
  - Syphilis screen, HIV
  - Heavy-metal exposure: lead, mercury
  - Ceruloplasmin, urine porphobilinogen as indicated
  - ESR, ANA

The following labs are used to assess for comorbidities and baseline values prior to antipsychotic initiation:
  - ECG for baseline QTc
– Blood glucose level, preferably fasting
– Lipid panel, preferably fasting
– Pregnancy test, if indicated
– Hepatitis C, Hepatitis B

**Follow-Up Tests & Special Considerations**
Clinical and laboratory tests for routine monitoring, at least yearly, if using antipsychotic medications (2)[A]:

- Weight, waist circumference, and blood pressure
- Fasting blood glucose level, hemoglobin A1C, fasting lipid panel
- CBC, blood chemistries, TSH
- Pregnancy test and prolactin level, if indicated
- ECG, monitoring for QTc prolongation
- Clinical assessment of extrapyramidal symptoms

**Diagnostic Procedures/Other**
Neuropsychologic testing: not a routine part of assessment but can help assess cognitive level to predict functioning and need for assistance

**Test Interpretation**
No diagnostic pathologic findings; however, ventriculomegaly is frequently seen on MRI with whole brain grey matter loss and white matter loss in medial temporal lobe structures preferentially.

**TREATMENT**

**MEDICATION**

**First Line**

- Two classes of antipsychotic medications: typical and atypical. First-line treatment is with an atypical antipsychotic given lower potential for extrapyramidal side effects.
  - Atypical (2nd generation)
    - Risperidone, olanzapine, ziprasidone, aripiprazole, quetiapine, paliperidone, iloperidone, asenapine, lurasidone, clozapine, brexpiprazole, cariprazine, pimavanserin (Parkinson disease related psychosis)
- Typical (1st generation)
  - Haloperidol, chlorpromazine, fluphenazine, trifluoperazine, perphenazine, thioridazine, thiothixene, loxapine

**Medication choice is based on clinical and subjective response and side effect profile (2)[A].**

- Sensitivity to extrapyramidal adverse effects: atypical
- For least risk of tardive dyskinesia: quetiapine, clozapine
- For least risk of metabolic syndrome: aripiprazole, ziprasidone, lurasidone

**For poor compliance/high risk of relapse: Injectable form of long-acting antipsychotic may be used.**
- Haloperidol (monthly), fluphenazine (3 to 6 weeks), risperidone (2 weeks), olanzapine (2 weeks or 4 weeks), aripiprazole (monthly), and paliperidone (3 months and monthly injections available)

**Usual oral daily dose (initial dose may be lower)**
- Chlorpromazine: 200 mg BID
- Aripiprazole: 10 to 30 mg/day
- Asenapine: 5 mg BID (sublingual)
- Fluphenazine: 5 mg BID
- Haloperidol: 5 mg BID
- Lurasidone: 40 to 80 mg/day (with meal)
- Olanzapine: 15 to 30 mg/day
- Paliperidone: 3 to 12 mg/day
- Perphenazine: 24 mg/day divided BID/ TID
- Quetiapine: 200 to 300 mg BID
- Risperidone: 3 mg/day
- Ziprasidone: 60 to 80 mg BID (with meal)
- Cariprazine: 1.5 to 6 mg/day
- Brexpiprazole: 2 to 4 mg/day
- Pimavanserin: 34 mg/day
- Clozapine: 200 mg BID
  - Start 12.5 mg/day and increase daily by 25 mg until dose of 300 mg/day split into BID dosing; do not exceed 900 mg/day.

**Effective in treatment of refractory or suicidal patients (2)[A]**

- Serious risk of agranulocytosis mandates registration with National Clozapine Registry and weekly to monthly monitoring of CBC with differential.
- Significant risk of seizure at higher doses
- Side effects can include myocarditis, DVT, sialorrhea, tachycardia, and weight gain.
ALERT
All antipsychotics are associated with weight gain and carry the risk of metabolic SE and tardive dyskinesia.

- Managing adverse effects of antipsychotics
  - Dystonic reaction (especially of head and neck): diphenhydramine 25 to 50 mg IM or benztropine 1 to 2 mg IM
  - Akathisia (restlessness): propranolol 20 to 30 mg BID or lorazepam 0.5 to 1 mg BID
  - Parkinsonism: trihexyphenidyl 2 mg BID (up to 15 mg daily) or benztropine 0.5 BID (1 to 4 mg/day); amantadine 100 mg daily (up to 300 mg daily)
  - Neuroleptic malignant syndrome: hyperthermia, autonomic dysfunction, and extrapyramidal symptoms; requires hospitalization and supportive management (IVF and cessation of offending neuroleptic)

- Geriatric considerations: All antipsychotics carry a black box warning for increased mortality risk in elderly patients with dementia.

- Adjunctive treatments
  - Benzodiazepines
    - May be effective adjuncts to antipsychotics during acute phase of illness
    - Useful for the treatment of catatonia
    - Withdrawal reactions with psychosis or seizures; risk for dependence and cognitive impairment
  - Mood stabilizers
    - Valproic acid may be effective adjunct for those with agitated/violent behavior (2)[A].
    - Lithium may be effective adjunct for patients with affective symptoms or schizoaffective disorder (2)[A].
  - Antidepressants: if prominent symptoms of depression are present
  - Metformin: helps minimize risk of metabolic SE with use of antipsychotics
  - Liraglutide: helps minimize risk of metabolic SE with use of clozapine or olanzapine (3)[B]

ISSUES FOR REFERRAL
- Consider referral in cases of suicidality, coexistence of an addiction, difficulty in engagement, or poor self-care.
- Patients with schizophrenia should receive multidisciplinary care from both a primary care physician and a psychiatrist.
- Family members often benefit from referral to family advocacy organizations
such as NAMI.

ADDITIONAL THERAPIES
- Family patient education and psychotherapy: These include specific treatments to reduce the impact of psychotic symptoms and to enhance social functioning. Cognitive-behavioral therapy has been shown to be effective for specific symptoms of schizophrenia ([4][A].
- Cognitive remediation is a new approach for cognitive retraining and psychosocial recovery.
- Vocational support programs have shown success in returning individuals to work.

SURGERY/OTHER PROCEDURES
- Electroconvulsive therapy (ECT) should be considered early for patients presenting with catatonic features when response to benzodiazepines is insufficient ([2][A].
- Surgical interventions are not available.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Omega-3 fatty acids may improve cognitive symptoms, but evidence remains inconclusive.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
- Initial stabilization focuses on maintaining a safe environment and reducing acute psychotic symptoms and agitation through the initiation of pharmacologic treatment.
- The decision to admit is usually based on the patient’s risk of self-harm or harm to others and the inability to care for self as governed by local legal statute.
- Monitor for safety concerns and establish a safe and supportive environment.
- Discharge criteria based on the patient’s ability to remain safe in the community. It reflects a combination of suicide risk, level of psychotic symptoms, support systems, and the availability of appropriate outpatient services.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Long-term symptom management and rehabilitation depend on engagement in ongoing pharmacologic and psychosocial treatment.
- Monitoring is based on evaluation of symptoms (including safety and psychotic symptoms), looking for the emergence of comorbidities, medication side effects, and prevention of complications.

DIET

- Newer atypical antipsychotics confer a higher risk of metabolic side effects such as diabetes, hypercholesterolemia, and weight gain.
- Although there are no specific dietary requirements, attention should be paid to the high risk of development of obesity and metabolic syndrome in individuals with schizophrenia.

PATIENT EDUCATION

- National Institute of Mental Health: Schizophrenia,
  www.nimh.nih.gov/health/topics/schizophrenia/index.shtml
- Helping a Family Member with Schizophrenia:
  www.aafp.org/afp/20070615/1830ph.html
- National Alliance on Mental Illness: www.NAMI.org

PROGNOSIS

- Typical course is one of remissions and exacerbations. Although uncommon, there are known cases of complete remission and of refractory illness.
- Negative symptoms are often most difficult to treat.
- About 20% attempt suicide. 5–6% die of suicide (1).
- Decreased life span related to comorbidities (coronary artery disease, pulmonary disease, or substance use disorders) and suboptimal care; guarded prognosis

COMPLICATIONS

- Side effects from antipsychotic medications including tardive dyskinesia, orthostatic hypotension, QTc prolongation, and metabolic syndrome
- Self-inflicted trauma and suicide
- Combative behavior toward others (Only 5% of crimes are caused by mental
illness including psychosis.) (5)

- Comorbid addictions, including nicotine

Algorithm: Delirium

CODES

mebooksfree.com
ICD10
- F20.9 Schizophrenia, unspecified
- F20.0 Paranoid schizophrenia
- F20.1 Disorganized schizophrenia

CLINICAL PEARLS
- A debilitating chronic mental illness that affects all cultures
- Schizophrenia is characterized by positive symptoms, including hallucinations, delusions, and negative symptoms, including flattened affect, anhedonia, amotivation, and social withdrawal.
- Requires a multidisciplinary team approach to assist with coping and treatment and promote recovery
SCLERITIS
Matthew J. Schear, DO, MS • Anne S. Steiner, MD

BASICS

DESCRIPTION

● Scleritis is a painful, inflammatory process of the sclera, part of the eye’s outer coat.
  – Categorized into anterior or posterior and diffuse, nodular, or necrotizing
  – Commonly associated with systemic disorders
  – Frequently requires systemic anti-inflammatory therapy
  – Potentially vision-threatening

● In contrast, episcleritis is a self-limited inflammation of the superficial episclera with only mild discomfort.

● System(s) affected: ocular

EPIDEMIOLOGY

● Mean age is 54 years (range 12 to 96).
● Predominant sex: female > male (1.6:1)

Incidence
Estimated to be 6 cases/100,000 people in the general population

Prevalence

● Anterior scleritis, about 94% of cases (1)[B]
  – Diffuse anterior scleritis, about 75% (most common)
● Remaining 6% have posterior scleritis.

ETIOLOGY AND PATHOPHYSIOLOGY

● Frequently associated with a systemic illness (1)[B]
  – Most commonly associated with rheumatoid arthritis
  – In about 38% of cases, scleritis is the presenting manifestation of an underlying systemic disorder.
  – Necrotizing scleritis has the highest association with systemic disease.
● Other etiologies
  – Proposed pathogenesis is dependent on type of scleritis. In necrotizing
scleritis, the predominant mechanism is likely due to the activity of matrix metalloproteinases.
- Drug-induced scleritis has been reported in patients on bisphosphonate therapy.
- Surgically induced necrotizing scleritis is exceedingly rare and occurs after multiple surgeries.
- Infectious scleritis occurs most commonly after surgical trauma, and *Pseudomonas aeruginosa* in poorly controlled diabetic patients is the most common causative organism (2) [B].

**RISK FACTORS**
Individuals with autoimmune disorders are most at risk.

**COMMONLY ASSOCIATED CONDITIONS**
- Rheumatoid arthritis (most common)
- Sjögren syndrome
- Granulomatosis with polyangiitis
- HLA-B27-associated ankylosing spondylitis
- Systemic lupus erythematosus
- Reactive arthritis
- Behçet disease
- Juvenile idiopathic arthritis
- Cogan disease
- Relapsing polychondritis
- Polyarteritis nodosa
- Sarcoidosis
- Inflammatory bowel disease
- Herpes zoster
- Herpes simplex
- HIV
- Syphilis
- Lyme disease
- Tuberculosis
- IgG4–related disease

**DIAGNOSIS**
HISTORY
- Redness and inflammation of the sclera
  - Can be bilateral in about 40% of cases (1)[B]
- Photophobia and tearing
- Pain ranging from mild discomfort to extreme localized tenderness
  - May be described as constant, deep, boring, or pulsating
  - Pain may be referred to the eyebrow, temple, or jaw.
  - Pain may awaken patient from sleep in early hours of morning.
  - Severe pain is most commonly associated with necrotizing scleritis (1)[B].

PHYSICAL EXAM
- Examine sclera in all directions of gaze by gross inspection.
  - A bluish hue may suggest thinning of sclera.
  - Inspect for degree of injection and extent of thinning.
- Check visual acuity.
  - Decrease in visual acuity of two or more Snellen lines occurs in about 16% of patients (1)[B].
- Slit-lamp exam using red-free light
  - Episcleritis: conjunctival and superficial vascular plexuses displaced anteriorly; blanches with phenylephrine
  - Scleritis: Deep episcleral plexus is the maximum site of vascular congestion, displaced anteriorly d/t edema of underlying sclera; characteristic blue or violet color, absent in patients with episcleritis
- Dilated fundus exam to rule out posterior involvement
- A complete physical exam, particularly of the skin, joints, heart, and lungs, should be done to evaluate for associated conditions.

DIFFERENTIAL DIAGNOSIS
- Conjunctivitis
- Episcleritis
- Iritis (anterior uveitis)
- Blepharitis
- Ocular rosacea

DIAGNOSTIC TESTS & INTERPRETATION
- Consider further tests if warranted by history and physical.
- Routine tests to exclude systemic disease
  - CBC, serum chemistry, urinalysis, ESR, and/or C-reactive protein, blood,
and urine cultures

- Specific tests for underlying systemic illness
  - Rheumatoid factor, anticyclic citrullinated peptide antibodies, ACE level, antineutrophil cytoplasmic antibodies, QuantiFERON-TB level, fluorescent treponemal antibody absorption (FTA-ABS), rapid plasma regain (RPR), lyme titers and antinuclear antibody may aid in the diagnosis.

- Further imaging studies, such as a chest x-ray and sacroiliac joint films, may be useful if a specific systemic illness is suspected.

- B-scan US to detect posterior scleritis. Look at thickness of sclera and for T-sign, fluid in Tenon’s space at interface between the optic nerve and sclera.

- MRI/CT scan may provide additional diagnostic benefit and detect orbital disease.

- Different subtypes of scleritis are associated with varying presentations and distinct findings:
  - Diffuse anterior scleritis: widespread inflammation
  - Nodular anterior scleritis: immovable, inflamed nodule
  - Necrotizing anterior scleritis: “with inflammation”: Sclera becomes transparent. Scleromalacia perforans without inflammation: painless and often associated with rheumatoid arthritis
  - Posterior scleritis: associated with retinal and choroidal complications; adjacent swelling of orbital tissues may occur.

**Diagnostic Procedures/Other**

Biopsy is not routinely required unless diagnosis remains uncertain after above investigations. Culture if suspect infectious etiology.

![TREATMENT](image)

**GENERAL MEASURES**

If scleral thinning, glasses/eye shield should be worn to prevent perforation.

**MEDICATION**

- First-line therapies for noninfectious scleritis (3)[C]
  - Oral NSAID therapy, choice based on availability, example is ibuprofen 600 to 800 mg PO TID–QID provided no contraindications exists; about 37% successful (4)[B]
  - Systemic steroids (initial if necrotizing scleritis and preferentially IV if
vision threatening, otherwise use if failure of NSAIDs), prednisone 40 to 60 mg PO QD, taper over 4 to 6 weeks. Use caution if suspect infectious etiology.

- Antimetabolites including methotrexate, azathioprine, mycophenolate mofetil, cyclophosphamide, and cyclosporine may be used as steroid-sparing agents. They are generally recommended if steroids cannot be tapered below 10 mg PO QD (4)[C].

**Second-line therapies (4)[C],(5)[A]**

- Immumomodulatory agents, infliximab, rituximab, and adalimumab can be used if patient has failed or is not a candidate for antimetabolites or calcineurin inhibitors. These agents are preferred over etanercept due to higher treatment success.

**Adjunct therapy considerations**

- Topical steroids: prednisolone acetate 1% under ophthalmologist care
- Subconjunctival triamcinolone acetonide injection only for nonnecrotizing, 40 mg/mL, 97% improvement after one injection; increased risk of ocular HTN, cataract, and globe perforation

**Necrotizing anterior scleritis and posterior scleritis**

- May require immunosuppressive therapy in addition to systemic steroids
- Treat aggressively due to possible complications if left untreated; may need patch grafting to maintain globe integrity

**Infectious**

- Antibiotic therapy resolves about 18% of cases, whereas the remaining often requires surgical intervention such as débridement (2)[B].

**ISSUES FOR REFERRAL**

- All patients with scleritis should be managed by an ophthalmologist familiar with this condition.
- Rheumatology referral for coexistent systemic disease is helpful for long-term success.

**ADDITIONAL THERAPIES**

Immunosuppressants used for autoimmune and collagen vascular disorders may be of help in active scleritis.

**SURGERY/OTHER PROCEDURES**

- In rare cases, scleral biopsy may be indicated to confirm infection or other etiology.
• Ocular perforation requires scleral grafting.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Avoid contact lenses—wear only if there is corneal involvement, which is rare.

Patient Monitoring
• Patient in the active stage of inflammation should be followed very closely by an ophthalmologist to assess the effectiveness of therapy.
• Medication use mandates close surveillance for adverse effects.

DIET
No special diet

PATIENT EDUCATION
Scleritis at PubMed Health:

PROGNOSIS
Scleritis is indolent, chronic, and often progressive.
• Diffuse anterior scleritis (best prognosis)
• Necrotizing anterior scleritis (worst prognosis)
• Recurrent bouts of inflammation may occur.
• Scleromalacia perforans has the highest risk of perforation of the globe.

COMPLICATIONS
• Decrease in vision, anterior uveitis, ocular HTN, and peripheral keratitis
• Cataract and glaucoma can result from disease or treatment with steroids.
• Ocular perforation can occur in severe stages.

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- H15.009 Unspecified scleritis, unspecified eye
- H15.019 Anterior scleritis, unspecified eye
- H15.039 Posterior scleritis, unspecified eye

**CLINICAL PEARLS**

- Episcleritis is a self-limited inflammation of the eye with mild discomfort. Scleritis is a painful, severe, and potentially vision-threatening condition. Both conditions can be associated with underlying inflammatory diseases.
- About 35% of all cases of scleritis are associated with a systemic disease such as rheumatoid arthritis. Necrotizing scleritis has the highest association.
SCLERODERMA

Ann M. Lynch, PharmD, RPh, AE-C • Deborah M. DeMarco, MD, FACP

BASICS

DESCRIPTION

- Scleroderma (systemic sclerosis [SSc]) is a chronic disease of unknown cause characterized by diffuse fibrosis of skin and visceral organs and vascular abnormalities.
- Most manifestations have vascular features (e.g., Raynaud phenomenon), but frank vasculitis is rarely seen.
- Can range from a mild disease, affecting the skin, to a systemic disease that can cause death in a few months.
- The disease is categorized into two major clinical variants (1).
  - Diffuse: distal and proximal extremity and truncal skin thickening
  - Limited
    - Restricted to the fingers, hands, and face
    - CREST syndrome (calcinosis, Raynaud phenomenon, esophageal dysmotility, sclerodactyly, telangiectasia)
- System(s) affected: include, but not limited to skin; renal; cardiovascular; pulmonary; musculoskeletal; gastrointestinal

Geriatric Considerations

Uncommon >75 years of age

Pediatric Considerations

Rare in this age group

Pregnancy Considerations

- Safe and healthy pregnancies are common and possible despite higher frequency of premature births.
- High-risk management must be standard care to avoid complications, specifically renal crisis.
- Diffuse scleroderma causes greater risk for developing serious cardiopulmonary and renal problems. Pregnancy should be delayed until
disease stabilizes.

**EPIDEMIOLOGY**

**Incidence**
- In the United States: 1 to 2/100,000/year
- Predominant age
  - Young adult (16 to 40 years); middle-aged (40 to 75 years); peak onset 30 to 50 years
  - Symptoms usually appear in the 3rd to 5th decades.
- Predominant sex: female > male (4:1)

**Prevalence**
In the United States: 1 to 25/100,000

**ETIOLOGY AND PATHOPHYSIOLOGY**
Pathophysiology involves both a vascular component and a fibrotic component. Both occur simultaneously. The inciting event is unknown, but there is an increase in certain cytokines after endothelial cell activation that are profibrotic (TGF-β and PDGF).
- Unknown
- Possible alterations in immune response
- Possibly some association with exposure to quartz mining, quarrying, vinyl chloride, hydrocarbons, toxin exposure
- Treatment with bleomycin has caused a scleroderma-like syndrome, as has exposure to rapeseed oil.

**Genetics**
Familial clustering is rare, but has been seen.

**RISK FACTORS**
Unknown

**DIAGNOSIS**

**HISTORY**
- Raynaud phenomenon is generally the presenting complaint (differentiated
from Raynaud disease, generally affecting younger individuals and without digital ulcers).

- Skin thickening, “puffy hands,” pruritus, and gastroesophageal reflux disease (GERD) are often noted early in the disease process.

**PHYSICAL EXAM**

- **Skin**
  - Digital ulcerations
  - Digital pitting
  - Tightness, swelling, thickening of digits
  - Hyperpigmentation/hypopigmentation
  - Narrowed oral aperture
  - SC calcinosis

- **Peripheral vascular system**
  - Telangiectasia

- **Joints, tendons, and bones**
  - Flexion contractures
  - Friction rub on tendon movement
  - Hand swelling
  - Joint stiffness
  - Polyarthritis
  - Sclerodactyly

- **Muscle**
  - Proximal muscle weakness

- **GI tract**
  - Dysphagia
  - Esophageal reflux due to dysmotility (most common systemic sign in diffuse disease)
  - Malabsorptive diarrhea
  - Nausea and vomiting
  - Weight loss
  - Xerostomia

- **Kidney**
  - Hypertension
  - May develop scleroderma renal crisis: acute renal failure (ARF)

- **Pulmonary**
  - Dry crackles at lung bases
  - Dyspnea

- **Nervous system**
– Peripheral neuropathy
– Trigeminal neuropathy

• Cardiac (progressive disease)
  – Conduction abnormalities
  – Cardiomyopathy
  – Pericarditis
  – Secondary cor pulmonale

DIFFERENTIAL DIAGNOSIS
• Mixed connective tissue disease/overlap syndromes
• Scleredema
• Nephrogenic systemic fibrosis
• Toxic oil syndrome (Madrid, 1981, affecting 20,000 people)
• Eosinophilia–myalgia syndrome
• Diffuse fasciitis with eosinophilia
• Scleredema of Buschke

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
• Nail fold capillary microscopy—drop out is most significant finding
• CBC
• Creatinine
• Urinalysis (albuminuria, microscopic hematuria)
• Antinuclear antibodies (ANA): positive in >90% of patients
• Anti–Scl-70 (anti-topoisomerase [ATA]) antibody is highly specific for systemic disease and confers a higher risk of interstitial lung disease (ILD).
• Anticentromere antibody usually associated with CREST variant
• Chest radiograph
  – Diffuse reticular pattern
  – Bilateral basilar pulmonary fibrosis
• Hand radiograph
  – Soft tissue atrophy and acro-osteolysis
  – Can see overlap syndromes such as rheumatoid arthritis
  – SC calcinosis

Follow-Up Tests & Special Considerations
• Pulmonary function tests (PFTs)
  – Decreased maximum breathing capacity
– Increased residual volume
– Diffusion defect
• Antibodies to U3-RNP—higher risk for scleroderma-associated pulmonary hypertension
• Anti–PM-Scl antibodies (for myositis) (2)[B]
• Anti-RNA polymerase III—higher risk for diffuse cutaneous involvement and renal crisis (3)[A]
• ECG (low voltage): possible nonspecific abnormalities, arrhythmia, and conduction defects
• Echocardiography: pulmonary hypertension or cardiomyopathy
• Nail fold capillary loop abnormalities
• Upper GI
  – Distal esophageal dilatation
  – Atonic esophagus
  – Esophageal dysmotility
  – Duodenal diverticula
• Barium enema
  – Colonic diverticula
  – Megacolon
• High-resolution CT scan for detecting alveolitis, which has a ground-glass appearance or fibrosis predominant in bilateral lower lobes

**Diagnostic Procedures/Other**
• Skin biopsy
  – Compact collagen fibers in the reticular dermis and hyalinization and fibrosis of arterioles
  – Thinning of epidermis, with loss of rete pegs, and atrophy of dermal appendages
  – Accumulation of mononuclear cells is also seen.
• Right-sided heart catheterization: Pulmonary hypertension is an ominous prognostic feature.

**Test Interpretation**
• Skin
  – Edema, fibrosis, or atrophy (late stage)
  – Lymphocytic infiltrate around sweat glands
  – Loss of capillaries
  – Endothelial proliferation
- Hair follicle atrophy

- Synovium
  - Pannus formation
  - Fibrin deposits in tendons

- Kidney
  - Small kidneys
  - Intimal proliferation in interlobular arteries

- Heart
  - Endocardial thickening
  - Myocardial interstitial fibrosis
  - Ischemic band necrosis
  - Enlarged heart
  - Cardiac hypertrophy
  - Pulmonary hypertension

- Lung
  - Interstitial pneumonitis
  - Cyst formation
  - Interstitial fibrosis
  - Bronchiectasis

- Esophagus
  - Esophageal atrophy
  - Fibrosis

### TREATMENT

#### GENERAL MEASURES

- Treatment is symptomatic and supportive.
- Esophageal dilation may be used for strictures.
- Avoid cold; dress appropriately in layers for the weather; be wary of air conditioning.
- Avoid smoking (crucial).
- Avoid fingersticks (e.g., blood tests).
- Elevate the head of the bed during sleep to help relieve GI symptoms.
- Use softening lotions, ointments, and bath oils to help prevent dryness and cracking of skin.
- Dialysis may be necessary in renal crisis.
MEDICATION

First Line

- ACE inhibitors (ACEIs): for preservation of renal blood flow and for treatment of hypertensive renal crisis
- Corticosteroids: for disabling myositis, pulmonary alveolitis, or mixed connective tissue disease (not recommended in high doses due to increased incidence of renal failure)
- NSAIDs: for joint or tendon symptoms; caution with long-term concurrent use with ACEIs (potential renal complications)
- Antibiotics: for secondary infections in bowel and active skin infections
- Antacids, proton pump inhibitors: for gastric reflux
- Metoclopramide: for intestinal dysfunction
- Hydrophilic skin ointments: for skin therapy
- Topical clindamycin, erythromycin, or silver sulfadiazine: for prevention of recurrent infectious cutaneous ulcers
- Consider immunosuppressives for treatment of life-threatening or potentially crippling scleroderma or interstitial pneumonitis such as cyclophosphamide for ILD (4).[B]

- Nitrates and dihydropyridine calcium-channel blockers for Raynaud phenomenon
- Avoidance of caffeine, nicotine, and sympathomimetics may ease Raynaud symptoms.
- PDE5 antagonists (e.g., sildenafil), prostanoids, and endothelin-1 antagonists are changing the management of pulmonary hypertension (5).
- Alveolitis: immunosuppressants and alkylating agents (e.g., cyclophosphamide)

ADDITIONAL THERAPIES

- Anti–TNF-α therapy: Preliminary suggestion is that these may reduce joint symptoms and disability in inflammatory arthritis, but small sample sizes and observational biases lend to the need for further well-designed, adequately powered, longitudinal clinical trials.
- Physical therapy to maintain function and promote strength
- Heat therapy to relieve joint stiffness

SURGERY/OTHER PROCEDURES

- Some success with gastroplasty for correction of GERD
- Limited role for sympathectomy for Raynaud phenomenon
Lung transplantation for pulmonary hypertension and ILD

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Patient Monitoring
- Monitor every 3 to 6 months for end-organ and skin involvement and medications. Provide encouragement.
- Echocardiology and PFTs yearly

DIET
Drink plenty of fluids with meals.

PATIENT EDUCATION
- Stay as active as possible, but avoid fatigue.
- Printed patient information available from the Scleroderma Federation, 1725 York Avenue, No. 29F, New York, NY 10128; (212) 427-7040
- Advise the patient to report any abnormal bruising or nonhealing abrasions.
- Assist the patient about smoking cessation, if needed.

PROGNOSIS
- Possible improvement but incurable
- Prognosis is poor if cardiac, pulmonary, or renal manifestations present early.

COMPLICATIONS
- Renal failure
- Respiratory failure
- Flexion contractures
- Disability
- Esophageal dysmotility
- Reflux esophagitis
- Arrhythmia
- Megacolon
- Pneumatosis intestinalis
- Obstructive bowel
- Cardiomyopathy
- Pulmonary hypertension
- Possible association with lung and other cancers
- Death

SEE ALSO
Morphea

CODES

ICD10
- M34.9 Systemic sclerosis, unspecified
- M34.1 CR(E)ST syndrome
- L94.0 Localized scleroderma [morphea]

CLINICAL PEARLS
- Raynaud phenomenon is frequently the initial complaint.
- Skin thickening, “puffy hands,” and GERD are often noted early in disease.
- Patients must be followed proactively for development of pulmonary hypertension or ILD.
SEASONAL AFFECTIVE DISORDER

Christopher White, MD, JD, MHA, FCLM

BASICS

DESCRIPTION

- Seasonal affective disorder (SAD) is a heterogeneous mood disorder with depressive episodes usually occurring in winter months, with full remissions in the spring and summer.
- Ranges from a milder form (winter blues) to a seriously disabling illness
- Must separate out patients with other mood disorders (such as major depressive disorder and bipolar affective disorder) whose symptoms persist during spring and summer months

EPIDEMIOLOGY

Incidence

- Affects up to 500,000 people every winter
- Up to 30% of patients visiting a primary care physician (PCP) during winter may report winter depressive symptoms.
- Predominant age: occurs at any age; peaks in 20s and 30s
- Predominant sex: female > male (3:1)

Prevalence

- 1–9% of the general population
- 10–20% of patients identified as having mood symptoms will have a seasonal component.

ETIOLOGY AND PATHOPHYSIOLOGY

The major theories currently involve the interplay of phase-shifted circadian rhythms, genetic vulnerability, and serotonin dysregulation.

- Melatonin produced by the pineal gland at increased levels in the dark has been linked to depressive symptoms; light therapy on the retina acts to inhibit melatonin secretion.
- Serotonin dysregulation, because it is secreted less during winter months, must be present for light therapy to work, and treatment with SSRIs appears to
reverse SAD symptoms.
- Decreased levels of vitamin D, often occurring during low-light winter months, may be associated with depressive episodes in some individuals experiencing SAD symptoms.

**Genetics**
- Some twin studies and a preliminary study on GPR50 melatonin receptor variants have suggested a genetic component.
- Recent studies indicate an association with the melanopsin gene (OPN4).
- Increased incidence of depression, ADHD, and alcoholism in close relatives

**RISK FACTORS**
- Most common during months of January and February: Patients frequently visit PCP during winter months complaining of recurrent flu, chronic fatigue, and unexplained weight gain.
- Working in a building without windows or other environment without exposure to sunlight

**GENERAL PREVENTION**
- Consider use of light therapy at start of winter (if prior episodes begin in October), increase time outside during daylight, or move to a more southern location.
- Bupropion (Wellbutrin) is an FDA-approved antidepressant for the prevention of SAD.

**COMMONLY ASSOCIATED CONDITIONS**
Some individuals with SAD have a weakened immune system and may be more vulnerable to infections.

**DIAGNOSIS**
- Carefully document the presence or absence of prior manic episodes.
- Screen for the existence of any suicidal ideation and safety risk factors.
- Remission of symptoms during spring and summer
- Symptoms have occurred for the past 2 years.
- Seasonal episodes associated with winter months substantially outnumber any nonseasonal depressive episodes.
- Under *DSM-5*, SAD is denoted by adding the “with seasonal pattern” specifier
to a diagnosis of major depressive disorder, recurrent.

HISTORY

- Symptoms of depression meeting the criteria for major depressive disorder are the following:
  - Sleep disturbance: either too much or too little
  - Lack of interest in life and absence of pleasure from hobbies/activities
  - Guilt: feelings of guilt or worthlessness
  - Energy: fatigue or constantly feeling tired
  - Concentration: difficulty with concentration and memory
  - Appetite: changes in appetite and weight
  - Psychomotor retardation: Patients feel slowed down with decreased activity.
  - Suicidal thoughts: Patients report thoughts of suicide.
- In SAD, hypersomnia, hyperphagia (craving for carbohydrates and sweets), and weight gain usually predominate. Despite sleeping more, patients report daytime sleepiness and fatigue. Cravings may lead to binge eating and weight gains >20 lb.
- Obtain collateral history if patient is unable to provide insight into the seasonal component.

PHYSICAL EXAM

Use exam to exclude other organic causes for symptoms. Focal neurologic deficits, signs of endocrine dysfunction, or stigmata of substance abuse should prompt further testing.

DIFFERENTIAL DIAGNOSIS

- Similar to that of major depression, meaning that organic causes of low energy and fatigue, such as hypothyroidism, anemia, and mononucleosis (or other viral syndromes), need to be considered.
- Other mood disorders without a seasonal component such as major depression, bipolar disorder, adjustment disorder, or dysthymia
- Symptoms should not be better accounted for by seasonal psychosocial stressors, which often accompany the winter holiday seasons.
- Substance abuse

DIAGNOSTIC TESTS & INTERPRETATION

- Thyroid-stimulating hormone to rule out hypothyroidism
- CBC to rule out anemia
Rule out electrolyte and glucose dysregulation.
25-OH vitamin D level
Pregnancy test for women of childbearing potential
Urine toxicology screen if substance abuse is a concern
Imaging is not useful unless focal neurologic finding or looking to exclude an organic cause.

**TREATMENT**

**MEDICATION**

Lack of evidence to determine whether light therapy or medication should be the first-line agent. Both supported by the literature and in some studies have equal efficacy. Medications have more side effects. Adherence to both remains a critical issue. The ultimate choice depends on the acuity of the patient and the comfort level of the prescribing clinician with each treatment modality (1)[B].

- SSRIs such as sertraline (Zoloft), paroxetine (Paxil), fluoxetine (Prozac), citalopram (Celexa), and escitalopram (Lexapro) in their traditional antidepressant doses (2)[B]
- Bupropion (Wellbutrin) is the only antidepressant currently approved by the FDA for the prevention of SAD (3)[B].

**ISSUES FOR REFERRAL**

- Patients with a history of ocular disease should be referred for an ophthalmologic exam before phototherapy and for serial monitoring.
- Patients who fail to respond or who develop manic symptoms or suicidal ideation once treatment is initiated should be considered for psychiatric referral.

**ADDITIONAL THERAPIES**

- Phototherapy using special light sources has been shown to be effective in 60–90% of patients, often providing relief with a few sessions (2,4)[B].
- Variables that can regulate effect are the following:
  - Light intensity: Although the minimum light source intensity is under investigation, at least 2,500 lux is suggested (domestic lights emit, on average, 200 to 500 lux). There is good evidence for 10,000 lux as the recommended source (2)[B].
  - Treatment duration: Exposure time varies based on intensity of light source,
with daily sessions of 30 minutes to a few hours.
- Time of treatment: Most patients respond better by using the light therapy early in the morning.
- Color of light source: Emerging data suggest that shorter sessions of lower intensity light-emitting diodes enriched in the blue spectrum have equal efficacy to the traditional white light treatment and possibly capable of being delivered in a transcranial manner (5)[B].

- Light box is placed on table several feet away, and the light is allowed to shine onto the patient’s eyes (sunglasses should be avoided). Ensure that the light box has an ultraviolet filter.
- Most common side effects are eye strain and headache. Insomnia can result if the light box is used too late in the day. Light boxes also can precipitate mania in some patients.
- Dawn simulation machines gradually increase illumination while the patient sleeps, simulating sunrise while using a significantly less intense light source.

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Work to reduce stress levels through meditation, progressive relaxation exercises, and/or lifestyle modification.
- The potential role of vitamin D supplementation is under investigation. Currently, there is a lack of consistent research to satisfactorily demonstrate that treatment improves SAD symptoms. Reported doses vary widely but typically are between 400 and 800 IU/day (6)[B].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
If the patient develops suicidal ideation as part of his or her depression or mania after treatment is initiated

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Regular monitoring by PCP or psychiatrist for response to treatment; patients may become manic when treated with SSRIs or light therapy.
**Patient Monitoring**
Patients should be seen in the outpatient clinic weekly to biweekly when initiating light or pharmacotherapy to monitor treatment results, side effects, and any increased suicidal thoughts if using SSRIs.

**DIET**
No specific diet modification needed

**PATIENT EDUCATION**
- Increase time outdoors during daylight.
- Rearrange home or work environment to get more direct sunlight through windows.

**PROGNOSIS**
Symptoms, if untreated, generally remit within 5 months with exposure to spring light, only to return in subsequent winters. If treated, patients usually respond within 3 to 6 weeks.

**COMPLICATIONS**
Development of suicidal ideation and mania are two outcomes the clinician needs to monitor.

**REFERENCES**

**ADDITIONAL READING**

**SEE ALSO**

- Bipolar I Disorder; Bipolar II Disorder; Depression
- Algorithm: Depressive Episode, Major

**CODES**

**ICD10**

- F33.9 Major depressive disorder, recurrent, unspecified
- F33.0 Major depressive disorder, recurrent, mild
- F33.1 Major depressive disorder, recurrent, moderate

**CLINICAL PEARLS**

- SAD is a subtype of major depressive disorder. Once the patient has a diagnosed mood disorder, such as depression or bipolar, ask whether the symptoms vary in a seasonal pattern to qualify for the diagnosis of SAD. Generally, these patients will report sleeping too much, eating too much (especially carbs and sweets), and gaining weight during winter months.
- As with all psychiatric diagnoses, ensure that the symptoms are not due to an
organic process or better explained by substance abuse.

- Lack of good evidence to decide whether light therapy or SSRIs should be the first-line agent. Guidelines suggest using SSRIs first if the patient is more acute or has contraindications to light therapy or the clinician is not comfortable with light therapy.

- Light therapy boxes are available from numerous online suppliers but are not extensively regulated; practitioners should take care to ensure that patients are using devices from reputable suppliers.

- If using SSRIs, recent studies indicate that some patients may begin to experience increased suicidal thoughts on therapy; these patients need to be monitored closely as outpatients every 1 to 2 weeks. Patients on light therapy also should be monitored closely initially in order to adjust treatment. Once stabilized, both groups of patients can be seen every 4 to 8 weeks during the winter months.

- All patients who demonstrate suicidal ideation or symptoms of mania should be referred for consideration of hospitalization.
An absence seizure is a generalized epileptic seizure characterized by a brief lapse of awareness.

**Absence Seizure Types**
Absence seizure types according to the International League Against Epilepsy (ILAE) 2010 classification include (1):

- Typical absence
  - Formerly called *petit mal seizures*
  - Abrupt-onset behavioral arrest, loss of awareness, and blank staring, sometimes with mild upward eye deviation, repetitive blinking
  - May include automatisms, tonic or atonic features, eyelid or facial clonus, autonomic features
  - Lasts 5 to 30 seconds
  - Immediate return to normal consciousness
  - Associated with genetic generalized epilepsies, namely, childhood absence epilepsy (CAE), juvenile absence epilepsy (JAE), and juvenile myoclonic epilepsy

- Atypical absence
  - Onset and offset less abrupt than typical absence seizures
  - Lasts 10 to 45 seconds
  - Impairment of consciousness often incomplete with continued purposeful activity
  - Postictal confusion sometimes occur.
  - Associated clinical features more pronounced and frequent than in typical absence; atonia is most common.
  - Associated with syndromic epilepsies, such as Lennox-Gastaut and nonsyndromic epilepsies in patients with developmental delay

- Absence with special features
  - Myoclonic absence:
    - Rhythmic clonic jerking at 2 to 4 Hz which lasts 5 to 10 seconds
Unlike myoclonic seizures with no impairment of consciousness, brief lapses of awareness are characteristic of myoclonic absence.

- Eyelid myoclonia:
  - Rhythmic clonic jerking of the eyelids at 5 to 6 Hz which lasts 3 to 5 seconds
  - Eyelid myoclonia with absence associated with an impairment of consciousness

Epilepsy Diagnoses
Specific diagnoses according to ILAE (2010):

- **CAE**
  - Also known as pyknolepsy
  - Typical absence seizures are the only seizure type in 90% of children.
  - 10% develop additional generalized tonic–clonic seizures.
  - Seizures last ~10 seconds and often occur hundreds of times per day.
  - Normal neurologic state and development
  - Spontaneous remission occurs in 65–70% of patients during adolescence.

- **JAE**
  - Typical absence seizures are the main seizure type.
  - Seizures last longer than in CAE and occur usually less than once a day.
  - Generalized tonic–clonic seizures occur in most patients, often in the first 1 to 2 hours after awakening.
  - Seizures often persist into adulthood.

EPIDEMIOLOGY

- **Predominant age**
  - CAE: onset ages 4 to 10 years, with peak at ages 5 to 8 years
  - JAE: onset ages 9 to 16 years, with peak at ages 10 to 12 years

- **Predominant gender**
  - Female > male (3:2 to 2:1)
  - Epilepsy with myoclonus has male predominance.

**Incidence**
6 to 8/100,000 per year

**Prevalence**
5 to 50/100,000
ETIOLOGY AND PATHOPHYSIOLOGY

- Corticoreticular theory implicates abnormal activity in thalamocortical circuits.
- Thalamic reticular nucleus is responsible for both normal sleep spindles and pathologic slow-wave discharges; contains inhibitory γ-aminobutyric acid-ergic (GABAergic) neurons
- These neurons affect low-threshold calcium currents.
- These circuits can fire in oscillatory/rhythmic fashion:
  - Normally, activation of GABA$_A$ receptors causes 10-Hz oscillations in sleep spindle frequency.
  - If GABA$_B$ receptors are strongly activated, oscillation frequency will be 3 to 4 Hz, similar to spike-and-wave typical absence seizure frequency.

Genetics

- 70–85% concordance occurs in monozygotic twins; 82% share EEG features.
- 33% concordance among first-degree relatives
- 15–45% have a family history of epilepsy.
- Complex multifactorial inheritance
- For childhood absence, genes/loci implicated include 6q, 8q24, and 5q14.
- Mutations of GABA$_A$ receptor and voltage-gated Ca$^{2+}$ channel are implicated.

COMMONLY ASSOCIATED CONDITIONS

- 3–8% of CAE cases evolve into juvenile myoclonic epilepsy.
- Associated with difficulties in visual attention and visuospatial skills, verbal learning and memory, and reduced language abilities
- Children with CAE have elevated rates of behavioral and psychiatric comorbidities including attentional deficits, anxiety, depression, isolation, and low self-esteem.
- A large study in 2010 detected overall normal cognition, but 35% of subjects had pretreatment attentional deficits that did not resolve with seizure control.

DIAGNOSIS

Seizures are often so brief that untrained observers are not aware of the occurrence.

HISTORY
Frequently diagnosed in children being evaluated for poor school performance.
Teachers report that child seems to daydream or zone out frequently.
Child will forget portions of conversations.
Child with normal IQ underperforms in school.

PHYSICAL EXAM
- Unless a child has another genetic or acquired abnormality, a neurologic exam usually is normal.
- Seizures may be frequent enough to be observed during physical exam:
  - Manifest by behavioral arrest: Child will stop speaking in midsentence, stare blankly, and so forth.
  - Automatisms (repetitive stereotyped behaviors) may be present.
  - Child resumes previous activity.
  - Absence seizures can have a variable effect on respiratory rate, but bradypnea is common.
- Seizures may be induced by hyperventilation:
  - Have the child blow on a pinwheel or similar exercise to provoke seizure.
  - Alternatively, ask the patient to perform hyperventilation with eyes closed and count. Patient will open eyes at onset of seizure and stop counting.
- Patient manifests unresponsiveness but retains postural tone in a typical absence seizure.

DIFFERENTIAL DIAGNOSIS
- Complex partial seizures
- Psychogenic nonepileptic seizures
- Attention deficit hyperactivity disorder (ADHD)
- Confusional states and acute memory disorders
- Migraine variants
- Panic/anxiety attacks
- Breath-holding spells
- Nonepileptic staring spells: suggestive features include:
  - Events do not interrupt play.
  - Events are first noticed by professional such as school teacher, speech therapist, occupational therapist, or physician (rather than parent).
  - During a staring spell, child is responsive to touch or other external stimuli.

DIAGNOSTIC TESTS & INTERPRETATION
- Drug levels are useful in evaluating symptoms of toxicity or for breakthrough
seizures.
- Follow blood chemistry, hepatic function, and blood counts specific to drug regimen.

**Initial Tests (lab, imaging)**
- EEG is standard for diagnosis.
  - Typical absence features: 3-Hz spike-and-wave activity on normal EEG background
  - Seizures bursts of 34-Hz spike-and-wave activity, which may slow to 2.5- to 3.0-Hz during seizure.
  - Seizure usually is evident clinically if bursts last >3 seconds, subtle changes of transient cognitive impairment may be evident with briefer seizures.
  - Hyperventilation and occasionally photic stimulation may induce seizure, thus confirming diagnosis of typical absence epilepsy. In contrast, atypical absence seizures are not susceptible to induction by hyperventilation or photic stimulation.
- Imaging is not routinely indicated in children with typical absence and normal neurologic exam and IQ.
  - Brain MRI is indicated in atypical absence and in children with mixed seizure types when combined with abnormal neurologic exam or low IQ.
  - If imaging is performed, MRI is preferable to CT scan due to higher sensitivity for anatomic abnormalities.
  - A review of the brain MRIs of 134 patients with idiopathic generalized epilepsy in 2006 showed 24% with structural abnormalities, 88% of which were nonspecific (2)[B].

**TREATMENT**

**GENERAL MEASURES**
- Review seizure precautions with every patient diagnosed with or suspected to have epilepsy.
- Seizure precautions include bathroom, kitchen, home, driving, outdoors, and sports safety topics as well as special considerations for parents.

**MEDICATION**
Concern regarding generic medications allowing more breakthrough seizures has not been supported in evidence-based studies (3)[A].
**Alert**
Certain common anticonvulsants may exacerbate absence including carbamazepine, oxcarbazepine, phenytoin, phenobarbital, tiagabine, vigabatrin, pregabalin, and gabapentin.

**First Line**
- Ethosuximide blocks T-type calcium channels:
  - First line, except in absence patients with tonic–clonic seizures (lacks efficacy)
  - High efficacy (4)[A], fastest onset of efficacy (5)[B], and fewer adverse attentional effects compared to valproic acid (4)[A]
  - Side effects: vomiting, diarrhea, abdominal discomfort, hiccups, headache, sedation
  - Adverse effects: rare blood dyscrasias (Monitor CBC.)
- Valproic acid has multiple mechanisms:
  - First choice in absence patients with tonic–clonic, myoclonic, mixed seizure types
  - Very effective but has highest rate of adverse events leading to treatment discontinuation, including negative attentional effects (4)[A]
  - Side effects: tremor, drowsiness, dizziness, weight gain, alopecia, sedation, vomiting
  - Adverse effects: teratogenicity, pancreatitis, thrombocytopenia, rare fulminant hepatic failure (especially in children <2 years)

**Second Line**
- Lamotrigine affects sodium channels:
  - Controls seizures but may be less efficacious than ethosuximide or valproic acid (4)[A]
  - May be equally as efficacious for new-onset CAE (5)[B]
  - Side effects: rash, diplopia, headache, insomnia, dizziness, nausea, vomiting, diarrhea
  - Adverse effects: rare Stevens-Johnson rash, more often when coadministered with valproic acid
- Topiramate affects GABA and excitatory neurotransmission:
  - FDA-approved for Lennox-Gastaut syndrome
  - Side effects: psychomotor slowing
  - Adverse effects: weight loss, renal stones, myopia, glaucoma (rare), anhidrosis
Levetiracetam is used off-label:
- Has been used as both monotherapy and adjunct therapy for absence seizures
- A small multicenter randomized controlled trial (RCT) showed modest efficacy but not statistically significant versus placebo (6)[C].
Zonisamide is also used off-label.
Clonazepam, nitrazepam, and clobazam may be effective in the short-term but are not recommended for long-term management due to development of tolerance (few months to a year) and side effects.

**Pregnancy Considerations**
Anticonvulsants, especially valproic acid, are associated with an increase in fetal malformations. Use of valproic acid in women who are or are likely to become pregnant generally is contraindicated. Obtain specialty consultation.

**ADDITIONAL THERAPIES**
- Most absence seizure patients respond to a single medication.
- Male sex and an early age at diagnosis are associated with the need for two medications to control the disease (7)[B].
- Vagal nerve stimulator (VNS) may be considered as an option for medically refractory absence epilepsy (8)[C].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Absence epilepsy rarely requires admission.
- Status epilepticus requires inpatient management.

**Discharge Criteria**
Resolution of status epilepticus

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Patients with associated tonic–clonic seizures should avoid high places and swimming alone.
- Absence rarely persists into adulthood, but affected adults may be restricted
from driving, working over open flames, and so forth, as with other
generalized and partial epilepsy subtypes.

- Patients should be monitored periodically by a neurologist for evolution of
  absence epilepsy into tonic–clonic or other seizure types.

**PROGNOSIS**

- Patients whose shortest pretreatment EEG seizures are >20 seconds in
duration are more likely to achieve seizure freedom, regardless of treatment

(9)[A].

- Of those with CAE without tonic–clonic seizures, 90% remit by adulthood.
- 35% of patients with tonic–clonic seizures experience complete remission of
  absence seizures.
- 15% of patients develop juvenile myoclonic epilepsy.

**COMPLICATIONS**

Reported frequencies of typical absence status epilepticus range from 5.8% to
9.4% of patients with CAE.

**CODES**

**ICD10**

- G40.409 Other generalized epilepsy and epileptic syndromes, not intractable, without status epilepticus
- G40.419 Oth generalized epilepsy, intractable, w/o stat epi
- G40.401 Oth generalized epilepsy, not intractable, w stat epi

**CLINICAL PEARLS**

- If parents are unable to determine the cause of a staring spell, try suggesting that parents mention something exciting or unexpected like “ice cream” during a spell to get the child’s attention rather than calling his or her name.
- To help aid with diagnosis during an exam, try having the child blow repetitively on a pinwheel (causing hyperventilation) to attempt to trigger absence seizure.
- Ethosuximide and valproic acid are first-line agents in treatment of absence seizures. Valproic acid and lamotrigine are recommended for absence patients with tonic–clonic and mixed seizure types.
SEIZURE DISORDER, PARTIAL
Noel Dunn, MD • David Haight, MD

BASICS

DESCRIPTION
- Seizures occur when abnormal synchronous neuronal discharges in the brain cause transient cortical dysfunction.
- Generalized seizures involve bilateral cerebral cortex from the seizure’s onset.
- Partial seizures originate from a discrete focus in the cerebral cortex.
- Partial seizures are further divided into simple and complex subtypes:
  - If consciousness is impaired during a partial seizure, it is classified as complex.
  - If consciousness is preserved, it is a simple partial seizure.

EPIDEMIOLOGY

Prevalence
Partial seizures occur in 20/100,000 persons in the United States.

ETIOLOGY AND PATHOPHYSIOLOGY
- Partial seizures begin when a localized seizure focus produces an abnormal, synchronized depolarization that spreads to a discrete portion of the surrounding cortex.
- The area of cortex involved in the seizure determines the symptoms; for example, an epileptogenic focus in motor cortex produces contralateral motor symptoms.
- In some cases, etiology is related to structural abnormalities that are susceptible to epileptogenesis. Most common etiologies vary by life stage:
  - Early childhood: developmental/congenital malformation, trauma
  - Young adults: developmental, infection, trauma
  - Adults 40 to 60 years of age: cerebrovascular insult, infection, trauma
  - Adults >60 years of age: cerebrovascular insult, trauma, neoplasm
- Complex partial seizures: A common cause is mesial temporal sclerosis.

Genetics
Benign rolandic epilepsy, a form of partial seizure disorder, has an autosomal
dominant inheritance pattern with penetrance depending on multiple factors.

**RISK FACTORS**
- History of traumatic brain injury (TBI)
- Children exposed to a thiamine-deficient formula

**COMMONLY ASSOCIATED CONDITIONS**
Epilepsy patients have a higher incidence of depression than the general population.

**DIAGNOSIS**
- Seizure activity usually stereotyped
- Duration: seconds to minutes, unless status epilepticus develops; status epilepticus may present as focal/generalized convulsions/ altered mental status without convulsions.
- Simple partial seizures
  - Simple partial seizures are characterized by localized symptoms. The patient is conscious. Symptoms may involve motor, sensory, or psychic systems.
  - Motor: Seizure activity in motor strip causes contraction (tonic) or rhythmic jerking (clonic) movements that may involve one entire side of body or may be more localized (i.e., hands, feet, or face).
    - Jacksonian march: As discharge spreads through motor cortex, tonic–clonic activity spreads in predictable fashion (i.e., beginning in hand and progressing up arm and to the face).
  - Sensory/psychic
    - Todd paralysis: after motor seizure, residual, temporary weakness in the affected area
    - Parietal lobe: sensory loss/paresthesias, dizziness
    - Temporal lobe: déjà vu, rising sensation in epigastrium, auditory hallucinations/forced memories, unpleasant smell/taste
  - Occipital: visual hallucinations
- Complex partial seizures
  - Impaired consciousness by definition
  - May have aura; this is start of seizure.
- Amnesia for the event, postictal confusion
  - Most often, focus in complex partial seizures is temporal/frontal.
– Motor manifestations may include dystonic posturing/automatisms (i.e., simple, repetitive movements of face and hands such as lip smacking, picking, or more complex actions such as purposeless walking).
– Frontal lobe seizure is characterized by brief, bilateral complex movements, vocalizations, often with onset during sleep.

HISTORY
- A detailed description of the seizure should be obtained from an observer.
- Review medication list for drugs that lower seizure threshold (e.g., tramadol, bupropion, theophylline).
- Obtain history of drugs of abuse (e.g., cocaine), as they may lower seizure threshold.
- Review history of any prior TBI.

PHYSICAL EXAM
Include neurologic exam, with attention to lateralizing signs suggestive of structural lesion.

DIFFERENTIAL DIAGNOSIS
- Syncope/postanoxic myoclonus
- Hypoglycemia
- Psychogenic nonepileptic seizure
- For hemiparesis following event
  – Transient ischemic attack
  – Hemiplegic migraine

DIAGNOSTIC TESTS & INTERPRETATION
- Serum electrolytes, including calcium, magnesium, phosphorus; hepatic function panel; CBC; urinalysis; urine drug screen; levels of antiepileptic drugs (AEDs) for breakthrough seizure; chest X-ray
- Elevated prolactin, if measured within 10 to 20 minutes of suspected seizure, or elevated creatine phosphokinase; if measured within 6 to 24 hours, may help to differentiate generalized/complex partial seizure from psychogenic nonepileptic seizure (1)[B].
- CSF exam if infection is suspected
- EEG should be considered in patients with first time unprovoked seizure (2) [B].
- Yield of EEG is increased by being obtained in the first 24 hours following
seizure and by sleep deprivation.
- EEG will typically show spikes/sharp waves over the seizure focus.
- Frontal lobe seizure focus may be difficult to detect by routine EEG.
- If difficulty with diagnosis, continuous video–EEG monitoring may be appropriate.
- Emergency evaluation of new seizure: CT scan to screen for hemorrhage and stroke

- In patients without recent neuroimaging, consider CT or MRI (2)[B].
- If planning epilepsy surgery, positron emission tomography (PET) scan and/or interictal single-photon emission computed tomography (SPECT) may be of value.
- Magnetoencephalography (MEG) aids in presurgical localization of epilepsy.

**TREATMENT**

**GENERAL MEASURES**
- Ask the patient to maintain a seizure diary.
- Note potential triggers, such as stress, sleep deprivation, drug use, discontinuation of alcohol/benzodiazepines, menses.

**MEDICATION**
- Current guidelines do not recommend for or against starting an AED after a single unprovoked seizure. Patients should be counseled that AEDs will reduce risk of repeat seizure over 2 years but have no effect on long-term remission (3)[C].
- AEDs act on voltage-gated ion channels, affect neuronal inhibition via enhancement of γ-aminobutyric acid (GABA, an inhibitory neurotransmitter), or decrease neuronal excitation. End result is to decrease the abnormal synchronized firing and to prevent seizure propagation.
- 50% of those with newly diagnosed partial seizures respond to, and tolerate, first AED trial. Up to 50% of those who fail the first AED trial will also fail a second AED trial (4)[B].
- Choose AED based on seizure type, side effect profile, and patient characteristics. Increase dose until seizure control is obtained/side effects become unacceptable.
- Attempt monotherapy, but many patients will require adjunctive agents.
- *Refractory to medications* is defined as failure of at least three anticonvulsants...
to achieve adequate control.

- AEDs may prevent seizures after a TBI in the short-term, although they provide no efficacy in long-term prevention (5)[B].
- Several AEDs induce/inhibit cytochrome P450 enzymes (watch for drug interactions).

**First Line**

- Carbamazepine: affects sodium channels; side effects include GI distress, hyponatremia, diplopia, dizziness, rare pancytopenia/marrow suppression, and exfoliative rash.
- Oxcarbazepine: affects sodium channels; side effects include dizziness, diplopia, hyponatremia, and headache.
- Lamotrigine: affects sodium channels
  - Side effects include insomnia, dizziness, and ataxia.
  - Risk of Stevens-Johnson reaction (potentially fatal exfoliative rash), especially when given with valproate, requires slow titration
- Levetiracetam: multiple mechanisms; side effects include sedation, ataxia, and irritability.

**Second Line**

- Phenytoin: affects sodium channels; side effects include ataxia, dizziness, diplopia, tremor, GI upset, gingival hyperplasia, and fever.
- Phenobarbital: multiple mechanisms; side effects include sedation and withdrawal seizures.
- Valproate: multiple mechanisms; side effects include GI upset, weight gain, alopecia, and tremor; less common, thrombocytopenia, hepatitis, pancreatitis
- Topiramate: multiple mechanisms; side effects include anorexia, cognitive slowing, sedation, nephrolithiasis, and anhidrosis.
- Gabapentin: multiple mechanisms; side effects include sedation, dizziness, and ataxia.
- Pregabalin: affects calcium channels; side effects include sedation, dizziness, and weight gain.
- Zonisamide: affects sodium channels
  - Side effects include sedation, anorexia, nausea, dizziness, ataxia, anhidrosis, and nephrolithiasis.
  - Cross-reaction with sulfa allergy

**Pregnancy Considerations**
- Folate should be prescribed for all women of childbearing age who are taking AEDs. AED therapy during the 1st trimester is associated with doubled risk for major fetal malformations (6% vs. 3%).
- Phenytoin in pregnancy may result in fetal hydantoin syndrome.
- Valproate is associated with neural tube defects and should be avoided in pregnancy when possible.
- Fetal insult from seizures following withdrawal of therapy also may be severe. Risk-to-benefit balance should be evaluated with high-risk pregnancy and neurology consultations. Most patients remain on anticonvulsants.
- AED levels should be monitored at least every trimester.

**ISSUES FOR REFERRAL**
For refractory seizures, consider referral to an epilepsy specialist.

**ADDITIONAL THERAPIES**
- Vagal nerve stimulator provides periodic stimulation to vagus nerve; may induce hoarseness, cough, and dysphagia. High-frequency stimulation in adults provides greater reduction in seizure frequency than low-frequency stimulation but also has greater rates of side effects (6)[B].
- Deep brain stimulation may decrease seizure frequency in medically refractive epilepsy, but its efficacy varies by seizure source location.
- Repetitive magnetic transcranial stimulation may reduce the frequency of seizures in individuals with refractory focal seizures.

**SURGERY/OTHER PROCEDURES**
- For refractory partial complex seizures with identifiable focus
- Preoperative testing, such as Wada test, should be done to decrease likelihood of inducing aphasia and memory loss.
- 34–74% will be seizure-free after temporal lobe surgery. Prognosis varies for surgical resection of extratemporal foci.
- Goal of surgical intervention is to reduce reliance on medications; most patients remain on anticonvulsants postoperatively.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
Admit for unremitting seizure (partial/secondary generalized status epilepticus).
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Most states have restrictions on driving for those with seizure disorders.
- Depending on seizure manifestation, may also recommend against activities such as swimming, climbing to heights, or operating heavy machinery.

Patient Monitoring

AED levels if concern over toxicity, noncompliance, or for breakthrough seizures.

Diet

Ketogenic or low-glycemic index diet may improve seizure control in some patients but is not well-tolerated.

Patient Education

Avoid potential triggers such as alcohol or drug use and sleep deprivation.

Prognosis

- Risk of seizure recurrence: ~30% after first seizure; of these, 50% will occur in the first 6 months, 90% in the first 2 years.
- Depends on seizure type; rolandic epilepsy has a good prognosis; temporal lobe epilepsy is more likely to be persistent.
- ~25–30% of all seizures are refractory to current medications.
- AEDs initiated after an initial seizure have been shown to decrease the risk of seizure over the first 5 years but are not demonstrated to reduce long-term risk of recurrence or mortality.
- The potential for AEDs to confer neuroprotection is under investigation.
- The risk of developing seizure after mild TBI remains high for a long period (>10 years).

Complications

- Risk of accidental injury
- Up to 50–60% of individuals with epilepsy will also have a mood disorder, the most common being depression and anxiety.
- 20–30% of individuals with epilepsy will have memory impairment.
REFERENCES

ADDITIONAL READING

CODES

**ICD10**

- G40.109 Local-rel symptc epi w simp prt seiz,not ntrct, w/o stat epi
- G40.209 Local-rel symptc epi w cmplx prt seiz,not ntrct,w/o stat epi
- G40.119 Local-rel symptc epi w simple part seiz, ntrct, w/o stat epi

CLINICAL PEARLS
- It is controversial whether AED treatment is indicated after a first seizure. Treatment should be strongly considered when a clear structural cause is identified/risk of injury from seizure is high (e.g., osteoporosis, anticoagulation).
- An EEG and neuroimaging (CT or MRI) should be considered in evaluating a first unprovoked seizure.
- Most pregnant women should continue anticonvulsant medications. AED levels should be monitored throughout the pregnancy.
- Postictal elevation in prolactin and CPK levels can help distinguish physiologic from psychogenic nonepileptic seizures.
BASICS

DESCRIPTION

- Seizure: sudden and transient symptoms (altered level of consciousness, motor manifestations) due to abnormal or synchronous electrical activity of neuronal networks
- Epilepsy: enduring preposition to generate epileptic seizures; defined as two or more unprovoked seizures apart in a >24-hour period
- Status epilepticus: epileptic seizure that lasts >5 minutes or multiple seizures without returning to normal between them. Classification: generalized, simple and complex partial, absence, nonconvulsive. Treatment varies depending of type.
- ILAE seizure classification, based on three key features:
  - Seizure origin: focal (previously partial), focal to bilateral, generalized
  - Awareness: aware, focal impaired awareness, generalized
  - Clinical features: motor, nonmotor (absence, behavior, cognitive, autonomic)
- System(s) affected: nervous
- Synonym(s): convulsion; attacks; spells

Pediatric Considerations
Breastfeeding is not contraindicated. Sedation of the infant should be monitored.

Pregnancy Considerations
- Preconception: Certain antiepileptic drug (AED) (P450 inducers) may cause hormonal contraceptive failure.
- Pregnancy: Avoid valproate as possible, due to increased teratogenicity and worse developmental outcomes. Epileptic patients should notify their neurologist before conception, if possible. During pregnancy, monitor AED levels every trimester for dose adjustment, continue folic acid supplementation, and screen for congenital abnormalities.
- Levetiracetam, topiramate, lamotrigine are alternatives for women of childbearing potential (1).
EPIDEMIOLOGY

Incidence
- 200,000 new cases of epilepsy are diagnosed in the United States annually, with 45,000 new cases in children <15 years of age.
- Pediatric (<2 years of age) and older adults (>65 years of age) more commonly present with new-onset seizures
- Predominant sex: male = female

Prevalence
- 2.7 million with seizure disorder
- 4 million people have had ≥1 seizures.
- 326,000 children (≤14 years of age) and 600,000 adults (>65 years of age) have a seizure disorder.

ETIOLOGY AND PATHOPHYSIOLOGY
- Synchronous and excessive firing of neurons, resulting in an imbalance of regulatory mechanisms in favor of excitatory activity. Seizures may be triggered by metabolic/medical conditions, but such seizures do not necessarily define the presence of epilepsy.
- Idiopathic
- Hippocampal sclerosis and other neurodevelopmental abnormalities of the brain
- Acute infection (meningitis, abscess, encephalitis)
- Metabolic and endocrine disorders
- Trauma
- Drug and alcohol withdrawal
- Tumor
- Vascular disease, including stroke and vasculitis
- Familial/genetic, infantile, and pediatric seizure syndromes (e.g., Lennox-Gastaut, benign familial, myoclonic epilepsy of infancy)
- Other etiologies (by age of onset)
  - Infancy (0 to 2 years)
    - Hypoxic-ischemic encephalopathy/other injury to cerebral cortex
    - Metabolic: hypoglycemia, hypocalcemia, hypomagnesemia, vitamin B₆ deficiency, phenylketonuria
  - Childhood (2 to 10 years): absence or febrile (usually <6 years) seizure
  - Adolescent (10 to 18 years): arteriovenous malformation
Late adulthood (>60 years)
  - Prevalence increases with age and is the highest >65-year-old patients.
  - Degenerative disease, including dementia
  - Most common causes for symptomatic seizures in elderly patients are acute stroke, metabolic disturbances (hypoglycemia, uremia, hepatic failure, electrolyte abnormality), and drugs. Initial diagnostic testing should be focused on these common etiologies.

Genetics
Family history increases risk 3-fold.

RISK FACTORS
History of congenital brain malformations, CNS infections, head trauma, stroke, tumors, neurocognitive degenerative diseases

GENERAL PREVENTION
Take measures to prevent head injuries. Avoid sleep deprivation. Avoid excessive alcohol intake.

COMMONLY ASSOCIATED CONDITIONS
Genetic syndromes (Angelman, tuberous sclerosis, Sturge-Weber), infections, tumors, drug abuse, alcohol and drug withdrawal, trauma, metabolic disorders

DIAGNOSIS
- Physiologic seizures are true cortical events and may require acute intervention.
- Psychogenic nonepileptic seizures (PNES) are also a differential diagnosis to consider.
- Conventional classification of seizures
  - Generalized seizures
    - Tonic–clonic: tonic phase: sudden loss of consciousness; clonic phase: sustained contraction followed by rhythmic contractions of all four extremities; postictal phase: headache, confusion, fatigue; clinically hypertensive, tachycardic, and otherwise hypersympathetic
    - Absence: impaired awareness and responsiveness
    - Atonic: abrupt loss of muscle tone
    - Myoclonic: repetitive muscle contractions
– Febrile seizures
  o Usually ≤6 years
  o Fever without evidence of any other defined cause of seizures
  o Recurrent febrile seizures probably do not increase the risk of epilepsy.
– Simple and complex focal seizures: usually present with auras. Correlation with focal EEG findings; can present with automatisms, staring, motor dystonias, postictal confusion
– Nonconvulsive status epilepticus: most commonly seen in ICU patients; no tonic–clonic activity seen so must diagnose with bedside EEG
– Status epilepticus: repetitive generalized seizures without recovery between seizures; considered a neurologic emergency
– PNES: nonrhythmic pattern of movement, eye closure during event, anterior tongue biting, history of psychiatric disorders. Patients can also have coexisting epilepsy.

HISTORY
• Eyewitness descriptions of event; patient impressions of what occurred before, during, and after the event
• Screen for etiologies, including provoking/ameliorating factors for the event, such as sleep deprivation.
• Ask about bowel/bladder incontinence, tongue biting, other injury, automatisms, or prior seizure activity.

PHYSICAL EXAM
Thorough neurologic exam; lateral tongue biting suggestive of generalized seizure, whereas tip of tongue more suggestive of nonepileptic event

DIFFERENTIAL DIAGNOSIS
• Syncope, orthostatic hypotension, convulsive syncope
• Transient ischemic attack
• PNES
• Complicated migraine
• Movement disorders: dystonias, dyskinesias
• Sleep disorders: cataplexy, narcolepsy
• Psychiatric disorders: conversion, malingering

DIAGNOSTIC TESTS & INTERPRETATION
A negative EEG does not rule out a seizure disorder. Interictal EEG sensitivity
may be as low as 20%; multiple EEGs (at least three) may increase sensitivity to 80% \(^{(2)}\).[C]

- Sleep deprivation may be helpful prior to EEG, and hyperventilation and photic stimulation during recording may increase sensitivity.
- Video EEG monitoring is used to differentiate PNES from true cortical events.
- EEG is necessary for diagnosis of nonconvulsive status epilepticus.

**Initial Tests (lab, imaging)**

- Glucose, sodium, potassium, calcium, phosphorus, magnesium, BUN, ammonia; drug and toxin screens
- AED levels (if patient is taking antiepileptic medication)
- CBC, UA, LP if needed: Rule out infection.
- Pregnancy test: will influence treatment selection
- Imaging is recommended for new-onset seizures. MRI is preferred to CT.
  - CT scan of brain: indicated routinely as initial evaluation, especially in the ER
  - Brain MRI: superior in evaluation of the temporal lobes (e.g., mesial temporal sclerosis), stroke, and other structural abnormalities

**Follow-Up Tests & Special Considerations**

- Drugs that may alter lab results: AED therapy may affect the EEG results dramatically.
- Inadequate AED levels may be altered by many medications such as erythromycin, sulfonamides, warfarin, cimetidine, and alcohol.
- Disorders that may alter lab results: Pregnancy decreases serum concentration.
- Bone scan to determine bone mineral density (BMD): generally done if patients are taking older AEDs such as phenytoin and carbamazepine

**Diagnostic Procedures/Other**

Lumbar puncture for spinal fluid analysis may be necessary to rule out meningitis if fever and/or impairment of consciousness are present.

**TREATMENT**

- Older adults are more sensitive to side effects from AEDs; therefore, target dose should be half of dosing for younger population \(^{(3)}\).[C]
- After presenting with an initial unprovoked seizure, 21–45% of patients will
have a recurrence within 2 years (4).

- Starting antiepileptic medications is likely to reduce recurrences of seizures but does not alter long-term outcomes or improve quality of life (4)[C].
- Patients with a single unprovoked seizure and associated risk factors that increase recurrence risk up to 60% (abnormal EEG, neurologic exam, or neuroimaging) can potentially benefit from starting therapy.

**MEDICATION**

- AED of choice: Select based on type of seizure, potential adverse effects/drug interactions, and cost.
- Monotherapy is preferred whenever possible. Treatment should begin with a single agent and the dose titrated until seizures are controlled or side effects become problematic. Consider a different agent if the first choice is not effective versus adding a second agent.
- Patients treated with loading doses of AED in status epilepticus can be started on maintenance dose of a different AED afterwards.

**First Line**

Treatment options include the following:

- Levetiracetam (Keppra): 1,000 to 3,000 mg/day in 2 doses
- Carbamazepine (Tegretol): 100 to 200 mg/day in 1 to 2 doses; therapeutic range, 4 to 12 mg/L
- Lamotrigine (Lamictal): 25 to 50 mg/day; adjust in 100-mg increments every 1 to 2 weeks to 300 to 500 mg/day in 2 doses.
- Oxcarbazepine (Trileptal): 300 mg BID, increase to 300 mg every 3 days; maintenance, 1,200 mg/day
- Lacosamide (Vimpat): 200 to 300 mg/day in 2 doses
- Ethosuximide (Zarontin): 750 to 1,250 mg/day divided BID (childhood absence seizures)
- Generalized status epilepticus: lorazepam 4 mg, fosphenytoin 20 mg/kg load, valproic acid 20 mg/kg load, levetiracetam 40 mg/kg load (5), lacosamide 300 mg load

**Second Line**

- Phenytoin (Dilantin): 200 to 400 mg/day in 1 to 3 doses; therapeutic range, 10 to 20 mg/L
- Valproic acid (Depakene): 750 to 3,000 mg/day in 1 to 3 doses to begin at 15 mg/kg/day; therapeutic range, 50 to 150 mg/L
- Topiramate (Topamax): 50 mg/day; adjust weekly to effect; 400 mg/day in 2 doses, max 1,600 mg/day
- Gabapentin (Neurontin): 1,800 to 3,600 mg in 3 to 4 doses for adjunct therapy
- Pregabalin (Lyrica): 150 to 300 mg/day in 2 to 3 doses
- Zonisamide (Zonegran): 100 to 400 mg in 1 to 2 doses
- Ezogabine (Potiga): 600 to 1,200 mg in 3 doses
- Perampanel (Fycompa): 4 to 12 mg daily
- Clonazepam (Klonopin): 1.5 to 8.0 mg in 2 to 3 doses
- Clobazam (Onfi): 20 to 40 mg in 1 to 2 doses
- Rufinamide (Banzel): 3,200 mg in 2 doses
- Brivaracetam (Briviact): (an analog of levetiracetam) 50 to 200 mg/day in 2 doses
- Perampanel (Fycompa): 4, 8, or 12 mg/day
- Contraindications: Refer to manufacturer’s profile of each drug.
- Precautions: Doses should be based on individual’s response guided by drug levels.
- Consider cautioning about increased risk of suicide, but risk of untreated seizures is far greater than increased risk of suicide.
- Patients are susceptible to sudden unexpected death in epilepsy, possibly due to cardiac arrhythmia.

**ISSUES FOR REFERRAL**
Referral and follow-up frequency is based on severity and patient’s wishes.

**SURGERY/OTHER PROCEDURES**
For patients that fail traditional therapy: lobectomy, resection, laser ablation, and vagus nerve stimulation

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- No evidence suggests that any complementary medicines reduce seizures, but they may induce serious drug interactions with prescribed AEDs.
- Psychological therapies may be used in conjunction with AED therapy. Cognitive-behavioral therapy, relaxation, biofeedback, and yoga all may be helpful as adjunctive therapy (6)[C].
- Patients with PNES should be referred for psychotherapy and psychiatry as needed.

mebooksfree.com
ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

- Outpatient therapy usually is sufficient, except for status epilepticus.
- Admissions to epilepsy monitoring units for video EEG monitoring may benefit patients with events that pose a diagnostic challenge or patients with intractable seizures already on two AED.
- Protect the airway and, if possible, protect the patient from physical harm; do not restrain. Administer acute AEDs.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Maintain adequate drug therapy; ensure compliance and/or access to medication. Drug therapy withdrawal and tapering of doses may be considered after a seizure-free 2-year period. Expect a 33% relapse rate in the following 3 years.

Patient Monitoring

- Monitor drug levels and seizure frequency.
- CBC and lab values (e.g., calcium, vitamin D) as indicated; BMD
- Monitor for side effects and adverse reactions.
- All patients currently taking any AED should be monitored closely for notable changes in behavior that could indicate the emergence/worsening of suicidal thoughts/behavior/depression.

DIET

Ketogenic diet may be beneficial in children in conjunction with AED therapy and refractory seizures.

PATIENT EDUCATION

Stress the importance of medication compliance and the avoidance of alcohol and recreational drugs.

- Individuals with uncontrolled seizures should be encouraged to avoid heights and swimming. Caution with cooking and unsupervised baths.
PROGNOSIS

- Depends on type of seizure disorder: ~70% will become seizure-free with appropriate initial treatment, 30% will continue to have seizures. The number of seizures within 6 months after first presentation is a prognostic factor for remission.
- ~90% who are seen for a first unprovoked seizure attain a 1- to 2-year remission within 4 or 5 years of the initial event (5).
- Life expectancy is shortened in persons with epilepsy.
- The case fatality rate for status epilepticus may be as high as 20%.

SEE ALSO

Seizures, Febrile; Status Epilepticus
CODES

ICD10
- R56.9 Unspecified convulsions
- P90 Convulsions of newborn
- G40.909 Epilepsy, unspecified, not intractable, without status epilepticus

CLINICAL PEARLS
- Initiation of treatment depends on multiple variables, including type of seizure, underlying risk factors, and further risk of recurrence.
- Semiology of event is very important for diagnosis of seizures versus PNES. Patients with PNES can have concomitant epileptic seizures.
- Patients in status epilepticus that received loading doses of a certain AED do not require to be continued on the same medication.
- To consider driving, states require seizure-free period from 3 to 12 months.
SEIZURES, FEBRILE
Swati Avashia, MD, FAAP, FACP, ABIHM

BASICS

DESCRIPTION

Febrile seizures occur in children aged 6 months to 5 years with fever ≥100.4°F (38°C) and absence of underlying neurologic abnormality, metabolic condition, or intracranial infection. Three distinct categories (1):

- Simple febrile seizure (70–75%; must meet all criteria)
  - Generalized clonic or tonic–clonic seizure activity without focal features
  - Duration <15 minutes
  - Does not recur within 24 hours
  - Resolves spontaneously
  - No history of previous afebrile seizure or seizure disorder
- Complex (CFS) (20–25%; only one criterion must be met)
  - Partial seizure, focal activity
  - Duration >15 minutes but <30 minutes
  - Recurrence within 24 hours
  - Postictal neurologic abnormalities (e.g., Todd paresis) (2)
- Febrile status epilepticus (FSE) (5%)
  - Lasts >30 minutes

EPIDEMIOLOGY

Incidence

- Approximately 500,000 febrile seizures occur in the United States annually.
- Peak incidence is 18 months of age (2).
- Only 6% of febrile seizures occur before age 6 months, and 4% of febrile seizures occur after age 3 years (3).
- Bimodal seasonal pattern that mirrors peaks of febrile respiratory (November to January) and gastrointestinal infections (June to August) (2)

Prevalence

- 2–5% of children in the white population aged 6 months to 3 years in United States and Western Europe (3)
Cumulative incidence varies in other populations (0.5–14%) (1).

**ETIOLOGY AND PATHOPHYSIOLOGY**
A variety of mechanisms have been proposed:
- A lower baseline seizure threshold in the age group affected by febrile seizures
- Familial genotypes may influence seizure thresholds.
- Fever may alter ion channel activity, resulting in increased circuit excitability.
- Cytokines released secondary to infection, specifically interleukin (IL)-1β, increase neuronal activity.

**Genetics**
- Evidence for genetic association:
  - Greater concordance in monozygotic than dizygotic twins
  - 25–40% of cases have positive family history (3).
  - Risk of febrile seizure with a previously affected sibling is increased.
  - Having two affected parents doubles a child’s risk of febrile seizure.
  - Mode of inheritance is multifactorial, although autosomal dominant inheritance reported (2).
- Several rare familial epileptic syndromes present with febrile seizure.

**RISK FACTORS**
- Any condition causing fever
- Risk increases with the number of affected first-degree relatives.
- Risk is increased for male children (1).
- Recent vaccination
  - As febrile seizures are a benign entity, the benefits of vaccination outweigh the risk.
  - Possible increased risk with vaccinations, mainly MMR and DTaP, is a matter of much debate (3), and absolute vaccination-associated risk is very low.
- Prenatal exposure to alcohol and tobacco, daycare attendance, premature birth, developmental delay, and prolonged NICU stay
- Children with iron deficiency anemia may have increased risk for febrile seizures. Consider checking for anemia if the history suggests a risk for iron deficiency (4)[C].

**GENERAL PREVENTION**
Prevention is not usually indicated given the benign nature of this condition, lack of effective interventions, and side effects of prophylactic medications.

COMMONLY ASSOCIATED CONDITIONS
- Viral infections: Common pathogens include human herpesvirus 6, influenza, parainfluenza, adenovirus, and respiratory syncytial virus (RSV).
  - HHV-6 infection found in 30% of FSE in one study (3)
- Bacterial infections: Frequently associated infections include otitis media, pharyngitis, urinary tract infection (UTI), pneumonia, and gastroenteritis.

DIAGNOSIS

HISTORY
- History of present illness:
  - Description of seizure:
    - Febrile seizures are generalized with clonic or tonic–clonic activity.
    - Absence, myoclonic, atonic, and focal seizures are atypical of febrile seizures and warrant further evaluation.
  - Seizure duration
  - Presence of postictal state (consistent with febrile seizure)
  - Number of seizures in previous 24 hours
  - Lethargy, irritability, or decreased level of consciousness as reported by the caretaker
  - Symptoms of underlying infection
  - Symptoms concerning for neurologic deficits
- Past medical history:
  - Existing conditions, including developmental delay, cerebral palsy, and metabolic disorders
  - Recent antibiotic course
  - History of febrile seizures
  - History of afebrile seizures or seizure disorder
  - History of head injury
  - Vaccination status, recent immunization
- Family history: febrile seizures, afebrile seizures, epilepsy, metabolic disorders, and other neurologic conditions
- Social history: factors concerning for child abuse
**PHYSICAL EXAM**
- Vital signs should be stable and consistent with intercurrent febrile illness; unstable vital signs or toxic appearance warrant further evaluation.
- Identify the presence or absence of focal deficits on a complete neurologic exam.
- Assess for signs of meningitis, including decreased level of consciousness, irritability, meningeal signs, bulging fontanelle, papilledema, and petechiae.
- Identify cause of fever.
- Assess thoroughly for manifestations of child abuse with a careful skin exam, inspection and palpation for occult trauma, and retinal exam if possible.

**DIFFERENTIAL DIAGNOSIS**
- Seizures due to an etiology other than febrile seizure:
  - Meningitis, encephalitis
  - Primary epilepsy
  - Neonatal seizure
  - Dravet syndrome
  - Intracranial mass
  - Nonaccidental trauma
  - Electrolyte abnormality
  - Hypoglycemia
  - Metabolic disorder
- Conditions presenting similarly to seizure:
  - Rigors
  - Crying
  - Benign myoclonus of infancy
  - Breath-holding spell
  - Choking episode
  - Tic disorder
  - Parasomnia
  - Arrhythmia
  - Metabolic disorder
  - Dystonic reaction

**DIAGNOSTIC TESTS & INTERPRETATION**
- Routine laboratory tests are not recommended to identify an underlying cause of a simple febrile seizure (2)[C].
- Rates of UTI in children with simple febrile seizures and in febrile children
without seizure are comparable; decisions regarding urinalysis should be based on current UTI screening guidelines (2)[B].

- Blood glucose is no longer routinely recommended (2)[B].

- Lumbar puncture
  - In studies of patients with simple febrile seizures conducted since the initiation of routine infant vaccination against *Haemophilus influenzae*, rates of acute bacterial meningitis were very low (0–0.8%).
  - Seizure is unlikely to be the only presenting symptom of meningitis. Symptoms indicating increased likelihood of meningitis include toxic appearance, altered level of consciousness, meningeal signs, focal neurologic deficits, bulging fontanelle, and petechiae.
  - Cases of bacterial meningitis in children with febrile seizures who return to baseline or in the absence of other signs or symptoms are rare (2).
  - Recommendations:
    - Lumbar puncture should be performed in a child with fever and seizure if meningeal signs are present or if there is concern for meningitis or other intracranial pathology based on history and exam (2)[B].
    - In infants aged 6 to 12 months, consider lumbar puncture if the child has not been vaccinated against *H. influenzae* or *Streptococcus pneumoniae* according to schedule (2)[C].
    - Consider lumbar puncture for children with fever and seizure who have recently been treated with antibiotics, as antibiotics may mask meningeal signs and symptoms (2)[C].
    - The yield of lumbar puncture in children with complex febrile seizure is very low, and the rate of acute bacterial meningitis in U.S. patients with complex febrile seizures is too low to routinely recommend lumbar puncture.
    - Neuroimaging is not routinely recommended for the purposes of identifying the cause of a simple febrile seizure (2)[B].

- Studies have demonstrated limited utility of emergent imaging in patients who meet criteria for complex febrile seizure; however, imaging may be indicated for history or exam findings concerning for bleed or structural lesion. Head CT scan is not routinely recommended for children with complex febrile seizures (1)[B].

**Diagnostic Procedures/Other**

- EEG is not recommended in neurologically normal children presenting with simple febrile seizure (2)[B].
There is mixed evidence for use of EEG after complex febrile seizures; some recommend outpatient EEG on follow-up because EEGs can show generalized slowing for 24 hours after initial presentation and up to 7 days after FSE (2).

**TREATMENT**

**GENERAL MEASURES**

- Acute seizure management
  - Airway: Position the patient laterally, suction secretions, and place a nasopharyngeal airway if necessary.
  - Breathing: Administer oxygen for cyanosis; consider bag-mask ventilation or intubation for inadequate ventilation.
  - Circulation: Establish IV access if first-line buccal or nasal midazolam is not effective.

Antipyretics are helpful for patient comfort but do not prevent seizure recurrence during the initial febrile episode (1)[A].

- Provide supportive care and treat underlying infection if necessary.

**MEDICATION**

*First Line*

Treat seizures of ≥5 minutes duration with anticonvulsants (2):

- Out of hospital: rectal diazepam 0.5 mg/kg, buccal midazolam 0.4 mg/kg, or nasal midazolam 0.2 mg/kg
- In hospital: IV or IM lorazepam 0.1 mg/kg or IV diazepam 0.2 mg/kg

**ISSUES FOR REFERRAL**

Simple febrile seizures do not require referral to a pediatric neurologist.

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Unstable vital signs
- Concerning findings on history or physical exam
- Prolonged seizure requiring anticonvulsants
- Persistent change in mental status
- Inpatient management of underlying condition is required.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

- Anticonvulsant prophylaxis during subsequent febrile episodes:
  - The American Academy of Pediatrics recommends against prophylaxis with anticonvulsants due to an unacceptable risk–benefit ratio (2)[B].
  - Intermittent oral and rectal diazepam are effective in reducing recurrence of simple and complex febrile seizures but are not recommended due to the benign nature of febrile seizures and because so many febrile seizures precede the development of the fever (2)[B].

- Antipyretic prophylaxis during subsequent febrile episodes (2)[A]:
  - No study has demonstrated that fever management will prevent recurrence.
  - Ibuprofen and acetaminophen are no more effective than placebo in preventing recurrence.

PATIENT EDUCATION

There is frequently a high degree of parental anxiety associated with febrile seizures. Suggested anticipatory guidance:

- Febrile seizures do not cause brain damage and are associated with a low risk for sequelae.
- Parents should be reassured after a simple febrile seizure that there is no negative impact on intellect, behavior, or risk of death (3)[B].
- Parents should be prepared for a high probability of recurrence.
- If seizure recurs, position the child safely and do not intervene inappropriately.
- Time the seizure; call rescue if the child turns blue, has difficulty breathing, or the seizure lasts >5 minutes.
- If the seizure spontaneously resolves in <5 minutes and the child is well but sleepy, seek immediate attention, but calling rescue is not necessary.

PROGNOSIS

- Recurrence:
  - Estimates of recurrence rates vary (30–50%).
  - 10% will experience three or more febrile seizures (2).
  - Factors associated with seizure recurrence include age <18 months at time of first episode, first-degree relative with history of febrile seizure, history of complex febrile seizures, lower peak temperatures, and shorter duration of fever prior to seizure occurrence (2).
Intellectual and behavioral outcomes
- Febrile seizures do not impact IQ, behavioral abnormalities, academic performance, or neurocognitive inattention (3).
- Outcomes in children with single and multiple febrile seizures are similar.

Subsequent development of epilepsy (2)
- Risk of epilepsy after a simple partial seizure is close to the overall rate in the general population.
- Risk is up to 7% in those with multiple simple febrile seizures age <12 months and a short duration of fever prior to seizure onset.
- Factors associated with increased risk include presenting with complex febrile seizure, family history of epilepsy or febrile seizures, cerebral palsy, developmental delay, low birth weight, and prematurity.

Mortality:
- There is not an increased risk for SIDS in siblings of children who have febrile seizures.

COMPLICATIONS
Seizure-related injury, aspiration pneumonia, side effects of prescribed medications or diagnostic procedures, and subsequent parental perception of the child as being vulnerable, especially during subsequent fevers

REFERENCES

ADDITIONAL READING
CODES

ICD10
- R56.00 Simple febrile convulsions
- R56.01 Complex febrile convulsions
- G40.901 Epilepsy, unsp, not intractable, with status epilepticus

CLINICAL PEARLS
- Febrile seizures are generally benign, and families can be reassured that children are at low risk of death, subsequent development of epilepsy, and learning or behavioral abnormalities.
- History and physical exam are important tools in identifying children presenting with febrile seizure who may be at greater risk for meningitis or other intracranial pathology.
- For simple febrile seizures, routine labs, lumbar puncture, neuroimaging studies, and EEG are not recommended in the absence of clinical suspicion of serious underlying pathology.
- Prophylaxis with anticonvulsants or antipyretics during subsequent febrile episodes is not recommended due to their lack of effectiveness and the risk of medication-associated side effects.
SEROTONIN SYNDROME
Jason Chao, MD, MS • Darrell Hulisz, RPh, PharmD • Eric Yeh, MD

BASICS
DESCRIPTION
- A potentially life-threatening adverse drug reaction that results from excessive stimulation of peripheral and CNS serotonergic receptors
- It is a concentration-dependent toxicity that can develop in any individual who has ingested drug combinations that synergistically increase synaptic 5-hydroxytryptamine (HT).
- Serotonin toxicity occurs in three main settings: (i) therapeutic drug use, which often results in mild to moderate symptoms; (ii) intentional overdose of a single serotonergic agent, which typically leads to moderate symptoms; and (iii) as the result of a drug interaction between numerous serotonergic agents (most commonly, selective serotonin reuptake inhibitors [SSRIs] and monoamine oxidase inhibitors [MAOIs]), most often associated with severe serotonin toxicity.
- Classically characterized by a triad of symptoms that include mental status change, neuromuscular hyperactivity, and autonomic instability
- Onset is usually within 24 hours with 60% of cases occurring within 6 hours of exposure to, or change in, dosing of a serotonergic agent. Rarely, cases have been reported weeks after discontinuation of serotonergic agents.

Geriatric Considerations
Elderly are at increased risk given use of polypharmacy.

Pregnancy Considerations
- Serotonin syndrome has similar manifestations in children and adults.
- General management is unchanged in children, other than medication dosing.

Pregnancy Considerations
- 3rd-trimester exposure to SSRIs has been associated with transient neonatal complications that may reflect either acute drug withdrawal or serotonergic toxicity.
Symptoms in neonates may include tremors, increased muscle tone, jitteriness, shivering, feeding/digestive disturbances, irritability, agitation, sleep disturbances, increased reflexes, excessive crying, and respiratory disturbances.

**EPIDEMIOLOGY**

Seen in about 14–16% of SSRI overdose patients

**Incidence**

- About 100,000 adverse events reported with antidepressant use including some deaths, annually. Most associated with SSRIs, either alone or in combination with other drugs. In a 2008 study, SSRIs alone were responsible for adverse events in 18.8% of cases, with 55.7% due to intentional causes, 39.5% unintentional, and remainder of causes unknown. Of patients reporting adverse effects with SSRIs, 46.6% had symptoms requiring hospitalization, and significant toxic effects occurred in 90 patients with two resultant deaths (1)[A].
- The incidence of serotonin syndrome is rising because serotonergic agents are increasingly used in clinical practice and in combination with other serotonergic agents.
- Predominant age: affects all age groups
- Predominant sex: male = female

**ETIOLOGY AND PATHOPHYSIOLOGY**

- The result of excessive stimulation in peripheral and CNS serotonergic receptors
- Risk is mediated in a dose-related manner to the action of 5-HT/5-HT agonists on 5-HT\textsubscript{1A} and/or 5-HT\textsubscript{2A} receptors. The development mechanism of the syndrome is unknown.
- It is hypothesized that the degree of serotonin elevation in blood plasma has to be 10–15% times above baseline levels to result in serotonin toxicity (2)[A].
- A number of drugs are associated with the serotonin syndrome, which usually involves combination with an SSRI. These include SSRIs (e.g., citalopram, escitalopram, fluoxetine, fluvoxamine, paroxetine, sertraline); MAOIs; SNRIs ( duloxetine, venlafaxine, desvenlafaxine); tricyclic antidepressants (e.g., amitriptyline); other antidepressants ( nefazodone, trazodone); anxiolytic ( buspirone); lithium; triptans; anticonvulsants (Depakote); analgesics (fentanyl, meperidine, pentazocine, tramadol); antibiotics ( linezolid, tedizolid...
[weak MAOI, ritonavir); over-the-counter (OTC) cough medications (dextromethorphan); some antipsychotics (risperidone, olanzapine); antiemetics (ondansetron, granisetron); other medications, such as metoclopramide, cyclobenzaprine, L-dopa; dietary supplements (tryptophan); herbal supplements (St. John’s wort, nutmeg); methylene blue; and drugs of abuse (e.g., methylenedioxymethamphetamine [MDMA], cocaine, D-lysergic acid diethylamide [LSD], and amphetamine).

- Initially, patients can develop a peripheral tremor, confusion, and ataxia; systemic signs are next (e.g., agitation, diaphoresis, hyperreflexia, and shivering). If it worsens, the severe signs of fever, jerking, and diarrhea may develop. Serotonin syndrome can last from hours to days after the offending agents are stopped and supportive care is initiated.
- Drug interactions are most often the cause of severe cases of serotonin syndrome. Many of the same classes of medications listed earlier are involved, especially MAOIs (including linezolid) with SSRIs.

Genetics
Unknown

RISK FACTORS
- Serotonergic agents
- Reported following ingestion of a single agent
- The greatest number of adverse events has been shown to be associated with SSRIs in combination with other substances, and the combination of SSRIs and MAOIs carries the greatest risk of developing serotonin toxicity.

GENERAL PREVENTION
- Consider drug–drug interactions when a multidrug regimen is required and avoid if possible.
- Caution patients about taking SSRIs with OTC medications (e.g., dextromethorphan) or herbal supplements (e.g., St. John’s wort) prior to consulting a physician.
- Clinician education
- Continual improvement in use of health information technology

DIAGNOSIS
- Serotonin syndrome is a clinical diagnosis.
Hunter Toxicity Criteria Decision Rules aid in the diagnosis of clinically significant serotonin toxicity (sensitivity, 84%; specificity, 97%). A patient who took a serotonergic agent, must have one of the following:

– Spontaneous clonus
– Inducible clonus plus agitation/diaphoresis
– Ocular clonus plus agitation/diaphoresis
– Tremor and hyperreflexia
– Hypertonia

– Temperature >38°C plus ocular clonus/inducible clonus (3)[A]

HISTORY

– Thorough drug history, including OTC remedies, dietary and herbal supplements, and illicit drugs. Ask about dose, formulation, and recent changes.
– Address possibility of drug overdose and obtain collateral information if intentional overdose is suspected.
– Elicit description of symptoms, including their onset and progression.

PHYSICAL EXAM

– Vital signs: tachycardia, hypertension, and hyperthermia (severe cases)
– Neuromuscular findings (seen in over half of patients with serotonin syndrome)
  – Hyperreflexia (greater in lower extremities)
  – Clonus (involuntary muscle contractions, most commonly tested by flexing foot upward rapidly; includes ocular)
  – Myoclonus (greater in lower extremities)
  – Tremor (greater in lower extremities)
  – Hypertonia
  – Bilateral Babinski sign
  – Akathisia
  – Tonic–clonic seizures (severe cases)
– Autonomic signs
  o Diaphoresis
  o Mydriasis
  o Flushing
  o Dry mucous membranes
  o Vomiting, diarrhea, increased bowel sounds
  o Mental status changes: anxiety, disorientation, delirium (4)[A]
Severe cases have led to altered level of consciousness, rhabdomyolysis, metabolic acidosis, and disseminated intravascular coagulation (DIC).

DIFFERENTIAL DIAGNOSIS
- Neuroleptic malignant syndrome (NMS)
- Anticholinergic fever (e.g., benztropine, diphenhydramine, oxybutynin, nifedipine, famotidine, atropine, scopolamine; plant poisoning from belladonna/“deadly nightshade,” datura, henbane, mandrake, brugmansia)
- Malignant hyperthermia
- Heat stroke
- CNS infection (meningitis, encephalitis)
- Sympathomimetic toxicity (cocaine, methamphetamine, PCP)
- Nonconvulsive seizures
- Hyperthyroidism (thyroid storm)
- Tetanus
- Rabies
- Acute baclofen withdrawal

DIAGNOSTIC TESTS & INTERPRETATION
- Serum serotonin levels do not correlate with clinical findings.
- Nonspecific lab findings that may develop include the following:
  - Elevated WBC count
  - Elevated creatine phosphokinase (CK or CPK)
  - Decreased serum bicarbonate
  - Elevated hepatic transaminases
- In severe cases, the following complications may develop:
  - DIC
  - Metabolic acidosis
  - Rhabdomyolysis
  - Renal failure
  - Myoglobinuria
  - Acute respiratory distress syndrome (ARDS) (3)[A]

TREATMENT
- Discontinue all serotonergic agents.
- Supportive care is the mainstay of therapy. This includes administration of oxygen and aggressive IV fluids, continuous cardiac monitoring, and
correction of vital signs.

- Benzodiazepines may be effective for the management of agitation in patients with serotonin syndrome.
- Administration of serotonin antagonists: Cyproheptadine (histamine and serotonin antagonist) may be useful if supportive measures and sedation (benzodiazepines) are unable to control agitation and correct vital signs.

- **Mild cases** (afebrile, tachycardia, shivering, diaphoresis, mydriasis, hyperreflexia, intermittent tremor or myoclonus)
  - Discontinue precipitating agent(s).
  - Supportive care
  - Sedation

- **Moderate cases** (temperature >38°C, autonomic instability, mydriasis, hyperactive bowel sounds, diarrhea, diaphoresis, ocular clonus, hyperreflexia, tremor, mild agitation, or hypervigilance)
  - Discontinue precipitating agent(s).
  - Supportive care
  - Sedation
  - Aggressive treatment of autonomic instability
  - Treatment with cyproheptadine should be initiated if agitation and vital sign abnormalities are unimproved with benzodiazepines and supportive care.
  - Hypotension from MAOI interactions should be treated with low doses of direct-acting sympathomimetics (e.g., norepinephrine, phenylephrine, epinephrine); indirect serotonin agonists, such as dopamine, should be avoided.
  - Severe hypertension and tachycardia should be treated with short-acting agents, such as nitroprusside or esmolol.
  - Avoid use of longer acting agents, such as propranolol.

- **Severe cases** (temperature >41.1°C, autonomic instability, delirium, muscular rigidity, and hypertonicity)
  - Discontinue precipitating agent(s).
  - Immediate sedation
  - Endotracheal intubation as clinically indicated
  - Paralysis as clinically indicated (maintained with nondepolarizing continuous paralytic agents such as vecuronium, cisatracurium, rocuronium)
    - Succinylcholine should not be used in cases of rhabdomyolysis to avoid exacerbation of hyperkalemia (5)[A].
    - Antipyretic medications are not effective (4)[A]; the increased body temperature is due to muscle activity, not an alteration in the hypothalamic
Avoid physical restraints, as it can worsen hyperthermia and lactic acidosis in agitated patients (5)[A].

**MEDICATION**

- Benzodiazepines: may be used to manage agitation in serotonin syndrome and also may correct mild increases in BP and heart rate. Use with caution in patients with delirium, given the known paradoxical effect of exacerbating delirium.
- Cyproheptadine (Periactin): Consider use if benzodiazepines and supportive measures are unable to control agitation and correct vital signs:
  - Adults: initial dose 12 mg PO (can also be crushed and given via nasogastric [NG] tube) followed by 2 mg q2h until clinical response observed; 12 to 32 mg of drug may be required in a 24-hour period.
  - Children
    - <2 years: 0.06 mg/kg q6h
    - 2 to 6 years: 2 mg q6h
    - 7 to 14 years: 4 mg q6h
- Unlikely to be effective in patients who have received activated charcoal

- Use of antipsychotics with 5-HT$_{2A}$ antagonist activity, such as olanzapine and chlorpromazine, is not recommended (4)[A].

**ISSUES FOR REFERRAL**

- Psychiatry: for assistance with medication management and follow-up care (inpatient psychiatric care vs. outpatient psychiatric follow-up)
- Toxicology/clinical pharmacology service
- Poison control center

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**

- Patients with known/suspected serotonin syndrome should be admitted to a medical inpatient unit for observation.
- Discharge criteria
  - Mental status has returned to baseline.
  - Stable vital signs
  - No increase in clonus
  - Close patient follow-up is ensured.
ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- In mild cases of serotonin toxicity, address risks and benefits of restarting offending agents. Serotonergic medications need to be titrated slowly, and patients must have close outpatient follow-up with physician.
- If patient developed severe serotonin syndrome, the offending agent should likely not be resumed unless precipitant for serotonin syndrome is found (e.g., combination with another serotonin agonist); the patient can be carefully monitored, or there is clear benefit versus risk of restarting the medication.

PROGNOSIS
- Generally favorable with early recognition of the syndrome and prompt initiation of treatment
- Most cases resolve within 24 hours of discontinuation of serotonergic agents; this can be longer depending on the drug’s half-life:
  - MAOIs can result in toxicity for several days.
  - SSRIs can result in toxicity for up to several weeks after discontinuation.
- ICU admission is often indicated in severe cases.

COMPLICATIONS
- Adverse outcomes, including death, are usually the consequence of poorly treated hyperthermia.
- Nonhyperthermic patients who survive typically do not have long-term sequelae.

REFERENCES

** ADDITIONAL READING **

** CODES **

**ICD10**

G25.79 Other drug induced movement disorders

**CLINICAL PEARLS**

Consider serotonin syndrome in patients with recent use of a serotonergic agent (particularly if multiple proserotonergic agents are involved) presenting with unexplained tachycardia, hypertension, hyperthermia, clonus, hyperreflexia, and change in mental status.
SEXUAL DYSFUNCTION IN WOMEN

Esther Guard, DO

BASICS

- Very common: ~40% of women surveyed in the United States have sexual concerns.
- May present as a lack of sexual desire, impaired arousal, inability to achieve orgasm or pain with sexual activity, and may be lifelong or acquired

DESCRIPTION

- Female sexual interest or arousal disorder—lack of or significantly reduced sexual interest or arousal as manifested by three of the following:
  - Absent or reduced interest in sexual activity
  - Absent or reduced sexual or erotic thoughts or fantasies
  - No or reduced initiation of sexual activity and unreceptive to partner’s attempts to initiate
  - Absent or reduced sexual excitement or pleasure during sexual activity in almost all (75–100%) of sexual encounters
  - Absent or reduced sexual interest or arousal in response to any internal or external sexual or erotic cues
  - Absent or reduced genital or nongenital sensation during sexual activity in almost all (75–100%) of sexual encounters
- Female orgasmic disorder—presence of either of the following in almost all (75–100%) occasions of sexual activity:
  - Marked delay in, marked infrequency of, or absence of orgasm
  - Markedly reduced intensity of orgasmic sensations
- Genito-pelvic pain or penetration disorder—persistent or recurrent difficulties with one or more of the following:
  - Vaginal penetration during intercourse
  - Marked vulvovaginal or pelvic pain during intercourse or penetration attempts
  - Marked fear or anxiety about vulvovaginal or pelvic pain in anticipation of, during, or because of vaginal penetration
  - Marked tensing or tightening of pelvic floor muscles during attempted vaginal penetration
ALERT
Symptoms must be present for ≥6 months; cause clinically significant distress or impairment; and not be better explained by a nonsexual mental disorder, a consequence of severe relationship distress, or other significant stressors

- System(s) affected: nervous; reproductive; genitourinary; psychiatric
- Synonym(s): hypoactive sexual desire disorder; sexual aversion disorder; female sexual arousal disorder; inhibited female orgasm

EPIDEMIOLOGY
In two large studies, approximately 40% of women reported sexual problems.

Incidence
Sexual problems are highest in women aged 45 to 64 years and then decline secondary to changes in sexual-related personal distress.

Prevalence
Low sexual desire is the most common manifestation, followed by difficulty with orgasm, difficulty with arousal, and sexual pain.

ETIOLOGY AND PATHOPHYSIOLOGY
The pathophysiology of sexual dysfunction is complex and multifactorial because it can be the result of any etiology that interferes with the female sexual response cycle (desire, arousal, orgasm, and resolution). Phases can vary in sequence, overlap, or be absent during all or some sexual encounters.

- Biologic
  - Disorders of the hypothalamic-pituitary-adrenal system, hormonal imbalance/disorders of ovarian function, menopause (surgical or natural), chronic illness (vascular disease, diabetes mellitus, and malignancy)
  - Prescription medications (SSRIs, MAOIs, TCAs, β-blockers)
  - Thyroid disease
  - Neuromuscular disease (multiple sclerosis, spinal cord damage)
- Psychological
  - Anxiety/depression
  - Maladaptive thoughts/behaviors
  - Interrelational difficulties
  - Body image issues
  - Drug and alcohol abuse

mebooksfree.com
– Sexual abuse

**RISK FACTORS**

- Advancing age/menopause
- Previous sexual trauma
- Lack of knowledge about sexual stimulation and response
- Chronic medical problems
  - Depression, anxiety, chronic pain syndromes, and other psychiatric disorders
  - Cardiovascular disease
  - Endocrine disorders
  - Dermatologic disorders
  - Neurologic disorders
  - Cancer
- Gynecologic issues
  - Childbirth
  - Pelvic floor or bladder dysfunction
  - Endometriosis
  - Uterine fibroids
  - Chronic vulvovaginal candidiasis/vaginal infections
  - Female genital mutilation
- Relationship factors such as couple discrepancies in expectations and/or cultural backgrounds and attitudes toward sexuality in family of origin
- Medications or substance abuse

**COMMONLY ASSOCIATED CONDITIONS**

- Marital/relationship discord
- Depression

**DIAGNOSIS**

- Female sexual dysfunction is diagnosed by utilizing a validated sexual function screening instrument and a structured interview, including detailed medical and sexual history, to confirm diagnosis.
  - Female Sexual Function Index
  - Brief Index of Sexual Functioning for Women
  - Brief Sexual Symptom Checklist
  - Decreased Sexual Desire Screener
The diagnosis requires that the sexual problem be recurrent or persistent and causes personal distress rather than be due solely to partner or relationship issues.

HISTORY

- Detailed sexual history (1)
  - Degree of personal distress
  - Lifelong versus acquired problem
  - Situational versus generalized problem
  - Cultural/societal beliefs regarding sexuality
  - History of sexual trauma
  - Concerns about safety, pregnancy, or STIs
  - Concerns regarding privacy
- Interpersonal relationship factors
  - Current relationship status
  - Family dysfunction
- Physiologic/biologic history
  - Urinary/anal incontinence
  - Medications (including herbal and OTC)
  - Pregnancy/childbirth history
  - Infertility
  - Menopausal status (natural, surgical, or postchemotherapy)
  - STIs and vaginitis
  - Pelvic surgery, injury, or cancer
  - Chronic pelvic pain
  - Abnormal genital tract bleeding
- Psychological history
  - Low self-image
  - Anxiety
  - Depression
  - Negative past sexual experiences
  - Substance misuse/abuse

PHYSICAL EXAM

- Most commonly, patients have a normal physical exam (1).
  - Assess for anatomic abnormalities.
  - Assess for scars or evidence of trauma.
  - Assess for vaginal atrophy, adequate estrogenization.
  - Assess for infection.
– Recognize signs of anxiety, apprehension, and pain during the speculum and pelvic exam.

- General physical exam, signs of chronic disease

**DIFFERENTIAL DIAGNOSIS**

- Medication side effects
- Vaginitis
- Decreased vaginal lubrication secondary to hormonal imbalance
- Decreased sensation secondary to nerve injury
- Multiple sclerosis
- Anatomic abnormalities
- Abdominal surgery (which can interfere with pelvic innervation)
- Depression
- Marital dysfunction, including domestic violence
- Pregnancy
- Pseudodyspareunia (use of complaint of pain to distance self from partner)

**DIAGNOSTIC TESTS & INTERPRETATION**

Laboratory studies are rarely helpful. There are no reliable correlations between serum hormone levels and sexual dysfunction.

*Initial Tests (lab, imaging)*

As needed to identify infections and other medical causes (1)[C]

**TREATMENT**

- Set realistic goals and expectations (2)[C].
- Address underlying medical and psychiatric conditions (3)[C].
- Review basic sex education, sexual response, heterogeneity of normal response, and sexual activity other than intercourse (2,4)[C].
- Education on communication (4)[C]
- Educate on healthy lifestyle, including diet, exercise, sleep, avoidance of tobacco, and reduced alcohol use (2,4)[C].
- Vaginal moisturizers and lubricants (4)[C]
- Cognitive-behavioral therapy (CBT) (individual or couples) to target maladaptive thoughts and behaviors and to disrupt the dysfunctional cycle (3,4)[C]
- Mindfulness-based CBT (2,4)[C]
Sex therapy: sensate focus, systematic desensitization exercises, homework exchanging physical touch with partner, scheduled attempt of sexual activity 3 times per week, or directed masturbation alone (3–5)[C]

Physical therapy/biofeedback (4,5)[C]

MEDICATION

Sexual dysfunction is often a multifactorial psychosocial condition. Using medications does not usually address the cause of the problem and can, in some cases, make the condition worse.

- Bupropion (2)[C]: adjunct for SSRI-induced sexual dysfunction. Improves sexual arousal and orgasm but not desire. Dose: bupropion SR 150 mg orally once or twice daily

- Flibanserin (3)[C],(6)[A]: possible improvement in sexual desire. Clinical improvement versus placebo is minimal, and side effects are common.
  Mechanism of action: 5-HT$_{1A}$ agonist and 5-HT$_{2A}$ antagonist. Dose: 100 mg at bedtime; FDA-approved for premenopausal women with hypoactive sexual desire

- Estrogen replacement with or without progestins (2,5)[C],(7)[A]: may improve sexual desire, vaginal atrophy, and clitoral sensitivity. Vaginal estrogen therapy (preferred route of administration) is available in cream, vaginal tablet, or ring form.

- Ospemifene (2,5)[C]: selective estrogen receptor modulator FDA-approved for dyspareunia due to vulvo- or vaginal atrophy in postmenopausal women.
  Dose: ospemifene 60 mg orally once daily

- Testosterone (2,3,5,8)[B]
  - Use in premenopausal women not supported by data
  - In naturally or surgically postmenopausal women, adding short-term testosterone to hormone replacement may increase desire.
  - >6 months use lacks data on safety and effectiveness
  - Side effects: hirsutism, androgenic alopecia, acne, decreased HDL, liver dysfunction; not FDA-approved for sexual dysfunction in women
  - Contraindicated in breast or endometrial cancer, thromboembolic disease, or coronary artery disease
  - Dose: oral methyltestosterone 1.25 to 2.50 mg/day (1/10 of men’s dose) or topical (patch, gel)

- Dehydroepiandrosterone (DHEA) (8)[C]: vaginal formulation 6.5 mg FDA-approved for dyspareunia due to vaginal atrophy in postmenopausal women

- Phosphodiesterase type 5 (PDE5) inhibitors: adjunct for SSRI or SNRI
induced sexual dysfunction

**ISSUES FOR REFERRAL**
Consider referral for CBT, marriage/couples counseling, pelvic floor therapy, or sex therapy.

**ADDITIONAL THERAPIES**
- Smoking cessation and reduction of alcohol intake
- For childhood trauma: scripting, psychotherapy, cognitive restructuring
- For prescription-drug causes: reduced dosages or change to different medication

**COMPLEMENTARY & ALTERNATIVE MEDICINE**
- Zestra for women botanical feminine massage oil: Small trial showed increased arousal, desire, genital sensation, ability to have orgasm, and sexual pleasure.
- Yohimbine: not recommended, potentially dangerous
- Ginseng and St. John’s wort: no evidence to support treatment of sexual dysfunction

**ONGOING CARE**

**DIET**
Weight reduction if overweight or obese

**PATIENT EDUCATION**
- American Association of Sex Educators, Counselors, and Therapists: [www.aasect.org](http://www.aasect.org)
- National Women’s Health Resource Center: [www.healthywomen.org](http://www.healthywomen.org)
- North American Menopause Society: [www.menopause.org](http://www.menopause.org)
- National Vulvodynia Association: [www.nva.org](http://www.nva.org)

**PROGNOSIS**
Lack of desire is most difficult type to treat with <50% success. Treatment is most successful with multidisciplinary approach.

CODES
ICD10

- R37 Sexual dysfunction, unspecified
- F52.0 Hypoactive sexual desire disorder
- N94.1 Dyspareunia

CLINICAL PEARLS

- Female sexual dysfunction is a common, complex, multifactorial problem.
- Usually, patients with sexual dysfunction have a normal physical exam.
- Symptoms of sexual dysfunction peak during perimenopause between the ages of 45 and 64 years.
- Combination of behavioral, physical, and medical therapy leads to greater treatment success.
SHOULDER PAIN
Caitlin G. Waters, MD • J. Herbert Stevenson, MD

BASICS

DESCRIPTION
- Shoulder pain commonly affects patients of all ages.
- Causes include acute trauma, overuse during sports, and activities of everyday living.
- Age plays an important role in determining the etiology of shoulder pain.
- Onset and characteristics of pain, weakness, mechanism of injury, and functional limitation help guide an accurate diagnosis.

EPIDEMIOLOGY
- Shoulder pain accounts for 16% of all musculoskeletal complaints.
- The lifetime prevalence of shoulder pain is ~70%.
- Predominant etiology varies with age:
  - <30 years: shoulder instability
  - 30 to 60 years: rotator cuff (RTC) disorder, impingement tendinopathy, partial tears
  - >60 years: full-thickness tear, glenohumeral OA

Incidence
The incidence of shoulder pain is 7 to 25 cases/1,000 patients, with a peak incidence in the 4th to 6th decades.

ETIOLOGY AND PATHOPHYSIOLOGY
Pathology varies with cause:
- Trauma—fracture, dislocation, ligament/tendon tear, acromioclavicular (AC) separation
- Overuse—RTC pathology, biceps tenosynovitis, bursitis, muscle strain, apophyseal injuries
- RTC disorders most commonly result from repetitive overhead activity, leading to RTC impingement with a three-stage progression:
  - Stage I: tendinopathy
  - Stage II: partial RTC tear
– Stage III: full-thickness RTC tear
● Subacromial bursitis can occur with RTC disorders but is rarely an isolated diagnosis.
● Age-related: In pediatric athletes, instability and physeal injuries are more common. With increasing age, the incidence of AC and glenohumeral joint OA, adhesive capsulitis, and RTC tear rises.
● Rheumatologic: rheumatoid arthritis, polymyalgia rheumatica, fibromyalgia
● Referred pain: neck, gallbladder

RISK FACTORS
● Repetitive overhead activity
● Overhead and upper extremity weight-bearing sports (baseball, softball, swimming, tennis, volleyball)
● Weight lifting: AC joint disorders
● Rapid increases in training frequency or load (often associated with improper technique)
● Muscle weakness or imbalance
● Trauma or fall onto the shoulder
● Diabetes, thyroid disorders and other autoimmune diseases, female gender, and age 40 to 60 years are risk factors for adhesive capsulitis.

GENERAL PREVENTION
● Maintain strength and range of motion (ROM).
● Avoid repetitive overhead activities (pitch counts).
● Proper technique (pitching, weight lifting)

 DIAGNOSIS
HISTORY
● Pain characteristics location:
  – Superior: AC pathology, trapezius strain
  – Lateral/deltoid pain: RTC pathology
  – Diffuse pain: RTC pathology, adhesive capsulitis, glenohumeral OA
● Descriptors:
  – Night pain, laying on affected side: RTC pathology, adhesive capsulitis, glenohumeral OA
  – Stiff shoulder: adhesive capsulitis, glenohumeral OA
• Aggravating movements:
  – Cross-body adduction, “scarf test”: AC pathology
  – Abduction/external rotation (reaching behind): instability, RTC pathology, glenohumeral OA
  – Overhead activity: RTC pathology, AC pathology, labrum pathology, glenohumeral OA
  – Turning neck, pain past elbow: cervical pathology
• Mechanism of injury
  – Forceful external rotation: traumatic shoulder instability/dislocation
  – Fall directly onto lateral shoulder: AC joint sprain, clavicular fracture
  – Repetitive overhead activity: RTC pathology
  – Fall on outstretched hand (FOOSH): shoulder separation; forearm/wrist fracture
• Age
  – Shoulder instability (subluxation, dislocation, multidirectional instability) is the most common cause of shoulder pain in young athletes (<30 years old).
  – RTC disorders are the most common cause of shoulder pain in patients >30 years old. Severity of RTC disorder increases with age.
  – Older patients (>60 years old) commonly have OA.
  – Trauma in a young person <40 years is more commonly associated with dislocation/subluxation. In patients >40 years, trauma is more commonly associated with RTC tear.

PHYSICAL EXAM
• Three main joints combine to create the shoulder: glenohumeral, AC, sternoclavicular.
• Four RTC muscles/tendons (SITS): supraspinatus (abduction), infraspinatus (external rotation), teres minor (external rotation, adduction), and subscapularis (adduction, internal rotation)
• Observe face and shoulder movements as patient disrobes, moves arm, and shakes hand.
• Inspect for malalignment, muscle atrophy, asymmetry, erythema, ecchymosis, and swelling. Scapular winging suggests long thoracic nerve or muscular (trapezius, serratus anterior) dysfunction. Prominent scapular spine with scalloped infraspinatus fossa suggests infraspinatus atrophy.
• Palpate SC joint, AC joint, acromion, biceps tendon for tenderness, warmth, bony step-offs.
• Evaluate active AND passive ROM and flexibility.
• Decreased active AND passive ROM are more common with adhesive
capsulitis. Normal abduction is to 180 degrees.

- Pain from 60 to 180 degrees suggests subacromial impingement; 120 to 180 degrees suggests AC joint pathology (1).
- Mildly decreased active and/or passive ROM may also indicate glenohumeral OA.
- Decreased active, full passive ROM: RTC pathology
- Evaluate for muscle strength, including grip, biceps, triceps, and deltoid.
- Test RTC strength: supraspinatus (empty can test), infraspinatus/teres minor (resisted external rotation, external lag test), subscapularis (lift-off test, belly press, resisted internal rotation).
- Pain with RTC strength testing indicates RTC pathology. Weakness could suggest tear.
- Special diagnostic tests
  - Neer RTC impingement test: Examiner internally rotates the patients arm and forcefully moves the arm through the full range of forward flexion or until reports of pain.
  - Hawkins RTC impingement test: Examiner forcefully moves the patient’s shoulder into internal rotation to the end or ROM or until reports of pain.
  - Drop-arm test for RTC tear: positive if patient is unable to smoothly control the lowering of their arm or to hold the arm in 90 degrees of abduction
  - Cross-arm adduction is painful in AC joint arthritis.
  - Speed, Yergason tests for biceps tendinopathy: With arm 30 degrees of flexion and palm supinated, patient attempts to flex the elbow against resistance. Pain over biceps is positive.
  - Apprehension, relocation test for anterior glenohumeral joint instability: Examiner supports the elbow of the patient and with the other hand holding the wrist, slowly externally rotates the humerus, patient apprehensive with maneuver.
  - Sulcus sign for inferior glenohumeral joint instability: Examiner pulls down with the hand grasping the subject’s elbow, positive if significant inferior movement of the arm, relative to shoulder.
  - O’Brien, clunk test for labral pathology: performed with arm at 90 degrees of flexion, 10 degrees of adduction, thumb pointed down, examiner resists flexion distally. Pain/clicking is positive.
  - Spurling test for cervical pathology: Lateral extension of neck with applied downward pressure to reproduce radicular symptoms is positive.

DIFFERENTIAL DIAGNOSIS

- Fracture (clavicle, humerus, scapula), contusion
RTC disorder: impingement, tear, calcific tendonitis
Subacromial bursitis
Scapulothoracic dyskinesis
AC joint pathology (AC separation/OA, osteolysis)
Biceps tenosynovitis or tear
Acromial apophysitis or os acromiale
Glenohumeral joint OA
Glenohumeral joint instability (acute dislocation or chronic multidirectional instability)
Adhesive capsulitis
Labral tear or associated bony pathology
Muscle strain (trapezius, deltoid, biceps)
Cervical radiculopathy
Other: autoimmune, rheumatologic, referred pain, septic joint (biliary/splenic, cardiac, pneumonia/lung mass)

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
- Shoulder pain can be accurately diagnosed with a careful history and physical exam. Symptoms should be evaluated in the context of the patient as a whole.
- A history of significant trauma, prolonged symptoms, or red flags (older age, fever, rest pain) suggests a need for imaging.
- Adults with nontraumatic shoulder pain of <4 weeks duration may not require initial imaging.
- Plain radiographs are first line:
  - Assess for fracture, degenerative changes, signs of dislocation (Bankart, Hill-Sachs deformity), signs of large RTC tear (sclerosis, proximal migration of humeral head), anatomic deformities contributing to impingement, and masses (tumor, cyst).
  - Standard views: anteroposterior, scapular Y, axillary
- EMG study of the upper extremity may help differentiate referred cervical pain and brachial plexopathy from a primary shoulder disorder.
- Obtain ECG if any suspicion for cardiac etiology.
- Serologic tests if autoimmune etiology is suspected.

**Follow-Up Tests & Special Considerations**
- CT scan can rule out occult fracture.
- MRI is gold standard for noninvasive soft tissue imaging, including RTC,
biceps tendon.
- MR arthrogram may be necessary to assess for labral tears or small/partial RTC tears.
- Ultrasound (US) helps assess RTC tears, biceps tendinopathies, and AC joint disorders.
- US is operator-dependent but in the hands of a good technician can be equivalent to MRI in detecting full-thickness tears (sensitivity 92%, specificity 94%) and partial-thickness tears (sensitivity 67%, specificity 94%) (1).

**Diagnostic Procedures/Other**
Consider diagnostic arthroscopy after noninterventional means have been exhausted if structural injury is suspected.

**Test Interpretation**
- Tendinosis rather than tendonitis is common with stage I impingement.
- Capsular scarring is the hallmark of adhesive capsulitis.
- RTC tendon calcifications with calcific tendonitis
- Tear enlargement and pain development in asymptomatic tears are more common with involvement of the dominant shoulder.

**TREATMENT**
- Treatment is based on underlying diagnosis.
- In general, conservative therapy includes activity modification, analgesics, and/or anti-inflammatory medicines in association with appropriate rehabilitative programs.
- Physical therapy almost always required for full resolution

**MEDICATION**

**First Line**
- Analgesics and anti-inflammatory medications for symptomatic relief:
  - Ibuprofen: 200 to 800 mg TID
  - Naproxen: 250 to 500 mg BID
  - Acetaminophen: not to exceed 3 g/day
- Corticosteroid injections (subacromial, glenohumeral, AC, subscapular bursa) can be used to acutely relieve pain due to RTC pathology, adhesive capsulitis,
OA, or scapulothoracic dyskinesis (2)[A].

- Steroid injections can improve ability to engage in rehabilitative activities.
- US guidance improves accuracy of anatomic placement of corticosteroid injections; long-term outcomes similar between US-guided versus nonguided versus NSAID; use after 6 to 8 weeks.

ISSUES FOR REFERRAL

- If etiology remains unclear, patient is not responsive to conservative care, for complicated or displaced fractures.
- Full-thickness RTC tears >1 cm (acute or chronic) in patients <65 years old or any tear with significant changes in functional status require surgical referral. These tears have a high rate of progression, fatty infiltration, or retraction with nonoperative care (3).

ADDITIONAL THERAPIES

- Physical therapy can benefit persistent RTC disorders, adhesive capsulitis, and shoulder instability.
- Manual therapy and exercises may improve pain and increase function in RTC disease.
- Manual manipulative therapy (MMT) by chiropractors, osteopathic physicians, or physical therapists improves pain with adhesive capsulitis, RTC, and soft tissue disorders. In adhesive capsulitis, MMT is generally less effective than glucocorticoid injections at 6-week mark, but both have similar long-term outcomes. Acupuncture may improve short-term pain and function in RTC impingement (4)[A].

SURGERY/OTHER PROCEDURES

- Surgery is recommended for shoulder pain caused by acute displaced fractures, large RTC tears (criteria as above). It also may be advised for multiple shoulder dislocation in patients <20 years of age.
- Surgery can be considered for shoulder pain unresponsive to conservative measures >3 to 6 months. Surgery is not more effective than active nonsurgical treatment in impingement syndrome (5)[A].
- Platelet-rich therapies need more conclusive evidence before routine use in treatment of MSK soft tissue injuries.

COMPLEMENTARY & ALTERNATIVE MEDICINE
Acupuncture may help with acute shoulder pain. There is no conclusive evidence for the effectiveness of acupuncture.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
Limit overhead activity to reduce impingement symptoms.

**PATIENT EDUCATION**
Refer to specific diagnosis for shoulder pain.

**PROGNOSIS**
Shoulder pain generally has a favorable outcome with conservative care, but recovery can be slow, with 40–50% of patients complaining of persistent pain or recurrence at 12 months.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

**ICD10**
- M25.519 Pain in unspecified shoulder
- S43.429A Sprain of unspecified rotator cuff capsule, init encntr
- M19.019 Primary osteoarthritis, unspecified shoulder

**CLINICAL PEARLS**

- RTC disorders (tendinopathy, tears) are the most common cause of shoulder pain in individuals >30 years of age.
- Shoulder instability (acute dislocation/subluxation or chronic instability) is the most common source of shoulder pain in individuals <30 years of age.
- Patients with diabetes are at increased risk for adhesive capsulitis.
- Most patients do well with a structured program of pain control and rehabilitation.
BASICS

DESCRIPTION

- Acute sinusitis is a symptomatic inflammation of ≥1 paranasal sinuses of <4 weeks’ duration resulting from impaired drainage and retained secretions accompanied by obstruction, facial pain/pressure/fullness, or both. Because rhinitis and sinusitis usually coexist, “rhinosinusitis” is the preferred term.
- Disease is subacute when symptomatic for 4 to 12 weeks, recurrent acute when ≥4 annual episodes without persistent symptoms in between, and chronic when symptomatic for >12 weeks.
- Uncomplicated rhinosinusitis has no extension of inflammation beyond paranasal sinuses and nasal cavity.
- System(s) affected: head/eyes/ears/nose/throat (HEENT), pulmonary

EPIDEMIOLOGY

- Affects one in eight adults accounting for >30 million individuals in the United States each year diagnosed with rhinosinusitis
- Diagnosis of acute bacterial rhinosinusitis remains the fifth leading reason for prescribing antibiotics.
- 0.5–2% of viral rhinosinusitis episodes have a bacterial superinfection.
- Viral cause in 90–98% of cases

Incidence

Incidence is highest in early fall through early spring (related to incidence of viral upper respiratory infection [URI]). Adults have two to three viral URIs per year; 90% of these colds are accompanied by viral rhinosinusitis. It is the fifth most common diagnosis made during family physician visits.

ETIOLOGY AND PATHOPHYSIOLOGY

- Important features
  - Inflammation and edema of the sinus mucosa
  - Obstruction of the sinus ostia
  - Impaired mucociliary clearance
• Secretions that are not cleared become hospitable to bacterial growth.
• Inflammatory response (neutrophil influx and release of cytokines) damages mucosal surfaces.
• Viral: vast majority of cases (rhinovirus; influenza A and B; parainfluenza virus; respiratory syncytial; adeno-, corona-, and enteroviruses)
• Bacterial (complicates 0.5–2% of viral cases)
  – More likely if symptoms worsen within 5 to 6 days after initial improvement
  – No improvement within 10 days of symptom onset
  – >3 to 4 days of fever >102°F and facial pain and purulent nasal discharge
  – Streptococcus pneumoniae, Haemophilus influenzae, and Moraxella catarrhalis are the most common bacterial pathogens.
  – Often overdiagnosed, which leads to overuse of and increasing resistance to antibiotics
  – Methicillin-resistant Staphylococcus aureus present in 0–15.9% of patients
• Fungal: seen in immunocompromised hosts (uncontrolled diabetes, neutropenia, use of corticosteroids) or as a nosocomial infection

**Genetics**
No known genetic pattern

**RISK FACTORS**
• Viral URI
• Allergic rhinitis
• Asthma
• Cigarette smoking
• Dental infections and procedures
• Anatomic variations
  – Tonsillar and adenoid hypertrophy
  – Turbinate hypertrophy, nasal polyps
  – Cleft palate
• Immunodeficiency (e.g., HIV)
• Cystic fibrosis (CF)

**GENERAL PREVENTION**
• Hand washing to prevent transmission of viral infection
• Childhood vaccinations up to date
• Avoid close contacts with symptomatic individuals.
Avoid smoking and exposure to second hand smoke.

**DIAGNOSIS**

- History and physical exam suggest and establish the diagnosis but are rarely helpful in distinguishing bacterial from viral causes.
- Use a constellation of symptoms rather than a particular sign or symptom in diagnosis.

**HISTORY**

- Symptoms somewhat predictive of bacterial sinusitis (1)[C]
  - Worsening of symptoms >5 to 6 days after initial improvement
  - Persistent symptoms for ≥10 days
  - Persistent purulent nasal discharge
  - Unilateral upper tooth or facial pain
  - Unilateral maxillary sinus tenderness
  - Fever
- Associated symptoms
  - Headache
  - Nasal congestion
  - Retro-orbital pain
  - Otalgia
  - Hyposmia
  - Halitosis
  - Chronic cough
- Symptoms requiring urgent attention
  - Visual disturbances, especially diplopia
  - Periorbital swelling or erythema
  - Altered mental status

**PHYSICAL EXAM**

- Fever
- Edema and erythema of nasal mucosa
- Purulent discharge
- Tenderness to palpation over sinus(es)
- Pain localized to sinuses when bending forward
- Transillumination of the sinuses may confirm fluid in sinuses (helpful if asymmetric; not helpful if symmetric exam).
**Pediatric Considerations**
- Sinuses are not fully developed until age 20 years. Maxillary and ethmoid sinuses, although small, are present from birth.
- Because children have an average of six to eight colds per year, they are at risk for developing sinusitis.
- Diagnosis can be more difficult than in adults because symptoms are often more subtle.

**DIFFERENTIAL DIAGNOSIS**
- Dental disease
- CF
- Wegener granulomatosis
- HIV infection
- Kartagener syndrome
- Neoplasm
- Headache, tension, or migraine

**DIAGNOSTIC TESTS & INTERPRETATION**
Diagnostic tests are not routinely recommended; no diagnostic tests can adequately differentiate between viral and bacterial rhinosinusitis (2)[C].
- None indicated in routine evaluation
- Routine use of sinus radiography discouraged because of the following:
  - ≥3 clinical findings have similar diagnostic accuracy as imaging.
  - Imaging does not distinguish viral from bacterial etiology.
- Limited coronal CT scan can be useful in recurrent infection or failure to respond to medical therapy.

**Diagnostic Procedures/Other**
Sinus CT if signs suggest extrasinus involvement or to evaluate chronic rhinosinusitis

**Test Interpretation**
- Inflammation, edema, thickened mucosa
- Impaired ciliary function
- Metaplasia of ciliated columnar cells
- Relative acidosis and hypoxia within sinuses
- Polyps
TREATMENT

Most cases resolve with supportive care (treating pain, nasal symptoms). Antibiotics should be reserved for symptoms that persist >10 days, onset with severe symptoms (high fever, purulent nasal discharge, facial pain) for at least 3 to 4 consecutive days, or worsening signs/symptoms that were initially improving (1,2)[C].

GENERAL MEASURES

- Hydration
- Steam inhalation 20 to 30 minutes TID
- Saline irrigation (Neti pot) or nose drops
- Sleep with head of bed elevated.
- Avoid exposure to cigarette smoke or fumes.
- Avoid caffeine and alcohol.
- Antibiotics are indicated only when findings suggest bacterial infection.
- Analgesics, NSAIDs
- Acute viral sinusitis is self-limiting; antibiotics should not be used.

MEDICATION

**First Line**

- Decongestants
  - Pseudoephedrine HCl
  - Phenylephrine nasal spray (limited use)
  - Oxymetazoline nasal spray (e.g., Afrin) (not to be used >3 days)
- Analgesics
  - Acetaminophen
  - Aspirin
  - NSAIDs
- Antibiotics
  
  - Antibiotics have a slight advantage over placebo at 7 to 14 days (3)[A], yet most improve without therapy.
  - Reserve antibiotic use for patients with moderate to severe disease.
  - Choice should be based on understanding of antibiotic resistance in the community.
  - Infectious Disease Society of America recommends the following (1)[C]:
    - Start antibiotics as soon as clinical diagnosis of acute bacterial sinusitis is
made.
  o Use amoxicillin-clavulanate rather than amoxicillin alone.
  o Amoxicillin-clavulanate 875/125 mg q12h; 2 g orally BID in geographic regions with high rates of resistant *S. pneumoniae*
  o Doxycycline: 100 mg PO BID an alternative to amoxicillin-clavulanate for initial therapy (adults only)
  o Trimethoprim-sulfamethoxazole (TMP/SMX) and 3rd-generation cephalosporins not recommended due to high rate of resistance (1)[C]
  o Treat for 5 to 7 days in adults if uncomplicated bacterial rhinosinusitis (IDSA low-moderate-quality evidence). Treat for 10 to 14 days in children if uncomplicated bacterial rhinosinusitis (IDSA low-moderate-quality evidence).
  
  American Academy of Pediatrics recommends the following (1)[C]:
  o Amoxicillin: 45 to 90 mg/kg/day in 2 divided doses if uncomplicated acute bacterial sinusitis in children
  o Amoxicillin-clavulanate: 80 to 90 mg/6.4 mg/kg/day in 2 divided doses for children with severe illness, recent antibiotics, or attending daycare
  o Levofloxacin: 10 to 20 mg/kg/day max 750 mg/day if history of type 1 hypersensitivity to PCN (1)[C]
  o Clindamycin (30 to 40 mg/kg/day) + cefixime (8 mg/kg/day in 2 divided doses) or cefpodoxime (10 mg/kg/day in 2 divided doses) (1)[C] for nontype 1 PCN allergy
  o Ceftriaxone: 50 mg/kg IM single dose if not able to tolerate oral meds (4)[C]

  Because allergies may be a predisposing factor, some patients may benefit from use of the following agents:
  
  Oral antihistamines
  o Loratadine (Claritin), fexofenadine (Allegra), cetirizine (Zyrtec), desloratadine (Clarinex), or levocetirizine (Xyzal)
  o Chlorpheniramine (Chlor-Trimeton)
  o Diphenhydramine (Benadryl)
  
  Leukotriene inhibitors (Singulair, Accolate), especially in patients with asthma
  
  Nasal steroids (i.e., fluticasone [Flonase])

**Second Line**

  Levofloxacin (Levaquin): 750 mg/day for 5 days or moxifloxacin 400 mg/day for 5 to 7 days (adults only) (1)[C]
  If no response to first-line therapy after 72 hours
– Broaden antibiotic coverage or switch to a different class, evaluate for resistant pathogens or other causes for treatment failure (i.e., noninfectious etiology), fluoroquinolones as above.

*Note:* Bacteriologic failure rates of up to 20–25% are possible with use of azithromycin and clarithromycin.

If lack of response to 3 weeks of antibiotics, consider the following:
– CT scan of sinuses
– Ear/nose/throat (ENT) referral

**ISSUES FOR REFERRAL**
Complications or failure of treatment

**ALERT**
- Meta-analyses have demonstrated no benefit of newer antibiotics over amoxicillin or doxycycline.
- Antibiotics recommendations vary with different guidelines. Patients seen by specialists are different from those in a primary care setting. Patients usually do not have complicated sinusitis in primary care setting.
  – American Academy of Otolaryngology—Head and Neck Surgery Foundation ([2][C]) recommends the following:
    - Consider watchful waiting without antibiotics in patients with uncomplicated mild illness (mild pain and temperature <101°F) with assurance of follow-up within 7 days.
- PCV-13 pneumococcal vaccine can be helpful in reducing chronic sinusitis in children ([5][B]).
- Use of intranasal steroids small but significant improvement in symptoms when used alone or in combination with antibiotics ([6][A])

**Precautions**
– Decongestants can exacerbate hypertension.
– Intranasal decongestants should be limited to 3 days to avoid rebound nasal congestion.

**Pregnancy Considerations**
- Nasal irrigation with saline, pseudoephedrine, most antihistamines, and some nasal steroids are safe during pregnancy and lactation.
- Antibiotics safe in pregnancy and lactation
  – Amoxicillin, amoxicillin-clavulanate, cephalosporins
- Antibiotic contraindicated: doxycycline, fluoroquinolones
- Antibiotic safe in lactation but not pregnancy: levofloxacin
SURGERY/OTHER PROCEDURES
- If medical therapy fails, consider sinus irrigation.
- Functional endoscopic sinus surgery is the preferred treatment for medically recalcitrant cases.
- Absolute surgical indications
  - Massive nasal polyposis
  - Acute complications: subperiosteal or orbital abscess, frontal soft tissue spread of infection
  - Mucocele or mucopyocele
  - Invasive or allergic fungal sinusitis
  - Suspected obstructing tumor
  - CSF rhinorrhea

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
Hospitalization for complications (e.g., meningitis, orbital cellulitis or abscess, brain abscess)

ONGOING CARE
FOLLOW-UP RECOMMENDATIONS
Return if no improvement after 72 hours or no resolution of symptoms after 10 days of antibiotics.

PATIENT EDUCATION

PROGNOSIS
Alleviation of symptoms within 72 hours with complete resolution within 10 to 14 days

COMPLICATIONS
- Serious complications are rare.
- Meningitis, orbital cellulitis, brain abscess
- Cavernous sinus thrombosis
Osteomyelitis, subdural empyema

REFERENCES

ADDITIONAL READING

CODES

ICD10

- J01.90 Acute sinusitis, unspecified
- J01.00 Acute maxillary sinusitis, unspecified
- J01.20 Acute ethmoidal sinusitis, unspecified
CLINICAL PEARLS

- When bacterial infection is present, patients recover somewhat more quickly with antibiotics, but the majority will recover with symptomatic treatment alone, and accurate diagnosis of bacterial sinusitis is very difficult.
- Multiple meta-analyses have demonstrated no benefit of newer antibiotics over amoxicillin or doxycycline.
- Overall NNT to prevent one persistent case at follow-up = 15; harm due to antibiotic-associated diarrhea is similar.
- Significant patient symptom relief with nasal saline spray or drops or irrigation (Neti pot)
SJÖGREN SYNDROME
Mariya Milko, DO, MS

**BASICS**

- Chronic inflammatory disorder characterized by lymphocytic infiltrates in exocrine organs
- Typically presents with diminished salivary and lacrimal gland function, resulting in sicca symptoms such as dry eyes (xerophthalmia), dry mouth (xerostomia), and parotid enlargement
- Extraglandular manifestations: arthralgia, myalgia, Raynaud phenomenon, pulmonary disease, GI disease, leukopenia, anemia, lymphadenopathy, vasculitis, renal tubular acidosis, lymphoma, CNS involvement with longitudinal transverse myelitis (>4 vertebral segments), and optic neuritis associated with anti–aquaporin-4 antibodies, PNS involvement with small fiber neuropathy
- Primary Sjögren: not associated with other diseases; HLA-DRB1*0301 and HLA-DRB1*1501 are the most common.
- Secondary Sjögren: complication of other rheumatologic conditions, most commonly rheumatoid arthritis; associated with HLA-DR4
- First described by Swedish ophthalmologist Henrik Sjögren (1899 to 1986)

**EPIDEMIOLOGY**

**Incidence**
Annual incidence: ~4/100,000. Primary Sjögren syndrome (SS) is one of the most common autoimmune diseases, affecting 1–4% of population.
- All races are affected.
- Predominant sex: female > male (9:1)
- Predominant age: can affect patients of any age but is most common in the elderly; onset typically in the 4th to 5th decades of life

**Prevalence**
SS affects 1 to 4 million people in the United States.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Multifactorial systemic autoimmune process characterized by infiltration of
glandular tissue by CD4 T lymphocytes

- Theorized that glandular epithelial cells present antigen to the T cells inducing cytokine production. There is also evidence for B-cell activation, resulting in autoantibody production and an increased incidence of B-cell malignancies.
- Etiology is unknown. Estrogen may play a role because SS is more common in women. Exogenous factors such as viral proteins (EBV, HCV, HTLV-1) have also been implicated.

**Genetics**
- A familial tendency suggests a genetic predisposition.
- Associations in the HLA regions *HLA-DQA1*0501, *HLA-DQB1*0201, and *HLA-DRB*0301 are the strongest genetic risk factors for SS.

**RISK FACTORS**
There are no known modifiable risk factors.

**GENERAL PREVENTION**
- No known prevention. Complications can be prevented by early diagnosis and treatment.
- Oral health providers play a key role in early detection and management of salivary dysfunction (1)[C].

**COMMONLY ASSOCIATED CONDITIONS**
Secondary SS associated with rheumatoid arthritis, scleroderma, systemic lupus erythematosus (SLE), polymyositis, HIV, hepatitis C, MCTD, PBC, hypergammaglobulinemic purpura, necrotizing vasculitis, autoimmune thyroiditis, chronic active hepatitis, mixed cryoglobulinemia

**Pregnancy Considerations**
Pregnant SS patients with anti-SSA Abs have increased risk of delivering fetus with skin rash and 3rd-degree heart block.

**DIAGNOSIS**
- 2016 ACR/EULAR classification criteria (2)[A]:
  - New classification criteria is based on five objective tests/items.
  - Patients with signs and/or symptoms suggestive of SS (the inclusion criteria is applicable if the patient is positive for one ocular/oral dryness symptom
based on the AECG questions or at least one positive domain from the EULAR SS disease activity index questionnaire) and a total score of ≥4 from the following meet criteria for primary SS.

- Positive serum anti-SSA/Ro antibody—3 points
- Focal lymphocytic sialadenitis with a focus score ≥1 foci/4 mm² from labial salivary gland biopsy—3 points.
- Abnormal ocular staining score of ≥5, or van Bijsterveld score of ≥4—1 point
- Schirmer test result of ≤5 mm/5 min—1 point
- An unstimulated salivary flow rate of ≤0.1 mL/min—1 point

- Ocular signs and symptoms
  - Troublesome dry eyes daily for ≥3 months
  - Recurrent sandy/gritty ocular sensation
  - Use of tear substitute ≥3 times per day

- Oral signs and symptoms
  - Daily symptoms of dry mouth for ≥3 months
  - Recurrent feeling of swollen salivary glands
  - Need to drink liquid to help swallow dry foods

- Other manifestations: chronic arthritis, type 1 RTA, tubular interstitial nephritis, rheumatoid arthritis, vasculitis, vaginal dryness, pleuritis, pancreatitis

**HISTORY**

- Decreased tear production; burning, scratchy sensation in eyes
- Difficulty speaking/swallowing, dental caries, xerotrachea
- Enlarged parotid glands or intermittent swelling (bilateral)
- Dyspareunia; vaginal dryness

- From consensus criteria and EULAR questionnaire:
  - (1) Have you had daily, persistent, troublesome dry eyes for >3 months?
  - (2) Do you have a recurrent sensation of sand or gravel in the eyes?
  - (3) Do you use tear substitutes >3 times a day?
  - (4) Have you had a daily feeling of dry mouth for >3 months?
  - (5) Do you frequently drink liquids to aid in swallowing dry food?

**PHYSICAL EXAM**

- Eye exam: dry eyes (keratoconjunctivitis sicca), decreased tear pool in the lower conjunctiva, dilated conjunctival vessels, mucinous threads, and filamentary keratosis (slit-lamp examination)
Mouth exam: dry mouth (xerostomia); decreased sublingual salivary pool (tongue may stick to the tongue depressor); frequent oral caries (sometimes in unusual locations such as the incisor surface and along the gum line); dark red tongue from prolonged xerostomia
Ear, nose, and throat exam: parotid enlargement, submandibular enlargement
Skin exam: nonpalpable or palpable vasculitic purpura (typically 2 to 3 mm in diameter and on the lower extremities)

Differential Diagnosis

Causes of ocular dryness: hypovitaminosis A, decreased tear production unrelated to autoimmune process, chronic blepharitis or conjunctivitis, impaired blinking (i.e., due to Parkinson disease or Bell palsy), infiltration of lacrimal glands (i.e., amyloidosis, lymphoma, sarcoidosis), low estrogen levels
Causes of oral dryness: anticholinergic medications, sialadenitis due to chronic obstruction, chronic viral infections (i.e., hepatitis C or HIV), radiation of head/neck
Causes of salivary gland swelling: unilateral: obstruction, chronic sialadenitis, bacterial infection, neoplasm; bilateral (asymmetric): IgG4-related disease, HIV bilateral (symmetric): hepatic cirrhosis, DM, anorexia/bulimia, acromegaly, alcoholism, hypolipoproteinemia, chronic pancreatitis, acute or chronic viral infection (i.e., mumps, Epstein-Barr virus [EBV]), coxsackievirus, echovirus, granulomatous diseases (i.e., tuberculosis, sarcoidosis)

Diagnostic Tests & Interpretation

Schirmer test (<5-mm wetness after 5 minutes)
Rose Bengal test (slit lamp)
Minor salivary gland biopsy (gold standard)
Auto antibodies: +ANAs (95%), +RF (75%)
In primary SS: +anti-Ro (anti-SSA, 56%) and +anti-La (anti-SSB, 30%)

Initial Tests (lab, imaging)

Preliminary lab workup

Basic labs: CBC with differential, BUN/creatinine (Cr), AST/ALT, ESR, C-reactive protein (CRP), urinalysis (UA)
Special labs: ANA, rheumatoid factor (RF), anti-Ro/SSA, anti-La/SSB, ESR, CRP
Anti-SSA and anti-SSB antibodies present in 33–74% and 23–52% of SS patients, respectively

Other autoantibodies-muscarinic type 3 receptor (M3R) and anti-α-fodrin are being explored with good specificity (3)[A].

Imaging may include:
- Imaging for xerostomia: salivary gland scintigraphy (insensitive but highly specific)
- Parotid gland sialography (should not be used in acute parotitis)
- MRI (correlates well with salivary gland biopsy)

A novel diagnostic tool is salivary gland US (SGUS) which is noninvasive and highly specific for salivary gland involvement in SS (4)[A].

**Diagnostic Procedures/Other**

- Salivary gland biopsy: used to confirm suspected diagnosis of SS or to exclude other causes of xerostomia and bilateral glandular enlargement
- Parotid biopsy if malignancy is suspected
- Lymph node biopsy to rule out pseudolymphoma or lymphoma if suspected

**Test Interpretation**

- Salivary gland histology shows focal collections of lymphocytes; immunocytology shows CD4+ T-cell lymphocyte predominance.
- SGUS parameters include:
  - Parenchymal nonhomogeneity—the most useful diagnostic marker (4)[A]
  - US inflammatory findings include hypoechoic and hyperechoic bands (4)[A].
  - Real-time sonoelastography (RTS) to quantify tissue rigidity and assess glandular damage (4)[A]

**TREATMENT**

- Treatment is primarily supportive.
- Treat sicca symptoms—dry eyes, dry mouth.
- Avoid medications that may worsen oral dryness (i.e., anticholinergics).
- Promote good oral hygiene.
- Treat systemic manifestations.
- Address fatigue and pain.
MEDICATION

- Therapy for sicca symptoms: artificial tears and ocular lubricants (5)[C]
- Topical therapy for dry mouth: liberally drinking sips of water, sugar-free lemon drops or artificial saliva preparations such as Salivart, Saliment, Xero-Lube, MouthKote
- Immunosuppressive therapy such as hydroxychloroquine can be used for systemic symptoms; however, it has not shown any benefit in relieving refractory sicca symptoms.
- Evoxac (cevimeline) may be prescribed for SS-associated xerostomia. It works by stimulating muscarinic cholinergic receptors to increase salivary gland secretion.
- Dry eyes are graded by severity of symptoms, conjunctival injection and staining, corneal damage, tear quality, and lid involvement. Artificial tears may be used; however, artificial tears with hydroxyethylcellulose or dextran are more viscous and can last longer.
- Acetaminophen or NSAIDs for arthralgias

First Line

- Xerostomia: sugar-free lozenges, especially malic acid, artificial saliva; pilocarpine 5 mg PO QID or cevimeline 30 mg PO TID
- Keratoconjunctivitis sicca: artificial tears and ocular lubricants for symptomatic relief, topical cyclosporine (Restasis), or autologous tears

Second Line

- Xerostomia: Interferon-α lozenges may enhance salivary gland flow.
- Keratoconjunctivitis sicca: topical glucocorticoids or topical NSAIDs (Use with caution.)
- Immunosuppressive therapy: antimalarials (e.g., hydroxychloroquine) for arthralgias, lymphadenopathies, and skin manifestations; may then consider methotrexate or cyclosporine, which showed subjective improvement but no significant objective improvement
- Early studies show improvement in fatigue with rituximab (6)[B].
- For life-threatening extraglandular manifestations, cyclophosphamide (PO or IV), mycophenolate mofetil, and azathioprine are often used.

ISSUES FOR REFERRAL

- Rheumatology to help manage systemic manifestations or resistant symptoms
- Oral health
Ophthalmology, for grading of severity and management of xerophthalmia

ADDITIONAL THERAPIES

- Patients should use vaginal lubricants, such as Replens, for vaginal dryness. Vaginal estrogen creams can help in postmenopausal women. Be alert for and treat vaginal yeast infections.
- Xerostomia: small sips of water, good dental care
- Keratoconjunctivitis sicca: Conserve tears with side shields or ski/swim goggles, humidifiers, and moist washcloths.
- Dehydroepiandrosterone (DHEA) does not offer improvement in fatigue and well-being above placebo.

SURGERY/OTHER PROCEDURES

Keratoconjunctivitis sicca: If refractory to artificial tears, punctal occlusion is the treatment of choice.

COMPLEMENTARY & ALTERNATIVE MEDICINE

- Some studies show acupuncture benefits saliva production and symptoms of xerostomia.
- There is insufficient evidence to determine the effects of electrostimulation devices on dry mouth symptoms or saliva production in patients with SS.

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS

May be required for extraglandular manifestations, such as cardiopulmonary disease, renal involvement, and CNS manifestations (e.g., optic neuritis, transverse myelitis, vasculitis, or ischemic stroke)

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

Frequency of follow-up depends on severity.

Patient Monitoring

- Monitor for complications, systemic manifestations, and relief of symptoms.
• Medicolegal pitfalls: Monitor for parotid tumor or lymphoma.

PATIENT EDUCATION
In most cases, simple measures are adequate: humidifiers, sips of water, chewing gum, or artificial tears.

PROGNOSIS
• Hypocomplementemia is an independent risk factor for premature death.
• Primary SS is associated with increased risks of malignancy, non-Hodgkin lymphoma, and thyroid cancer.

COMPLICATIONS
Complications include dental caries, gum disease, dysphagia, salivary gland calculi, keratitis, conjunctivitis, and scarring of the ocular surface.

REFERENCES
CODES

ICD10
- M35.00 Sicca syndrome, unspecified
- M35.02 Sicca syndrome with lung involvement
- M35.09 Sicca syndrome with other organ involvement

CLINICAL PEARLS
- Many symptoms of SS can be treated with simple interventions such as artificial tears and sugar-free lozenges.
- Consider lacrimal duct plugs for dry eyes.
- Consider SS in patients with unexplained lung disease and +ANA.
- Patients with primary SS may have an increased incidence of celiac disease.
SLEEP APNEA, OBSTRUCTIVE

Elizabeth Kardas, MD • Jeremy Golding, MD, FAAFP

BASICS

DESCRIPTION
- Obstructive sleep apnea (OSA) is defined as repetitive episodes of cessation of airflow (apnea) through the nose and mouth during sleep due to obstruction at the level of the pharynx.
  - Apneas often terminate with a snort/gasp.
  - Repetitive apneas produce sleep disruption, leading to excessive daytime sleepiness (EDS).
  - Associated with oxygen desaturation and nocturnal hypoxemia
  - Usual course is chronic.
- System(s) affected: cardiovascular; nervous; pulmonary
- Synonym(s): sleep apnea syndrome; nocturnal upper airway occlusion

EPIDEMIOLOGY

Incidence
- Predominant age: middle-aged men and women
- Predominant sex: male > female (2:1)

Prevalence
- Up to 15% in men, 5% in women
- Prevalence is higher in obese/hypertensive patients.

ETIOLOGY AND PATHOPHYSIOLOGY
OSA occurs when the naso- or oropharynx collapses passively during inspiration. Anatomic and neuromuscular factors contribute to pharyngeal collapse which leads to hypoxic arousal.
- Anatomic abnormalities, such as increased soft tissue in the palate, tonsillar hypertrophy, macroglossia, and craniofacial abnormalities, predispose the airway to collapse by decreasing the area of the upper airway or increasing the pressure surrounding the airway.
- During sleep, decreased muscle tone in the naso- or oropharynx contributes to
airway obstruction and collapse.
- Upper airway narrowing may be due to the following:
  - Obesity, redundant tissue in the soft palate
  - Enlarged tonsils/uvula
  - Low soft palate
  - Large/posteriorly located tongue
  - Craniofacial abnormalities
  - Neuromuscular disorders
  - Alcohol/sedative use before bedtime

**RISK FACTORS**
- Obesity (strongest risk factor)
- Age >40 years
- Alcohol/sedative intake before bedtime
- Smoking
- Nasal obstruction (due to polyps, rhinitis, or deviated septum)
- Anatomic narrowing of nasopharynx (e.g., tonsillar hypertrophy, macroglossia, micrognathia, retrognathia, craniofacial abnormalities)
- Acromegaly
- Hypothyroidism
- Neurologic syndromes (e.g., muscular dystrophy, cerebral palsy)

**GENERAL PREVENTION**
Weight control and avoidance of alcohol and sedatives at night can help to prevent airway collapse.

**COMMONLY ASSOCIATED CONDITIONS**
- Common
  - Hypertension
  - Obesity
  - Daytime sleepiness
  - Metabolic syndrome
- Rare
  - Cardiac arrhythmias
  - Cardiovascular disease
  - Congestive heart failure
  - Pulmonary hypertension
  - Nasal obstructive problems
DIAGNOSIS

HISTORY

- Elicit a complete history of daytime and nighttime symptoms. Symptoms can be insidious and may have been present for years.
- Daytime symptoms
  - EDS or fatigue (cardinal symptom) (1)
    - Mild symptoms are those that occur during quiet activities (e.g., reading, watching television).
    - More severe symptoms are those that occur during dynamic activities (e.g., work, driving).
  - Tired on morning awakening “nonrestorative sleep”
  - Sore/dry throat
  - Poor concentration, memory problems, irritability, mood changes, behavior problems (in children)
  - Morning headaches
  - Decreased libido
  - Depression
- Nighttime symptoms
  - Loud snoring (present in 60% of people with OSA)
  - Snort/gasp that arouses patient from sleep but not usually to full consciousness
  - Disrupted sleep
  - Witnessed apneic episodes at night

Screening—the USPSTF found (2017) that there is insufficient evidence to screen for OSA in asymptomatic adults or in adults with unrecognized symptoms (2)[A]. The USPSTF found no studies that evaluated the effect of screening for OSA on health outcomes.

PHYSICAL EXAM

- OSA is commonly associated with obesity. It is unlikely to be found in those with normal body weight who do not snore (1).
- Focused head and neck exam
  - Short neck with large circumference
  - Oropharynx
    - Narrowing of the lateral airway wall
    - Tonsillar hypertrophy
    - Macroglossia
Micrognathia/retrognathia
- Soft palate edema
- Long/thick uvula
- High, arched hard palate
- Nasopharynx
- Deviated nasal septum
- Poor nasal airflow

**DIFFERENTIAL DIAGNOSIS**

- Other causes of EDS such as the following:
  - Narcolepsy
  - Idiopathic daytime hypersomnolence
  - Inadequate sleep time
  - Depressive episodes with EDS
  - Periodic limb movements disorder

- Respiratory disorders with nocturnal awakenings such as the following:
  - Asthma
  - Chronic obstructive pulmonary disease
  - Congestive heart failure

- Central sleep apnea (respiratory effort is absent as compared to OSA where effort is present)

- Sleep-related choking/laryngospasm
- Gastroesophageal reflux
- Sleep-associated seizures (temporal lobe epilepsy)

**DIAGNOSTIC TESTS & INTERPRETATION**

*Initial Tests (lab, imaging)*

- When clinically indicated
  - Thyroid-stimulating hormone to evaluate hypothyroidism
  - CBC to evaluate anemia and polycythemia, which can indicate nocturnal hypoxemia
  - Fasting glucose in obesity to evaluate for diabetes
  - Rare: arterial blood gases to evaluate daytime hypercapnia

- Cephalometric measurements from lateral head and neck radiographs aid in surgical treatment.

*Diagnostic Procedures/Other*

- The gold standard for OSA is a full-night, in-laboratory polysomnography
(PSG), a nighttime sleep study (1)[A].

- Demonstrates severity of hypoxemia, sleep disruption, and cardiac arrhythmias associated with OSA and elevated end-tidal CO$_2$
- Shows repetitive episodes of cessation/marked reduction in airflow despite continued respiratory efforts
- Apneic episodes must last at least 10 seconds and occur 10 to 15 times per hour and cause decreased oxygen saturation to be considered clinically significant.
- Complete PSG is expensive, and health insurance may not cover the cost.

- Multiple sleep latency testing is a diagnostic tool used to measure the time it takes from the start of a daytime nap period to the first signs of sleep (sleep latency). It provides an objective measurement of daytime sleepiness.
- The apnea-hypopnea index (AHI) is defined as the total number of apneas and hypopneas divided by the total sleep time in hours.
  - Mild OSA: AHI = 5 to 15
  - Moderate OSA: AHI = 15 to 30
  - Severe OSA: AHI >30
- Split-night PSG (as compared to a full-night PSG) occurs when patients are diagnosed with OSA within the first part of the night and then they can initiate positive pressure device titration during the second half of the night.
- Drugs that may alter the test results include benzodiazepines and other sedatives that can amplify the severity of apnea seen during the sleep study.
- Early data suggest that home-based diagnosis using portable monitoring devices may be an alternative to laboratory-based PSG if the test is of sufficient duration (3)[B].

## TREATMENT

- Lifestyle modification is the most frequently recommended treatment for mild to moderate OSA. This includes weight loss, exercise, and avoidance of alcohol, smoking, and sedatives, especially before bedtime.
- Weight loss—shown to decrease the severity of symptoms in obese patients. Lifestyle modifications should be seen as adjunctive rather than curative therapy (4)[A], and a lack of improvement of symptoms with lifestyle modification should not preclude patients from receiving other therapy such as continuous positive airway pressure (CPAP).
- Position changes—if OSA is present only when supine, keep the patient off
his or her back when sleeping (e.g., tennis ball worn on back of nightshirt or using a sleep position trainer).

- Positive airway pressure—the most effective therapy for mild, moderate, or severe OSA is CPAP (5)[A]. Treatment with CPAP uses a mask interface and a flow generator to prevent airway collapse, thus helping to prevent apnea, hypoxia, and sleep disturbance. Compared with inactive controls, CPAP significantly improves both objective (24-hour systolic and diastolic blood pressures) and subjective measures (Epworth Sleepiness Scale) in OSA patients with symptoms of daytime sleepiness. CPAP may also decrease the risk for atherosclerosis as well as improves insulin resistance in nondiabetic patients. Early data show that these benefits may not be seen in patients who do not have symptoms of daytime sleepiness.

- Several types of mask interfaces, including nasal masks, oral masks, and nasal pillows exist for CPAP therapy. Short-term data suggest that nasal pillows are the preferred interface in almost all patients. In patients with compliance difficulty, a different choice of interface may be appropriate.

- Oral appliances to treat OSA are available and often subjectively preferred by patients (mandibular advancement devices vs. tongue retaining devices). Although oral appliances have been shown to improve symptoms compared with inactive controls, they are not as effective for reduction of respiratory disturbances as CPAP over short-term data. Treatment with oral appliances may be considered in patients who fail to comply with CPAP therapy.

**MEDICATION**
Medications are yet to be proven effective in treating OSA. Further studies in this area are needed.

**First Line**
Some short-term data found fluticasone nasal spray, mirtazapine, physostigmine, and nasal lubricant of some benefit; longer term studies needed

**ISSUES FOR REFERRAL**
If sleep apnea is suspected, patient should be referred for a sleep study evaluation.

**SURGERY/OTHER PROCEDURES**
Surgical corrections of the upper airway include alteration of the uvula and/or palate such as uvulopalatopharyngoplasty (UPPP), tracheostomy, and
craniofacial surgery. Currently, no evidence supports the use of surgery for the treatment of OSA (6)[A].

ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS
On admission, patients should continue to use CPAP/dental devices if they do so at home. They should bring in their own appliance and know their CPAP settings.

ONGOING CARE
Lifelong compliance with weight loss or CPAP is necessary for successful OSA treatment.

DIET
Overweight and obese patients should be encouraged to lose weight, and all patients must avoid weight gain. Weight loss alone could reduce symptoms of OSA.

PATIENT EDUCATION
- Weight loss and avoidance of alcohol and sedatives may reduce OSA symptoms particularly in severe cases.
- Significantly sleepy patients should not drive a motor vehicle/operate dangerous equipment.

PROGNOSIS
- EDS is reduced dramatically with appropriate apnea control.
- Lifelong compliance with weight loss or CPAP is necessary for effective treatment of OSA, but long-term adherence is poor.
- If untreated, OSA is progressive.
- Significant morbidity and mortality with OSA usually due to motor vehicle accidents or are secondary to cardiac complications, including arrhythmias, cardiac ischemia, and hypertension. Data insufficient on whether identification and treatment changes outcomes.

COMPLICATIONS
Untreated OSA may increase the risk for development of hypertension, stroke,
myocardial infarction, diabetes, cardiovascular disease, and work-related and driving accidents, but it is unclear that treatment reduces or prevents any of these problems.

**Pediatric Considerations**

- The prevalence of pediatric OSA is 1–2% in children 4 to 5 years of age, and the peak incidence is between 3 and 6 years of age.
- Predominant sex: male = female
- Etiology: The most common cause is tonsillar hypertrophy. Additional causes are obesity and craniofacial abnormalities. OSA is also seen in children with neuromuscular diseases, such as cerebral palsy and spinal muscular atrophy, due to abnormal pharyngeal muscle control.
- Signs and symptoms
  - Nighttime: loud snoring, restlessness, and sweating
  - Daytime: hyperactivity and decreased school performance
  - EDS is not a significant symptom.
- Diagnosis: Gold standard is PSG. (PSG may be an even better tool in children due to lessened night-to-night variation. There is a lack of studies showing efficacy of home-based diagnostic studies vs. PSG in children.) Abnormal AHI is different in children: >1 to 2/hr is abnormal.
- Treatment: Surgery is the first-line treatment in cases due to tonsillar enlargement (reduces symptoms in 70%). Some data suggest improved academic performance if tonsillectomy is performed for OSA. For cases due to obesity/craniofacial abnormalities, patients can use CPAP treatment.

**Geriatric Considerations**

The presence of sleep apnea in the geriatric population may be associated with earlier onset of mild cognitive impairment as well as Alzheimer dementia at an earlier age. The rate of decline of cognitive function may be slowed by the usage of CPAP.

**REFERENCES**

**ADDITIONAL READING**

**CODES**

*ICD10*
CLINICAL PEARLS

- OSA is characterized by repetitive episodes of apnea often terminating in a snort/gasp.
- Laboratory PSG is the key to diagnosis.
- CPAP is the most effective form of treatment for both mild to moderate and moderate to severe OSA.
- Central sleep apnea may mimic OSA.
SLEEP DISORDER, SHIFT WORK
Ronald G. Chambers Jr., MD, FAAFP • Cindy J. Chambers, MD, MAS, MPH

BASICS

DESCRIPTION

- The human system relies on a circadian rhythm coordinated by the suprachiasmatic nucleus (SCN), an endogenous clock in the hypothalamus that links the nervous system to the endocrine system (1).
- A shift in work schedule can desynchronize this circadian pacemaker.
- The major environmental factor disrupting or resetting the circadian rhythm is light at night (LAN) (1).
- Shift work disorder (SWD), classified as a circadian rhythm sleep disorder, is caused by a misalignment between the internal circadian rhythm and the required sleep–wake schedule due to erratic or nighttime shift work (2).
- Diagnostic criteria for SWD require all criteria for circadian rhythm disorder in addition to:
  - Criteria for circadian rhythm disorder:
    - Persistent/recurrent sleep disruption due to either an alteration in the circadian (24-hour) timekeeping system or misalignment between endogenous circadian rhythm and exogenous factors that affect sleep
    - Insomnia/excessive daytime sleepiness or both
    - Impairment in occupational, educational, or social functioning
  - Criteria for SWD:
    - Insomnia/excessive sleepiness, accompanied by reduced sleep time, associated with a recurring work schedule that overlaps with the usual time for sleep
    - Symptoms associated with shift work schedule are present for at least 3 months.
    - Sleep log or actigraphy monitoring (with sleep diaries) for at least 14 days demonstrates disturbed sleep (insomnia) and circadian and sleep-time misalignment.
    - Sleep disturbance is not due to another current sleep disorder, mental disorder, medical disorder, substance use disorder, or medication use.
Epidemiology

Prevalence
- Shift work includes night shifts, evening shifts, or rotating shifts. Approximately 15–25% of the workforce in the United States are shift workers (2).
- SWD has been estimated to affect 10–23% of 22 million American shift workers, with a prevalence estimate of approximately 2–5% of the general population (14% night shift workers and 8% of rotating shift workers) (3).

Pathophysiology
- Circadian rhythms are present in multiple biologic functions, including body temperature, hormone levels, blood pressure, metabolism, cellular regeneration, sleep–wake cycles, and DNA transcription and translation (2).
- Transcription factors involved in circadian rhythms (the “molecular clock”) control production of many proteins expressed with a periodicity of approximately 24 hours. This molecular clock is self-sustaining and requires a daily reset or it may become out of sync with environmental cues (zeitgebers) (2).
- The most powerful zeitgeber (timekeeper) is light. Light transmitted from the retinohypothalamic tract of the eye to the SCN of the hypothalamus upregulates the production of the “clock gene” (PER) (2).
- Periods of darkness cause the SCN to induce melatonin release from the pineal gland, which can also help to reset the molecular clock (2).
- A dyssynchrony between the endogenous molecular clock and external cues (most notably light/dark cycles) is responsible for circadian rhythm disorders and can impact both physical and mental health (2).

Risk Factors
- Shift work, including night shifts, early morning shifts, or rotating shifts
- Younger age and “eveningness” (a.k.a. “night owls”) may protect against the development of SWD (2).

Genetics
No genetic predisposition has been described.

General Prevention
- Limit rotating shifts.
Use bright light during shifts.
Schedule brief (10- to 20-minute) naps during shifts, if possible.

COMMONLY ASSOCIATED CONDITIONS
- Shift workers often have impaired immediate free recall, decreased processing speed, and selective attention impairments that may worsen with longer duration of shift work (2).
- Shift workers also have a higher risk of vehicular accidents, job-related injuries, absenteeism, and quality control errors (2).
- SWD has been associated with gastrointestinal (GI) disease, specifically peptic ulcer disease, cardiovascular disease (CVD), ischemic stroke, infertility, mood disorders, and pregnancy complications (2,4).
- There is also a possible increased risk of breast and prostate cancer. The International Agency for Research on Cancer (IARC) has classified shift work involving a circadian disruption as a probable carcinogen (1).

DIAGNOSIS
Primarily a clinical diagnosis. There are some useful diagnostic aids.

HISTORY
- A careful history is critical. Assess for difficulty falling asleep, staying asleep, or nonrestorative sleep.
- Note the following in particular (5)[C]:
  - Sleep/wake habits
  - Degree of alertness or sleepiness
  - Sleep environment
  - Light exposure before, during, and after the shift
  - Job-related factors: length of shift, number of consecutive shifts, commute after shift
  - Medications and over-the-counter (OTC) stimulants such as caffeine or energy drinks
  - Impact on social and domestic responsibilities (including drowsy driving)
- Evaluate for symptoms of other sleep disorders, which often coexist and can exacerbate SWD such as the following:
  - Loud snoring and pauses in breathing during sleep (obstructive sleep apnea [OSA])
  - Sudden sleep attacks and leg symptoms (restless legs syndrome [RLS])
– Falling asleep at inappropriate times, drop attacks, and daytime fatigue (narcolepsy)

**PHYSICAL EXAM**
Evaluate for depression, GI disease, CVD, and potential cancer risk as well as signs of OSA such as obesity, a large neck, and a tight oropharynx (5)[C].

**DIFFERENTIAL DIAGNOSIS**
- Other primary sleep disorders: OSA, RLS, narcolepsy, and psychophysiologic insomnia
- Other circadian rhythm sleep disorders such as delayed sleep phase disorder or jet lag syndrome. Distinguishing among these can be challenging.

**DIAGNOSTIC TESTS & INTERPRETATION**
Given possible increased risk; screen for CVD and cancer among shift workers.

**Initial Tests (lab, imaging)**
Fasting lipid panel, fasting glucose, age-appropriate cancer screenings

**Diagnostic Procedures/Other**
- A sleep/wake diary recording the patient’s sleep/wake habits, amount of sleep, naps during waking hours, and mood (1 to 2 weeks) (5)[C]
- Actigraphy (a mechanical device, often worn on the arm/leg, to measure movement) serves as a gross measure of time and amount of activity and rest (5)[C].
- Polysomnography measures sleep duration and quality. It is not typically used to diagnose SWD but may help rule out other sleep/wake disorders, such as sleep apnea and narcolepsy (2)[C].
- Other diagnostic tools are available, including the Multiple Sleep Latency Test (MSLT), the Morningness-Eveningness Questionnaire (MEQ), and the Epworth Sleepiness Scale (ESS) (2)[C].

**Test Interpretation**
Sleep diaries and actigraphy data often reveal:
- Increased sleep latency
- Decreased total sleep time
- Frequent awakenings
- Most people revert to nocturnal sleeping on their days off. Every workweek,
they must “start over” to shift circadian rhythms to align with work schedules.

TREATMENT

- The only therapeutic modality recommended by the American Academy of Sleep Medicine is planned (prescribed) sleep schedules (6)[C].
- Other commonly used strategies include sleep hygiene optimization, bright light, melatonin, caffeine, other stimulants, hypnotics, and medication sleep aids (discussed below).

GENERAL MEASURES

- Sleep hygiene: An important first step in approaching the treatment of sleep disorders is proper sleep hygiene. This includes minimizing exposure to bright light before and during scheduled sleep periods (maintain a dark sleeping space, wear dark sunglasses following work shift, wear an eye mask to sleep), maintain a quiet sleep environment (wear ear plugs to sleep, disconnect phone/doorbell), retrain core body temperature to shifted sleep/wake schedule (maintain cool sleeping quarters), and avoid use of stimulants during second half of work shift (2)[C].
- Sleep time: protected time for sleep prior to and following work shifts with strategic naps where possible (5)[C]
- Work/social/domestic factors: Treat psychosocial stress, depression, encourage healthy eating habits, limit substance use, increase exercise to at least 30 minutes 5 times per week (not within 2 to 4 hours of bedtime) (5)[C].
- Work-related interventions: If possible, reduce number of consecutive shifts (<4) or reduce shift duration (<12 hours), allow adequate time between shifts (>11 hours), move heavy workload outside circadian nadir (04:00 to 07:00) (5)[C].
- Bright light: Several studies demonstrate that timed bright light and darkness promote adaptation to night work (7)[C].
- Bright light therapy with conventional light/light boxes (10,000 lux preferable, but >1,000 lux will help) 30 min/day during the night/early morning shift prior to the nadir of the core body temperature rhythm (7)[C]

MEDICATION

Sleep-promoting medications:

- Melatonin may help shift circadian rhythms and can increase the quality and
duration of sleep as well as increase alertness during the work shift.

- Ramelteon (Rozerem), a melatonin receptor agonist, is not FDA-approved for treating SWD but may be helpful in improving daytime sleep (2)[C].
- Antidepressants: Doxepin (tricyclic) and trazodone are FDA-approved for the treatment of insomnia. Given at low doses, doxepin and trazodone can improve sleep without residual daytime impairment (2)[C].
- Intermediate-acting hypnotics such as zolpidem (Ambien) or eszopiclone (Lunesta) can cause postsleep sedation (2)[C]. Long-term use is discouraged due to potential for tolerance/dependence.
- Suvorexant (Belsomra) is an orexin receptor antagonist approved for the treatment of insomnia.

Wakefulness-promoting medications:
- Modafinil (Provigil) and armodafinil (Nuvigil) are FDA-approved for excessive sleepiness in patients with SWD and can reduce daytime sleepiness and improve cognitive performance (2)[C].
- Prophylactic caffeine use immediately prior to work shift and during work shift (5)[C].

**First Line**

**Circadian shift/sleep promoting:** Melatonin 3 mg PO or sublingual, 30 minutes before daytime sleep period. Take only when the patient is home and able to go to bed (2)[C].

**Second Line**

- Wakefulness-promoting:
  - Modafinil initially 200 mg PO 1 hour prior to work shift
  - Armodafinil 150 mg PO 1 hour prior to work shift. Long-acting (12 to 16 hours, depending on food intake) use judiciously in SWD to impede a patient’s ability to sleep after the shift.
- Sleep promoting:
  - Nonbenzodiazepine hypnotics:
    - Zolpidem 5 to 10 mg or eszopiclone 1 to 3 mg immediately prior to bed; suvorexant 10 to 20 mg PO 30 minutes prior to bed
  - Antidepressants
    - Doxepin (3 to 6 mg) and trazodone (25 to 150 mg), 1 to 2 hours prior to bed (2)[C]
  - Benzodiazepines: Estazolam, flurazepam, quazepam, temazepam, and triazolam are FDA-approved for the treatment of insomnia. Due to high risk of tolerance/withdrawal, use cautiously for short-term treatment of
insomnia (2)[C].

– In general, hypnotics may improve daytime sleep but do not appear to improve sleep maintenance or nighttime alertness. They may also cause residual sedation during work hours. This may worsen SWD symptoms (2) [C].

**ISSUES FOR REFERRAL**

Refer to a sleep specialist for suspicion of other primary sleep disorders or dependence on hypnotics, alcohol, or stimulants.

**ONGOING CARE**

**PATIENT EDUCATION**

- Discuss sleep hygiene and optimizing the sleep environment.
- Shift workers who need to sleep in the daytime should ensure a cool, dark, and quiet sleep environment.
- Reserve bedroom for sleeping and intimacy only. Remove televisions, cell phones, tablets and laptop computers from the bedroom.
- When going to sleep, turn clock away from bed and discourage prolonged reading in bed.
- Blackout shades help achieve the proper darkness.

ADDITIONAL READING
- Sleep Diary: http://www.helpguide.org/life/pdfs/sleep_diary.pdf

CODES
ICD10
G47.26 Circadian rhythm sleep disorder, shift work type

CLINICAL PEARLS
- SWD is associated with shortened and disturbed sleep, fatigue, decreased alertness, cognitive decrements, increased injuries and accidents, reproductive problems, and risks to cardiovascular and GI health.
- SWD has been classified as a probable carcinogen (possible association with breast and prostate cancer).
- The first diagnostic step in SWD is to obtain and evaluate an accurate sleep diary.
SMELL AND TASTE DISORDERS

Beth K. Mazyck, MD • Daniel B. Kurtz, PhD, BS

BASICS

DESCRIPTION

- The senses of smell and taste allow a full appreciation of the flavor and palatability of foods and also serve as a warning system against toxins, polluted air, smoke, and spoiled food.
- Physiologically, the chemical senses aid in normal digestion by triggering GI secretions. Smell/taste dysfunction may have a significant impact on quality of life.
- Loss of smell occurs more frequently than loss of taste, and patients frequently confuse the concepts of flavor loss (as a result of smell impairment) with taste loss (an impaired ability to sense sweet, sour, salty, or bitter).
- Smell depends on the functioning of CN I (olfactory nerve) and CN V (trigeminal nerve).
- Taste depends on the functioning of CNs VII, IX, and X. Because of these multiple pathways, total loss of taste (ageusia) is rare.
- Systems affected: nervous, upper respiratory

EPIDEMIOLOGY

Incidence

There are ~200,000 patient visits a year for smell and taste disturbances.

Prevalence

- Predominant sex: male > female. Men begin to lose their ability to smell earlier in life than women.
- Predominant age: Chemosensory loss is age dependent:
  - Age >80 years: 80% have major olfactory impairment; nearly 50% are anosmic.
  - Ages 65 to 80 years: 60% have major olfactory impairment; nearly 25% are anosmic.
  - Age <65 years: 1–2% have smell impairment.
- Estimated >2 million affected in the United States
ETIOLOGY AND PATHOPHYSIOLOGY

- Smell and/or taste disturbances:
  - Nutritional factors (e.g., malnutrition, vitamin deficiencies, liver disease, pernicious anemia)
  - Endocrine disorders (e.g., thyroid disease, diabetes mellitus, renal disease)
  - Head trauma
  - Migraine headache (e.g., gustatory aura, olfactory aura)
  - Sjögren syndrome
  - Toxic chemical exposure
  - Industrial agent exposure
  - Aging
  - Medications (see below)
  - Neurodegenerative diseases (e.g., multiple sclerosis, Alzheimer disease, cerebrovascular accident, Parkinson disease)
  - Infections (e.g., upper respiratory infection [URI], oral and perioral infections, candidiasis, coxsackievirus, AIDS, viral hepatitis, herpes simplex virus)

- Possible causes of smell disturbance:
  - Nasal and sinus disease (e.g., allergies, rhinitis, rhinorrhea, URI)
  - Cigarette smoking
  - Cocaine abuse (intranasal)
  - Hemodialysis
  - Radiation treatment of head and neck
  - Congenital conditions
  - Neoplasm (e.g., brain tumor, nasal polyps, intranasal tumor)
  - Systemic lupus erythematosus (SLE)
  - Bell palsy
  - Oral/perioral skin lesion
  - Damage to CN I/V
  - Possible association with psychosis and schizophrenia

- Possible causes of taste loss:
  - Oral appliances
  - Dental procedures
  - Intraoral abscess
  - Gingivitis
  - Damage to CN VI, IX, or X
  - Stroke (especially frontal lobe)

- Selected medications that reportedly alter smell and taste:
– Antibiotics: amikacin, ampicillin, azithromycin, ciprofloxacin, clarithromycin, doxycycline, griseofulvin, metronidazole, ofloxacin, tetracycline, terbinafine, β-lactamase inhibitors
– Anticonvulsants: carbamazepine, phenytoin
– Antidepressants: amitriptyline, doxepin, imipramine, nortriptyline
– Antihistamines and decongestants: zinc-based cold remedies (Zicam)
– Antihypertensives and cardiac medications: acetazolamide, amiloride, captopril, diltiazem, hydrochlorothiazide, nifedipine, propranolol, spironolactone
– Anti-inflammatory agents: auranofin, gold, penicillamine
– Antimanic drugs: lithium
– Antineoplastics: cisplatin, doxorubicin, methotrexate, vincristine
– Antiparkinsonian agents: levodopa, carbidopa
– Antiseptic: chlorhexidine
– Antithyroid agents: methimazole, propylthiouracil
– Lipid-lowering agents: statins

**Genetics**
May be related to underlying genetically associated diseases (Kallmann syndrome, Alzheimer disease, and other neurodegenerative disorders, migraine syndromes, rheumatologic conditions, endocrine disorders)

**RISK FACTORS**
- Age >65 years
- Poor nutritional status
- Smoking tobacco products

**GENERAL PREVENTION**
- Eat a well-balanced diet, with appropriate vitamins and minerals.
- Maintain good oral and nasal health, with routine visits to the dentist.
- Do not smoke tobacco products.
- Avoid noxious chemical exposures/unnecessary radiation.

**Geriatric Considerations**
- Elders are at particular risk of eating spoiled food or inadvertently being exposed to natural gas leaks owing to anosmia from aging.
- Anosmia also may be an early sign of degenerative disorders and has been shown to predict increased 5-year mortality (1)[B].
**Pediatric Considerations**
- Smell and taste disorders are uncommon in children in developed countries.
- In developing countries with poor nutrition (particularly zinc depletion), smell and taste disorders may occur.
- Delayed puberty in association with anosmia (± midline craniofacial abnormalities, deafness, or renal abnormalities) suggests the possibility of Kallmann syndrome (hypogonadotropic hypogonadism).

**Pregnancy Considerations**
- Pregnancy is an uncommon cause of smell and taste loss or disturbances.
- Many women report increased sensitivity to odors during pregnancy as well as an increased dislike for bitterness and a preference for salty substances.

**COMMONLY ASSOCIATED CONDITIONS**
- URI, allergic rhinitis, dental abscesses

**DIAGNOSIS**
Smell and taste disturbances are symptoms; it is essential to look for possible underlying causes.

**HISTORY**
- Symptoms of URI, environmental allergies
- Oral pain, other dental problems
- Cognitive/memory difficulties
- Current medications
- Nutritional status, ovolactovegetarian
- Weight loss or gain
- Frequent infections (impaired immunity)
- Worsening of underlying medical illness
- Increased use of salt and/or sugar to increase taste of food
- Neurodegenerative disease

**PHYSICAL EXAM**
Thorough HEENT exam

**DIFFERENTIAL DIAGNOSIS**
- Epilepsy (gustatory aura)
- Epilepsy (olfactory aura)
- Memory impairment
- Psychiatric conditions

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**
Consider (not all patients require all tests)

- CBC
- Liver function tests
- Blood glucose
- Creatinine
- Vitamin B$_{12}$ level
- Thyroid-stimulating hormone (TSH)
- Serum IgE

- CT scanning is the most useful and cost-effective technique for assessing sinonasal disorders and is superior to an MRI in evaluating bony structures and airway patency. Coronal CT scans are particularly valuable in assessing paranasal anatomy (2)[B].

**Follow-Up Tests & Special Considerations**

Diagnosis of smell and taste disturbances is usually possible through history; however, the following tests can be used to confirm:

- Olfactory tests
  - Smell identification test: evaluates the ability to identify 40 microencapsulated scratch-and-sniff odorants (3)[B]
  - Brief smell identification test (4)[B]

- Taste tests (more difficult because no convenient standardized tests are presently available): Solutions containing sucrose (sweet), sodium chloride (salty), quinine (bitter), and citric acid (sour) are helpful.
- An MRI is useful in defining soft tissue disease; therefore, a coronal MRI is the technique of choice to image the olfactory bulbs, tracts, and cortical parenchyma; possible placement of an accessory coil (TMJ) over the nose to assist in imaging
TREATMENT

GENERAL MEASURES
- Appropriate treatment for underlying cause
- Quit smoking (5)[B].
- Treatment of underlying nasal congestion with nasal decongestants and/or nasal/oral steroids (6)[B]
- Surgical correction of nasal blockage/nasal polyps
- Some drug-related smell or taste loss or dysgeusias can be reversed with cessation of the offending medication, but it may take many months.
- Stop repeated oral trauma (e.g., appliances, tongue-biting behaviors).
- Proper nutritional and dietary assessment (2)[C]
- Formal dental evaluation

MEDICATION
- Treat underlying causes as appropriate. Idiopathic cases will often resolve spontaneously.
- Consider trial of corticosteroids topically (e.g., fluticasone nasal spray daily to BID) and/or systemically (e.g., oral prednisone 60 mg daily for 5 to 7 days) (6)[B].
- Zinc and vitamins (A, B complex) when deficiency is suspected

ISSUES FOR REFERRAL
- Consider referral to an otolaryngologist or neurologist for persistent cases.
- Referral to a subspecialist at a regional smell and taste center when complex etiologies are suspected

SURGERY/OTHER PROCEDURES
If needed for treatment of underlying cause

ONGOING CARE

DIET
- Weight gain/loss is possible because the patient may reject food or may switch to calorie-rich foods that are still palatable.
- Ensure a nutritionally balanced diet with appropriate levels of nutrients,
vitamins, and essential minerals.

**PATIENT EDUCATION**
- Caution patients not to overindulge as compensation for the bland taste of food. For example, patients with diabetes may need help in avoiding excessive sugar intake as an inappropriate way of improving food taste.
- Patients with chemosensory impairments should use measuring devices when cooking and should not cook by taste.
- Optimizing food texture, aroma, temperature, and color may improve the overall food experience when taste is limited.
- Patients with permanent smell dysfunction must develop adaptive strategies for dealing with hygiene, appetite, safety, and health.
- Natural gas and smoke detectors are essential; check for proper function frequently.
- Check food expiration dates frequently; discard old food.

**PROGNOSIS**
- In general, the olfactory system regenerates poorly after a head injury. Most patients who recover smell function following head trauma do so within 12 weeks of injury.
- Patients who quit smoking typically recover improved olfactory function and flavor sensation.
- Many taste disorders (dysgeusias) resolve spontaneously within a few years of onset.
- Phantosmias that are flow dependent may respond to surgical ablation of olfactory mucosa.
- Conditions such as radiation-induced xerostomia and Bell palsy generally improve over time.

**COMPLICATIONS**
- Permanent loss of ability to smell/taste
- Psychiatric issues with dysgeusias and phantosmia

**REFERENCES**

ADDITIONAL READING

CODES

**ICD10**

- R43.9 Unspecified disturbances of smell and taste
- R43.1 Parosmia
- R43.2 Parageusia

CLINICAL PEARLS

- Smell disorders are often mistaken as decreased taste by patients.
- Most temporary smell loss is due to nasal passage obstruction.
- Actual taste disorders are often related to dental problems or medication side effects.
- Gradual smell loss is very common in the elderly; extensive workup in this population may not be indicated if no associated signs/symptoms are present.
but may be predictive of 5-year mortality.
SOMATIC SYMPTOM (SOMATIZATION) DISORDER

William G. Elder, PhD

BASICS

DESCRIPTION

- A pattern of one or more somatic symptoms recurring or persisting for >6 months that are distressing or result in significant disruption of daily life.
- Conceptualization and diagnostic criteria for somatic symptom presentations were significantly modified with the advent of DSM-5. Somatic symptom disorder (SSD) is similar in many aspects to the former somatization disorder, which required presentation with multiple physical complaints, no longer based on symptoms counts; current diagnosis is based on the way the patient presents and perceives his or her symptoms.
- SSD now includes most presentations that would formerly be considered hypochondriasis. Hypochondriasis has been replaced by illness anxiety disorders, which is diagnosed when the patient presents with significant preoccupation with having a serious illness in the absence of illness-related somatic complaints.
- Somatization increases disability independent of comorbidity, and individuals with SSD have health-related functioning that is two standard deviations below the mean.
- Symptoms may be specific (e.g., localized pain) or relatively nonspecific (e.g., fatigue).
- Symptoms sometimes may represent normal bodily sensations or discomfort that does not signify serious disease.
- Suffering is authentic. Symptoms are not intentionally produced or feigned.

EPIDEMIOLOGY

Incidence

- Usually, first symptoms appear in adolescence.
- Predominant sex: female > male (10:1)
- Type and frequency of somatic complaints may differ among cultures, so symptom reviews should be adjusted based on culture; more frequent in
cultures without Western/empirical explanatory models

**Prevalence**
- Expected 2% among women and <0.2% among men
- Somatization seen in up to 29% of patients presenting to primary care offices
- Somatic concerns may increase, but other features of the presentation decrease such that prevalence declines after age 65 years.

**ETIOLOGY AND PATHOPHYSIOLOGY**
Patients with SSD demonstrate different patterns of heart rate variability. Although this cannot be used to clinically, it does point to the differences in psychophysiology of SSD.

**Genetics**
Consanguinity studies and single nucleotide polymorphism genotyping indicate that both genetic and environmental factors contribute to the risk of SSD.

**RISK FACTORS**
- Child abuse, particularly sexual abuse, has been shown to be a risk factor for somatization.
- Symptoms begin or worsen after losses (e.g., job, close relative, or friend).
- Greater intensity of symptoms often occurs with stress.

**COMMONLY ASSOCIATED CONDITIONS**
Comorbid with other psychiatric conditions is yet to be determined but is likely to be 20–50% with anxiety, depression, or personality disorders.

**DIAGNOSIS**
- Determining that a somatic symptom is medically unexplained is unreliable, and it is inappropriate to diagnose a mental disorder solely because a medical diagnosis is not demonstrated. Rely on symptoms and presentation rather than ruling out medical causes in making the SSD diagnosis.
- Illness anxiety and somatic distress are independent but often co-occur.

**HISTORY**
- One or more somatic complaints, with sometimes a grossly positive review of symptoms
SSD involves patient excessive thoughts, feelings, or behaviors associated with symptoms or associated health concerns manifested by at least one of the following:
- Disproportionate and persistent thoughts about the seriousness of the symptoms
- Persistent high level of anxiety about health or symptoms
- Excessive time or energy devoted to symptoms or health concerns

Diagnoses no longer rely on symptom counts, but common symptoms include:
- Pain symptoms related to different sites such as head, abdomen, back, joints, extremities, chest, or rectum, or related to body functions such as menstruation, sexual intercourse, or urination
- GI symptoms such as nausea, bloating, vomiting (not during pregnancy), diarrhea, intolerance of several foods
- Sexual symptoms such as indifference to sex, difficulties with erection or ejaculation, irregular menses, excessive menstrual bleeding, or vomiting throughout all 9 months of pregnancy
- Pseudoneurologic symptoms such as impaired balance or coordination, weak or paralyzed muscles, lump in throat or trouble swallowing, loss of voice, retention of urine, hallucinations, numbness (to touch or pain), double vision, blindness, deafness, seizures, amnesia or other dissociative symptoms, loss of consciousness (other than with fainting); none of these is limited to pain.

Patients with SSD frequently use alternative treatments, which should be explored for their effects on health and physical functioning.

**PHYSICAL EXAM**
Physical exam remarkable for absence of objective findings to explain the many subjective complaints

**DIFFERENTIAL DIAGNOSIS**
- Other psychiatric illnesses must be ruled out:
  - Depressive disorders
  - Anxiety disorders
  - Schizophrenia
  - Other somatic disorders: illness anxiety disorder, conversion disorder
  - Factitious disorder
  - Body dysmorphic disorder
- Malingering
- General medical conditions, with vague, multiple, confusing symptoms, must
be ruled out.
- Systemic lupus erythematosus
- Hyperparathyroidism
- Hyper- or hypothyroidism
- Lyme disease
- Porphyria

**DIAGNOSTIC TESTS & INTERPRETATION**
Several screening tools are available that help to identify symptoms as somatic:

- Patient Health Questionnaire (PHQ)-15 (screens and monitors symptoms)
- Minnesota Multiphasic Personality Inventory (MMPI) (identifies somatization)

**Initial Tests (lab, imaging)**

- Laboratory test results do not support the subjective complaints.
- Imaging studies do not support the subjective complaints.

**Test Interpretation**
None are identified.

**TREATMENT**

**GENERAL MEASURES**

- The goal of treatment is to help the person learn to control the symptoms (1) [B].
- A supportive relationship with a sympathetic health care provider is the most important aspect of treatment:
  - Regular scheduled appointments should be maintained to review symptoms and the person’s coping mechanisms (at least 15 minutes once a month).
  - Acknowledge and explain test results.
- The involvement of a single provider is important because a history of seeking medical attention and “doctor shopping” is common.
- Antidepressant or antianxiety medication and referral to a support group or mental health provider can help patients who are willing to participate in their treatment.
- Patients usually receive the most benefit from primary care providers who accept the limitations of treatment, listen to their patient’s concerns, and
provide reassurance.
● It is not helpful to tell patients that their symptoms are imaginary.

MEDICATION
● Fluoxetine has been shown to have efficacy with illness anxiety disorder (formerly hypochondriasis), although >50% of those patients did not respond to the medication (2)[B].
● Antidepressants (e.g., SSRIs) help to treat comorbid depression and anxiety (3)[C].

ISSUES FOR REFERRAL
● Discourage referrals to specialists for further investigation of somatic complaints.
● Referrals to support groups or to a mental health provider may be helpful.

ADDITIONAL THERAPIES
Treatments have not been evaluated for this recently reformulated disorder. However, there are numerous studies with positive outcomes for patients with various forms of somatization or medically unexplained symptoms.
● Treatment typically includes long-term therapy, which has been shown to decrease the severity of symptoms.
● Individual or group cognitive-behavioral therapy addressing health anxiety, health beliefs, and health behaviors has been shown to be the most efficacious treatment for somatoform disorders. Cognitive processes modified in therapy include patient tendencies to ruminate and catastrophize (4)[A].

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
Patients should have regularly scheduled follow-up with a primary care doctor, psychiatrist, and/or therapist.

PATIENT EDUCATION
Encourage interventions that decrease stressful elements of the patient’s life:
● Psychoeducational advice
● Increase in exercise
- Pleasurable private time

**PROGNOSIS**
- Chronic course, fluctuating in severity
- Full remission is rare.
- Individuals with this disorder do not experience any significant difference in mortality rate or significant physical illness.
- Patients with this diagnosis do experience substantially greater functional disability and role impairment than nonsomatizing patients (5).

**COMPICATIONS**
- May result from invasive testing and from multiple evaluations that are performed while looking for the cause of the symptoms
- A dependency on pain relievers or sedatives may develop.

**REFERENCES**

**ADDITIONAL READING**
- Sharma MP, Manjula M. Behavioural and psychological management of

CODES

ICD10
- F45.9 Somatoform disorder, unspecified
- F45.20 Hypochondriacal disorder, unspecified

CLINICAL PEARLS
- With the advent of DSM-5, diagnosis is now based on a pattern of symptoms rather than an absence of medical explanation.
- A clue is accumulation of several diagnoses with >13 letters (e.g., chronic fatigue syndrome, fibromyalgia syndrome, reflex sympathetic dystrophy, temporomandibular joint syndrome, carpal tunnel syndrome, mitral valve prolapse).
- Inability of more than three physicians to make a meaningful diagnosis suggests somatization.
- Acknowledge the patient’s pain, suffering, and disability.
- Do not tell patients the symptoms are “all in their head.”
- Emphasize that this is not a rare disorder.
- Discuss the limitations of treatment while providing reassurance that there are interventions that will lessen suffering and reduce symptoms.
SPINAL STENOSIS

N. Wilson Holland, MD, FACP, AGSF • Birju B. Patel, MD, FACP, AGSF

BASICS

DESCRIPTION
Narrowing of the spinal canal and foramen:

- Spondylosis or degenerative arthritis is the most common cause of spinal stenosis, resulting from compression of the spinal cord by disc degeneration, facet arthropathy, osteophyte formation, and ligamentum flavum hypertrophy.
- The L4–L5 level is most commonly involved.

EPIDEMIOLOGY

The prevalence of spinal stenosis increases with age due to “wear and tear” on the normal spine.

Incidence
Symptomatic spinal stenosis affects up to 8% of the general population.

Prevalence
- The prevalence of spinal stenosis is high if assessed solely by imaging in elderly patients. Not all patients with radiographic spinal stenosis are symptomatic. The degree of radiographic stenosis does not always correlate with patient symptoms. Lumbar MRI shows significant abnormalities in 57% of patients >60 years.
- Predominant age: Symptoms develop in 5th to 6th decades (congenital stenosis is symptomatic earlier).

ETIOLOGY AND PATHOPHYSIOLOGY

- Spinal stenosis can result from congenital or acquired causes. Degenerative spondylosis is most common.
- Disc dehydration leads to loss of height with bulging of the disc annulus and ligamentum flavum into the spinal canal, increasing facet joint loading.
- Facet loading leads to reactive sclerosis and osteophytic bone growth, further
compressing spinal canal, and foraminal elements.

- Other causes of acquired spinal stenosis include:
  - Trauma
  - Neoplasms
  - Neural cysts and lipomas
  - Postoperative changes
  - Rheumatoid arthritis
  - Diffuse idiopathic skeletal hyperostosis
  - Ankylosing spondylitis
  - Metabolic/endocrine causes: osteoporosis, renal osteodystrophy, and Paget disease

**Genetics**

No definitive genetic links

**RISK FACTORS**

Increasing age and degenerative spinal disease

**GENERAL PREVENTION**

There is no proven prevention for spinal stenosis. Symptoms can be alleviated with flexion at the waist:

- Leaning forward while walking
- Pushing a shopping cart
- Lying in flexed position
- Sitting
- Avoiding provocative maneuvers (back extension, ambulating long distances without resting)

**DIAGNOSIS**

**HISTORY**

- Helps distinguish spinal stenosis from other causes of back pain and peripheral vascular disease.
  - Insidious onset and slow progression are typical; discomfort with standing, paresthesias, and weakness (often bilateral) (1)[C]
  - Symptoms *worsen with extension* (prolonged standing, walking downhill or downstairs).
– Symptoms *improve with flexion* (sitting, leaning forward while walking, walking uphill or upstairs, lying in a flexed position).

- Neurogenic claudication (i.e., pain, tightness, numbness, and subjective weakness of lower extremities) may mimic vascular claudication.

**PHYSICAL EXAM**

Neurologic exam may be normal. Key exam areas:

- Examine gait (rule out cervical myelopathy or intracranial pathology).
- Loss of lumbar lordosis
- Evaluate range of motion of lumbar spine.
- Pain with extension of the lumbar spine is typical.
- Straight-leg raise test may be positive if nerve root entrapment is present.
- Muscle weakness is usually mild and involves the L4, L5, and (rarely) S1 nerve roots.
- About half of patients with symptomatic stenosis have a reduced or absent Achilles reflex. Some have reduced or absent patellar reflex.

**DIFFERENTIAL DIAGNOSIS**

- Vascular claudication. Symptoms of vascular claudication do not improve with leaning forward and usually abate with standing or rest.
- Disc herniation
- Cervical myelopathy

**DIAGNOSTIC TESTS & INTERPRETATION**

Generally, a clinical diagnosis. Imaging (MRI is best) is used to stage severity and plan treatment.

**Initial Tests (lab, imaging)**

- CBC, ESR, C-reactive protein (if considering infection or malignancy)
- New back pain lasting >2 weeks or back pain accompanied by neurologic findings in patients >50 years generally warrants neuroimaging.
- MRI is the modality of choice.
- CT myelography is an alternative to MRI but is invasive and has higher risk of complications.
- Plain radiography helps exclude other causes of new back pain (e.g., malignant lytic lesions) but does not reveal the underlying pathology.
- Radiologic abnormalities in general do not correlate with the clinical severity.
**Diagnostic Procedures/Other**
Surgical decompression is definitive for patients who are symptomatic after nonoperative treatment:

- Spinal stenosis generally does not lead to neurologic damage.
- Surgery may be required for pain relief to increase mobility and improve quality of life.

**Test Interpretation**
Common radiographic findings include decreased disc height, facet hypertrophy, and spinal canal and/or foraminal narrowing.

**TREATMENT**

- In general, nonoperative interventions are preferred in the absence of progressive or debilitating neurologic symptoms:
  - Physical therapy, exercise, weight management, medications, and epidural steroid injections are options. There is insufficient evidence to definitively guide clinical practice.
  - Patients should understand that the benefits of surgery may diminish over time.
  - Rule out other neuropathies and peripheral vascular disease.

- Spinal decompression and physical therapy yield similar effects (2)[A].
- There is controversy about fusion being performed with decompression because of a future spondylolisthesis risk (3)[C].

**MEDICATION**

**First Line**
NSAIDs: Consider potential for GI side effects, fluid retention, and renal failure.

**Second Line**
- Tramadol—currently a schedule IV-controlled substance; has the potential to cause confusion, dizziness, lower seizure threshold, and increase fall risk in the elderly; should be used with caution
- The available evidence does not support the routine use of epidural steroid injections. Judicious injections may be reasonable in certain cases.
- Use opioids sparingly and only when other treatments have failed to control
severe pain.

**Geriatric Considerations**
- Anti-inflammatory medications should be used with caution in the elderly due to the risks of GI bleeding, fluid retention, renal failure, and cardiovascular risks.
- Side effects of opioids include constipation, confusion, urinary retention, drowsiness, nausea, vomiting, and the potential for dependence and abuse.
- >10% of elderly lack Achilles reflexes.

**ISSUES FOR REFERRAL**
Patients in unremitting pain or with a neurologic deficit should see a neurosurgeon.

**ADDITIONAL THERAPIES**
- Patients with spinal stenosis are typically able to ride a bicycle (leaning forward tends to relieve symptoms).
- Aquatic therapy (helpful for muscle training and general conditioning)
- Strengthening of abdominal and back muscles
- Gait training
- Although a brace or corset may help in the short term, use is not recommended for prolonged periods due to development of paraspinal muscle weakness.
- Encourage physical activity to prevent deconditioning.

**SURGERY/OTHER PROCEDURES**
- Surgery is indicated when symptoms persist despite conservative measures.
- Age alone should not be an exclusion factor for surgical intervention. Cognitive impairment, multiple comorbidities, and osteoporosis may increase the risk of perioperative complications in the elderly.
- The traditional approach is laminectomy and partial facetectomy.
- Fusion is no longer a standard of care; patients with lumbar spinal stenosis decompression surgery plus fusion surgery did not result in better clinical outcomes at 2 years and 5 years than did decompression surgery alone (4)[B].
- The evidence for use of the Aperius interspinous implant device is inconclusive (5)[C].
- A unilateral partial hemilaminectomy combined with transmedial decompression may adequately treat stenosis with less morbidity in the
elderly (6)[C].

**ADMISSION, INPATIENT, AND NURSING CONSIDERATIONS**
- Admission criteria/initial stabilization: acute or progressive neurologic deficit
- Discharge criteria: improved pain or after neurologic deficit has been addressed

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**
- Follow up based on progression of symptoms.
- No limitations to activity; patients may be as active as tolerated. Exercise should be encouraged.

*Patient Monitoring*
Patients are monitored for improvement of symptoms and development of any complications.

**DIET**
Optimize nutrition for weight management.

**PATIENT EDUCATION**
- Activity as tolerated, if no other pathology is present (e.g., fractures)
- Patients should present for care if they develop progressive motor weakness and/or bladder/bowel dysfunction.
- Patients should know the natural history of the condition and how best to relieve symptoms.

**PROGNOSIS**
- Spinal stenosis is generally benign, but the pain can lead to limitation in ADLs and progressive disability.
- Surgery usually improves pain and symptoms in patients who fail nonoperative treatment.
- Surgical outcomes are similar in terms of pain relief and functional improvement for patients of all ages.
COMPLICATIONS

- Severe spinal stenosis can lead to bowel and/or bladder dysfunction.
- Surgical complications include infection, neurologic injury, chronic pain, and disability.

Algorithm: Low Back Pain, Acute

CODES

**ICD10**

- M48.00 Spinal stenosis, site unspecified
- M48.06 Spinal stenosis, lumbar region
- M48.04 Spinal stenosis, thoracic region
CLINICAL PEARLS

- Spinal stenosis typically presents as neurogenic claudication (pain, tightness, numbness, and subjective weakness of lower extremities), which can mimic vascular claudication.
- Flexion of the spine generally relieves symptoms associated with spinal stenosis.
- Spinal extension (prolonged standing, walking downhill, and walking downstairs) can worsen symptoms of spinal stenosis.
- Consider urgent surgery for patients with cauda equina/conus medullaris syndrome or progressive bladder dysfunction. Other patients with lumbar spinal stenosis typically do well with initial conservative management.
SPRAIN, ANKLE

Shane L. Larson, MD • Julia S. Fast, DO

BASICS

DESCRIPTION

The most common cause of ankle injury comprising a significant proportion of sports injuries:

- Types of ankle sprains: lateral, medial, and syndesmotic (or high ankle sprain)
  - Lateral ankle sprains are the most common, accounting for up to 89% of all ankle sprains (1):
    - In lateral ankle sprains, the anterior talofibular ligament (ATFL) is most likely to be injured.
    - The calcaneofibular ligament (CFL) is the second most likely ligament to be injured.
    - The posterior talofibular ligament (PTFL) is the least likely to be injured.
  - Medial ankle sprains (5–10%) result from an injury to the deltoid ligament.
  - Syndesmotic (“high ankle sprain”) injuries account for 5–10% of ankle sprains.
    - The syndesmosis between the distal tibia and distal fibula bones consists of the anterior, posterior, and transverse tibiofibular ligaments; the interosseous ligament; and interosseous membrane.

- Ankle sprains are classified according to the degree of ligamentous disruption:
  - Grade I: mild stretching of a ligament with possible microscopic tears
  - Grade II: incomplete tear of a ligament
  - Grade III: complete ligament tear

Geriatric Considerations

Increased risk of fracture in patients with preexisting bone weakness (osteoporosis/osteopenia)

Pediatric Considerations

- Increased risk of physeal injuries instead of ligament sprain because ligaments have greater tensile strength than physis
- Inversion ankle injuries in children may have a concomitant fibular physeal injury (Salter-Harris type I or higher fracture).
Consider tarsal coalition with recurrent ankle sprains.

**EPIDEMIOLOGY**

**Incidence**
- Ankle sprains are more common in childhood and adolescents, particularly in active individuals (2).
- 1/2 of all ankle sprains are sports related; highest incidence in indoor/court sports (basketball, volleyball, tennis), followed by football and soccer (3).
- Most common sports injury
- More common in males age <30 years and females >30 years old

**Prevalence**
- 25% of sports injuries in the United States
- 75% of all ankle injuries are sprains.

**ETIOLOGY AND PATHOPHYSIOLOGY**
- Lateral ankle sprains result from an inversion force with the ankle in plantar flexion.
- Medial ankle sprains are due to forced eversion while the foot is in dorsiflexion.
- Syndesmotic sprains result from eversion stress/extreme dorsiflexion along with internal rotation of tibia.

**RISK FACTORS**
- The greatest risk factor is a prior history of an ankle sprain (3–34% recurrence rate).
- Postural instability, gait alterations
- Joint laxity and decreased proprioception are not risk factors.

**GENERAL PREVENTION**
- Improve overall physical conditioning:
  - Training in agility and flexibility
  - Single-leg balancing
  - Proprioceptive training
- Taping and bracing may help prevent primary injury in selected sports (i.e., volleyball, basketball, football) or reinjury (4). Taping and bracing do not reduce sprain severity.
- Weight loss may help in overweight patients (4)[A].
COMMONLY ASSOCIATED CONDITIONS
- Contusions
- Fractures
  - Fibular head fracture/dislocation (Maisonneuve)
  - Fracture of the base of the 5th metatarsal
  - Distal fibula physeal fracture (includes Salter-Harris fractures in pediatric patients; most common type of pediatric ankle fracture)

DIAGNOSIS

HISTORY
- Elicit specific mechanism of injury (inversion vs. eversion)
- Popping/snapping sensation during the injury
- Previous history of ankle injuries
- Ability to ambulate immediately after the injury
- Rapid onset of pain, swelling, or ecchymosis
- Location of pain (lateral/medial)
- Difficulty bearing weight
- Past medical history of systemic disorders

PHYSICAL EXAM
- Timing: Initial assessment for laxity may be difficult due to pain, swelling, and muscle spasm. Repeating exam ~5 days after injury often improves sensitivity.
- Compare to uninjured ankle for swelling, ecchymosis, weakness, and laxity.
- Neurovascular exam
  - Palpate ATFL, CFL, PTFL, and deltoid ligament for tenderness.
  - Palpate lateral and medial malleolus, base of 5th metatarsal, navicular, and entire fibula.
    - High ankle sprain associated with fracture of proximal fibula
- Grade I sprain: mild swelling and pain; no laxity; able to bear weight/ambulate without pain
- Grade II sprain: moderate swelling and pain; mild laxity with firm end point noted; weight bearing/ambulation painful
- Grade III sprain: severe swelling, pain, and bruising; laxity with no end point; significant instability and loss of function/motion; unable to bear weight/ambulate
- Swelling less sensitive for grade of tear in pediatric patient

Special tests:
- Anterior drawer test to check for ATFL laxity
- Talar tilt test to check laxity in CFL (with inversion) or deltoid ligament (eversion)
- Squeeze test: Compress tibia and fibula midcalf to check for syndesmotic injury; sensitivity 30%, specificity 93.5%
- Dorsiflexion/external rotation test: Positive test is pain at syndesmosis with rotation; sensitivity 20%, specificity 85%

DIFFERENTIAL DIAGNOSIS
- Tendon injury
  - Tendinopathy/tendon tear
- Fracture and/or dislocation of the ankle/foot
- Hindfoot/midfoot injuries
- Nerve injury
- Contusion

DIAGNOSTIC TESTS & INTERPRETATION

Initial Tests (lab, imaging)
- Ottawa Ankle Rules (nearly 100% sensitive, 30–50% specific) determine need for radiographs to rule out ankle fractures (patient must be 18 to 55 years; certain patients, e.g., diabetics with diminished sensation, may still need radiographs):
  - Pain in malleolar zone
  - Inability to bear weight (walk ≥4 steps) immediately and in the exam room
  - Bony tenderness at tip/posterior edge of the lateral/medial malleolus
    - Note: Ottawa rule for foot imaging: reported pain in the midfoot zone AND pain with palpation of navicular or base of 5th metatarsal OR inability to bear weight immediately and in the ER/office
  - Although Ottawa rules are highly sensitive, they should not overrule clinical judgment.
- If radiographs are indicated, obtain anteroposterior, lateral, and mortise views of the ankle.
  - Small avulsion fractures are associated with grade III sprains.
- Consider CT if radiographs are negative but occult fracture is suspected clinically.
- MRI is the gold standard for soft tissue imaging but is expensive and rarely
necessary.
– Syndesmotic ankle sprains: MRI is more sensitive.
● US is a good second-line imaging option with sensitivity comparable to MRI with experienced sonographers and providers.

Follow-Up Tests & Special Considerations
If patient’s condition does not improve in 6 to 8 weeks, consider CT, MRI, or US. Failure to resolve could indicate an injury such as a fracture or osteochondral lesion of the talus.

TREATMENT

GENERAL MEASURES
● Most grade I, II, and III lateral ankle sprains can be managed conservatively.
● Conservative therapy: PRICE (protection, relative rest, ice, compression, elevation) (4)[A]
● Protection/compression: For grade I/II sprains, lace-up bracing is superior to air-filled/gel-filled ankle brace, which is superior to elastic bandage/taping to provide support and decrease swelling.
  – Note: The combination of air-filled brace and compression wrap is superior to each individual modality for return to preinjury joint function at 10 days and 1 month following grade I and II sprains.
  – Grade III sprains should have short-term immobilization (10 days) with below-the-knee cast, followed by a semirigid brace (air cast). If a patient refuses casting, a 10-day period of strict non–weight bearing with air cast splint and elastic bandage is a comparable alternative if non–weight bearing is maintained.
● Rest: Initially, activity as tolerated. Early mobilization and physical therapy speed recovery/reduce pain:
  – Weight bearing, as tolerated
  – Consider crutches if unable to bear weight.
  – Initiate exercises as early as tolerated. Limit to pain-free range of motion.
  – Start mobilization by tracing the alphabet with the foot or toes.
  – Resistance exercises with an elastic band
● Ice: Ice for first 3 to 7 days reduces pain and decreases recovery time.
● Elevation: Elevate ankle to decrease swelling.
MEDICATION
- NSAIDs: preferably oral; topical forms (e.g., diclofenac 1% gel) may be used to minimize GI side effects. PRN NSAID dosing has similar outcomes to scheduled dosing with improved safety profile.
  - Example: naproxen 500 mg BID PRN
- Acetaminophen 650 mg q4–6h (max outpatient therapy dose: 3,250 mg/day)
- Opioids (<5 days) if severe pain

ISSUES FOR REFERRAL
- Malleolar/talar dome fracture
- Syndesmotic sprain
- Dislocation/subluxation
- Tendon rupture
- Ongoing instability
- Uncertain diagnosis

ADDITIONAL THERAPIES
Physical therapy:
- After the acute phase of the injury, patients with grade II or III sprain should start physical therapy as soon as possible to increase range of motion, strength, flexibility, and improve proprioceptive balance (wobble board/ankle disk).
- Functional rehabilitation prevents chronic instability and speeds healing.
- Athletes should undergo sport-specific rehabilitation before returning to play.

SURGERY/OTHER PROCEDURES
- Surgery is typically reserved for treatment of complicated recurrent sprains and certain syndesmotic sprains.
- Patients with chronic ankle instability who fail functional rehabilitation or with poor tissue quality may need anatomic repair/reconstructive surgery.

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS
- After an ankle sprain, consider ankle-stabilizing orthoses (air stirrup braces,
lace-up supports, athletic taping, etc.) for athletes participating in high-risk sports to prevent future ankle sprains.

- Moderate and severe sprains require ankle orthoses for $\geq 6$ months during sports participation.
- Gradual return to play for athletes with a grade I lateral ankle sprain can generally be accomplished in 1 to 2 weeks; grade II sprain return to play time is 2 to 3 weeks; grade III sprain is approximately 4 weeks.
- Syndesmotic sprains take longer (~8 to 9 weeks) to heal than lateral ankle sprains.

**Patient Monitoring**
If athletes continue to have symptoms when they return to play or if a patient has pain for 6 to 8 weeks after injury, repeat examination and imaging.

**PATIENT EDUCATION**
- Crutch training
- Provide training on proper use of elastic bandages, brace, and/or orthoses.
- Demonstrate mobilization exercises (alphabet trace, towel grab).

**PROGNOSIS**
- Earlier physical therapy and mobilization with bracing allows for faster return to daily living and/or sports.
- Higher grade sprains, older patient age, and initial non–weight-bearing status have poorer prognosis and longer recovery.
- Ligamentous strength does not return for months after the injury.

**COMPLICATIONS**
- Joint instability
- Intermittent swelling/pain if not properly treated
- 5–33% continue to have pain 1 year postinjury.
- Accumulation of cartilage damage, leading to degenerative changes

**REFERENCES**

ADDITIONAL READING

CODES

ICD10
- S96.919A Strain of unsp msl/tnd at ank/ft level, unsp foot, init
- S93.499A Sprain of other ligament of unspecified ankle, init encntr
- S93.419A Sprain of calcaneofibular ligament of unsp ankle, init

CLINICAL PEARLS

- Children are at an increased risk of physeal injuries because ligaments are stronger than physes.
- Conditioning, including proprioceptive training, before participating in sports and throughout the season helps to prevent ankle sprains.
- Functional rehabilitation, rather than total immobilization, is recommended.
for quicker return to sport and work.

- Patients who do not adequately rehabilitate an ankle sprain are at increased risk for recurrence and chronic ankle instability.
- If patient’s condition is not improving in 6 to 8 weeks, consider advanced imaging with CT, MRI, or US.
SPRAINS AND STRAINS

Cory N. Mitchell, MD • J. Herbert Stevenson, MD

BASICS

DESCRIPTION

- Sprains are complete or partial ligamentous injuries either within the body of the ligament or at the site of attachment to bone.
  - Classified as grade 1, 2, or 3 (AMA Ligament Injury Classification)
    o Grade 1: stretch injury without ligamentous laxity
    o Grade 2: partial tear with increased ligamentous laxity but firm end point on exam
    o Grade 3: complete tear with increased ligamentous laxity and no firm end point on exam
  - Usually secondary to trauma (e.g., falls, twisting injuries, motor vehicle accidents)
  - Physical exam is the key to accurate diagnosis.

- Strains are partial or complete disruptions of the muscle, muscle–tendon junction, or tendon.
  - Classified as
    o First degree: minimal damage to muscle, tendon, or musculotendinous unit
    o Second degree: partial tear to the muscle, tendon, or musculotendinous unit
    o Third degree: complete disruption of the muscle, tendon, or musculotendinous unit
  - Often associated with overuse injuries

Geriatric Considerations

More likely to see associated bony injuries due to decreased joint flexibility and increased prevalence of osteoporosis and osteopenia

Pediatric Considerations

- Sprains and strains account for 24% of pediatric injuries.
- 3 million pediatric sports injuries occur annually.
- Consider physeal/apophyseal injuries in the skeletally immature patient.
EPIDEMIOLOGY

Incidence
~80% of all U.S. athletes experience a sprain or strain at some point.

Prevalence
- Ankle sprains are among the most common injuries in primary care, accounting for ~30% of sports medicine clinic visits. Most ankle sprains are due to inversion injuries (lateral sprains) involving the anterior talofibular ligament; account for 650,000 annual ER visits in the United States
- Predominant age
  - Sprains: any age in physically active patient
  - Strains: usually 15 to 40 years of age
- Predominant sex: male > female for most; female > male for sprain of anterior cruciate ligament

ETIOLOGY AND PATHOPHYSIOLOGY
- Trauma, falls, motor vehicle accidents
- Excessive exercise; poor conditioning
- Improper footwear
- Inadequate warm-up and stretching before activity
- Prior sprain or strain

RISK FACTORS
- Prior history of sprain or strain is greatest risk factor for future sprain/strain.
- Change in or improper footwear, protective gear, or environment (e.g., surface)
- Sudden increase in training schedule or volume
- Tobacco use, medication adverse effects

GENERAL PREVENTION
- Appropriate warm-up and cool-down exercises
- Use proper equipment and footwear.
- Balance training programs improve proprioception and reduce the risk of ankle sprains.
- Semirigid orthoses may prevent ankle sprains during high-risk sports, especially in athletes with history of sprain.
- Proprioception and strength training decrease injury risk; stretching does not
COMMONLY ASSOCIATED CONDITIONS
- Effusions, ecchymosis, hemarthrosis
- Stress, avulsion, and/or other fractures
- Syndesmotic injuries
- Contusions
- Dislocations/subluxations

DIAGNOSIS

HISTORY
- Obtain thorough description of mechanism of injury including activity, trauma, baseline conditioning, and prior musculoskeletal injuries.
- May describe feeling or hearing pop or snap

PHYSICAL EXAM
- Inspect for swelling, asymmetry, ecchymosis, and gait disturbance.
- Palpate for tenderness.
- Evaluate for decreased range of motion (ROM) of joint and joint instability/laxity.
- Evaluate for strength.
- Sprains
  - Grade 1: tenderness without laxity; minimal pain, swelling; little ecchymosis; can bear weight
  - Grade 2: tenderness with increased laxity on exam but firm end point; more pain, swelling; often ecchymosis; some difficulty bearing weight
  - Grade 3: tenderness with increased laxity on exam and no firm end point; severe pain, swelling; obvious ecchymosis; difficulty bearing weight

DIFFERENTIAL DIAGNOSIS
- Tendonitis
- Bursitis
- Contusion
- Hematoma
- Fracture
- Osteochondral lesion
- Rheumatologic process
DIAGNOSTIC TESTS & INTERPRETATION

- **Ankle**
  - Anterior drawer test assesses integrity of anterior talofibular ligament.
  - Talar tilt test assesses integrity of calcaneofibular ligament.
  - Squeeze test assesses for syndesmotic injury.
  - Palpate lateral and medial malleoli.
- **Knee**
  - Valgus/varus stress tests assess integrity of medial and lateral collateral ligaments, respectively.
- **Shoulder**
  - Positive apprehension test may indicate glenohumeral ligament sprain.
- **Radiographs** help rule out bony injury; stress views may be necessary. Obtain bilateral radiographs in children to rule out growth plate injuries.
- **Use Ottawa foot and ankle rules** (age 18 to 55 years) to determine if radiographs are necessary.
- **Ankle films**: required if pain in the malleolar zone and
  - Bone tenderness in posterior aspect distal 6 cm of tibia or fibula or
  - Unable to bear weight immediately or in emergency department
- **Foot films**: required if midfoot zone pain is present and
  - Bone tenderness at base of 5th metatarsal or
  - Bone tenderness at navicular or
  - Inability to bear weight immediately or in emergency department

Follow-Up Tests & Special Considerations

- **CT scan** if occult fracture is suspected
- **MRI** is the gold standard for imaging soft tissue structures, including muscle, ligaments, and intra-articular structures. If tibiofibular syndesmotic disruption is suspected, MRI is highly accurate for diagnosis.
- **Ultrasound evaluation** of a variety of muscles, tendons, and ligaments by a skilled operator allows for dynamic evaluation of potential sprain/strain that can add to traditional diagnostic imaging.

Diagnostic Procedures/Other

Surgery may be required for some partial and complete sprains depending on location, mechanism, and chronicity.
TREATMENT

GENERAL MEASURES

- Acute: protection, relative rest (activity modification), ice, compression, elevation, medications, modalities (PRICEMM) therapy
- Ankle sprains: Compression stockings didn’t affect pain, swelling, or time to pain-free walking but did show decreased time to return to sport (1)[B].
- Grade 1, 2 ankle sprain: functional treatment with brace, orthosis, taping, elastic bandage wrap
  - Ankle braces (lace-up, stirrup-type, air cast) are a more effective functional treatment than elastic bandages or taping (2)[A].
- Grade 3 ankle sprain: Short period of immobilization may be needed.
- Refer for early physical therapy.
- For high-level athletes with more extensive damage (e.g., biceps or pectoralis disruption), consider surgical referral.

MEDICATION

First Line

- Acetaminophen: not to exceed 3 g/day
- NSAIDs
  - Ibuprofen: 200 to 800 mg TID
  - Naproxen: 250 to 500 mg BID
  - Diclofenac: 50 to 75 mg BID
- Opioids can be considered acutely for severe pain, but discretion is advised.
- Acetaminophen and NSAIDs have similar efficacy in reducing pain after soft tissue injuries with less GI side effects; NSAIDs are better than narcotics.
- Topical diclofenac, ibuprofen, ketoprofen are effective for pain related to strains and sprains, especially in gel form or patch (3)[A].
- Platelet-rich plasma injections may aid recovery in treatment of muscle strains, but more studies are needed.

ISSUES FOR REFERRAL

- ACL sprain in athletes/physically active
- Salter-Harris physeal fractures
- Joint instability especially chronic
- Tendon disruption (i.e., Achilles, biceps, ACL)
- Lack of improvement with conservative measures
ADDITIONAL THERAPIES

- Physical therapy is a useful adjunct after a sprain, particularly if early mobilization is crucial.
  - Proprioception retraining
  - Core strengthening
  - Eccentric exercises
  - Thera-Band exercises

After hamstring strain, frequent daily stretching and progressive agility and trunk stabilization exercises may speed recovery and reduce risk of reinjury (4)[A]. Rehab protocols emphasizing eccentric/lengthening exercises are more effective than conventional exercises (5)[B].

SURGERY/OTHER PROCEDURES

- Casting and surgery are reserved for select partial and complete sprains. Need for surgery depends on the neurovascular supply to the injured area as well as the ability to attain full ROM and stability of the affected joint. The need for surgery also depends on activity level and patient preference.
- For primary management of acute lateral ankle sprains, there is no difference between surgical versus conservative therapy. Risks are increased with surgical intervention.
- Chronic ankle instability affects 10–20% of people who sustain an acute sprain. If conservative management fails and laxity is present, surgery is considered (6)[A].
- Percutaneous needle tenotomy versus surgical tenotomy are available as options for chronic tendinosis (chronic, recurrent strains).

ONGOING CARE

FOLLOW-UP RECOMMENDATIONS

If the affected joint has full strength and ROM, the patient can advance activity as tolerated using pain as a guide for return to activity.

Patient Monitoring

After initial treatment, consider early rehabilitation. Limit swelling and work on increasing ROM.
DIET
Weight loss if obese

PATIENT EDUCATION
- Injury prevention through proprioceptive training and physical therapy
- ROM and strengthening exercises to restore functional capacity

PROGNOSIS
Favorable with appropriate treatment and rest. Duration of recovery depends on the severity of injury.

COMPLICATIONS
- Chronic joint instability
- Arthritis
- Muscle contracture
- Chronic tendinopathy

REFERENCES
ADDITIONAL READING

Tendinopathy

CODES

ICD10

- S93.409A Sprain of unsp ligament of unspecified ankle, init encntr
- S96.919A Strain of unsp msl/tnd at ank/ft level, unsp foot, init
- S43.50XA Sprain of unspecified acromioclavicular joint, initial encounter

CLINICAL PEARLS

For acute injury, remember PRICEMM:

- Protection of the joint
- Relative rest (activity modification)
- Apply ice.
- Apply compression.
- Elevate joint.
- Medications/ice for pain
- Other modalities as needed
- Wean out of brace as tolerated to limit atrophy of stabilizing muscles.
SQUAMOUS CELL CARCINOMA, CUTANEOUS

Mercedes E. Gonzalez, MD • Herbert P. Goodheart, MD

BASICS

- Squamous cell carcinoma (SCC) is a malignant epithelial tumor arising from epidermal keratinocytes. Cutaneous (nonmucous membrane) SCC is the second most common form of skin cancer.
- Lesions most frequently occur on sun-exposed sites of elderly, fair-skinned individuals. Most SCCs arise in actinic keratoses (solar keratoses). SCCs that develop from actinic keratoses are slow-growing, minimally invasive, and unaggressive. Thus, the prognosis of an SCC arising from an actinic keratosis is usually excellent because distant metastases are extremely rare.
- An SCC may also appear de novo without a preceding actinic keratosis or emerge from a preexisting human papillomavirus (HPV) infection (verrucous carcinoma).
- SCCs may develop from causes other than sun exposure such as within an old burn scar or on sites previously exposed to ionizing radiation.
- Metastases are more likely to occur in thicker tumors >6-mm deep (1). Other risk factors for metastases include lesions that arise on the ears, the vermillion border of the lips, or on mucous membranes. An SCC located on sites that received ionizing radiation on the skin of organ transplant recipients, in chronic inflammatory lesions (e.g., discoid lupus erythematosus), in long-standing scars or cutaneous ulcers (e.g., venous stasis ulcers), or other nonhealing wounds, also have an increased rate of metastasis.
- System(s) affected: skin/exocrine
- Synonym(s): squamous cell carcinoma of the skin; epidermoid carcinoma; prickle cell carcinoma

EPIDEMIOLOGY

- Predominant age: elderly population
- Predominant sex: males > females
- In the United States, >700,000 new cases each year

Incidence
The escalating incidence in the United States is due to an increase in sun exposure in the general population, aging of the population, earlier and more frequent diagnosis of SCC, and the increase of immunosuppressed patients.

The incidence is highest in Australia and in the Sun Belt of the United States.

**ALERT**

Bowen disease (SCC in situ) and frank SCC are two of the few skin cancers that should be considered in African Americans. Such non–sun-related SCCs tend to arise on the extremities de novo, in an old scar, or in a lesion of discoid lupus erythematosus.

**ETIOLOGY AND PATHOPHYSIOLOGY**

- Exact mechanisms are not established; however, SCC is thought to arise from a multistep process that begins with a single mutated keratinocyte.
- UV radiation damages skin cell nucleic acids (DNA), resulting in a mutant clone of the tumor suppressor gene \( p53 \). This leads to an uncontrolled growth of skin cells containing a mutated \( p53 \) gene. Additional mutations in genes controlling cellular proliferation and/or death lead to squamous cell dysplasia, which then progresses to SCC in situ and later invasive SCC that has the potential for metastasis.
- Cumulative UV radiation (including tanning salons, and psoralen-UV-A [PUVA] phototherapy) over a lifetime is the major etiologic factor in SCC (2)
- A high prevalence of HPV DNA from SCC tissue has been noted in immunocompromised as well as immunocompetent specimens of SCC tissue (3).
- Other causative agents: ionizing radiation exposure, inorganic arsenic exposure, coal tar, and other oil derivatives
- Immunosuppression by medications or disease such as HIV/AIDS

**Genetics**

- Persons of Irish or Scottish ancestry have the highest prevalence of SCC.
- Caucasians with the red hair/fair skin phenotype (associated with certain variant alleles of the human melanocortin-1 receptor [MC1R]) are predisposed to SCC.
- SCC is rare in people of African and Asian descent, although it is the most common form of skin cancer in these populations.
RISK FACTORS

- Older age
- Male sex: However, incidence is increasing in females due to lifestyle changes (e.g., suntan parlors, shorter dresses).
- Chronic sun exposure: SCC is noted more frequently in those with a greater degree of outdoor activity (e.g., farmers, sailors, gardeners).
- Patients with multiple actinic keratoses
- Personal or family history of skin cancer
- Northern European descent
- Fair complexion, fair hair, light eyes
- Poor tanning ability, with tendency to burn
- Organ transplant recipients, chronic immunosuppression (especially azathioprine, voriconazole, or sirolimus) (4)
- Exposure to chemical carcinogens (e.g., arsenic, tar) or ionizing radiation
- Smoking
- Therapeutic UV and ionizing radiation exposure
- Defects in cell-mediated immunity related to lymphoproliferative disorders (chronic lymphocytic leukemia [CLL], lymphoma)
- HPV infection
- Chronic scarring and inflammatory conditions
- Specific genodermatoses (e.g., xeroderma pigmentosum, oculocutaneous albinism, and dystrophic epidermolysis bullosa)

GENERAL PREVENTION

Sun-avoidance measures: sunscreens, hats, clothing, and sunglasses with UV protection; tinted windshields and side windows in cars; sun-protective garments

COMMONLY ASSOCIATED CONDITIONS

- Some investigators consider an actinic keratosis to be an early SCC, although relatively few ultimately are found to develop into an SCC.
- Actinic cheilitis and leukoplakia of the mucous membranes of the lips
- Cutaneous horn (see following discussion)
- Xeroderma pigmentosum albinism
- Immunosuppression
- Chronic skin ulcers, preexisting scars, burns
DIAGNOSIS

PHYSICAL EXAM

Lesions occur chiefly on chronically sun-exposed areas.

- Face and backs of the forearms and hands
- Bald areas of the scalp and top of ears in men
- The sun-exposed “V” of the neck as well as the posterior neck below the occipital hairline
- In elderly females, lesions tend to occur on the legs and other sun-exposed locations.
- In African Americans, equal frequency in sun-exposed and unexposed areas

Clinical appearance

- Generally slow-growing, firm, hyperkeratotic papules, nodules, or plaques
- Most SCCs are asymptomatic, although bleeding, pain, and tenderness may be noted.
- Lesions may have a smooth, verrucous, or papillomatous surface.
- Varying degrees of ulceration, erosion, crust, or scale
- Color is often red to brown, tan, or pearly (indistinguishable from basal cell carcinoma).

Clinical variants of SCC

- Bowen disease (SCC in situ): solitary lesion that resembles a scaly psoriatic plaque
- Invasive SCC: often a raised, firm papule, nodule, or plaque. Lesions may be smooth, verrucous, or papillomatous, with varying degrees of ulceration, erosion, crust, or scale.
- Cutaneous horn: SCC with an overlying cutaneous horn. A cutaneous horn represents a thick, hard, fingernail-like keratinization produced by the SCC. Bowen disease may also produce a cutaneous horn on its surface.
- Erythroplasia of Queyrat refers to Bowen disease of the glans penis, which manifests as one or more velvety red plaques.
- Subungual SCC appears as hyperkeratotic lesions under the nail plate or on surrounding periungual skin, often mimicking warts (5).
- Marjolin ulcer: an SCC evolving from a new area of ulceration or elevation at site of a scar or ulcer
- HPV-associated SCC: virally induced; an SCC most commonly seen as a new or enlarging warty growth on penis, vulva, perianal area, or periungual region
- Verrucous carcinoma: subtype of SCC that is extremely well differentiated,
can be locally destructive, but rarely metastasizes. Lesions are “cauliflower-like” verrucous nodules or plaques.

– Basaloid SCC: less common than typical SCC; seen more often in men aged 40 to 70 years

**ALERT**

Subungual SCC: Such lesions typically mimic warts.

**DIFFERENTIAL DIAGNOSIS**

- Actinic keratosis: Early SCC lesions may be clinically difficult, if not impossible, to distinguish from a precursor actinic keratosis.
- Basal cell carcinoma may be indistinguishable from an SCC, particularly if the lesion is ulcerated.
- Keratoacanthoma: This lesion also may be clinically and histopathologically impossible to differentiate from an SCC; it is considered by some to be a low-grade variant of an SCC.
- Verruca vulgaris: The appearance of common warts is often similar to that of SCC lesions.
- Seborrheic keratosis
- Pyoderma gangrenosum
- Venous stasis ulcer
- Chemical or thermal burn

**DIAGNOSTIC TESTS & INTERPRETATION**

**Initial Tests (lab, imaging)**

- Surgical biopsy to ensure diagnosis: shave, punch, excisional, or incisional biopsy
- Sentinel lymph node biopsy is rarely used to identify micrometastases in patients with high-risk SCC and clinically negative nodes. Whether the early detection of lymph node metastasis leads to enhanced survival in SCC is unknown.
- Patients with lymphadenopathy should be evaluated for metastases with CT scanning, MRI, US, or PET.

**Test Interpretation**

- Noninvasive SCC is characterized by an intraepidermal proliferation of atypical keratinocytes. Hyperkeratosis, acanthosis, and confluent parakeratosis are seen within the epidermis. Cellular atypia, including pleomorphism,
hyperchromatic nuclei, and mitoses are prominent. Atypical keratinocytes may be found in the basal layer and often extend deeply down the hair follicles, but they do not invade the dermis.

- In the in situ type of SCC (Bowen disease), atypia involves the full thickness of the epidermis, but the basement membrane remains intact.
- An invasive SCC penetrates through the basement membrane into the dermis. It has various levels of anaplasia and may manifest relatively few to multiple mitoses and display varying degrees of differentiation, such as keratinization.
- Poorly differentiated tumors are clinically more aggressive. SCCs proliferate first by local invasion. Metastases, when they do occur, spread via local lymph ducts to local lymph nodes.

**ALERT**

Melanoma: An amelanotic melanoma and ulcerated melanoma may also be impossible to distinguish from an SCC.

**TREATMENT**

**MEDICATION**

**First Line**

- Total excision: preferred method for SCCs, permitting histologic diagnosis of the tumor margins
- Electrodesiccation and curettage (ED&C)
  - Best for small lesions (generally <1 cm) on flat surfaces (e.g., forehead, cheek) and SCC in situ (Bowen disease). ED&C may be used to treat superficially invasive SCCs that lack high-risk characteristics, but it is not appropriate for certain high-risk anatomic locations.
- Cryosurgery with LN₂ in selected lesions, such as SCC in situ
- Micrographic (Mohs) surgery is a microscopically controlled method of removing skin cancers that allows for controlled excision and maximum preservation of normal tissue. It has the highest cure rate (94–99%) of all surgical treatments. Mohs surgery may be indicated for the following:
  - Large, recurrent or invasive SCCs (e.g., to bone or cartilage)
  - Lesions with a poorly delineated clinical border
  - Locations where preservation of normal tissue is extremely important (e.g., tip of the nose, eyelids, ala nasi, ears, lips, and glans penis)
- Radiation therapy is a primary treatment option that is generally restricted to
older patients who are physically debilitated or are unable to undergo or refuse to undergo excisional surgery.

**Second Line**
- Immunotherapy with topical imiquimod (Aldara) 5% cream has been successfully used for the treatment of SCC in situ (Bowen disease), actinic keratoses, genital warts, and superficial basal cell carcinomas (6)[A].
- Topical chemotherapy: topical formulations of 5-fluorouracil (5-FU) (6)[A]
- Intralesional 5-FU and bleomycin has also been used successfully to treat SCCs.
- Photodynamic therapy (PDT): PDT involves application of a photosensitizer (given topically or systemically) followed by exposure to a light source used primarily to treat large numbers of solar keratoses and is not recommended for treatment of invasive SCCs.
- In patients with multiple or recurrent SCCs or those at high risk, such as organ transplant recipients, chemoprevention with systemic retinoids, such as acitretin, may be effective for reducing the number of new SCCs, treating existing SCCs, and reducing the risk of recurrence.

**ADDITIONAL THERAPIES**
For metastatic SCC, oral 5-FU has been used alone or in combination with SC interferon. More recently, epidermal growth factor receptor (EGFR) inhibitors, such as cetuximab (7)[C], are used in combination with systemic chemotherapy for metastatic disease.

**SURGERY/OTHER PROCEDURES**
- Complete lymphadenectomy of the draining nodal basin for high-risk tumors
- Metastatic disease requires aggressive management by a multidisciplinary team, involving plastic, ENT/maxillofacial, general and oncologic surgeons.

**ONGOING CARE**

**FOLLOW-UP RECOMMENDATIONS**

**Patient Monitoring**
Skin exam every month for 3 months, 6 months after treatment, and then yearly
PATIENT EDUCATION

Skin self-exam: Encourage sun-avoidance techniques, protective clothing, sunscreens, and so forth. Artificial tanning devices should be avoided.

PROGNOSIS

- For low-risk SCCs: a 90–95% cure rate with appropriate treatment
- Overall, head and neck lesions have better prognosis; however, lip and ear lesions metastasize more frequently when compared with other sites.
- The ability to produce scale (*keratinization*) indicates a tendency for a lesion to be more differentiated and less likely to metastasize.
- Softer, nonkeratinizing lesions are not as well differentiated and thus are more likely to spread.
- Lesions ≥2 cm are more likely to recur.
- SCCs that arise in areas of non–sun-exposed skin or have a greater tendency to metastasize
- An SCC arising on a mucous membrane or in a chronic ulcer should be regarded as potentially metastatic.
- Recurrence rate and mortality is greater in immunosuppressed patients, especially solid-organ transplant recipients.
- SCCs that are deeply invasive (≥6 mm in SC fat), or have perineural involvement, are more likely to metastasize.
- When SCC does metastasize, it usually occurs within several years from the time of diagnosis and involves draining lymph nodes.
- Once nodal metastasis of cutaneous SCC has occurred, the overall 5-year survival rate has historically been in the range of 25–35%.

COMPICATIONS

- Untreated, an SCC becomes indurated, with a tendency to ooze, ulcerate, or bleed.
- Local recurrence
- Metastatic disease

REFERENCES

**ADDITIONAL READING**

**CODES**

**ICD10**

- C44.92 Squamous cell carcinoma of skin, unspecified
- C44.320 Squamous cell carcinoma of skin of unspecified parts of face
- C44.42 Squamous cell carcinoma of skin of scalp and neck

**CLINICAL PEARLS**
- SCCs that develop from actinic keratoses are generally unaggressive.
- Solid organ transplant patients have a 65-fold increased risk of SCC relative to the general population.
- Unlike most basal cell carcinomas, SCCs of the skin are associated with a risk of metastasis, especially those arising on mucous membranes, chronic ulcers, or in immunocompromised patients.
- A subungual SCC can easily be mistaken for a wart.
STRESS FRACTURE

David A. Ross, MD, CAQSM • Nicole A. Ross, DO

BASICS

DESCRIPTION

- Overuse injuries caused by cumulative microdamage from repetitive bone loading
- Stress fractures occur in different situations:
  - Fatigue fracture: abnormal stress applied to normal bone (e.g., young college athletes or new military recruits with increased physical activity demands and inadequate conditioning)
  - Insufficiency fracture: normal stress applied to structurally abnormal bone (e.g., femoral neck fracture in osteopenic bone)
  - Combination fracture: abnormal stress applied to abnormal bone (e.g., female long-distance runners with premature osteoporosis from female athletic triad)
- Weight-bearing bones of the lower extremity are most commonly affected at the following sites:
  - Tibia/fibula
  - Metatarsal bones
  - Navicular
  - Femoral neck
  - Pars interarticularis
- Less commonly affected sites:
  - Pelvis
  - Calcaneus
  - Ribs
  - Ulna
- High-risk stress fractures occur in zones of tension or areas with poor blood supply and are more likely to result in fracture displacement and/or nonunion. High-risk sites include the following:
  - Tension side of femoral neck
  - Anterior tibial diaphysis
  - Sesamoids
  - Pars interarticularis of lumbar spine (L4, L5)
– 5th metatarsal at metaphyseal–diaphyseal junction
– Proximal 2nd metatarsal
– Medial malleolus
– Tarsal navicular
– Patella
– Talar neck

● Synonym(s): march fracture; fatigue fracture

EPIDEMIOLOGY

Incidence
● Greatest incidence in 15- to 27-year-olds
● Females more commonly affected than males
● Affects 9–21% of track and field athletes annually
● Up to 95% of stress fractures occur in the lower extremities (1)[A].
● Among runners, stress fractures account for 15–20% of all musculoskeletal related injuries (1)[A].

● Across all sports, the most commonly injured body sites are the lower leg (40.3%), foot (34.9%), lower back/lumbar spine/pelvis (15.2%) (2)[C].
● Occurs in <1% of general population

Prevalence
● Affects 5% of military recruits
● Affects 1–3% of college athletes

ETIOLOGY AND PATHOPHYSIOLOGY
● Bone is dynamic and constantly remodeling in response to applied physiologic stress.
● Repetitive loading or overuse causes microfractures that don’t heal due to imbalance between bone resorption and bone formation.
● If microdamage accumulates in excess of reparation, bony fatigue leads to stress fracture.

RISK FACTORS
● Intrinsic (1)[A]
  – Females are at 2.3 times higher risk than males.
  – Female athlete triad (low energy availability with or without disordered eating, menstrual dysfunction, and low bone mineral density)
  – History of previous stress fracture—increases risk of future stress fracture
by 5 times
- History of osteoporosis, osteomalacia, rheumatoid arthritis, prolonged corticosteroid therapy
- Body composition—increased risk of stress fractures with BMI <19
- Skeletal malalignment: pes cavus, pes planus, leg length discrepancies, excessive forefoot varus, tarsal coalitions, prominent posterior calcaneal process, tight heel cords
- Biomechanical factors such as increased vertical loading rate (e.g., heel-to-toe running instead of forefoot striking)
- Muscle fatigue and decreased lean muscle mass
- Extremes of body size and composition
- Previous inactivity or low aerobic fitness

Extrinsic (1)[A]
- Type of exercise—both male and female athletes who participate in running, track and field, cross country, and gymnastics are at highest risk (2)[C].
- Training regimen—running >32 km/week increases risk by 2 times in all athletes, by 3 times in female athletes.
- Nutritional/dietary habits—history of a diagnosed eating disorder
- Rapid increase in mileage, running pace, or training volume
- Inappropriate footwear
- Hard training surface
- Inadequate recovery or rest and training with fatigued muscle
- There is no evidence that use of oral contraceptives is related to stress fracture risk.

GENERAL PREVENTION
- Avoid abrupt increases in physical activity (no more than 10% increase in load per week).
- Reduce intensity and duration of activity if new-onset pain.
- Proper footwear
- Increasing dynamic physical activity (jumping; plyometric training) increases bone density and resistance to mechanical stress.
- Decrease vertical loading rate either by switching to forefoot strike running or (if continuing with heel-to-toe strike) by using a heel pad insert.
- Shock-absorbing foot inserts may help.
- Increased calcium and vitamin D intake may reduce stress fractures in female runners and military recruits.
COMMONLY ASSOCIATED CONDITIONS

- Osteoporosis/osteopenia
- Female athlete triad
- Metabolic bone disorders

DIAGNOSIS

HISTORY

- Insidious onset of vague bony pain over period of weeks. Pain is typically worse with physical activity.
- Rest initially relieves pain.
- If untreated, pain progresses and may occur earlier during training sessions or even at rest. Pain also becomes more localized.
- History of recent change in training intensity, alteration in training terrain, and/or footwear.
- Assess dietary practices: energy availability, disordered eating, and weight fluctuations, calcium and vitamin D intake.
- Assess menstrual history: menarche, oligomenorrhea, or amenorrhea.

PHYSICAL EXAM

- Height, weight, BMI, and any stigmata of disordered eating (cold extremities, hypercarotenemia, lanugo hair, calluses on back of fingers, poor oral hygiene, parotid gland hypertrophy, bradycardia, or orthostatic hypotension)
- Antalgic gait
- Point or percussion tenderness over injury site—a vibrating tuning fork over the fracture site may intensify pain; in shin splints, pain is typically diffuse tenderness along the length of the posteromedial tibial shaft and a lack of edema.
- Swelling may be present.
- Specific tests:
